This is an alert message to the DSM. It occurs when protected host encounters an error transforming the data on device during IDT process.

Solution: Please contact Thales Support for troubleshooting and recovery.

ESG-INFO: Data transformation complete on [GuardPoint]

This message is a notification to the DSM admin that the protected host has completed the data transformation of the specified ES GuardPoint.

ESG-ALERT: Failed to resize <device-name>

This alert is a notification to the DSM admin that the protected host has failed to update the change to the device size in the ES Header on the device.

Solution: Please contact Thales Support for troubleshooting and recovery.

FSADM-ALERT: ESG required Signature Set for system utilities may have to be resigned

This alert is a notification to the DSM admin that the recent system upgrade to the protected host may have updated the binary files listed in the signature set for restricting root access.

Solution: Upon this notification you must immediately re-sign the affected or all the binary files to prevent them from accessing protected data. Refer to "[Linux System Utilities for Signing](#)" on page 191.

File System is not automatically mounted after IDT completes

An Efficient Storage device with a file system that has been configured to automatically mount may fail to automatically mount while the device undergoes data transformation through IDT. Following is a sample log message in the kernel ring buffer that reports a failed attempt to access a device during IDT. You can ignore this message.

```
Vormetric SecVM: secvm_map during IDT ((dc 00000000c3537611)
```

When access to a device is to mount the file system, the kernel ring buffer may also report a second error message indicating that a file system failed to mount due to data corruption. You can ignore this message. This occurs because the mount command is issued after the device has been guarded but before data transformation through IDT is complete. While IDT is in progress, the device cannot be used, so any attempt to mount the file system will fail.

Solution: Manually mount the file system after IDT is complete.

Chapter 18: CipherTrust InPlace Data Transformation for Linux

This chapter contains the following sections:

Introduction to CipherTrust InPlace Data Transformation (IDT)	209
Requirements for IDT-Capable GuardPoints	209
The CTE Private Region and IDT Device Header	210
IDT-Capable GuardPoint Encryption Keys	211
Guarding an IDT-Capable Device on Linux	214
Changing the Encryption Key on Linux IDT-Capable Devices	222
Guarding an IDT-Capable Device with Multiple IO Paths on Linux	225
Linux System and IDT-Capable GuardPoint Administration	226
Resizing Guarded IDT Devices	228
Use Cases Involving IDT-Capable GuardPoints	228
Alerts and Errors on Linux	228

Note

Currently, this feature is only supported on the DSM. Support for this feature will be added to CipherTrust Manager in a future release.

Introduction to CipherTrust InPlace Data Transformation (IDT)

CTE offers CipherTrust InPlace Data Transformation (IDT) Capable Device GuardPoints on Linux. IDT-Capable GuardPoints allow you to guard devices by transforming the plain-text data to cipher-text on the host device. The data transformation process is called CipherTrust InPlace Data Transformation (IDT). The term “IDT-Capable” refers to the data transformation capability available on IDT-Capable GuardPoints.

IDT is not the same as the legacy offline data transformation. IDT is a block level data transformation with built-in resiliency to recover from system crashes during the data transformation process. IDT uses the CTE Private Region to manage the entire transformation process (For details, see ["The CTE Private Region and IDT Device Header" on the next page](#)).

IDT partitions the data on a device in segments of 1MB in size and transforms one or multiple segments, up to 60 segments, in parallel. The IDT process preserves existing data in a segment during transformation in the CTE Private Region, and then transforms the data in-place. IDT also maintains the segments undergoing transformation in the CTE Private Region. In the event of system crash, IDT will recover the segments undergoing transformation at the time of crash and then resume the transformation process.

Another advantage of IDT over legacy offline data transformation is that IDT does not require a separate policy for data transformation. Instead, IDT allows you to initialize each device as either a “new device” with no existing data or as an “existing device” with existing data that needs to be transformed. You can then apply any IDT policy to any combination of new and existing devices and IDT will immediately guard the new devices while starting the IDT transformation process on the existing devices. New devices are immediately available for use while existing devices are inaccessible until the IDT process completes and all data has been converted from plain-text to cipher-text.

Requirements for IDT-Capable GuardPoints

- IDT-Capable GuardPoints are available for Linux with CTE 6.3.1 or later. They also require DSM version 6.4.2 or later.

- The host server must use the Advanced Encryption Standard instruction set (AES-NI).
- The DSM policy assigned to the IDT-Capable GuardPoint must be of type “In-place Data Transformation - Device” and use an XTS-AES 256 encryption key.
- In order to create an IDT-Capable GuardPoint on a raw device, the device must be either:
 - Exported from an external storage system to the host device.
 - On a locally-attached disk.
- Devices protected by an IDT-Capable GuardPoint cannot currently be initialized/added as physical volumes for use by LVM. When LVM support is added, it will be announced in the CTE Release Notes.
- Existing devices divided into one or more logical partitions *cannot* be guarded as IDT-Capable Device GuardPoints. Logical partitions in such devices cannot be accessed or separately guarded after guarding the device.

For example, the logical partition `/dev/sda1` or `/dev/sda2` inside `/dev/sda` cannot be accessed after guarding `/dev/sda` as IDT-Capable GuardPoint. Using `/dev/securem/dev/sda1` is invalid as `/dev/securem/dev/sda1` is not a GuardPoint and cannot be guarded, and, as such, would not provide access to clear-text data on `/dev/sda1`. However, you can guard individual partitions, such as `/dev/sda1` or `/dev/sda2`, as IDT-Capable GuardPoints without guarding the entire `/dev/sda` device.

The CTE Private Region and IDT Device Header

IDT-Capable GuardPoints require a small amount of disk space in the standard CTE Private Region. The reserved space is where CTE stores metadata information to identify IDT-Capable GuardPoints and to perform all data transformation and rekey operations in a resilient manner to avoid data loss or integrity issues due to system failures. The IDT-specific reserved space within the CTE Private Region is known as the IDT Device Header. By default, when you initialize a device as an IDT-Capable GuardPoint, CTE reserves 63 MB of space starting at the first sector on the device for the CTE Private Region.

CTE writes the IDT Device Header into the CTE Private Region when the device is guarded for the first time. If there is existing data on the device, the data at the start of the device is relocated to the available free space on the device and CTE creates the CTE Private Region starting at the first sector. For details, see ["Initialize a Linux Device with Existing Data" on page 216](#).

CTE Private Region Location

Normally, CTE requires that the CTE Private Region be embedded at the beginning of the device. IDT, however, allows you to specify that the CTE Private Region for an IDT-Capable GuardPoint should be located in a central CTE metadata directory on the host called `/vte/vte-metadata-dir` (default: `/opt/vte/vte-metadata-dir`). If you use this option, CTE stores the CTE Private Region and IDT Device Header for the device in this directory. The location of the CTE Private Region for a device is determined when you first initialize the device as an IDT-Capable GuardPoint. For details, see ["Initializing an IDT-Capable Device" on page 215](#).

WARNING

Access to the CTE metadata directory is local to the CTE protected host. Devices whose access is shared across multiple CTE protected hosts in a cluster *must* be configured with the CTE Private Region embedded in those devices. Using a centralized metadata directory for shared devices will lead data corruption.

The location of the CTE Private Region does not affect CTE's functionality, but there are some considerations if you choose to use the centralized metadata directory `/vte/vte-metadata-dir`:

- Thales recommends that you keep the metadata for the device on the device if at all possible. You should only use the centralized metadata directory if the device cannot be expanded to accommodate the CTE Private Region.
- The centralized CTE metadata directory must be guarded by the DSM Administrator to prevent accidental modification or deletion of the CTE metadata. If the CTE metadata directory is not guarded, any attempt to configure or enable an IDT-Capable GuardPoint using the centralized metadata directory will be rejected. The policy associated with the metadata directory must:
 - Deny all users (including the root user) the ability to modify or remove any files in the metadata directory.
 - Use the key rule `clear_key` so that the metadata is stored in clear text.
- You must back up this directory whenever you back up a device that uses the directory. You will not be able to restore a protected device without access to its corresponding metadata in `/vte/vte-metadata-dir`.
- Devices with existing data do not need to be resized to accommodate the CTE Private Region, so there are no disk size discrepancies between system utilities such as `fdisk` and any other applications. However, Thales still recommends that you do not shrink an IDT-Capable GuardPoint even if the CTE Private Region is not embedded on the device.

Device Size

If you embed the CTE Private Region on the device itself, after configuring and guarding the IDT-Capable GuardPoint on the device, the device size reported to applications is the size of the device minus the space reserved for the CTE Private Region. This can lead to a discrepancy between the disk size reported by some applications versus the size reported by system utilities such as `fdisk`.

WARNING

Do not shrink IDT-Capable GuardPoints. Due to the relocation of user data from the CTE Private Region, if you shrink the device, you may corrupt data on the device.

The IDT Device Header contains both the available device size and the size of the CTE Private Region. To view the IDT Device Header, use the `voradmin idt status <device-name>` command. The **Exported Disk Size** field shows the disk size available for use by other applications. The **Private Region Size** field shows the disk size reserved for CTE. For example:

```
# voradmin idt status /dev/sdc2
IDT Header on /dev/secvm/dev/sdc2
    Version: 1
    Change: 0
    Private Region Size: 129024 sectors
    Exported Device Size: 9627648 sectors
    Key UUID: 9cc3c8e4-7ea7-310f-85c7-6f911de1ab52
    Mount Path: None
```

The `voradmin idt status` command also reports the UUID of the XTS-AES 256 key applied to the device.

IDT-Capable GuardPoint Encryption Keys

IDT-Capable GuardPoints must be encrypted using XTS-AES 256 keys. An XTS-AES 256 type key is a 512-bit key composed of two components:

- The first 256 bits of the key is the AES 256 encryption key component.
- The second 256 bits is the tweak component.

You create XTS keys on the DSM using the "Add Agent Key" function.

Note

When you create agent keys for IDT-Capable GuardPoints, you do not need to check the "KMIP Accessible" box on the "Add Agent Key" page. If you do check the KMIP Accessible option, the IDT-Capable GuardPoint ignores this setting.

The DSM generates a UUID, along with other relevant attributes, for each newly-added key. The DSM then provides the key and its attributes to the CTE protected host when the policy containing the key is pushed to the host device. CTE stores the key and its attributes, including the key's UUID, in the IDT Device Header. The first time a device is guarded as IDT-Capable GuardPoint, CTE writes the IDT Header on the device before data transformation takes place, if data transformation is required.

Key Attributes - Example

The following figure illustrates the parameters you should specify to add a new XTS-AES 256 key named IDT_DEMO_KEY_1. Note the algorithm and encryption mode specified for the key.

The screenshot shows the 'Add Agent Key' dialog box with the 'Symmetric' tab selected. The configuration is as follows:

Field	Value
Name	IDT_DEMO_KEY_1
Description	Initial key for IDT
Template	[Dropdown menu]
Expiration Date	12/31/2020
Algorithm	AES256
Encryption Mode - for VTE agents only	XTS
KMIP Accessible	☐
Key Type	Cached on Host
Unique to Host	☐
Key Creation Method	Generate
Key Refresh Period - for VAE keys only (minutes)	18000
Automatic Key Rotation	☐

Buttons: OK, Cancel

The following figure illustrates the general properties of IDT_DEMO_KEY_1 after adding the key. Note the UUID of the key. This UUID is stored in the IDT Device Header on all devices encrypted with this key, allowing you to verify which key is being used on each device.

Edit Agent Key	
General	
Name	IDT_DEMO_KEY_1
UUID	9cc3c8e4-7ea7-31f1-85c7-8f911de1ab52
Source	From DSM
Description	Initial Key for IDT
Creation Date	5/14/20
Expiration Date	12/31/2020
Algorithm	AES256
Encryption Mode - for VTE agents only	XTS
KMIP Accessible	☐
Key Type	Cached on Host
Unique to Host	☐
Key Refresh Period - for VMS keys only (minutes)	10080

Policy Requirements for IDT-Capable GuardPoints

IDT-Capable GuardPoints require a policy of type **In-place Data Transformation - Device** with a single key rule specifying the key names for **Current Key** and **New Key**. The **Current Key** name is `clear_key` or an XTS-AES 256 key name, depending on whether the data on the device has already been encrypted.

- If there is no existing data on the device or if the existing data on the device has not yet been encrypted, specify `clear_key` for **Current Key**. In the **New Key** field, specify the name of the XTS-AES 256 key that you want to use to encrypt the data on the device.
- If the existing data on the device has already been encrypted, specify the name of the key used to encrypt the data in the **Current Key** field and the name of the new XTS-AES 256 key you want to use to rekey the data in the **New Key** field. When the policy is pushed to the host, CTE will rekey the data on the device using the key specified in **New Key**. In other words, the **New Key** field specifies the XTS-AES 256 production key name to apply to device.

In all cases, the **New Key** field specifies the XTS-AES 256 production key name that you want to use to encrypt the data on the device. After you guard an existing device with an In-place Data Transformation - Device policy, CTE transforms the existing data using the New Key. When the process is finished, the New Key becomes the Current Key for that device, and all data will be encrypted or decrypted with that key. The IDT Device Header contains the UUID of the key currently being used to encrypt/decrypt data on the device. To view the current key UUID, use the `voradmin idt status <device-name>` command.

You may add security rules to restrict certain user/process access to protected devices. For suggestions, see ["Use Cases Involving IDT-Capable GuardPoints" on page 228](#).

The following figure shows an example of a simple policy named `IDT_DEMO_POLICY_1` with policy type "In-place Data Transformation - Device", a simple security rule that permits access to all users and programs, and that uses `clear_key` as the current key and `IDT_DEMO_KEY_1` as the key to encrypt the data on any device associated with this policy.

Add Policy - IDT_DEMO_POLICY_1

Guarding an IDT-Capable Device on Linux

In order to guard an IDT-Capable device, you need to:

1. Make sure the devices you intend to guard meet the requirements for IDT-Capable GuardPoints. For details, see ["Requirements for IDT-Capable GuardPoints" on page 209](#).
2. Install the CTE Agent and register the host with the DSM if it is not already registered. IDT does not require any special registration options or licenses. For details, see the *CTE Agent for Linux Quick Start Guide*.
3. Initialize the device using the `voradmin idt config [new|xform]` command to specify whether there is any existing data on this device that needs to be encrypted and to configure the location of the CTE Private Region. For details, see ["Initializing an IDT-Capable Device" on the facing page](#).
4. Log on to the DSM to apply an IDT-Capable GuardPoint to the device. For details, see ["Guard the Linux Device with an IDT-Capable GuardPoint" on page 218](#).

WARNING

For devices with shared access across multiple CTE Protected hosts in a cluster, you must designate one and only one of the nodes in the cluster as the node on which you plan to initialize and guard the device for the first time. The designated node must be the only one that accesses the device until the entire initial data transformation process has completed. This requires guarding each shared device at the designated host level rather than at the host group level if you are using a host group to manage the CTE Protected nodes in your cluster. DO NOT initialize or guard any device on multiple nodes in the cluster simultaneously, because multiple nodes attempting to transform the same data can corrupt the data on the entire device.

Initializing an IDT-Capable Device

When you initialize an IDT-Capable storage device, the process specifies:

- Whether there is existing data on the device that needs to be encrypted.
- Where you want to store the CTE Private Region, which contains the IDT Device Header along with metadata that identifies the IDT-Capable device as a guarded device. You can embed the CTE Private Region on the device itself or in the central CTE metadata directory on the host. (For details, see ["The CTE Private Region and IDT Device Header" on page 210.](#))

How you initialize the device depends on whether it is a new device or an existing device that already has data that needs to be transformed into cipher-text. For details, see:

- ["Initialize a New Linux Device" below](#)
- ["Initialize a Linux Device with Existing Data" on the next page](#)

Initialize a New Linux Device

Run the `voradmin idt config new` command to initialize a new device. The `new` option specifies that the device does not hold user data so no initial data transformation is required. For a shared device that is accessed from multiple protected hosts, you must initialize the device only once and on only one protected host.

Note

To configure devices with multiple IO paths for Linux, see ["Changing the Encryption Key on Linux IDT-Capable Devices" on page 222.](#)

1. Log into the device as `root`.
2. Run the `voradmin idt config [-external] new [-c <n>] <device-name>` command, where:
 - `-external` is an optional parameter that tells CTE you want to use the centralized CTE metadata directory instead of embedding the CTE Private Region on the device itself. If you use this option, you must have configured and guarded the centralized CTE metadata directory as described in ["CTE Private RegionLocation" on page 210](#).
 - `new` (required) indicates that the device contains no data (it is a new disk). As soon as you push the IDT policy from the DSM, the device will be available as a guarded IDT-Capable GuardPoint.
 - `-c <n>` (optional). If you use this option, CTE sets the number of data transformation jobs to run in parallel to the number specified in `<n>`. `<n>` can be an integer between 1 and 60 (default: 8).

Each data transformation job transforms 1MB worth of data and requires CPU resources in addition to three I/O operations as part of data transformation. Each job reads 1MB of data from the device, preserves the data in the CTE Private Region, rekeys the data to cipher-text, and writes the transformed data to the device. If you increase the number of parallel jobs, the data transformation process will complete faster but there will be an increased performance impact on the system. Only increase the `-c` option if you are certain that the system resources are available to handle the additional load.

The value for the `-c` option you specify here remains in effect for all subsequent data transformations (such as any data rekeys) until you specify a new value.
 - `<device-name>` (required). Specifies the device name. For example, `/dev/sdc2`.

For example, if you want to initialize a new Linux disk named `/dev/sdc2` using 10 parallel data transformation jobs with the CTE Private Region embedded on the device, you would specify:

```
# voradmin idt config new -c 10 /dev/sdc2
```

If you want to initialize a new Linux disk named `/dev/sdc2` using the default number of parallel data transformations but with the CTE Private Region in the centralized CTE metadata directory, you would specify:

```
# voradmin idt config -external new /dev/sdc2
```

3. To verify that the disk has been initialized, run the `voradmin idt status` command.

```
# voradmin idt status /dev/sdc2
```

Device `/dev/sdc2` is configured to guard as IDT-Capable GuardPoint
4. At this point the DSM Administrator can protect the device as an IDT-Capable GuardPoint through the DSM Management Console. For details, see ["Guard the Linux Device with an IDT-Capable GuardPoint" on page 218](#).

Note

The initialization process prepares the device to be guarded but does not actually guard it. You need to assign an IDT-Capable GuardPoint to the device in the DSM before the device is actually protected.

Initialize a Linux Device with Existing Data

If the device has existing data, you need to use the `voradmin idt config xform` command to initialize the disk for CTE. Unless you are using the centralized CTE metadata directory, this command examines the current disk size and computes the size required to hold the existing data plus the CTE Private Region at the beginning of the device. After the CTE initialization is complete, you then need to resize the device before you can guard it with an IDT-Capable GuardPoint.

WARNING

If access to the device is shared access across multiple CTE Protected hosts in a cluster, be sure to initialize the device on one and only one of the CTE hosts.

The following procedure describes how to initialize the device for CTE. Note that the existing data is not altered in any way until after you perform this procedure and you guard the data with an IDT-Capable GuardPoint. CTE does *not* begin transforming the data from clear-text to cipher-text until the IDT-Capable GuardPoint has been applied and the encryption key has been pushed to the device through the GuardPoint Policy.

1. Log into the device as `root`.
2. Run the `voradmin idt config [-external] xform [-c <n>] <device-name>` command, where:
 - `-external` is an optional parameter that tells CTE you want to use the centralized CTE metadata directory instead of embedding the CTE Private Region on the device itself. If you use this option, you will not have to resize the device but you must have configured and guarded the centralized CTE metadata directory as described in "[CTE Private RegionLocation](#)" on page 210.
 - `xform` (required) indicates that the device contains existing data. CTE will transform all existing data on the device from clear-text to cipher-text as soon as you guard the device. The device will be inaccessible until the transformation is complete, and the device must remain offline during the entire transformation process. No user access will be permitted until all data has been transformed.
 - `-c <n>` (optional). If you use this option on Linux, CTE sets the number of data transformation jobs to run in parallel to the number specified in `<n>`. `<n>` can be an integer between 1 and 60 (default: 8).

Each data transformation job transforms 1MB worth of data and requires CPU resources in addition to three I/O operations as part of data transformation. Each job reads 1MB of data from the device, preserves the data in the CTE Private Region, rekeys the data to cipher-text, and writes the transformed data to the device. If you increase the number of parallel jobs, the data transformation process will complete faster but there will be an increased performance impact on the system. Only increase the `-c` option if you are certain that the system resources are available to handle the additional load.

The value for the `-c` option you specify here remains in effect for all subsequent data transformations (such as any data rekeys) until you specify a new value.

- `<device-name>` (required). Specifies the device name. For example, `/dev/sdc3`.

For example, if you want to initialize an existing Linux disk named `/dev/sdc3` using 10 parallel data transformation jobs with the CTE Private Region embedded on the device, you would specify:

```
# voradmin idt config xform -c 10 /dev/sdc3
```

Device `/dev/sdc3` must be resized to at least 9893888 sectors (4831 MBs) before guarding as IDT-Capable GuardPoint

In this case you must manually resize the Linux disk by at least 9893888 sectors before you can guard it. After you guard the disk, you can expand it again later but you cannot shrink it unless you remove the GuardPoint.

If you want to initialize the same device using the centralized CTE metadata directory, you would specify:

```
# voradmin idt config xform -external -c 10 /dev/sdc3
```

Note that you do not get a message about resizing the device because the CTE Private Region will not be embedded on the device.

3. To verify that the disk has been initialized, run the `voradmin idt status` command.

```
# voradmin idt status /dev/sdc3
```

Device `/dev/sdh` is configured to guard as an IDT-Capable GuardPoint

4. If you are embedding the CTE Private Region on the device, at this point, you need to resize the device using your standard disk management tools before you can guard it. Make sure you increase the device size by at least the amount shown in the `voradmin idt config xform message`.

You cannot assign an IDT-Capable GuardPoint to the device until it has been resized. If you do not resize the device, the GuardPoint assignment will fail.

5. After the device has been resized or the centralized CTE metadata directory has been configured and guarded, the DSM Administrator can protect the device as an IDT-Capable GuardPoint through the DSM Management Console as described in ["Guard the Linux Device with an IDT-Capable GuardPoint" below](#).

Note

The initialization process prepares the device to be guarded but does not actually guard it. You need to assign an IDT-Capable GuardPoint to the device in the DSM before the device is actually protected. In addition, the initialization process is only kept in memory until the device is guarded or rebooted. If the device is rebooted before you guard it, you will need to perform the initialization procedure again.

Guard the Linux Device with an IDT-Capable GuardPoint

Note

For details about how to create a GuardPoint, see the chapter, "Managing GuardPoints", in the *DSM Administration Guide*.

After the device has been initialized, you can guard the device as an IDT-Capable GuardPoint from the DSM Management Console. For existing devices, as soon as the GuardPoint configuration has been pushed to the host and the status changes to guarded, CTE begins transforming the data on the disk using the encryption key associated with the GuardPoint Policy.

WARNING

If access to the device is shared access across multiple CTE Protected hosts in a cluster, be sure to guard the device on one and only one of the CTE hosts.

1. Log on to the DSM Management Console as an administrator of type Security with Host role permissions, type Domain and Security, or type All.
2. Make sure that you know what Policy you want to associate with the GuardPoint or create a new **In-place Data Transformation - Device** policy if needed. The policy you use for IDT must use an XTS-AES 256 key as the key rule. For details, see ["IDT-Capable GuardPoint Encryption Keys" on page 211](#).
3. Select **Hosts > Hosts** on the menu bar. The *Hosts* window opens.
4. Click the target host in the **Host Name** column. The Edit Host window opens to the General tab for the selected host.
5. Click the **GuardPoints** tab and then click **Guard**. The Guard window opens.
6. In the **Policy** field, select the In-place Data Transformation - Device policy you identified or created earlier in this procedure. CTE will use the XTS-AES 256 key associated with this policy to encrypt the data on the device.

7. In the **Type** field, select either **Raw or Block Device (Auto Guard)** or **Raw or Block Device (Manual Guard)**.

If you select **Auto Guard**, CTE starts the guard process as soon as the policy is pushed to the host. You enable, disable, guard, and unguard the GuardPoint in the DSM. If you want to have the device automatically guarded and mounted at system start up, add the device to `/etc/fstab`. For details, see ["Auto Mount Options for File System Devices on Linux" on page 226](#).

If you select **Manual Guard**, You guard the GuardPoint on the protected host with the `secfsd -guard <path>` command and unguard it with the `secfsd -unguard <path>` command. At system startup, you must guard the device and then mount it. This gives you more control over when data transformations occur because CTE will not start encrypting or rekeying the device until you manually start the process.

8. In the **Path** field, add the path for the device you want to guard. For example, `/dev/sdc2` and `/dev/sdc3`.

If you specify multiple paths in this field, all specified devices will be guarded and all will be encrypted with the encryption key specified in the associated policy.

The devices you specify here must already have been initialized as described in ["Initializing an IDT-Capable Device" on page 215](#). They can be new devices, devices with existing data, or a mix of both.

9. Make sure the **In-place Data Transformation - Device** check box is checked. If this option is not selected, the host will *not* enable the device as an IDT-Capable GuardPoint.

10. Click **OK**.

The DSM pushes the policy and the IDT-Capable GuardPoint configuration to the host and the CTE Agent on the host writes the IDT Device Header into the CTE Private Region for the specified devices. If this is a new device, the status changes to guarded and the disk is available for user access immediately.

If there is existing data on the device, CTE begins transforming the data from clear-text to cipher-text as soon as the IDT-Capable GuardPoint configuration is available and the device status changes to guarded. The device will remain inaccessible until this data transformation completes. The length of time required to transform the data depends on the amount of existing data and the number of parallel data transformation jobs specified on the `voradmin config` command. For details, see ["Data Relocation and Transformation on Existing Linux Devices" on the next page](#).

To see the data transformation progress, use the `voradmin idt xform status <device-name>` command, as described in ["Viewing Device Status and the IDT Device Header" on page 225](#).

After the device is initialized and guarded, the protected device must be accessed through the CTE device pathname. This pathname corresponds to the `secvm` device. For example, the Linux device pathname `/dev/sdc2` becomes `/dev/secvm/dev/sdc2` as soon as the process is complete.

Notes

- Be sure to use the secvm device name when using file system management tools such as `mkfs` and `fsck`.
- Do not use the device mapper names corresponding to IDT-Capable GuardPoints for GuardPoint administration on protected hosts.

Data Relocation and Transformation on Existing Linux Devices

When you add an IDT-Capable GuardPoint to a device that has been initialized with the `voradmin idt xform` command and you opted to embedded the CTE Private Region on the device, CTE first relocates existing data in the region of the device designated as CTE Private Region. The data is relocated to the end of the device, into the new space allocated when you resized the device. The relocation occurs once when the device is guarded for the first time. No relocation is necessary for subsequent rekeys on the device.

Relocation of data is transparent to applications accessing data through the IDT-Capable GuardPoint. CTE will map application I/O requests over the private region to the relocated region. After guarding the device, you can grow the device size further if necessary. However, you cannot shrink the device size.

IDT does not require a separate policy for data transformation. If you initialized the device with the `xform` option, CTE starts the IDT process when transformation is required. During the IDT process, access to the device is blocked until the IDT process completes and all the data on the device has been encrypted.

```
# voradmin idt status xform /dev/sdc3
Status:          In-Process
                Relocation Zone 9764864 (relocated = 1)
                SegSpc 27, Xformation Range: 3217 ... 4799, SegIDs: 4795 4796 4791 4792 4797 4798
4799
                KeyID:          2793      Key Name:      IDT_DEMO_KEY_1
                Old KeyID:       0         Old Key Name: clear_key

# dd if=/dev/secvm/dev/sdc3 of=/dev/null bs=512 count=1
dd: failed to open 'dev/secvm/dev/sdc3': Resource temporarily unavailable

# voradmin idt status xform /dev/sdc3
Status:          Complete
                Relocation Zone 9764864 (relocated = 1)
                SegSpc 27, Xformation Range: 3217 ... 20189, SegIDs: none
                KeyID:          2793      Key Name:      IDT_DEMO_KEY_1
                Old KeyID:       0         Old Key Name: clear_key

# dd if=/dev/secvm/dev/sdc3 of=/dev/null bs=512 count=1
1+0 records in
1+0 records out
512 bytes (512 B) copied, 0.000989039 s, 518 kB/s
```

Thin-Provisioned Devices

IDT skips transforming thin-provisioned regions of a device. Data returned to IDT as sequence of clear-text zeros, in sector size granularity, is indication of possible sparse or un-allocated regions of the device that do not have to be transformed.

IDT Recovery From Crash

IDT is fault tolerant in the event of system crashes. IDT keeps track of the transformation process over the entire device. In the event of a crash, IDT will automatically resume transformation from the point of failure as soon the GuardPoint is enabled after system startup.

If you find the transformation status set to **In-Progress** when the GuardPoint is not enabled, the **In-Progress** state reflects an earlier system crash after which the GuardPoint has not been enabled to recover from the interruption in the IDT process.

Example of Creating an IDT-Capable GuardPoint on an Existing Linux Device

The following example shows the process of initializing an existing Linux device using `voradmin idt config xform` and guarding it as an IDT-Capable GuardPoint from the viewpoint of the Linux root user. In this example, all files in `/bin/*` are copied to a temporary location outside the device, then compared with the corresponding files on the device after the device has been resized and encrypted. The comparison proves that the file system is unchanged after the encryption process has completed.

First, we verify that the device is not protected, then we check the current size of the disk and create the copy of the files in `/bin/*`. After that, we run the `voradmin idt config xform` command to initialize the device.

```
# voradmin idt status /dev/sdc1
Device /dev/sdc1 is not configured as IDT-Capable
# fdisk -l /dev/sdc1
Disk /dev/sdc1: 21.1 GiB, 21103640576 bytes, 41218048 sectors
Units: sectors of 1 * 512 = 512 bytes
Sector size (logical/physical): 512 bytes / 512 bytes
I/O size (minimum/optimal): 512 bytes / 4194304 bytes
# mkfs.xfs /dev/sdc1
meta-data=/dev/sdc1             isize=256    agcount=4, agsize=1288064 blks
      =                       sectsz=512    attr=2, projid32bit=1
      =                       crc=0        finobt=0, sparse=0
data      =                       bsize=4096   blocks=5152256, imaxpct=25
      =                       sunit=0      swidth=0 blks
naming    =version 2           bsize=4096   ascii-ci=0 ftype=1
log       =internal log       bsize=4096   blocks=2560, version=2
      =                       sectsz=512    sunit=0 blks, lazy-count=1
realtime  =none               extsz=4096   blocks=0, rtextents=0
# mount -t xfs /dev/sdc1 /xfs
# cp /bin/* xfs
# voradmin idt config xform /dev/sdc1
Device /dev/sdc1 must be resized to at least 41347072 sectors (40378 MBs) before guarding
as IDT-Capable GuardPoint
```

At this point, you need to resize the device using your device management tools. You must increase the size by at least 41347072 sectors (40378 MBs). After the device has been resized, you can verify the new size:

```
# fdisk -l /dev/sdc1
Disk /dev/sdc1: 21.2 GiB, 21169700864 bytes, 41347072 sectors
Units: sectors of 1 * 512 = 512 bytes
Sector size (logical/physical): 512 bytes / 512 bytes
I/O size (minimum/optimal): 512 bytes / 4194304 bytes
```

After the device has been resized, the DSM Administrator can guard the device with the desired In-place Data Transformation - Device policy. If the DSM Administrator chooses Auto Guard, data transformation begins as soon as the policy is pushed to the host. If the DSM Administrator chooses Manual Guard, data transformation does not begin until the Linux root user initiates it with the `secfsd -guard` command. Once data transformation begins, the Linux root user can check the progress using the `voradmin idt status xform` command.

```
# secfsd -guard /dev/sdc1
secfsd: Path is guarded
# voradmin idt status xform /dev/sdc1
Status:          In-Process
Relocation Zone 9764864 (relocated = 1)
SegSpc 27, Xformation Range: 3217 ... 4799, SegIDs: 4795 4796 4791 4792 4797 4798
```

4799

```
KeyID:          2793      Key Name:      IDT_DEMO_KEY_1
Old KeyID:      0         Old Key Name:  clear_key
```

After the status has changed to completed, you can compare the current version of the files in `/bin/*` with the ones you copied earlier.

```
# voradmin idt status xform /dev/sdc1
Status:          Complete
Relocation Zone  9764864 (relocated = 1)
SegSpc 27, Xformation Range: 3217 ... 20189, SegIDs: none
KeyID:          2793      Key Name:      IDT_DEMO_KEY_1
Old KeyID:      0         Old Key Name:  clear_key

# voradmin idt status /dev/sdc1
IDT Header on /dev/secvm/dev/sdc1
Version:          1
Change:          0
Private Region Size: 129024 sectors
Exported Device Size: 41218048 sectors
Key UUID:        9cc3c8e4-7ea7-310f-85c7-6f911de1ab52
Mount Path:      None

# mount -t xfs /dev/secvm/dev/sdc1 /xfs
# for file in '/bin/ls /sfx'; do cmp /bin/$file /xfs/$file; done
# umount /xfs
```

Changing the Encryption Key on Linux IDT-Capable Devices

To meet various compliance requirements, you may want to change the key that CTE has used to encrypt IDT-Capable GuardPoints. Thales refers to this changing of encryption keys as “Key rotation” or “Rekey”. Unlike the Live Data Transformation product offered by Thales for file systems on traditional storage devices, to change the encryption key on an IDT-Capable GuardPoint, the device must be taken offline. The data on the device will be inaccessible during the key rotation process.

WARNING

For devices with shared access across multiple CTE Protected hosts in a cluster, you must designate one and only one of the nodes in the cluster as the node on which you plan to initialize and guard the device for rekey. The designated node must be the only one that accesses the device until the entire rekey process has completed. This requires guarding each shared device at the designated host level rather than at the host group level if you are using a host group to manage the CTE Protected nodes in your cluster. DO NOT initialize or guard any device on multiple nodes in the cluster simultaneously, because multiple nodes attempting to transform the same data can corrupt the data on the entire device.

1. Log on to the DSM Management Console as an administrator of type Security with Host role permissions, type Domain and Security, or type All.
2. Make sure that you know what Policy you want to associate with the GuardPoint or create a new **In-place Data Transformation - Device** policy if needed. The key rule must specify the current XTS-AES 256 key that the GuardPoint is currently using as well as the new XTS-AES 256 key that you want to use to transform the protected data.

You can either create a new In-place Data Transformation - Device policy or you can change the keys assigned to an existing In-place Data Transformation - Device policy. If you use an existing policy however, the new key you specify cannot have been previously used to encrypt the IDT-Capable GuardPoint. If you want to rekey the GuardPoint using a previously-used key, you must create a new policy in order to do so.

The following screenshot shows a policy named IDT_DEMO_POLICY_2 for rekey that uses IDT_DEMO_KEY_1 as the current key and IDT_DEMO_KEY_2 as the new key:

Including both the current key and the new key in the policy ensures that both keys will be available during the rekey process, even if something happens and the key information in stored in the CTE Private Region becomes unavailable.

Do not push this policy to the host yet.

3. Shut down any applications accessing the GuardPoint you are planning to rekey. If the GuardPoint is mounted as a file system, you must also unmount the file system.
4. Once the data can no longer being accessed, you can unguard the GuardPoint on the DSM.
 - a. If the GuardPoint is a manual device GuardPoint, you must first unguard it using the `secfsd -unguard` command on the CTE host before you unguard it on the DSM. If it is an automatic GuardPoint, you can skip this step and simply unguard the GuardPoint in the DSM.

The following example checks the guard status of `/dev/sdc1` and gets the current key name, then unguards the device.

```
# secfsd -status guard
GuardPoint  Policy                Type                ConfigState  Status  Reason
-----
/dev/sdc2   IDT_DEMO_POLICY_1  rawdevice          guarded      guarded  N/A
/dev/sdc3   IDT_DEMO_POLICY_1  rawdevice          guarded      guarded  N/A
/dev/sdc1   IDT_DEMO_POLICY_1  manualrawdevice    guarded      guarded  N/A

# voradmin idt status xform /dev/sdc1
Status:      Complete
Relocation Zone 0 (relocated = 0)
SegSpc 27, Xformation Range: 4294967295 ... 4294967295, SegIDs: none
KeyID:       2793    Key Name: IDT_DEMO_KEY_1
Old KeyID:   0       Old Key Name: clear_key

# secfsd -unguard /dev/sdc1
secfsd: Path is not guarded

# secfsd -status guard
GuardPoint  Policy                Type                ConfigState  Status  Reason
-----
/dev/sdc2   IDT_DEMO_POLICY_1  rawdevice          guarded      guarded  N/A
/dev/sdc3   IDT_DEMO_POLICY_1  rawdevice          guarded      guarded  N/A
/dev/sdc1   IDT_DEMO_POLICY_1  manualrawdevice    unguarded    not guarded  Inactive
```

- b. Return to the DSM Management Console, select the GuardPoint in the GuardPoints table, and click **Unguard** to unguard the device in the DSM.

Wait until the GuardPoint has been removed from the DSM.

5. Return to the device and run the `voradmin idt rekey` command. After you run the `voradmin` command, the IDT Device Header is temporarily removed from the device.

```
# voradmin idt rekey /dev/sdc1
Enter YES to prepare device /dev/sdc3 for rekey -> YES
# voradmin idt status /dev/sdc1
Device /dev/sdc1 is configured to guard as IDT-Capable GuardPoint
```

Note: For manual GuardPoints, you must unguard the device both using `secfsd -unguard` and the DSM Management Console before you can use the `voradmin idt rekey` command.

6. In the DSM, guard the device with the new **In-place Data Transformation - Device** policy you created earlier. If you selected a Manual GuardPoint, use `secfsd -guard` to activate the new policy and start the data transformation to the new key.

During the IDT process, user access to the GuardPoint is blocked until IDT completes the transformation process.

The following example shows how to use `secfsd -guard` on manual GuardPoint `/dev/sdc1`, and the status messages that occur during the rekey process. If you are using an automatic GuardPoint, you do not need to use the `secfsd -guard` command. Instead, the rekey process starts as soon as you push the new policy from the DSM.

```
# secfsd -guard /dev/sdc1
secfsd: Path is guarded
# secfsd -status guard
```

GuardPoint	Policy	Type	ConfigState	Status	Reason
/dev/sdc2	IDT_DEMO_POLICY_1	rawdevice	guarded	guarded	N/A
/dev/sdc3	IDT_DEMO_POLICY_1	rawdevice	guarded	guarded	N/A
/dev/sdc1	IDT_DEMO_POLICY_2	manualrawdevice	guarded	guarded	Data transformation in progress

```
# voradmin idt status xform /dev/sdc1
Status: In-Progress
Relocation Zone 0 (relocated = 0)
SegSpc 27, Xformation Range: 3987 ... 3993, SegIDs: 3991 3987 3988 3992 3989 3990
3993
KeyID: 2921 Key Name: IDT_DEMO_KEY_2
Old KeyID: 2793 Old Key Name: IDT_DEMO_KEY_1
```

7. After the `xform` status shows as completed, you can restart all application workloads on the guarded device.

```
# voradmin idt status xform /dev/sdc1
Status: Complete
Relocation Zone 0 (relocated = 0)
SegSpc 27, Xformation Range: 4768 ... 4768, SegIDs: none
KeyID: 2921 Key Name: IDT_DEMO_KEY_2
Old KeyID: 2793 Old Key Name: IDT_DEMO_KEY_1
# secfsd -status guard
```

GuardPoint	Policy	Type	ConfigState	Status	Reason
/dev/sdc2	IDT_DEMO_POLICY_1	rawdevice	guarded	guarded	N/A
/dev/sdc3	IDT_DEMO_POLICY_1	rawdevice	guarded	guarded	N/A
/dev/sdc1	IDT_DEMO_POLICY_2	manualrawdevice	guarded	guarded	N/A

Guarding an IDT-Capable Device with Multiple IO Paths on Linux

Each individual IO path from a server node to a storage controller is treated as a separate device on the host. DM-Multipath on a Linux host provides a management framework to group the individual IO paths to the same LUN into a single multipath device. If you use DM-Multipath to manage devices on the protected host, the individual devices that correspond to each IO path to the LUN cannot be configured for guarding as IDT-Capable, as those devices are under control of DM-Multipath. To guard such devices, you must guard the device mapper generated by DM-Multipath (multipathd) under the `/dev/mapper` directory.

Note

IDT and Efficient Storage are the only feature of CTE that exclusively support guarding of device mapper generated devices under DM-Multipath framework.

The following example illustrates the procedure for guarding a device mapper generated device with the alias name `/dev/mapper/mpathA`.

1. Create a **In-place Data Transformation - Device** policy using an XTS-AES 256 key as the key rule.
2. On the host, prepare the device to be configured as IDT-Capable using the `voradmin idt config [-external] new|xform [-c n] <mapper-alias-name>` command.
For example, if the disk is a new disk with no existing data, you would enter:

```
# voradmin idt config new /dev/mapper/mpathA
```

If the disk has existing data that you want to encrypt, you would enter:

```
# voradmin idt config xform /dev/mapper/mpathA
```
3. On the DSM, guard `/dev/mapper/mpathA` as Device GuardPoint using the policy created above. Be sure to check the **In-place Data Transformation - Device** check box.
4. For Manual Guard configuration, enable the GuardPoint using the `secfsd` command as follows:

```
# secfsd -guard /dev/mapper/mpathA
```
5. For Auto Guard, wait for the `/dev/mapper/mpathA` device to be guarded on the protected host.
6. Once the device is guarded, provide the pathname of the `secvm` device to applications and/or file system operations. For example, `/dev/secvm/dev/mapper/mpathA`.

Viewing Device Status and the IDT Device Header

After you guard a device, you can view the status of that device using the `voradmin idt [xform] status <device-name>` command, where:

- `xform` (optional). If you specify this option, CTE shows the status of any data transformation processes happening on the device. If you do not specify this option, CTE displays the IDT Device Header for the device.
- `<device-name>` (required). The standard Linux name of the device whose status you want to view. (For example, `/dev/sdc2`.)

For example, if you want to view the IDT Device Header for the Linux device `/dev/sdc2`, you would enter:

```
# voradmin idt status /dev/sdc2
IDT Header on /dev/secvm/dev/sdc2
      Version:                      1
      Change:                       0
Private Region Size:                129024 sectors
Exported Device Size:               9627648 sectors
      Key UUID:                    9cc3c8e4-7ea7-310f-85c7-6f911de1ab52
      Mount Path:                  None
```

If you want to view the data transformation status on `/dev/sdc2`, you would enter:

```
# voradmin idt status xform /dev/sdc3
Status:          In-Process
Relocation Zone  9764864 (relocated = 1)
SegSpc 27, Xformation Range: 3217 ... 4799, SegIDs: 4795 4796 4791 4792 4797 4798
4799
KeyID:           2793      Key Name:      IDT_DEMO_KEY_1
Old KeyID:       0        Old Key Name:  clear_key
```

The **Status** field displays **In-Progress** if a data transformation process is running, and **Completed** if the process has finished.

Linux System and IDT-Capable GuardPoint Administration

voradmin IDT Commands on Linux

The `voradmin` command is a command line utility for management of CTE specific configuration and status reporting. The `voradmin` command also supports configuration management related IDT-Capable GuardPoints (IDT).

For details about the Linux `voradmin idt` command options, see the man page for the `voradmin` command.

File System Mount Points on Linux

You can create and mount a file system on an IDT-Capable GuardPoint. CTE imposes one restriction on the mount point pathname selected for a device. Once you mount the device on a pathname, you cannot change the mount point to a different pathname. This restriction is enforced to allow the file system mount point to be guarded using a separate policy to enforce access control rules on the mounted file system namespace.

The following example shows the mount point of the IDT-Capable GuardPoint as the `/xfs` directory. The example also shows a failed attempt to mount the file system on a different directory pathname.

```
# voradmin idt status /dev/sdc1
IDT Header on /dev/secvm/dev/sdc1
Version:          1
Change:          0
Private Region Size: 129024 sectors
Exported Device Size: 9627648 sectors
Key UUID:         9cc3c8e4-7ea7-310f-85c7-6f911de1ab52
Mount Path:       /xfs
# umount /xfs
# mkdir /other-xfs
# mount -t xfs /dev/secvm/dev/sdc2 /other-xfs
mount: permission denied
# mount -t xfs /dev/secvm/dev/sdc2 /xfs
```

Auto Mount Options for File System Devices on Linux

IDT-Capable GuardPoints containing file systems can also be added to the `/etc/fstab` configuration file for auto mount at startup or unmount at shutdown. An entry can be for a GuardPoint configured for either Auto Guard or Manual Guard. For more information about Auto and Manual Guard options, see ["Guard the Linux Device with an IDT-Capable GuardPoint" on page 218](#).

Use the device path corresponding to an IDT-Capable GuardPoint device when specifying `fstab` entries, such as `/dev/secvm/dev/sdh`. Do not use the native device pathnames, such as `/dev/sdh`, or device mapper device names. You must also include several settings in the `fstab` entry for each IDT-Capable GuardPoint, as shown in the following table:

Option	Description
<code>x-systemd.requires=secvm-barrier.service</code>	Ensure that the IDT-Capable GuardPoint is enabled before the device is mounted at startup and disabled after the device is unmounted at shutdown. The <code>secvm-barrier.service</code> service is a proxy for all the services that make up CTE.
<code>nofail</code>	The system boot will proceed without waiting for the IDT-Capable device if it can't be mounted successfully.
<code>x-systemd.wanted-by=<idt device>.device</code>	Required for Linux distributions running <code>systemd</code> 242 or later. Instructs <code>systemd</code> to add a <code>Wants=</code> dependency on the IDT-Capable device to ensure that, when the device becomes available, this mount operation is executed. <code><idt device>.device</code> is the name of the device specified in <code>fstab</code> with the <code>'/'</code> replaced with <code>'.'</code> . For example, <code>/dev/secvm/dev/sdb</code> becomes <code>dev-secvm-dev-sdb.device</code> .

This is an example of an entry in `/etc/fstab` for an IDT-Capable GuardPoint with an xfs file system that is mounted on `/xfs`:

```
/dev/secvm/dev/sdh /xfs xfs x-systemd.requires=secvm-barrier.service, \
x-systemd.wanted-by=dev-secvm-dev-sdh.device,nofail 0 0
```

For information about configuring `systemd` for CTE, see [Chapter 6: "CTE and systemd" on page 76](#).

Linux System Utilities for Signing

The following table includes recommendations on the system and file system specific utilities for inclusion in the signature set to allow or deny root execution.

EXT Utilities	Deny/Allow	XFS	Deny/Allow	Generic Utilities	Deny/Allow
<code>badblock</code>	Allow	<code>fsck.xfs</code>	Allow	<code>mount</code>	Allow
<code>debugfs</code>	Deny	<code>mkfs.xfs</code>	Allow	<code>umount</code>	Allow
<code>e2freefrag</code>	Allow	<code>xfs_repair</code>	Allow	<code>dmsetup</code>	Allow
<code>e2fsck</code>	Allow	<code>xfs_admin</code>	Allow		
<code>e2image</code>	Allow	<code>xfs_bmap</code>	Allow		
<code>e2label</code>	Allow	<code>xfs_check</code>	Allow		
<code>e2undo</code>	Allow	<code>xfs_copy</code>	Deny		
<code>filefrag</code>	Allow	<code>xfs_db</code>	Deny		
<code>fsck.ext2</code>	Allow	<code>xfs_estimate</code>	Allow		
<code>fsck.ext3</code>	Allow	<code>xfs_freeze</code>	Allow		
<code>fsck.ext4</code>	Allow	<code>xfs_fsr</code>	Allow		
<code>logsave</code>	Allow	<code>xfs_growfs</code>	Allow		
<code>mke2fs</code>	Allow	<code>xfs_info</code>	Allow		
<code>mkfs.ext2</code>	Allow	<code>xfs_logprint</code>	Allow		

EXT Utilities	Deny/Allow	XFS	Deny/Allow	Generic Utilities	Deny/Allow
mkfs.ext3	Allow	xfs_mdrestore	Allow		
mkfs.ext4	Allow	xfs_metadump	Allow		
resize2fs	Allow	xfs_mkfile	Deny		
tune2fs	Allow	xfs_ncheck	Allow		

Resizing Guarded IDT Devices

Devices configured as IDT-Capable can be resized using the system-provided resizing utilities. If you are using a file system on the GuardPoint, you can mount the file system after resizing the device and then grow the file system to the new size using the appropriate utility such as `xfs_growfs` or `resize2fs`.

WARNING

Do not shrink IDT-Capable GuardPoints. Due to relocation of user data from the CTE Private Region, if you shrink the device, you may corrupt data on the device.

1. Stop applications from accessing the IDT-Capable GuardPoint.
 - Unmount the file system if the device is mounted.
 - Disable the IDT-Capable GuardPoint on the DSM if using Auto Guard or on the host with the `secfsd -unguard <device-name>` command if using Manual Guard.
2. Use the native disk management tools to resize the device.
3. After resizing the device, check the size of the device with the `fdisk -l` or similar command. Note that you cannot use the `voradmin idt status` command to verify the new size of the device at this point because the size information is not updated in CTE until the IDT-Capable GuardPoint is re-enabled.
4. If the reported size does not match what you expect, you may need to rescan your storage devices using the command appropriate for the device's connection type.
5. Once the expected size is achieved, enable the IDT-Capable GuardPoint and restart your applications.

This process is identical to resizing an ES GuardPoint. For an example of that process with CTE-Efficient Storage, see ["Example: Resizing a Linux Device" on page 195](#).

Use Cases Involving IDT-Capable GuardPoints

IDT-Capable GuardPoints support all of the use cases that apply to ES GuardPoints. For details, see ["Use Cases Involving Efficient Storage GuardPoints" on page 196](#).

Alerts and Errors on Linux

This section lists the alerts and errors that may be encountered during system operations.

Encryption key on device has not been made available

This alert may appear as the reason for a GuardPoint not to have been enabled. The message appears in the output of `secfsd -status guard` command. The status indicates that the encryption key specified in the policy for the GuardPoint has not been made available to the protected host.

Solution: Check the host's connectivity with the DSM.

Specified policy disagrees with metadata set on the Guard Path

This alert may appear as the reason for a GuardPoint not to have been enabled. The message appears in the output of `secfsd -status guard` command. The status indicates that the key specified in the policy for the GuardPoint does not match with the key stored in the IDT Device Header.

Solution: Un-guard the device and check the name and UUID of the key in the IDT Device Header using `voradmin idt status <device-name>` and `voradmin idt status xform <device-name>` commands and compare the name and UUID with the key name specified in the policy. Correct the discrepancy and re-guard the device.

Device has not been configured for IDT-Capable or Efficient Storage

This alert may appear as the reason for a GuardPoint not to have been enabled. The message appears in the output of `secfsd -status guard` command. The status indicates that the device has been properly guarded as an IDT-Capable GuardPoint on the DSM but the device has not been initialized for guarding as IDT-Capable.

Solution: The most probable cause of this error is that you did not initialize the device for guarding as IDT-Capable on protected host. It's also possible that the guarded device has already configured for guarding as Ean IDT-Capable GuardPoint. If the device needs to be initialized for guarding as IDT-Capable, see ["Initializing an IDT-Capable Device" on page 215](#).

Device not resized for guarding as IDT-Capable or Efficient Storage

This message appears in the output of `secfsd -status guard` command and indicates that the IDT-Capable GuardPoint was not successfully enabled. The status indicates that the newly guarded IDT-Capable GuardPoint, which has been initialized with `xform` option of `voradmin`, has not been resized to accommodate storage space for the CTE Private Region.

Solution: Unguard the IDT-Capable GuardPoint from the DSM, resize the LUN and verify that the host sees the expanded size, and then guard the IDT-Capable GuardPoint from the DSM.

Data transformation failed

This message appears in the output of `secfsd -status guard` command and indicates that the IDT-Capable GuardPoint was not successfully guarded. The status indicates that the protected host encountered an error while transforming the data on the device during IDT.

Solution: Consult with the system and/or storage admin to check on the health of the LUN in the storage array. You may contact Thales Support for troubleshooting and recovery if there has not been a report of any error on the LUN.

Data transformation in progress

This message appears in the output of `secfsd -status guard` command and indicates that the IDT-Capable GuardPoint was not successfully enabled. The status indicates that the protected host is transforming the data on the device.

Solution: You must wait for data transformation to complete. Check the status of transformation by running `voradmin idt status xform <device name>`. Access to the device is blocked until transformation completes.

Device <device-name> is configured to guard as Efficient Storage GuardPoint

This error message is reported by the `voradmin` command when initializing a device as an IDT-Capable GuardPoint that has already been initialized for guarding as an Efficient Storage GuardPoint.

Solution: The device has already been initialized for guarding as Efficient Storage and is probably waiting to be guarded as an ES GuardPoint. If you want to change the device to an IDT-Capable GuardPoint, you can remove the ES configuration by running `voradmin esg delete <device-name>` and then re-initializing the device as an IDT-Capable GuardPoint as described in ["Initializing an IDT-Capable Device" on page 215](#).

Device <device-name> is configured as Efficient Storage GuardPoint

This error message is reported by the `voradmin` command when initializing a device as IDT-Capable that is already being guarded as an Efficient Storage GuardPoint.

Solution: The device is already guarded by an Efficient Storage GuardPoint. If you want to change it to an IDT-Capable GuardPoint, you would need to decrypt the data, delete the Efficient Storage GuardPoint, then reinitialize the device as an IDT-Capable GuardPoint.

Device <device-name> is configured to guard as IDT-Capable GuardPoint

This error message is reported by the `voradmin` command when initializing a device as an IDT-Capable GuardPoint that has already been initialized for guarding as an IDT-Capable GuardPoint.

Solution: The device has already been initialized for guarding as IDT-Capable and is probably waiting to be guarded as an IDT-Capable GuardPoint through the DSM. Alternatively, if you want to remove the IDT-Capable configuration, use the `voradmin idt delete <device-name>` command.

Device <device-name> is configured as IDT-Capable GuardPoint

This error message is reported by the `voradmin` command when initializing a device that is already being guarded as an IDT-Capable GuardPoint.

Solution: The device is already guarded by an IDT-Capable GuardPoint.

GuardPoint for device <device-name> still guarded on DSM

This error message is reported by the `voradmin` command when attempting to initialize a device for rekey or removing the device as IDT-Capable.

Solution: Unguard the IDT-Capable GuardPoint from the DSM, wait for the protected host to process the update, and then rerun the `voradmin` command.

Failed to open device <device-name>, error Device or resource busy

This message occurs when `voradmin` detects that the target device is busy.

Solution: The device may already be in use by other application. Rerun the `voradmin` command when the device is no longer in use.

Device <device-name> is not configured as IDT-Capable

This error message is reported by the `voradmin` command when attempting to delete a device as an IDT-Capable GuardPoint.

Solution: This message indicates that the target device has been not initialized for guarding as IDT-Capable. The message may also be reported if the specified device has been initialized for guarding as IDT-Capable but it has not been guarded yet. In this case, it removes the preparation made by `voradmin`. You can remove the IDT-Capable configuration status on the device by running `voradmin idt delete <device-name>`. You may see the same error message again, and if you do, you can ignore it.

Abort! Error: Could not stop secfs, secvm device(s) busy

This error occurs during CTE shutdown when there is a busy CTE protected device.

Solution: Verify that all applications directly accessing `secvm` protected GuardPoints have been shut down. Ensure that all file systems on top of a `secvm` protected devices are under the control of `systemd` and have been unmounted before attempting to shut down the agent.

Abort! Error: Could not unmount file systems

This error occurs during CTE shutdown when a file system under the control of `systemd` fails to unmount.

Solution: Verify that file systems on top of an IDT-Capable GuardPoint devices are not busy and then rerun the agent shut down command.

A dependency job for idt.mount failed. See 'journalctl -xe' for details

This error occurs during CTE startup when system fails to mount a file system. This error message is typically accompanied by a long timeout during the CTE startup process.

Solution: Check that the underlying device is available and that the IDT-Capable GuardPoint was successfully applied on the device. Once the device is available, the file system will automatically finish mounting.

ESG/IDT-ALERT: IO error on header for [GuardPoint]

This is an alert message to the DSM. It occurs when CTE encounters a general error when attempting to access the private region on an IDT-Capable device.

Solution: An I/O error attempting to read or write to the device may have been caused by errors on the host or storage array. Consult with the system and/or storage admin to check on the health of the LUN in the storage array. You may contact Thales Support for troubleshooting and recovery if there has been no report of errors on the LUN.

ESG/IDT-ALERT: Data transformation failure on [GuardPoint]

This is an alert message to the DSM. It occurs when protected host encounters an error transforming the data on device during IDT process.

Solution: Please contact Thales Support for troubleshooting and recovery.

ESG/IDT-INFO: Data transformation complete on [GuardPoint]

This message is a notification to the DSM admin that the protected host has completed the data transformation of the specified IDT-Capable GuardPoint.

ESG/IDT-ALERT: Failed to resize <device-name>

This alert is a notification to the DSM admin that the protected host has failed to update the change to the device size in the IDT Device Header on the device.

Solution: Please contact Thales Support for troubleshooting and recovery.

FSADM-ALERT: ESG/IDT required Signature Set for system utilities may have to be resigned

This alert is a notification to the DSM admin that the recent system upgrade to the protected host may have updated the binary files listed in the signature set for restricting root access.

Solution: Upon this notification you must immediately re-sign the affected or all the binary files to prevent them from accessing protected data. See ["Linux System Utilities for Signing" on page 227](#).

File System is not automatically mounted after IDT completes

An IDT-Capable device with a file system that has been configured to automatically mount may fail to automatically mount while the device undergoes data transformation through IDT. Following is a sample log message in the kernel ring buffer that reports a failed attempt to access a device during IDT. You can ignore this message.

```
Vormetric SecVM: secvm_map during IDT ((dc 00000000c3537611))
```

When access to a device is to mount the file system, the kernel ring buffer may also report a second error message indicating that a file system failed to mount due to data corruption. You can ignore this message. This occurs because the mount command is issued after the device has been guarded but before data transformation through IDT is complete. While IDT is in progress, the device cannot be used, so any attempt to mount the file system will fail.

Solution: Manually mount the file system after IDT is complete.

Chapter 19: CTE with Teradata Database Appliances

CipherTrust Transparent Encryption (CTE) offers IDT-Capable GuardPoints on Linux for protecting data on raw devices. The IDT solution offers data encryption, data transformation, and access control on storage devices. The principles behind CTE's IDT-Capable GuardPoints can also be applied to protect Teradata Database Appliances. (For details about IDT, see [Chapter 18: "CipherTrust InPlace Data Transformation for Linux" on page 209](#).)

Note

Currently, this feature is only supported on the DSM. Support for this feature will be added to CipherTrust Manager in a future release.

This chapter contains the following sections:

IDT-Capable GuardPoints and Teradata Database Appliances	233
Requirements and Considerations	233
Guarding a Teradata Database Device	235
Changing the Encryption Key on Teradata Devices	243
Access Rules to Apply on the Teradata Database Appliance	244
Replication of IDT Metadata Files Across Members of a Clique	248
Best Practices	250
Uninstalling CTE from the Teradata Cluster	251
Alerts and Errors	252

IDT-Capable GuardPoints and Teradata Database Appliances

The Teradata Database Appliance must be protected by an IDT-Capable GuardPoint. The CipherTrust InPlace Data Transformation (CTE-IDT) feature offers capabilities such as initial data transformation and access control on protected raw devices. The transformation capability transforms existing clear-text data on a device to cipher-text, and allows for subsequent re-transformation using another encryption key.

You must be familiar with CTE and DSM support for IDT-Capable GuardPoints before you can configure CTE to work with Teradata. For details about CTE-IDT, see [Chapter 18: "CipherTrust InPlace Data Transformation for Linux" on page 209](#).

Requirements and Considerations

Location of the CTE Private Region

The CTE Private Region contains the metadata CTE requires in order to support initial transformation of data on the device and subsequent data transformation to other encryption keys. By default, CTE creates the CTE Private Region at the beginning of the guarded device. If data already exists on the device, CTE requires that the device to be expanded by 63 MB to make room for the CTE Private Region. The existing data in the first 63MB of the device is then migrated into the expanded space and the beginning of the device is reserved for the CTE metadata. This data relocation is totally transparent to applications and users.

With a Teradata Database Appliance, however, CTE cannot create the CTE Private Region at the beginning of the Teradata pdisk devices because the disks in the Appliance cannot be expanded. Therefore, for Teradata Databases, CTE stores the metadata in special directory called the CTE Metadata Directory located at

`/var/opt/teradata/vormetric/vte-metadata-dir`. This directory contains all of the metadata for every Teradata Database device that is protected by CTE.

While this does not affect the functionality of CTE, it does affect the way administrators need to back up the Teradata Database because both the Teradata Database and the metadata directory must be backed up together. You will not be able to restore a Teradata Database without access to the associated metadata in the CTE metadata directory.

Metadata File Access and Teradata Clusters

A Teradata *cluster* can contain multiple hosts. The members of a cluster that share access to pdisk devices belong to a *clique*. When you create an IDT-Capable GuardPoint on a pdisk, the metadata for that GuardPoint must be available to all members of the clique. CTE automatically replicates the metadata files across the members of a clique when the metadata is created or changed. For details, see ["Replication of IDT Metadata Files Across Members of a Clique" on page 248](#).

Additional Requirements and Considerations

- The Teradata kernel must be at minimum version 4.4.140-96.54.TDC-default on every node of the Teradata Database Appliance on which you plan to install CTE. Refer to the release notes document for CTE releases for compatibility requirements between the kernel releases from Teradata and CTE releases.

CAUTION

Be sure the version of the Teradata Database is fully compatible with CTE.

The Parallel Upgrade Tool (PUT) component of Teradata Database has been enhanced to discover CTE protected devices. The Parallel Upgrade Tool (PUT) component of Teradata (TDput) must be version `TDput-03.09.06.09` or higher. This capability in the PUT component must be available in your Teradata Database.

The Parallel Database Extensions (PDE) component of Teradata (ppde) must be version `ppde-16.20.53.07` or higher. This capability in the PDE component must be available in your Teradata Database.

The Teradata I/O Scheduler (tdsched) component must be version `01.04.02.02-1` or higher. This capability in the I/O Scheduler component must be available in your Teradata Database.

Contact your Teradata Customer Support Representative if you are unsure of the availability of this functionality in your Teradata cluster.

- The CTE Agent must be installed in `/opt/teradata/vormetric` on every node in the Teradata cluster. In order to specify this location, use the `-d` option when installing CTE. For example:

```
# ./vee-fs-7.0.0-47-sles12-x86_64.bin -d /opt/teradata/vormetric
```

Note: The CTE Agent can be installed without stopping the Teradata Database service.

- The CTE metadata directory `/var/opt/teradata/vormetric/vte-metadata-dir` must be guarded by the DSM Administrator to prevent accidental modification or deletion of the CTE metadata files. If the CTE metadata directory is not guarded, any attempt to configure or enable an IDT-Capable GuardPoint on the Teradata appliance will be rejected.

The standard CTE policy associated with the metadata directory must:

- Deny all users (including the root user) the ability to modify or remove any files in the metadata directory.
- Specify the key `clear_key` in the key rule so that the metadata is stored in clear text.

The following figure shows a sample policy for guarding the CTE metadata directory:

- The Teradata Database service must be stopped in order to upgrade an existing CTE Agent installation. To stop the Teradata Database service, use the `tpareset -x Stopping Database` command.
- The Teradata Database service must be stopped before CTE can rekey any guarded devices, and the service must remain stopped until CTE has finished rekeying *all* guarded devices on the appliance.

Guarding a Teradata Database Device

In order to guard a Teradata Database device, you need to:

1. Install CTE on every node in your Teradata Database Appliance. During this procedure you will register each node (also called the 'protected host') with the DSM. For details, see ["Install CTE on the Teradata Database Appliance" below](#).
2. Identify the devices that you want to guard as IDT-Capable GuardPoints. For details, see ["Identify the Devices to Be Guarded" on the next page](#).
3. Select the initial configuration method that you want to use. For details, see ["Select the Initial Configuration Method" on page 237](#).
4. Initialize and guard the devices using the selected initialization method. For details, see ["Initialize and Guard the Database Devices Using the Standard Initialization Method" on page 237](#) or ["Initialize and Guard the Teradata Database Devices Using the Backup/Restore Method" on page 240](#).

Note

You must use the "In-place Data Transformation - Device" policy type when guarding those devices.

Install CTE on the Teradata Database Appliance

CTE must be installed on every node in the Teradata cluster, including any Hot Standby Nodes. When you install CTE on every node in your Teradata cluster and register each node with the DSM, keep the following things in mind:

- You must have AES-NI available on the host.
- The Teradata kernel must be at version 4.4.140-96.54.TDC-default, or higher, on the Teradata Database Appliance on which you plan to install CTE. Refer to CTE release notes for compatibility between CTE and Teradata kernel releases.
- Your version of Teradata Database must be fully compatible with CTE for supporting the pdisk devices protected as IDT-Capable GuardPoints.
- The CTE Agent must be installed in `/opt/teradata/vormetric`. In order to specify this location, use the `-d` option when installing CTE. For example:

```
# ./vee-fs-7.0.0-47-sles12-x86_64.bin -d /opt/teradata/vormetric
```

WARNING

Before you install or upgrade CTE, you must stop the Teradata Database and any other applications that access the database devices directly or through the database service. Failure to stop the applications will result in a failure to install or upgrade CTE.

CAUTION

Be sure to install the CTE Agent in a file system with sufficient free storage space. The minimum available free space is the number of pdisks in your cluster multiplied by 63MB.

For details about installing the CTE Agent and registering it with the DSM, see ["Configuring CTE for Linux with a DSM" on page 39](#).

Identify the Devices to Be Guarded

Storage devices in Teradata clusters are known as pdisks. A pdisk is a slice of a LUN exported from the backend storage system attached to the nodes in a cluster. For example, the pdisk named `/dev/pdisk/dsk304` is a symbolic link to the slice on the LUN called `/dev/disk/by-id/tdmp-360080e500043092c0000b46f5c34c018-part3`, as shown below:

```
# ls -l /dev/pdisk/dsk304
lrwxrwxrwx 1 root root 70 May 18 12:21 /dev/pdisk/dsk304 -> /dev/disk/by-id/tdmp-360080e500043092c0000b46f5c34c018-part3
```

CTE guards the devices represented by the pdisks in the Teradata cluster. In the example above, the device that you must configure and guard as an IDT-Capable GuardPoint is `/dev/disk/by-id/tdmp-360080e500043092c0000b46f5c34c018-part3`. You cannot use the symbolic link name when initializing or guarding the storage devices.

To identify the disks available to the Teradata cluster and require CTE protection, look in `/dev/pdisks` on each node in the cluster. Any symbolic links that point to a Linux device path are the disks that should be initialized.

CAUTION

Do *not* enter the path name of the pdisk device when initializing it for guarding or in the DSM when you actually guard the device.

Select the Initial Configuration Method

Thales supports two methods for the initial configuration of Teradata Database devices:

- **Standard Initialization Method.** This method configures devices for initial encryption of existing clear-text data on the database devices. The time required to encrypt may take hours or even days, depending on the volume of data, the number of database devices and nodes, and the bandwidth of the storage back-end of database devices. For details, see ["Initialize and Guard the Database Devices Using the Standard Initialization Method" below](#).
- **Backup/Restore Initialization Method.** This method skips the initial encryption step but requires a full backup of the database and the engagement of Teradata Customer Support to assist you with some configuration steps at the Teradata database level in preparation for the full restore of database after the database devices are protected. The length of time required for this method depends on the length of time it takes to back up, and then fully restore, your Teradata database. For details about using this method, see ["Initialize and Guard the Teradata Database Devices Using the Backup/Restore Method" on page 240](#).

Initialize and Guard the Database Devices Using the Standard Initialization Method

The following procedure describes how to perform the initial configuration of your database devices using the Standard Initialization Method. This procedure encrypts the existing data in place and does not require you to backup your Teradata database when initially deploying CTE. It may, however, take several hours, or even days, to complete depending on the volume of data, the number of database devices and nodes, and the bandwidth of the storage back-end of database devices.

WARNING

For each device, you must designate *one and only one* of the nodes in the cluster as the node on which you plan to initialize and guard the device for the first time. The designated node must be the only one that guards the device until the entire initial data transformation process has completed. **DO NOT** initialize or guard any device on multiple nodes in the cluster simultaneously, because multiple nodes attempting to transform the same data can corrupt the data on the entire device.

1. Shut down the Teradata Database so that the devices you want to protect can be configured. You cannot initialize an online database device.
2. For each device, designate one of the nodes in the cluster as the node you will use for the initial data transformation when the device is guarded for the first time.
3. Log into the designated node in the Teradata Database Appliance and run the `voradmin idt config` `[-external] [new|xform] [-c <n>] <device-name>` command, where:
 - `[new|xform]` (required) indicates whether data already exists on the device. If the device contains no data (it is a new disk), specify `new`. If the device contains data that you want to keep, specify `xform`. Most installations of Teradata Appliance are expected to have `pdisk`s populated with data, therefore most often you will use the `xform` option. When you use `xform`, CTE will transform all existing data on the device from clear-text to cipher-text as soon as you guard the device on the Appliance. The device will be inaccessible until the transformation is complete, and the device must remain offline to the Teradata Database service during the entire transformation process. No user access will be permitted until all data has been transformed.
 - `-external` (required). You *must* use this option when initializing any Teradata device. With this option, CTE writes the CTE Private Region to a metadata file located in the CTE metadata directory. For details, see ["Location of the CTE Private Region" on page 233](#).

- `-c <n>` (optional). If you use this option, CTE sets the number of data transformation jobs to run in parallel to the number specified in `<n>`. `<n>` can be an integer between 1 and 60 (default: 8).

Each data transformation job transforms 1MB worth of data and requires CPU resources in addition to three I/O operations as part of data transformation. Each job reads 1MB of data from the device, preserves the data in the CTE private region, rekeys the data to cipher-text, and writes the transformed data to the device. If you increase the number of parallel jobs, the data transformation process will complete faster but there will be an increased performance impact on the system. Only increase the `-c` option if you are certain that the system resources are available to handle the additional load.

The value for the `-c` option you specify here remains in effect for all subsequent data transformations (such as any data rekeys) until you specify a new value.

- `<device-name>` (required). The name of the Teradata Database device that you want to initialize.

For example:

```
# voradmin idt config -external xform -c 20 \  
/dev/disk/by-id/tcmdp-360080e500043092c0000b46f5c34c018-part3
```

4. Repeat the `voradmin idt config` command for each device you want to initialize. If you want to distribute the processing load among all the nodes in the cluster, make sure that you run the `voradmin idt config` command for each device on the node you designated for the purpose. The node on which you run the `voradmin idt config` command must also be the node that performs the initial data transformation.
5. After you initialize the devices, you need to use the DSM Management Console to designate those devices as an IDT-Capable GuardPoints and assign the In-place Data Transformation - Device policy (or policies) you want to use on those devices as described in ["Guard the Devices as IDT-Capable GuardPoints" below](#).

Guard the Devices as IDT-Capable GuardPoints

WARNING

For each device, you must designate one and only one of the nodes in the cluster as the node on which you plan to initialize and guard the device for the first time. The designated node must be the only one that accesses the device until the entire initial data transformation process has completed. This requires guarding each device at the designated host level rather than at the host group level. **DO NOT** initialize or guard any device on multiple nodes in the cluster simultaneously, because multiple nodes attempting to transform the same data can corrupt the data on the entire device.

1. Log on to the Management Console as an administrator of type Security with Host role permissions, type Domain and Security, or type All.
2. Select **Hosts > Hosts** on the menu bar. The *Hosts* window opens.
3. Click the target host in the **Host Name** column. The Edit Host window opens to the General tab for the selected host.
4. In the **Policy** field, select a In-place Data Transformation - Device policy from the list of available policies. The policy must meet the requirements described in ["Policy Requirements for IDT-Capable GuardPoints" on page 213](#).

Note: For information about how to create a GuardPoint, see the chapter, "Managing GuardPoints", in the *DSM Administration Guide*.

5. In the *Type* field, select **Raw or Block Device (Auto Guard)**.

6. In the *Path* field, add the Linux device name for the device you want to guard. For example, `/dev/disk/by-id/tdmp-360080e500043092c0000b46f5c34c018-part3`. Do *not* enter the symbolic `pdisk` device name for a Teradata disk.
7. Make sure the In-place Data Transformation - Device check box is selected. An example of this is shown below.

8. Click **OK**.

The DSM pushes the policy and the GuardPoint configuration to the node in the cluster and the CTE Agent on the node writes the IDT Device Header into the CTE Private Region in the local CTE metadata directory on the node.

If this is a new device, the status changes to guarded immediately. If there is existing data on the device, CTE begins transforming the data from clear-text to cipher-text as soon as the GuardPoint configuration is available and the device status changes to guarded. The device will remain inaccessible until this data transformation completes. The length of time required to transform the data depends on the amount of existing data and the number of parallel data transformation jobs specified on the `voradmin config` command. To see the data transformation progress, use the `voradmin idt xform status <device-name>` command, as described in ["Viewing Device and Data Transformation Status" on the next page](#).

Devices with existing data are transformed from clear-text to cipher-text using the encryption key specified in the selected policy through the CipherTrust InPlace Data Transformation (CTE-IDT) process. For details on how CTE does data transformation on IDT-Capable GuardPoints, see [Chapter 18: "CipherTrust InPlace Data Transformation for Linux" on page 209](#).

WARNING

The initial data transformation of each device must be executed on *one and only one* of the nodes in the cluster. DO NOT initialize or guard the device on multiple nodes in the cluster before the initial data transformation has completed, because doing so initiates the data transformation process on the device on multiple nodes. The simultaneous attempts to transform the data for the first time can cause data corruption of all data on the entire device.

After the device is initialized and guarded, the protected device must be accessed through the device pathname corresponding to the `secvm` device. For example, if you guard the Linux device `/dev/disk/by-id/tdmp-360080e500043092c0000b46f5c34c018-part3`, the pathname becomes `/dev/secvm/dev/disk/by-id/tdmp-360080e500043092c0000b46f5c34c018-part3` as soon as the process is complete.

9. After all the Teradata Database devices have been guarded, disable the guarded IDT-Capable GuardPoints on each designated node and then enable those GuardPoints at the Host Group level on all the nodes in the clique.
10. After guarding your devices and before starting your database, you must change the current configuration of your cluster to reflect the status of the pdisk devices guarded as IDT-Capable GuardPoints. See the **Rebuild Vconfig Only** option of the Teradata Parallel Upgrade Tool (PUT) service to apply the guarded status of the pdisk devices into your database configuration. The **Rebuild Vconfig** process applies the guarded configuration status of each pdisk and resets the pdisk symbolic link to the CTE `secdm` device.

WARNING

You must complete this step before starting your database. Failure to do so will result in database failures and potential corruption of your database.

For example, the pdisk `/dev/pdisk/dsk304` is linked to the `secdm` device after **Rebuild Vconfig Only** commits the guarded status of pdisk on each node:

```
# ls -l /dev/pdisk/dsk304 \
lrwxrwxrwx 1 root root 70 May 18 12:21 /dev/pdisk/dsk304 -> /dev/disk/by-id/tdmp-360080e500043092c0000b46f5c34c018-part
```

11. After all the Teradata Database devices have been guarded in the clique and the **Rebuild Vconfig Only** on TDput has been executed, start the Teradata Database:

```
/etc/init.d/tpa start
```

Viewing Device and Data Transformation Status

After you guard a Teradata Database device, you can view the status of that device using the `voradmin idt status [xform] <device-name>` command, where:

- `xform` (optional). If you specify this option, CTE shows the status of any data transformation processes happening on the device. If you do not specify this option, CTE displays the IDT Device Header for the device.
- `<device-name>` (required). The name of the Teradata Database device that you want to initialize. This must be the actual device name and not the symbolic pdisk name.

For example, if you want to view the status of device `/dev/disk/by-id/tdmp-360080e500043092c0000b46f5c34c018-part3`, you would enter:

```
# voradmin idt status /dev/disk/by-id/tdmp-360080e500043092c0000b46f5c34c018-part3
```

If you want to check the data transformation progress on the device `/dev/disk/by-id/tdmp-360080e500043092c0000b46f5c34c018-part3`, you would enter:

```
# voradmin idt status xform \
/dev/disk/by-id/tdmp-360080e500043092c0000b46f5c34c018-part3
```

The **Status** field displays **In-Progress** if a data transformation process is running, and **Completed** if the process has finished.

Initialize and Guard the Teradata Database Devices Using the Backup/Restore Method

The Standard Initialization Method encrypts the Teradata database devices using In-place data transformation. Because Teradata Appliance models range in both storage and node sizes within a cluster, the time it takes to encrypt the existing data in-place on these large scale models may exceed the desired timeframe.

To address this issue on an existing Teradata database, you can configure CTE on Teradata Appliances using the Backup and Restore method to retain existing data. The total time required to configure your Teradata Appliances with CTE using this method depends on how long your backup/restore application takes to restore the database.

To use this method, you must:

1. Backup the entire Teradata database, including all meta files required for a full restore of that database.
2. Install and configure CTE on the Teradata database devices.
3. Work with Teradata Customer Support to initialize a `sysinit` on the Teradata Appliance cluster in preparation for a full database restore.
4. Perform a full restore of the Teradata database from the backup to the CTE protected devices. CTE automatically encrypts the data as it is restored to each protected device.

Prerequisites

Before starting this process, the following prerequisites must be completed:

- Make sure you have met the requirements described in ["Requirements and Considerations" on page 233](#).
- Create or identify the XTS-AES 256 key that you will use for the In-place Data Transformation - Device policy you will apply to the IDT-Capable GuardPoints.
- Create a **Standard** policy that will be used to guard the CTE Metadata Directory (`/var/opt/teradata/vormetric/vte-metadata-dir`).
- Create an **In-place Data Transformation - Device** policy that will be used to guard the Teradata Database Devices. This policy must use an XTS-AES 256 key.
- Identify all of the devices that need to be guarded as described in ["Identify the Devices to Be Guarded" on page 236](#).

Procedure

1. Using a Teradata certified backup application, backup your *entire* Teradata database. The backup needs to include the Data Dictionary, the user database, and everything else that is required for a successful restore of your database. Contact your Teradata Customer Support representative for the requirements for a full backup.
2. After confirming that your backup of the Teradata database completed and successful, shutdown the Teradata database.

```
# tpareset -x -f "shutting down for CTE installation"
```
3. Install CTE in `/opt/teradata/vormetric` on all nodes in the Teradata cluster and register them to a DSM server as described in ["Install CTE on the Teradata Database Appliance" on page 235](#).

```
# ./vee-fs-7.0.0-47-sles12-x86_64.bin -d /opt/teradata/vormetric
```
4. Create the CTE metadata directory (`/var/opt/teradata/vormetric/vte-metadata-dir`) on all nodes in the cluster.

```
# . pcl -shell "mkdir -p /var/opt/teradata/vormetric/vte-metadata-dir"
```
5. If you are using the Teradata Intelibase model, do the following. If you are using the Teradata Inteliflex model, proceed to Step 6.
 - a. Log on to the DSM, click the **Hosts** tab, and set the GuardPoint to the CTE Metadata Directory (`/var/opt/teradata/vormetric/vte-metadata-dir`) using the Standard policy that was created for the metadata directory on all the nodes in the Teradata cluster.
 - b. On each node, identify the list of disks that will be configured and guarded as "new" devices as described in ["Identify the Devices to Be Guarded" on page 236](#).

- c. On each node, configure each disk to be guarded as a new IDT-Capable device using the `voradmin idt config -external new` command.

```
# voradmin idt config -external new \  
/dev/disk/by-id/tdmp-360080e500043092c0000b46f5c34c018-part3
```

Note: Make sure that you configure each device using the `new` option. This option tells CTE to guard the device without transforming the data.

- d. Log on the DSM, click the **Hosts** tab, and select one of the host in the clique to set the GuardPoints for all the devices that have been initialized as new IDT-Capable devices using the In-place Data Transformation - Device policy that you created.

Repeat this step for all other hosts until all initialized devices have been guarded with an In-place Data Transformation - Device policy.

6. If you are using the Teradata Inteliflex model, do the following. Otherwise, proceed to Step 7.

- a. Designate one of the nodes in a clique as the node on which you will perform the first-time initialization and guarding procedures for each device. For example, if you have a 4 clique cluster, you must designate a total of 4 nodes, one from each clique.
- b. Log on to the DSM, click the **Host Groups** tab, and create a host group for each clique. For example, if your Inteliflex cluster has 4 cliques, you would create 4 host groups, one for each clique. For example, cluster-clique-1, cluster-clique-2, cluster-clique-3, and cluster-clique-4.

- c. On the **Host Groups** tab, click the name of one of the host groups you just created in the Host Group **Name** column. Click on the **Members** tab and add the designated node from the clique as a member of this host group.

For example, if you clicked on the host group clust-clique-1, you would add the designated node from clique 1 to this host group.

Repeat this step until all designated nodes have been added to the Host Group that matches their clique. In the previous example, you would have one designated node in each of the 4 host groups that you created.

- d. On the **Host Groups** tab, click the name of one of the host groups you just created in the Host Group **Name** column. Click on the **GuardPoints** tab and add a GuardPoint for the CTE Metadata Directory (`/var/opt/teradata/vormetric/vte-metadata-dir`) using the Standard policy that was created for the metadata directory on all the nodes in the Teradata cluster.

Repeat this step for each Host Group you created for your cliques. In the previous example, you would add the metadata directory GuardPoint in each of the 4 host groups that you created.

- e. On the designated node for each clique, identify the list of disks that will be configured and guarded as a "new" IDT device as described in ["Identify the Devices to Be Guarded" on page 236](#).

- f. Configure each disk device on the designated node to be guarded as a new IDT-Capable device using the `voradmin idt config -external new` command.

```
# voradmin idt config -external new \  
/dev/disk/by-id/tdmp-360080e500043092c0000b46f5c34c018-part3
```

Note: Make sure that you configure each device using the `new` option. This option tells CTE to guard the device without transforming the data.

- g. For each of the other designated nodes you identified, identify the list of devices to be guarded and configure them using the `voradmin idt config -external new` command.

Repeat this configuration process until all devices on all designated nodes that you want to guard have been configured as new IDT-Capable devices.

- h. On the **Host Groups** tab, click the name of one of the host groups you just created in the Host Group **Name** column. Click on the **GuardPoints** tab and add a GuardPoint for each device that you initialized as a new IDT-Capable device using an In-place Data Transformation - Device policy.

Repeat this step on each one of the host groups you created.

The guarded devices will immediately be set as guarded on the designated node through the host group. However, as part of Teradata cluster support, each guarded device will have its metadata file replicated across all nodes in a clique as described in ["Replication of IDT Metadata Files Across Members of a Clique" on page 248](#). You must wait for metadata replication to complete for each clique in a cluster before continuing to the next step. This process takes approximately 1 second per disk that was guarded. So if you guarded 10 disks, you need to wait approximately 10 seconds. Verify that the number of metadata files on each clique matches with the designated node using the following command:

```
# pcl -shell "ls /var/opt/teradata/vormetric/vte-metadata-dir | wc -l"
```

The number of metadata files on each node in the clique should also match the number of devices in that clique. For example, if you have a clique with 10 devices in it, then the results of the above `pcl` command should show 10 metadata files on each node in the clique.

- i. After metadata replication is completed on all cliques, log on the DSM and click the **Hosts Group** tab, then click the name of one of the host groups you just created in the Host Group **Name** column. Click the **Members** tab and add the rest of the nodes that belong to that clique to the Host Group. After all the nodes have been added, the DSM automatically pushes the existing GuardPoints out to the newly added members.

Repeat this step for each one of the Host Groups that you created for your cliques.

7. Verify that all nodes in a clique shows all the devices as guarded.

```
# pcl -shell "secfsd -status guard"
```

8. Work with Teradata Customer Support to perform a `sysinit` of the Teradata appliances in preparation for the full database restore.
9. Restore your Teradata database from backup.

Changing the Encryption Key on Teradata Devices

To meet various compliance requirements, you may want to change the key that CTE has used to encrypt the Teradata Database devices. This process is called “Key rotation” or “Rekey”.

If you want to rekey a Teradata Database device, you can either:

- Follow the process for standard IDT-Capable GuardPoints. For details, see ["Changing the Encryption Key on Linux IDT-Capable Devices" on page 222](#).
- Use the Backup/Restore method as described in ["Initialize and Guard the Teradata Database Devices Using the Backup/Restore Method" on page 240](#). The only differences between the initial configuration described in that section and rekey process are:
 - You do not need to change the policy assigned to the CTE Metadata Directory.
 - You need to create a new In-place Data Transformation - Device policy that specifies a key rule with the existing key used to encrypt the Database devices in the **Current Key** field and the new XTS-AES 256 key you want to use to encrypt the data in the **New Key** field.
 - When you re-guard the designated node in each clique, make sure you use the new policy so that CTE knows it needs to re-encrypt the data with the new key after you restore the devices from the backup.

Note

Make sure you stop the Teradata database before you rekey the devices.

WARNING

Rekeying a device must be executed only on *one and only one* of the nodes in the cluster. DO NOT prepare the device for rekey or guard the device with the new rekey policy on multiple nodes in the cluster because doing so initiates the data transformation process on the device on multiple nodes. The simultaneous attempts to rekey the data can cause data corruption of all data on the entire device.

Access Rules to Apply on the Teradata Database Appliance

This section provides the instructions for creating a sample policy and signature sets specific to a Teradata Database Appliance to deny unprivileged users access to clear-text data on guarded devices. Such a policy requires the inclusion of specific security rules to restrict access to the Teradata Device GuardPoints for specific set of users, groups, and/or processes.

1. In the DSM Management Console, edit the host entry for the Teradata Database Appliance.
2. Go to the **Host Settings** tab and add `/usr/pde/bin/pdmain` to the list of binaries.

3. Create a signature set for system processes that require access to guarded devices. The following system processes on the Teradata Database Appliance *must* be permitted access:

- /usr/lib/systemd/systemd-udevd
- /sbin/dmsetup
- /opt/teradata/vormetric/agent/vmd/bin/get_disks
- /sbin/pvdisplay
- /sbin/lvdisplay

You can include additional processes as needed. In the following example, this signature set is called TD-Demo-System-Process.

4. Create a signature set for Teradata Database processes that require access to guarded devices. The following directories contain the Teradata binaries that require access:

- /usr/pde/bin/*
- /usr/tdbms/bin/*
- /opt/teradata/gsctools/bin/*

You can include additional processes as needed. In the following example, this signature set is called TD-Demo-TD-Binaries.

5. Create a system-level process set to associate the signature set created for the system-level processes in step 3. In the following example, this process set is called TD-Demo-system-process.

6. Create a Teradata Database process set to associate the signature set for the Teradata Database binaries created in step 4. In the following example, this process set is called TD-Demo-TD-process.

7. Create the user set for the Teradata trusted group on your appliance. In the example below, the trusted group name on the Teradata Appliance is `tdtrusted`.

8. If you have any other trusted groups that you want to include in your security rule, add a user set for each one of those trusted groups. You can add as many user sets to the policy as you need.

9. Create a user set for the root user and any other privileged users you want to add. In the example below, only the root user is trusted to access the guarded Teradata devices.

10. Verify that you have the complete signature sets, process sets, and user sets as shown in the examples below.

11. Apply the policy to the Teradata Device GuardPoints. For example:

Replication of IDT Metadata Files Across Members of a Clique

For Teradata, metadata for IDT-Capable GuardPoints is stored in external files in the CTE metadata directory. Because the Teradata appliance is a cluster of multiple hosts (or nodes) that share access to the same devices across multiple nodes, a metadata file must be replicated across the nodes that are in the same clique within the cluster, including Hot Standby nodes. Replication is required when the initial data transformation has been completed, and it is required again during subsequent rekeys. The availability of the metadata files on all members of the clique is critical for high availability of Teradata database in the event of a node failure because the data on the device cannot be accessed without the encryption key stored in the metadata.

Upon completion of data transformation on each device, the CTE Agent on that device automatically replicates the metadata file for that device to the other nodes in the clique using the Teradata `pcl` command. CTE uses `pcl` to both determine the other members of the clique and to replicate the metadata to those other members. When the metadata is replicated on the remote nodes, any existing metadata for the recently-transformed device already on those nodes is replaced with the updated metadata files sent by the CTE Agent. This replacement is achieved by sending the updated metadata file to all the remote nodes through `pcl` and replacing each existing metadata file on the remote nodes with the most recent metadata files.

Specific Issues to Consider

This section describes specific problems that may be encountered during data transformation and metadata replication. Manual user intervention will be required to recover from the reported issues. For troubleshooting and recovery steps, see ["Alerts and Errors" on page 252](#).

General PCL Error

If the `pcl` command fails during the replication process, a message indicating the error will be logged on the DSM. The messages on DSM are tagged with IDT-TD-ALERT. For example:

- IDT-TD-ALERT: Node <node name> did not respond to `pcl` command
- IDT-TD-ALERT: Failed to distribute IDT-Capable metadata file to remote nodes

These errors indicate that the node specified in the first error did not respond to a `pcl` command during metadata distribution and so the metadata distribution must be manually performed across the clique before access to the device is possible.

Offline Node in Clique During Data Transformation

If a node is offline during data transformation and metadata replication process, CTE will log a message on the DSM that metadata replication to the target node failed. The administrator will be required to manually replicate the metadata file to the offline node when the node comes online. The metadata file must be replicated before the database is brought up.

To do so, run the `voradmin td distribute <device name>` command to distribute the metadata file of each device. The command will copy or update the metadata file on the host that has come online. For example:

```
# voradmin td distribute \  
/dev/disk/by-id/tdmp-360080e500043092c0000b46f5c34c018-part3
```

Adding a New Node to a Clique

When you add a new node to an existing clique, the metadata files of all disks shared in the clique must be manually replicated to the newly added node before any of the guarded devices on the new node are enabled. This should be done manually using the `voradmin td distribute` command, as described above, by the Teradata administrator as part of joining the cluster.

Interoperability with Host Groups

For Teradata, when you create a new IDT-Capable GuardPoint using the `voradmin idt config xform` command, or when you subsequently rekey an existing IDT-Capable GuardPoint with the `voradmin idt rekey` command, the device must be initialized and guarded on one and only one of the nodes in the cluster. That means the IDT-Capable GuardPoint cannot be part of a Host Group when an IDT-Capable GuardPoint is created or rekeyed because membership in a Host Group means that any data transformation on any member of the Host Group is initiated for that member on all nodes in the Host Group simultaneously. In the case of a Teradata cluster, multiple nodes simultaneously trying to perform data transformation on a particular device can lead to data corruption of all data on the entire device.

After the device has been guarded or rekeyed and the metadata files have been replicated to other members of the Teradata clique, then you can then rejoin the host with the Host Group.

To configure a new device whose host is part of a host group:

1. In the DSM, make sure that there is no GuardPoint for the device at the Host Group level.
2. Designate one of the nodes in the cluster as the node you will use to initialize the GuardPoint and for the initial data transformation when the device is guarded for the first time.
3. On the designated node, initialize the device using the `voradmin idt config -external xform <device name>` command. For details, see ["Initialize and Guard the Database Devices Using the Standard Initialization Method" on page 237](#).
4. In the DSM, guard the device on the designated node using an In-place Data Transformation - Device policy. For details, see ["Guard the Devices as IDT-Capable GuardPoints" on page 238](#).
5. Wait for the data transformation to complete on the host and for CTE to replicate the metadata to the other members of the clique.
6. You can verify that the metadata file has been distributed to the other nodes in the clique by running `md5sum /var/opt/teradata/vormetric/vte-metadata-dir/vormetric/secvm_<device>_metadata` on each node in

the clique.

7. In the DSM, remove the IDT-Capable GuardPoint you added earlier in this procedure.
8. Guard the device through the Host Group to make sure that all nodes in the cluster recognize it as guarded.

To rekey a new device whose host is part of a host group:

1. In the DSM, unguard the IDT-Capable GuardPoint through the Host Group and make sure that it has been removed from all nodes in the cluster.
2. Designate one of the nodes in the cluster as the node you will use to prepare the GuardPoint for rekeying and to perform the data transformation when the device is guarded with the new policy.
3. On the designated node, prepare the device for rekey using the `voradmin idt rekey <device name>` command.
4. On the other nodes in the clique, make sure that the device metadata has been renamed running `ls /var/opt/teradata/vormetric/vte-metadata-dir/vormetric/secvm_<device>_metadata*` on each of the other nodes. On these other nodes, the metadata file for the device should be renamed to `/var/opt/teradata/vormetric/vte-metadata-dir/vormetric/secvm_<device>_metadata_xforming`.
5. In the DSM, guard the device on the designated node with the In-place Data Transformation - Device policy that specifies the new key you want to use for the device.
6. Wait for the data transformation process to complete, and then make sure that the metadata for the device has been updated on the other nodes in the clique and the renamed metadata files have been removed. Each node should have identical copies of `/var/opt/teradata/vormetric/vte-metadata-dir/vormetric/secvm_<device>_metadata` and `/var/opt/teradata/vormetric/vte-metadata-dir/vormetric/secvm_<device>_metadata_xforming` should *not* exist on any node.
7. In the DSM, remove the IDT-Capable GuardPoint you created earlier in this procedure on the designated node.
8. Guard the device through the Host Group to make sure that all nodes in the cluster recognize it as guarded.

Best Practices

Using a of Host Group to Guard Metadata Directories

Thales recommends that customers use a host group exclusively for guarding and management of the CTE external metadata directories across all nodes in Teradata cluster. (For details about the CTE metadata directory, see ["Location of the CTE Private Region" on page 233.](#))

By using a Host Group, the same DSM policy can be applied to the external metadata directory (`/opt/vte/vte-metadata-dir`) on all of the CTE protected nodes in the cluster.

Using a Host Group for Guarding Teradata Devices in a Clique

Thales recommend that customers use a Host Group on the DSM to guard and manage the devices shared by all CTE protected nodes in a clique. Each clique in the cluster should be associated with a separate Host Group. When configuring the Host Group, the members for that host group are the nodes that belong within a clique in the cluster.

Example 1: If you have a cluster consisting of 4 cliques where there are 2 nodes sharing disks in each clique, you would create 4 Host Groups, one for each clique. In each Host Group, you would add the 2 nodes that are associated with the clique.

Example 2: If you have a cluster consisting of 1 clique where there are 6 nodes sharing disks in the clique, you want to create 1 host group with all 6 members that belong within that clique.

Below is an example of the Host Groups for a cluster consisting of three cliques and one metadata group:

Name	Cluster Group	Description	Sharing
TD-clique1-clique-1		host group for cluster1-clique-1	
TD-clique1-clique-2		host group for cluster1-clique-2	
TD-clique1-clique-3		host group for cluster1-clique-3	
TD-clique1-metadata		host group for cluster1-metadata	

Best Practice for Preparation for Initial Data Transformation or Rekey

With large amount of data managed in Teradata clusters, duration of initial data transformation and/or subsequent rekey can be very long and challenging because the database must be stopped during the entire data transformation process. Although you cannot transform data without shutting down the database, you may be able to reduce the transformation time by distributing the transformation of the guarded devices across multiple nodes in your cluster.

Because multiple nodes in a cluster within a clique share access to the same devices, you can designate a subset of devices to each node within the clique for initial data transformation or subsequent rekey. This requires unguarding all of the IDT-Capable devices in the Host Group associated with the clique and re-enabling each IDT-Capable GuardPoint only on the node designated for the data transformation of that IDT-Capable GuardPoint. The device then remains unguarded on other nodes until the data transformation completes.

After the data transformation completes, you can then enable the guarded devices at the Host Group level. Enabling the guarded device at Host Group level enables the guarded devices on all the nodes within the clique to share access to the device.

After transforming data and guarding each device on all the nodes, you can then restart the database.

As described in ["Interoperability with Host Groups" on page 249](#), the metadata file for each device is replicated to the hosts in the cluster that share access to the device. As noted, replication of metadata files is automatic.

Uninstalling CTE from the Teradata Cluster

The following procedure describes how to remove CTE from your Teradata cluster. Note that uninstalling CTE will unprotect the pdisk devices that CTE is protecting/encrypting. Because the data on the pdisks remain encrypted after uninstalling CTE, the entire clear-text data must be restored to the pdisks from backup. Therefore, you must have a full backup of your database to restore to your cluster before you uninstall CTE. See the Teradata Administration Guide or your Teradata Customer Support Representative for information about backing up your database in full.

Note

You must be familiar with CTE operations for protecting Teradata clusters and IDT-Capable GuardPoints.

To uninstall CTE:

1. Make sure you have access to a full database backup so that you can restore your Teradata database after uninstalling CTE.
2. Shut down your Teradata database.

3. Use the `secfsd -status guard` command to view the full list of device GuardPoints guarded by CTE on each node of your cluster. From this information, create a consolidated list of GuardPoints with one entry per device in the consolidated list. Note that the devices accessed by the nodes in the same clique are shared devices on each node. The consolidated list must include all devices that are protected in your cluster.
4. Perform the following steps on the DSM:
 - a. Click on the host group name associated with your Teradata cluster and then click the **GuardPoints** tab.
 - b. Select the device names listed in GuardPoints table. The devices listed in GuardPoints table are the same devices listed in the consolidated list of devices compiled in step 3.
 - c. Click the **Disable** button to disable the selected device GuardPoints on all nodes in the cluster.
 - d. Wait for device status to change from green circle to red circle in the Status column for all the selected devices.
 - e. Select the same devices.
 - f. Click the **Unguard** button to remove the selected device GuardPoints on all nodes in the cluster.
5. Perform the following steps on one of the nodes of every clique in your cluster:
 - a. Run the `voradmin idt delete` command to delete the IDT-Capable GuardPoint configuration recorded for each device. This command automatically deletes the GuardPoint configuration across the nodes in the same clique.

```
# voradmin idt delete <device name>
```
 - b. Repeat the previous step on the other devices in your cluster, if any.
6. Go back to the DSM and do the following:
 - a. Select the Metadata Directory GuardPoint in the GuardPoints table of the same host group.
 - b. Click Disable to disable the Metadata GuardPoint directory on every node in the cluster.
 - c. Select the Metadata Directory GuardPoint in the GuardPoints table again and then click Unguard to remove the Metadata Directory GuardPoint on all the nodes in the cluster.
7. On every node in the cluster:
 - a. Run the following command to stop CTE service on each node

```
# /etc/vormetric/secfs stop
```
 - b. Run the following command to uninstall the CTE Agent on each node:

```
# /opt/teradata/vormetric/agent/vmd/bin/uninstall
```

To restore to the full backup of the database to your cluster, contact your Teradata Customer Support Representative (CSR) to perform System Initializer and do a full restore of the database from your backup.

Alerts and Errors

This section lists the alerts and errors that may be encountered during system operations on Teradata Appliance. Refer to Alerts and Errors listed in the chapter on IDT-Capable Device GuardPoints for additional Alerts and Errors.

General Errors

The errors in this section indicate what step failed during CTE system operations for Teradata clusters and will always be paired with an operation error which indicates which CTE system operation failed. For example:

- IDT-TD-ALERT: Node <node name> did not respond to pcl command
- IDT-TD-ALERT: Failed to complete rekey on remote nodes

This pairing of errors indicates that the steps after data transformation were unsuccessful and that the `voradmin` command `voradmin td rekeyed <device name>` is the one that failed.

For details about the `voradmin td rekeyed` command, see the `voradmin` manpage.

IDT-TD-ALERT: Node <node name> did not respond to pcl command

The node listed did not respond to a `pcl` command to perform an operation.

Solution: Check if the node is still online and responding. If it is, run the `voradmin` command to repeat the failed operation. This error message will always be accompanied by one of the other IDT-TD-ALERTS which will determine which `voradmin` command to run to correct the error.

IDT-TD-ALERT: Node <node name> failed to perform voradmin task

The node listed failed to perform a `voradmin` command invoked through `pcl`.

Solution: Correct the issue blocking `voradmin` and run the `voradmin` command to repeat the failed operation. This error message will always be accompanied by one of the other IDT-TD-ALERTS which will determine which `voradmin` command to run to correct the error.

IDT-TD-ALERT: Failed to find clique for disk <device>

CTE failed to locate the clique for the device specified.

Solution: Verify that `/usr/lib/tmpfiles.d/pdisk.conf` is properly configured on all nodes in the Teradata cluster.

IDT-TD-ALERT: Failed to move or rename IDT-Capable metadata file on remote nodes

This error can be due to two issues; one, metadata files that have been distributed to the remote nodes cannot be moved into the metadata directory, or two, metadata files on remote nodes cannot be renamed in preparation for rekey.

Solution: For the first issue, rerun `voradmin td distribute <node name> <device name>` command once any other problems have been resolved. For the second issue rerun `voradmin td rekey <device name>` to prepare for rekey again once any other problems have been resolved.

For details about the `voradmin td` commands, see the `voradmin` manpage.

IDT-TD-ALERT: Failed to get GuardPoint status on remote nodes

The GuardPoint for the device is still present on the DSM for remote nodes or CTE failed to ascertain the GuardPoint status for remote nodes.

Solution: Verify that the GuardPoint for the device has been removed from the DSM for remote nodes and then rerun the `voradmin` command. This error message will always be accompanied by one of the other IDT-TD-ALERTS which will determine which `voradmin` command to run to correct the error.

Operation Errors

These errors indicate which CTE system operation failed and what command should be run upon resolution of the issue that caused the error.

IDT-TD-ALERT: Failed to distribute IDT-Capable metadata file to remote nodes

CTE failed to copy the IDT-Capable metadata file from the current node to all nodes in the clique.

Solution: Correct any issues blocking `pcl` or `voradmin` and then run `voradmin td distribute <node name> <device name>` to attempt copying the metadata file over to the remote node.

For details about the `voradmin td distribute` command, see the `voradmin` manpage.

IDT-TD-WARNING: Failed to delete IDT-Capable metadata file on remote nodes

CTE was unable to remove the IDT-Capable metadata file for a device from a remote node.

Solution: Run `voradmin idt delete <device name>` on the remote node after correct issues impeding `voradmin`. Members of the clique that have successfully removed the metadata file will not be adversely affected if an attempt to remove an already de-configured device occurs.

IDT-TD-ALERT: Failed to complete rekey on remote nodes

CTE was unable to complete the rekey operation on remote nodes to make the device available for guarding again.

Solution: Correct the issue and run `voradmin td rekeyed <node name> <device name>` to signal the remote node that rekey is complete and provide an updated copy of the metadata file to that remote node.

Chapter 20: Upgrading CTE on Linux

This chapter describes how to upgrade an existing VTE for Linux host to CipherTrust Transparent Encryption (CTE) for Linux.

Note

Currently, you can only upgrade a VTE for Linux host to CTE version 7.0.0.47 if you continue to use the DSM as your key manager. You cannot upgrade a VTE host to CTE and then register the upgraded CTE host with CipherTrust Manager. The migration path to CipherTrust Manager will be available in a future release.

This chapter contains the following sections:

Upgrading CTE	255
Scheduled Upgrade Feature	256

Upgrading CTE

This section describes the generic instructions for interactively upgrading CTE. If there are any changes to this procedure for the current release of CTE, those changes will be documented in the CTE Release Notes.

If you want to schedule an upgrade to occur the next time the system boots, see ["Scheduled Upgrade Feature" on the next page](#).

1. Stop any application accessing files in the GuardPoint.
2. Log on to the host where you will upgrade CTE. You must have root access.
3. Copy or mount the installation file onto the host system.
4. Start the upgrade by executing the install program for the release to which you want to upgrade. If you want to automatically accept the CTE License Agreement, you can include the `-y` parameter.

For example, the following command upgrades the product to version 7.0.0.47 after the user manually reviews and accepts the CTE License Agreement:

```
# ./vee-fs-7.0.0-47-rh8-x86_64.bin
```

The following command upgrades the product to version 7.0.0.47 but automatically accepts the CTE License Agreement:

```
# ./vee-fs-7.0.0-47-rh8-x86_64.bin -y
```

5. Follow the prompts. During an upgrade, the following message displays. Enter Y at the prompt:

```
Upgrade detected: this product will be stopped and restarted.
Do you wish to proceed with the upgrade? (Y/N) [Y]: Y
Installation success.
```

You will not do the registration steps since CTE is already registered with the DSM.

6. To verify that the upgrade was successful, use the `vmd -v` command:

```
$ vmd -v
Version 6, Service Pack 2
7.0.0.47
2020-09-20 09:45:20 (IST)
Copyright (c) 2009-2020, Thales. All rights reserved.
```

Scheduled Upgrade Feature

This section describes how to run the scheduled upgrade feature on CTE for Linux systems. This option is available for CTE version 6.1.3 or later.

Note

Scheduled upgrade on reboot is not supported on HDFS nodes.

Warnings for CTE for Linux

- As with prior CTE versions, DSM connectivity is required during upgrade.
- Yum updates or OS patches should be done prior to CTE upgrade on reboot.
- If you upgrade from a compatible kernel to an incompatible kernel, the `secfs` module will fail to load on the next reboot.
- You may see the following behavior if the upgrade on reboot fails due to crash or power failure (this is similar to a failure during a normal upgrade).
 - If a crash or power failure occurs before the upgrade executes, the upgrade will not take place, and the currently installed CTE version continues to run after the reboot. Restart the system to upgrade successfully.
 - If a crash or power failure occurs during the upgrade, CTE may enter an inconsistent state. The only way to restore is to enter single-user mode and delete all the files or directories related to CTE.
 - If a crash or power failure occurs after a successful upgrade, then the new version will run on the next reboot. No user intervention is required in this case.
- During reboot or shutdown, all applications and services dependent on CTE services must be stopped before a scheduled update takes place. Failure to stop these services can result in an aborted scheduled upgrade during the system reboot. Examples of situations that may cause an aborted upgrade are applications with open files in a CTE GuardPoint, or a third party anti-virus software doing periodic scans.

See the `systemd` chapter in the *CTE Agent for Linux Advanced Configuration and Integration Guide* for examples of how to set up CTE start/stop dependencies with other programs.

Using the Scheduled Upgrade Feature

The following procedure describes how to use `voradmin` to schedule an upgrade that will be applied the next time the machine reboots.

1. If you want to check which version of CTE for Linux you currently have installed, use the `vmd -v` command:

```
$ vmd -v
Version 6, Service Pack 2
6.3.1.38
2020-09-20 11:09:40 (IST)
Copyright (c) 2009-2020, Thales. All rights reserved.
```

2. To schedule an upgrade on reboot, use the `voradmin upgrade schedule <path to CTE installer> -y [-p <path to temp upgrade directory>]` command, where:
 - `<path to CTE installer>` is the full path to the CTE installation file for the release to which you want to upgrade. For example, `./vee-fs-7.0.0-47-rh8-x86_64.bin`.
 - `-y` is an optional parameter that automatically accepts the CTE License Agreement. If you do not specify this parameter, the installer displays the CTE License Agreement and you must manually accept it before the upgrade can be scheduled.

- `-p <path to temp upgrade directory>` is an optional parameter that specifies the path to a directory in which you want CTE to store the temporary files it needs during the upgrade. The default is `/var/tmp/`.

To use this option:

- The currently installed version of CTE must be 6.3.1 or later.
- The version of CTE to which you are upgrading must be version 6.3.1 or later.
- The specified path must not be inside a GuardPoint or be a symbolic link.

For example, if you are upgrading from version 6.3.1.38 to version 7.0.0.47 and you want to automatically accept the license agreement and use the temporary directory `/temp_dir/`, you would enter:

```
$ voradmin upgrade schedule ./vee-fs-7.0.0-47-rh8-x86_64 -y -p /temp_dir/
Linux Kernel 3.10.0-862.el7.x86_64 is supported with the CTE version 7.0.0.47 being
installed.
Created symlink from /etc/systemd/system/multi-user.target.wants/secfs-upgrade.service to
/usr/lib/systemd/system/secfs-upgrade.service.
Successfully scheduled upgrade on reboot to build 7.0.0.47.
```

If you want to manually accept the CTE License Agreement and let the installer use the default temporary directory `/var/tmp/`, you would enter:

```
$ voradmin upgrade schedule ./vee-fs-7.0.0-47-rh8-x86_64
```

The installation script runs and displays the license agreement. When prompted, enter “Y” to proceed with the installation, or “N” to cancel it.

```
Do you accept this license agreement? (Y/N) [N] Y
Linux Kernel 3.10.0-862.el7.x86_64 is supported with the CTE version 7.0.0.47 being
installed.
Upgrade on reboot detected: this product will be upgraded on shutdown/reboot.
Do you wish to proceed with the upgrade? (Y/N) [Y]: Y
Created symlink from /etc/systemd/system/multi-user.target.wants/secfs-upgrade.service to
/usr/lib/systemd/system/secfs-upgrade.service.
Successfully scheduled upgrade on reboot to build 7.0.0.47.
```

3. If you want to verify that the upgrade was successfully scheduled, use the `voradmin upgrade show` command:

```
$ voradmin upgrade show
Upgrade on reboot is currently scheduled.
Current CTE version is 6.3.1.38, upgrade on reboot scheduled for CTE 7.0.0.47.
```

4. Reboot the machine, then log in and verify that the upgrade was successful.

```
$ vmd -v
Version 6, Service Pack 2
7.0.0.47
2020-09-20 09:45:20 (IST)
Copyright (c) 2009-2020, Thales. All rights reserved.
```

Note

Appropriate logs will be logged in syslog.

Performing a Manual Upgrade When an Upgrade is Already Scheduled

If an administrator runs a manual upgrade after an upgrade has already been scheduled, the installer displays the following warning:

```
WARNING: upgrade on reboot is already scheduled for 7.0.0.47.
Do you want to cancel scheduled upgrade on reboot ? (Y/N) [Y] :
```

If the administrator does *not* cancel the scheduled upgrade, the scheduled upgrade takes precedence and the manual upgrade fails with the message:

```
Already scheduled upgrade on reboot remains intact.  
Installation failure.
```

If the administrator wants proceed with the manual upgrade immediately, they must enter Y at the prompt to cancel the scheduled upgrade:

```
WARNING: upgrade on reboot is already scheduled for 7.0.0.47.  
Do you want to cancel scheduled upgrade on reboot ? (Y/N) [Y] : Y  
Removed symlink /etc/systemd/system/multi-user.target.wants/secfs-upgrade.service.  
WARNING: upgrade on reboot is cancelled for 7.0.0.47. Proceeding with manual upgrade.  
Upgrade detected: this product will be stopped and restarted.  
Do you wish to proceed with the upgrade? (Y/N) [Y]: Y  
.....  
Upgrade success.
```

To verify that the upgrade succeeded, the administrator can use the `vmd -v` command:

```
$ vmd -v  
Version 6, Service Pack 2  
7.0.0.47  
2020-09-20 09:45:20 (IST)  
Copyright (c) 2009-2020, Thales. All rights reserved.
```

Voradmin Commands for the Scheduled Upgrade Feature

To view the current CTE version, use the `vmd -v` command:

```
$ vmd -v  
Version 6, Service Pack 2  
6.3.1.38  
2020-09-20 11:09:40 (IST)
```

To schedule an upgrade on reboot, use the `voradmin upgrade schedule <path to CTE installer> [-y] [-p <path to temp upgrade directory>]` command, where:

- `<path to CTE installer>` is the full path to the CTE installation file for the release to which you want to upgrade. For example, `./vee-fs-7.0.0-47-rh8-x86_64.bin`.
- `-y` is an optional parameter that automatically accepts the CTE License Agreement.
- `-p <path to temp upgrade directory>` is an optional parameter that specifies the path to a directory in which you want CTE to store the temporary files it needs during the upgrade. The default is `/var/tmp/`.

To use this option:

- The currently installed version of CTE must be 6.3.1 or later.
- The version of CTE to which you are upgrading must be version 6.3.1 or later.
- The specified path must not be inside a GuardPoint or be a symbolic link.

For example, to schedule an upgrade on reboot to version 7.0.0.47 and automatically accept the CTE License Agreement and use the temporary install directory `/temp_dir/`, you would enter:

```
$ voradmin upgrade schedule ./vee-fs-7.0.0-47-rh8-x86_64.bin -y -p /temp_dir/
```

To get information about a scheduled upgrade:

```
$ voradmin upgrade show  
Upgrade on reboot is currently scheduled.  
Current CTE version is 6.3.1.38, upgrade on reboot scheduled for CTE 7.0.0.47.
```

If no upgrade has been scheduled, this command displays the following:

```
$ voradmin upgrade show  
Upgrade on reboot has not been scheduled.
```

To cancel an existing scheduled upgrade on reboot:

```
$ voradmin upgrade cancel  
Removed symlink /etc/systemd/system/multi-user.target.wants/secfs-upgrade.service.  
Successfully cancelled upgrade on reboot
```

Chapter 21: Uninstalling CTE from Linux

Considerations

- The CTE Agent must be removed from the Linux host before the host is removed from the key manager with which it is registered.
- Database applications like DB2 and Oracle can lock the user space while they run. If the uninstall fails because a GuardPoint is in use, determine which applications are using the files in the GuardPoint and stop them. Then run the uninstall again.
- Commands like `fuser` and `lsof` might not reveal an active GuardPoint because they detect active usage, not locked states. Although it may appear that a GuardPoint is inactive, it may be in a locked state. Under this condition, software removal may fail with an error similar to the following:

```
/home: device is busy.
```

Procedure

1. Stop any application from accessing files in the GuardPoint.
2. In the key manager with which this host is registered, do the following:
 - Decrypt any data you want to use after uninstall. After the CTE Agent software is removed, access to data is no longer controlled. If data was encrypted, it will remain encrypted. If decrypted or copied out of the GuardPoint, the data is visible as clear text.

This decryption must be done on *every* GuardPoint on the host if you want to access all existing data on the host.

- Make sure the Agent and System locks have been disabled for the host.
- Thales recommends that you remove all GuardPoints from the host before you uninstall the CTE Agent.

Do not remove the host from the key manager yet.

3. Log on to the host as `root`.
4. Change the directory to an unguarded location (for example, `/`).

CAUTION

Do not change (`cd`) into the `/opt/vormetric` directory or into any directory below `/opt/vormetric`. If you run the uninstaller from `/opt/vormetric` or any of its subdirectories, the package removal utility may fail and return the following message:

You are not allowed to uninstall from the `/opt/vormetric` directory or any of its sub-directories.

Agent uninstallation was unsuccessful.

5. Start the uninstall. Type:

```
# /opt/vormetric/DataSecurityExpert/agent/vmd/bin/uninstall
Would you like to uninstall the vee-fs package? (Y/N) [Y]: Y
.....
Success!
```

6. Remove the host record from the key manager.

CTE Agent for Windows Advanced Configuration and Integration Guide

Release 7.0.0

Document Version 1

September 22, 2020

The bottom half of the page features a dark blue background with abstract geometric shapes. On the left, there is a large, bright blue triangle pointing upwards. Below it, a smaller, darker blue triangle points upwards. In the bottom left corner, there is a blue circle with a dotted pattern. The right side of the page has a vertical gradient from dark blue at the top to a lighter blue at the bottom, with a dotted pattern at the very bottom.

All information herein is either public information or is the property of and owned solely by Thales DIS France S.A. and/or its subsidiaries or affiliates who shall have and keep the sole right to file patent applications or any other kind of intellectual property protection in connection with such information.

Nothing herein shall be construed as implying or granting to you any rights, by license, grant or otherwise, under any intellectual and/or industrial property rights of or concerning any of Thales DIS France S.A. and any of its subsidiaries and affiliates (collectively referred to herein after as "Thales") information.

This document can be used for informational, non-commercial, internal and personal use only provided that:

- The copyright notice below, the confidentiality and proprietary legend and this full warning notice appear in all copies.
- This document shall not be posted on any network computer or broadcast in any media and no modification of any part of this document shall be made.

Use for any other purpose is expressly prohibited and may result in severe civil and criminal liabilities.

The information contained in this document is provided "AS IS" without any warranty of any kind. Unless otherwise expressly agreed in writing, Thales makes no warranty as to the value or accuracy of information contained herein.

The document could include technical inaccuracies or typographical errors. Changes are periodically added to the information herein. Furthermore, Thales reserves the right to make any change or improvement in the specifications data, information, and the like described herein, at any time.

Thales hereby disclaims all warranties and conditions with regard to the information contained herein, including all implied warranties of merchantability, fitness for a particular purpose, title and non-infringement. In no event shall Thales be liable, whether in contract, tort or otherwise, for any indirect, special or consequential damages or any damages whatsoever including but not limited to damages resulting from loss of use, data, profits, revenues, or customers, arising out of or in connection with the use or performance of information contained in this document.

Thales does not and shall not warrant that this product will be resistant to all possible attacks and shall not incur, and disclaims, any liability in this respect. Even if each product is compliant with current security standards in force on the date of their design, security mechanisms' resistance necessarily evolves according to the state of the art in security and notably under the emergence of new attacks. Under no circumstances, shall Thales be held liable for any third party actions and in particular in case of any successful attack against systems or equipment incorporating Thales products. Thales disclaims any liability with respect to security for direct, indirect, incidental or consequential damages that result from any use of its products. It is further stressed that independent testing and verification by the person using the product is particularly encouraged, especially in any application in which defective, incorrect or insecure functioning could result in damage to persons or property, denial of service or loss of privacy.

 Chapter 7: Using CTE with Microsoft SQL	 74
Using CTE with SQL	74
Using LDT with SQL FILESTREAM	74
Using CTE with SQL FileTables	74
Considerations	74
Advantages	75
Supported FileTables Use Cases	75
CTE Data Transformation of existing files in FileTables	75
Protect files in SQL FileTables with CTE	75
Protect files with SQL AlwaysOn Availability Groups with CTE	76

Install CTE on remote systems and guard the SQL Server VNN names	76
Unsupported FileTables Use Cases	76
Installing CTE on Microsoft SQL AlwaysOn	76
Methods for Initial Encryption	77
Configuration 1	77
Configuration 2	77
Configuration 3	78
Configuration 4	78
Data Transformation (Encryption in place)	79
Copy/Restore	79
SQL Server Policy Tuning	79
Using LDT with SQL AlwaysOn	79

Chapter 8: Secure Start 81

Secure Start Overview	81
Prerequisites	81
Encrypt by Moving the AD Service into a Guarded Directory	82
Create the AD GuardPath directory	82
Apply Secure Start GuardPoints to a Directory with the DSM	82
Apply Secure Start GuardPoints to a Directory with CipherTrust Manager	83
Verify the Secure Start GuardPoint with CLI	83
Move the AD Database into the Secure Start GuardPoint	83
Encrypt Data in Place with Offline Transformation	84
Encrypt with an LDT Transformation Policy	84
Configure the Time Out Failure	84
Recover a Server After it Loses Connection to the DSM	85
DSRM Mode	85
Other Use Cases	86
Boot a Windows Server in Azure	86
Best Practices for Encrypting and Protecting the AD Service	86
Access Control with Secure Start	86
Creating a Minimal Policy Required for AD with Access Control	86
Creating a Restricted Policy in DSRM Mode	87
Guard Directories	88
Perform Subsequent System State Backups	88

Chapter 9: Exchange DAG 89

Exchange DAG Overview	89
Use Case tested and supported by Exchange DAG with CTE	89

Recommendations	90
Requirements	90
Preparing your Exchange DAG Environment for Encrypting/Decrypting with CTE	91
Encrypting with LDT in the Exchange DAG environment	92
Decrypting with LDT in the Exchange DAG environment	93
Encrypting with a Standard CTE Policy in the Exchange DAG Environment	94
Unsupported Use Cases	94
Chapter 10: Storage Spaces Direct	96
S2D Overview	96
Deployment Options	96
Supported Use Cases	97
Chapter 11: Using CTE with Quantum StorNext	98
Overview of using CTE with Quantum StorNext	98
CTE and Quantum StorNext Compatibility	98
Supported StorNext Server and Client Configurations	98
Supported GuardPoint and Key Settings for SNFS File Systems	99
Supported Concurrent Access Read/Write Scenarios	99
Setting up CTE and Quantum StorNext Integration	100
Integration Task Overview	100
Installing and Configuring a Quantum StorNext MDC Server for Use with CTE	101
Installing and configuring Quantum StorNext DLC Clients for Use with CTE	101
Choosing a Mounting Method	101
Installing the CTE Agent on Each StorNext LAN client	101
Chapter 12: CTE-Efficient Storage for Windows	102
Introduction to CTE-Efficient Storage	102
Requirements and Considerations	102
CTE-Efficient Storage Enhanced Storage Arrays	103
Storage Arrays Compatible with CTE-Efficient Storage	103
Sharing Encryption Keys	103
Storage Array Registration	104
Efficient Storage Device Header and CTE Private Region	104
Device Size	104
DSM Domain Enabled for KMIP	104
ES GuardPoint Encryption Keys	105
Key Attributes - Example	105
KMIP Key Object	106

Policy Requirements for ES GuardPoints	107
Guarding an Efficient Storage Device on Windows	108
Requirements for Efficient Storage GuardPoints on Windows	108
Limitations for ES GuardPoints on Windows	109
Register the Windows Host with DSM	110
Initialize Windows CTE-Efficient Storage Devices	111
Initialize New Windows Devices	111
Initialize and Resize Existing Windows Devices	113
Guard the Windows Device with an ES GuardPoint	115
Data Relocation on Existing Windows Devices	116
Data Transformation on Existing Windows Devices	117
CTE-IDT Recovery From Crash	117
Windows System and ES GuardPoint Administration	117
voradmin esg list disk	118
voradmin esg config	118
voradmin esg status	118
voradmin esg status [xform] <device-label>	118
voradmin esg delete	119
Changing the Encryption Key for a Windows ES GuardPoint	119
Requirements and Considerations	120
Creating a New DSM Policy for Key Rotation	120
Rekeying the Windows Device	120
Resizing Guarded Efficient Storage Devices	123
Use Cases involving Efficient Storage GuardPoints	124
Use Case 1: Single Encryption Key	124
Use Case 2: Device-Level GuardPoints	124
Use Case 3: Directory-Level GuardPoints	126
Use Case 4: Full Device Protection	129
Alerts and Errors on Windows	132
ESG-ALERT: Data transformation failure on [GuardPoint]	132
ESG-INFO: Data transformation complete on [GuardPoint]	132
Disk label validation failed. Check your disk label and run command again.	132
Failed to get disk information	132
Boot partition is present on the disk. Disk or LUN can not be protected using CTE agent.	133
The disk is dynamic disk. This disk or LUN can not be protected using CTE agent.	133
Failed to initialize disk	133
Disk is already initialized/guarded with CTE ESG protection	133
Failed to initialize disk with CTE ESG protection. Size must be greater than %xMB, Current size: %yMB	133
Disk is initialized successfully with CTE ESG protection.	133

Disk is initialized successfully with CTE ESG protection. Disk must be Resized to at least 128MB before guarding as Efficient Storage GuardPoint	133
Failed to initialize disk with CTE ESG protection. The specified disk does not exist or is not online.	133
Disk with specified label does not exist. Please select another disk.	134
Header deletion failed with error code	134
Disk is protected with CTE ESG. Please unguard the disk before deleting ESG header.	134
CTE ESG header deleted successfully.	134
CTE ESG header does not exist on the selected disk. Please select another disk	134
Chapter 13: Upgrading CTE on Windows	135
To Upgrade in Windows Silently	135
Verify the Windows Installation	135
Resolving Problems that Prevent Silent Install	136
CTE Scheduled Upgrade	136
Scheduling a CTE Upgrade on the Command Line	136
Scheduling a CTE Upgrade Interactively (self-extracting .exe only)	137
Show Scheduled CTE Upgrades	137
Cancel a Scheduled CTE Upgrade	137
Workaround for MSI CTE Typical, Silent, and Scheduled Upgrades	137
Finding The Name Used For A Previous MSI Installation or Upgrade	138
MSI File Name Lookup Method 1: PowerShell	138
MSI File Name Lookup Method 2: Windows Registry	138
Chapter 14: Uninstalling CTE from Windows	139
Appendix 15: Troubleshooting and Best Practices	140

Preface

The CTE Agent for Windows Advanced Configuration and Integration Guide provides information about advanced installation, configuration, and integration options for CTE for Windows.

The CTE Agent Documentation Set

The following guides are available for CTE Agent:

- *CTE Agent for Linux Quick Start Guide*
- *CTE Agent for Linux Advanced Configuration and Integration Guide*
- *CTE Agent for Windows Quick Start Guide*
- *CTE Agent for Windows Advanced Configuration and Integration Guide*
- *CTE Agent for AIX Installation and Configuration Guide*
- *CTE-Live Data Transformation with Data Security Manager*
- *CTE-Live Data Transformation with CipherTrust Manager*
- *Compatibility Matrix for CTE Agent with CipherTrust Manager*
- *Compatibility Matrix for CTE Agent with Data Security Manager*
- *Compatibility Matrix for CTE Agent for AIX with CipherTrust Manager*
- *Compatibility Matrix for CTE Agent for AIX with Data Security Manager*
- *Release Notes for CTE for Linux Version 7.0.0.47*
- *Release Notes for CTE for Windows Version 7.0.0.47*
- *Release Notes for CTE for AIX Version 7.0.0.11*

Document Conventions

The document conventions describe common typographical conventions and important notice and warning formats used in Thales technical publications.

Typographical Conventions

This section lists the common typographical conventions for Thales technical publications.

Table 3-1: Typographical Conventions

Convention	Usage	Example
bold regular font	GUI labels and options.	Click the System tab and select General Preferences.
<i>bold italic monospaced font</i>	variables or text to be replaced	https://<Token Server name>/admin/ Enter password: <Password>
regular monospaced font	Command and code examples XML examples	Example: session start iptarget=192.168.253.102

Table 3-1: Typographical Conventions (continued)

Convention	Usage	Example
<i>italic regular font</i>	GUI dialog box titles	The <i>General Preferences</i> window opens.
	File names, paths, and directories	<i>/usr/bin/</i>
	Emphasis	<i>Do not</i> resize the page.
	New terminology	<i>Key Management Interoperability Protocol (KMIP)</i>
	Document titles	See <i>CTE Agent for Windows Advanced Configuration and Integration Guide</i> for information about CipherTrust Transparent Encryption.
quotes	File extensions Attribute values Terms used in special senses	"js", ".ext" "true" "false", "0" "1+1" hot standby failover

Notes, tips, cautions, and warnings

Notes, tips, cautions, and warning statements may be used in this document.

A Note provides guidance or a recommendation, emphasizes important information, or provides a reference to related information. For example:

Note

It is recommended to keep tokenization keys separate from the other encryption/decryption keys.

A tip is used to highlight information that helps you complete a task more efficiently, such as a best practice or an alternate method of performing the task.

Tip

You can also use Ctrl+C to copy and Ctrl+P to paste.

Caution statements are used to alert you to important information that may help prevent unexpected results or data loss. For example:

CAUTION

Make a note of this passphrase. If you lose it, the card will be unusable.

A warning statement alerts you to situations that can be potentially hazardous to you or cause damage to hardware, firmware, software, or data. For example:

WARNING

Do not delete keys without first backing them up. All data that has been encrypted with deleted keys cannot be restored or accessed once the keys are gone.

Sales and Support

If you encounter a problem while installing, registering, or operating this product, please refer to the documentation before contacting support. If you cannot resolve the issue, contact your supplier or Thales Customer Support.

Thales Customer Support operates 24 hours a day, 7 days a week. Your level of access to this service is governed by the support plan arrangements made between Thales and your organization. Please consult this support plan for further information about your entitlements, including the hours when telephone support is available to you.

For support and troubleshooting issues:

- <https://supportportal.thalesgroup.com>
- (800) 545-6608

For Thales Sales:

- <https://cpl.thalesgroup.com/>
- CPL_Sales_AMS_TG@thalesgroup.com
- (888) 267-3732

Chapter 1: Overview of CTE

CTE includes several unique utilities to help you encrypt and manage your data. It also integrates with several third-party platforms such as Oracle, Microsoft SQL, and Quantum StorNext.

This document describes the installation and advanced configuration options for CTE, as well as detailed information about how to integrate CTE with the supported third-party products.

CTE Terminology

The CTE documentation set uses the following terminology:

Term	Description
CTE	CipherTrust Transparent Encryption is a suite of products that allow you to encrypt and guard your data. The main software component of CTE is the CTE Agent, which must be installed on every host whose devices you want to protect. Note This suite was originally called Vormetric Transparent Encryption (VTE), and some of the names in the suite still use "Vormetric". For example, the default installation directory is C:\Program Files\Vormetric\DataSecurityExpert\agent\.
CTE Agent	The software that you install on a physical or virtual machine in order to encrypt and protect the data on that machine. After you have installed the CTE Agent on the machine, you can use CTE to protect any number of devices or directories on that machine.
key manager	An appliance that stores and manages data encryption keys, data access policies, administrative domains, and administrator profiles. Thales offers two key managers for use with CTE, the Vormetric Data Security Manager (DSM) and CipherTrust Manager.
host / client	In this documentation, host and client are used interchangeably to refer to the physical or virtual machine on which the CTE Agent is installed. The difference comes from the key manager you are using. The DSM refers to the machines as hosts, while the CipherTrust Manager refers to them as clients.
GuardPoint	A device or directory to which a CTE data protection and encryption policy has been applied. CTE will control access to, and monitor changes in, this device and directory, encrypting new or changed information as needed.

CTE Components

The CTE solution consists of two parts:

- The *CTE Agent software* that resides on each protected virtual or physical machine (host). The CTE Agent performs the required data encryption and enforces the access policies sent to it by the *key manager*. The communication between the CTE Agent and the key manager is encrypted and secure.
After the CTE Agent has encrypted a device on a host, that device is called a *GuardPoint*. You can use CTE to create GuardPoints on servers on-site, in the cloud, or a hybrid of both.
- A *key manager* that stores and manages data encryption keys, data access policies, administrative domains, and administrator profiles. After you install the CTE Agent on a host and register it with a key manager, you can use the key manager to specify which devices on the host that you want to protect, what encryption keys are used to protect those devices, and what access policies are enforced on those devices.

Thales offers two key managers that work with CTE:

- CipherTrust Manager, Thales's next generation key manager that supports most CTE for Windows features.
- The *Vormetric Data Security Manager* (DSM), Thales's legacy key manager that supports all CTE for Windows features.

Both key managers can be set up as either a security-hardened physical appliance or a virtual appliance. Both provide access to the protected hosts through a browser-based, graphical user interface as well as an API and a CLI. Thales recommends that you use the CipherTrust Manager unless you need a feature that is only supported by the DSM, as described below.

The CipherTrust Manager currently supports all CTE for Windows features *except* for CTE-Efficient Storage. (For details about CTE-Efficient Storage, see the *CTE Agent for Windows Advanced Configuration and Integration Guide*.)

You must select one and only one key manager per host or host group. While you could have some hosts registered with a CipherTrust Manager and some registered with a DSM, you cannot have the same host registered to both a CipherTrust Manager and a DSM.

Note: For a list of CTE versions and supported operating systems, see the *Compatibility Matrix for CTE Agent with CipherTrust Manager* and the *Compatibility Matrix for CTE Agent with Data Security Manager*.

How to Protect Data with CTE

CTE uses policies created in the associated key manager to protect data. You can create policies to specify file encryption, data access, and auditing on specific directories and drives on your protected hosts. Each GuardPoint must have one and only one associated policy, but each policy can be associated with any number of GuardPoints.

Policies specify:

- Whether or not the resting files are encrypted.
- Who can access decrypted files and when.
- What level of file access auditing is applied when generating fine-grained audit trails.

A Security Administrator accesses the DSM or CipherTrust Manager through a web browser. You must have administrator privileges to create policies using either key manager. The CTE Agent then implements the policies once they are pushed to the protected host.

CTE can only enforce security and key selection rules on files inside a guarded directory. If a GuardPoint is disabled, access to data in the directory goes undetected and ungoverned. Disabling a GuardPoint and then allowing unrestricted access to that GuardPoint can result in data corruption.

Chapter 2: Getting Started with CTE for Windows

This chapter describes how to install CTE for Windows, register it with your selected key manager, and then create a simple GuardPoint on the protected host. It contains the following sections:

Installation Workflow	15
Installing CTE with No Key Manager Registration	15
Configuring CTE for Windows with CipherTrust Manager	16
Configuring CTE for Windows with a DSM	32

Installation Workflow

In order to install and configure CTE, you need to perform the following high-level tasks:

1. Select which key manager you want to use. The Vormetric Data Security Manager and the CipherTrust Manager have different requirements and support different features, so you must make this decision first. For details, see ["CTE Components" on page 13](#).
2. If you want to install the CTE Agent without registering with a key manager, see ["Installing CTE with No Key Manager Registration" below](#). However, you cannot protect any data on the host until it has been registered. Otherwise, set up your systems according to the requirements of the selected key manager. For details, see one of the following:
 - [Chapter 1: "Configuring CTE for Windows with CipherTrust Manager" on page 1](#).
 - ["Configuring CTE for Windows with a DSM" on page 32](#).
3. Create your policies, encryption keys, and GuardPoints using the selected key manager. For details, see one of the following:
 - ["Guarding a Device with CipherTrust Manager" on page 26](#).
 - ["Guarding a Device with the DSM" on page 57](#).

Installing CTE with No Key Manager Registration

The following procedure installs the CTE Agent on the host but does not register it with a key manager. You cannot protect any data on the host until the CTE Agent is registered with one of the supported key managers. For a comparison of the available key managers, see ["CTE Components" on page 13](#).

If you want to register the CTE Agent immediately after installing it, see ["Configuring CTE for Windows with CipherTrust Manager" on the next page](#) or ["Configuring CTE for Windows with a DSM" on page 32](#).

1. Log on to the host as a Windows user with System Administrator privileges.
2. Copy the CTE installation file onto the Windows system.
3. Double-click the installation file. The InstallShield Wizard for CipherTrust Transparent Encryption opens.
4. Verify the version of CTE you are installing and click **Next**.
5. On the *License Agreement* page, accept the License Agreement and click **Next**.

6. On the *Destination Folder* page, click **Next** to accept the default folder or click **Change** to select a different folder. When you are done, click **Next**.

Notes

- Thales recommends that you install CTE in the default installation directory, `C:\Program Files\Vormetric\DataSecurityExpert\agent\`
- You must install the CTE Agent on the same drive as Windows. For example, if Windows is installed on the `C:` drive, you must install the CTE Agent on the `C:` drive.

7. On the *Ready to Install* page, click **Install**. When the installation is finished, the **Install Shield Wizard Completed** window opens.
8. To tell the installer that you want to register later, clear the check box for **Register CipherTrust File System now**, then click **Finish**.
9. Reboot the host system to complete the installation.

Configuring CTE for Windows with CipherTrust Manager

This section describes how to install and configure CTE on Windows systems that you plan to register with a CipherTrust Manager. If you want to register CTE with a Vormetric Data Security Manager (DSM), see ["Configuring CTE for Windows with a DSM" on page 32](#).

The installation and configuration process consists of three basic steps:

1. Gather the information needed for the install and set up your network as described in ["Installation Prerequisites" on the facing page](#).
2. Install CTE on the protected host as described in ["Interactive Installation on Windows" on page 18](#) or ["Silent Installation on Windows" on page 20](#).
3. Register the protected host with a key manager and make sure that they can communicate with each other. This process can be done as part of the initial installation or at any point after the CTE Agent has been installed.

Assumptions

- The IP addresses, routing configurations, and DNS addresses allow connectivity between the key manager and all hosts on which the CTE Agent is installed.
- If the protected host is a virtual machine, the VM is deployed and running.
- For all types of upgrades, including interactive (GUI-based) and scheduled upgrades, the protected host must be able to connect to the key manager that it is registered to or the upgrade will fail.

Requirements

- You must install CTE on the system drive. Do *not* install CTE on a network share volume.
- The host on which you want to install CTE *must* support AES-NI hardware encryption.

Installation Prerequisites

This section lists the installation requirements and options you should consider before installing CTE.

Installation Method Options

There are two methods for installing CTE:

- **Interactive installation:** This is the most common and recommended type of installation. Use this for installing CTE on one host at a time using a standard InstallShield installation and registration wizard. See ["Interactive Installation on Windows" on the next page](#).
- **Silent installation:** Create pre-packaged installations by providing information and answers to the installation questions. Use silent installations when installing on a large number of hosts. See ["Silent Installation on Windows" on page 20](#).

Network Setup Requirements

- The IP addresses, routing configurations, and DNS addresses must allow connectivity of the Windows system on which you plan to install CTE to the CipherTrust Manager. After the Windows system is registered as a client with the CipherTrust Manager, the client must be able to poll the CipherTrust Manager in case there are any changes to the encryption keys, policies, or GuardPoints.
- If the system is a virtual machine, the VM must be deployed and running.

Port Configuration Requirements

If a protected client must communicate with the CipherTrust Manager through a firewall, see the CipherTrust Manager documentation to determine which of the ports must be opened through the firewall.

The default port for communication between the CipherTrust Manager and the CTE Agent is 443. If this port is already in use, you can set the port to a different number during the CTE Agent installation.

Hardware Association Feature

CTE's hardware association feature associates the installation of CTE with the machine's hardware. When enabled, hardware association prohibits cloned or copied versions of CTE from contacting the key manager and acquiring cryptographic keys. Hardware association works on both virtual machines and hardware clients.

You can enable hardware association during CTE registration process. You can disable hardware association by re-running the registration program.

To verify if hardware association (cloning prevention) is enabled on the protected client, access the Windows command line and run the `vmsec.exe hwok` command. The default location of `vmsec.exe` is `C:\Program Files\Vormetric\DataSecurityExpert\agent\vm\bin`.

To change the status from enable to disable or vice versa:

1. Open the system tray and right-click on the CipherTrust Lock icon.
2. Select **Register Host**.
3. Follow the prompts to re-register CTE with the CipherTrust Manager.
4. Select **Enable hardware association** in the wizard.

CTE Windows Installation Checklist

Use this table to verify prerequisites and collect the information you need for the installation.

Checklist item	Status
Get the CTE installation binary from Thales support, either self-extracting .exe file or MSI. The format for the self-extracting executable CTE file name is: vee-fs-<release>-<build>-<system>.exe Example: vee-fs-7.0.0-47-win64.exe The format for MSI CTE file name is: vee-<agent_type-build-system>.msi For example: vee-fs-7.0.0-47-win64.msi	
Get the Fully Qualified Domain Name (FQDN) of the CipherTrust Manager.	
Get the registration token for the CipherTrust Manager.	
Determine if you want to do an interactive (InstallShield) or silent (command line) install.	
Determine the Administrator password for the client.	
Get the CipherTrust Manager client profile name to associate with this client, unless you want to use the default client profile.	
Determine if you will register the IP address or the FQDN of the client. If you want to use the FQDN, make sure that there is a communication channel between the client and the CipherTrust Manager as described in "Installation Prerequisites" on the previous page .	
Decide if your environment will only support client-initiated communication as described in "Installation Prerequisites" on the previous page . Note: Thales recommends that you only use this option if your environment will not allow two-way communication between the CTE Agent and the CipherTrust Manager.	
Open the appropriate ports as described in "Port Configuration Requirements" on the previous page . The default CTE Agent port is 7024 for two-way communication.	
Decide if you want to enable cloning prevention as described in "Hardware Association Feature" on the previous page .	
Synchronize the host clock to the CipherTrust Manager clock.	

Interactive Installation on Windows

The Windows interactive install uses a standard InstallShield wizard that asks you a series of questions during the installation. You can also install CTE using a silent installer which pre-packages the install information. This allows you to install CTE on a large number of hosts. (For more information, see ["Silent Installation on Windows" on page 20](#)).

After you install CTE, you are prompted to register it immediately with a key manager. CTE must be registered with a key manager before you can protect any of the devices on the host. However, you may postpone the registration if you plan to register CTE later.

The following procedure describes how to install the CTE Agent on the host and then register the CTE Agent with a CipherTrust Manager. If you want to install CTE and register it with a Vormetric Data Security Manager, see ["Configuring CTE for Windows with a DSM" on page 32](#).

Prerequisites

Make sure you have the following information from the CM Administrator:

- The registration token for the CipherTrust Manager with which you plan to register the CTE Agent.
- The name of the profile you intend to assign to the client if you want to use a profile other than the default client profile.
- Optionally, the name of the host group you want this client to be a part of.

Procedure

1. Log on to the host as a Windows user with System Administrator privileges.
2. Copy the CTE installation file onto the Windows system.
3. Double-click the installation file. The InstallShield Wizard for CipherTrust Transparent Encryption opens.
4. Verify the version of CTE you are installing and click **Next**.
5. On the *License Agreement* page, accept the License Agreement and click **Next**.
6. On the *Destination Folder* page, click **Next** to accept the default folder or click **Change** to select a different folder. When you are done, click **Next**.

Notes

- Thales recommends that you install CTE in the default installation directory, `C:\Program Files\Vormetric\DataSecurityExpert\agent\`
- You must install the CTE Agent on the same drive as Windows. For example, if Windows is installed on the `C:` drive, you must install the CTE Agent on the `C:` drive.

7. On the *Ready to Install* page, click **Install**. When the installation is finished, the **Install Shield Wizard Completed** window opens.
8. On the *InstallShield Wizard Completed* page, make sure the **Register CipherTrust Transparent Encryption** **now** check box is selected and click **Finish**. The installer opens the Register Host wizard.
9. In the Register Host dialog box, verify the host's machine name and click **Next**.
10. On the *Gathering agent information* page, select the **File System** check box and click **Next**.
11. On the *Gathering Key Manager information* page, enter the FQDN or IP address of the primary CipherTrust Manager.

When you are done, click **Next**. CTE communicates with the selected CipherTrust Manager to validate what features have been licensed and are available to the CTE Agent.

12. On the *Gathering host name information* page:
 - Specify the host name or IP address of the client. You can select the host name from the drop-down list or type it in the field.
 - To enable cloning prevention, select the **Enable Hardware Association** check box. For details, see ["Hardware Association Feature" on page 17](#).
 - If you want to have CipherTrust Transparent Encryption - Live Data Transformation available on the client, select the **Enable LDT Feature** check box. For details on CTE-LDT, see *CTE-Live Data Transformation with CipherTrust Manager*.

When you are done, click **Next**.

13. On the *Gathering registration information* page, enter the following:
- **Registration token:** The registration token for the CipherTrust Manager with which you want to register this host.
 - **Profile name:** The name of the profile that you want to associate with this host. This name must match exactly the name of the profile in the CipherTrust Manager. If you do not specify a profile name, the CipherTrust Manager associates the default client profile with this client.
 - **Host group** (optional): The name of the client group to which the client will be added.
 - **Host description** (optional): A user-defined description of the client. This description will be displayed in the CipherTrust Manager.

WARNING

The registration token, profile name, and client group name are case-sensitive. If any of these are entered incorrectly, the client registration will not succeed. If the registration fails, click Back in the installer and verify that the case is correct for all entries on this page.

When you are done, click **Register**. CTE contacts the CipherTrust Manager and attempts to register the client with the specified options. The Register Host dialog box displays a message with the results of the registration request.

If the registration completed successfully, click **Finish**.

14. Restart the client to complete the installation process on the client.
15. After the host has rebooted, you can verify the installation by checking CTE processes:
- a. In the system tray of the protected host, right-click the CipherTrust Lock icon.
 - b. Select **Status**. Review the information in the **Status** window to confirm that the correct CTE version is installed and registered.
16. In CipherTrust Manager, change the client password using the manual password creation method. This password allows users to access encrypted data if the client is ever disconnected from the CipherTrust Manager. For details on changing the password, see the CipherTrust Manager documentation.

Silent Installation on Windows

Silent install refers to using the command line to install CTE in a non-interactive session. Use silent install to roll out CTE installations or upgrades to large numbers of hosts or to reduce your time and interaction as an administrator. Thales provides two types of installation binaries for silent installation:

- Self-extracting .exe
- Windows Installer Package (MSI).

Note: Thales supports installing or upgrading CTE with Microsoft System Center Configuration Manager (SCCM) using MSI installation binaries. For details, see your SCCM documentation.

For details, see one of the following procedures:

- ["Silent Installation Using the exe File" on the facing page](#)
- ["Silent Installation Using the MSI File" on page 23](#)

Silent Installation Using the exe File

The following sections discuss how to install CTE for Windows silently and then register the CTE Agent with a CipherTrust Manager using the exe file. To install silently using the MSI file or using the Microsoft System Center Configuration Manager (SCCM), see ["Silent Installation Using the MSI File" on page 23](#).

Prerequisites

Make sure you have the following information from the CM Administrator:

- The registration token for the CipherTrust Manager with which you plan to register the CTE Agent.
- The name of the profile you intend to assign to the client if you want to use a profile other than the default client profile.
- Optionally, the name of the host group you want this client to be a part of.

Procedure

1. Log on to the host as a Windows user with System Administrator privileges.
2. Copy the CTE installation `exe` file onto the Windows system.
3. Run the installation exe file using the following syntax:

```
<Installation_executable> /s /v"/qn INSTALLDIR=\"install-dir\" REGISTERHOSTPTS=\"Options\"
```

where:

- `/s` (required) specifies that this is a silent install.
- `/v` (required) specifies that you want to pass command line options and values of public properties through to the installer.
- `/qn` (required) specifies that the install should be non-interactive and that no GUI should be displayed.
- `INSTALLDIR=\"install-dir\"` is an optional parameter specifying the installation directory you want to use. If you omit this parameter, CTE installs in the directory `C:\Program Files\Vormetric\DataSecurityExpert\agent\`

Note: Thales recommends that you install CTE in the default directory if at all possible.

- `REGISTERHOSTPTS=\"Options\"` (required if you want to register CTE) is a list of options that you want the installer to use. The common options are:

Parameter	Description
<i>CipherTrust Manager host name</i>	Required if you want to register CTE with a CipherTrust Manager.
<code>-token</code>	The registration token for the CipherTrust Manager with which you plan to register this client. Required for registration.
<code>-profile</code>	Specifies the client profile in the CipherTrust Manager that will be associated with this client. If this value is omitted, the CipherTrust Manager uses the default client profile.
<code>-domain=domain_name</code>	Specifies the domain name with which this CTE Agent will be associated.

Parameter	Description
<code>-hostgroup=clientgroup_name</code>	Specifies the optional client group with which this client will be associated.
<code>-agent=your.agent.name.com</code>	FQDN of the host on which the CTE Agent is being installed. If this value is not specified, the installer uses the host's IP address.
<code>-keyagentpwd</code>	The administrative password for the CTE Agent. Required if the CTE Agent is being registered with a CipherTrust Manager. This password allows users to access encrypted data on the client if it is disconnected from the CipherTrust Manager.
<code>-useip</code>	Use the IP address of the protected host instead of host name. Used when <code>-agent</code> is not supplied.
<code>-description="description"</code>	Specifies a description for the host. This description is displayed in the DSM. If an entry for this host already exists in the DSM and the host already has a description, CTE does <i>not</i> overwrite the existing description even if this option is specified.
<code>-port=port</code>	Specifies the port number this CTE Agent should use.
<code>-usehwsig</code>	Specify this option when you want to associate this installation with the machine hardware for cloning prevention.
<code>-enableldt</code>	Specify this option to automatically enable and register CTE-LDT (Live Data Transformation) during silent install.

Note: If you want to enter an option with spaces in any value, it must be surrounded in two double-quotes with an escape character (\) before each double-quote. If the syntax is incorrect, the installation will fail.

Example: Custom Install Directory and Host Description with Spaces

The following example specifies that:

- CTE will be installed in the custom directory `C:\cte\custom dir`.
- The CipherTrust Manager host name is `my-key-mgr.example.com`.
- The CipherTrust Manager registration token is `12345` (`-token` parameter).
- The host will be registered using the host name `my-host.example.com` (`-agent` parameter).
- The host will be registered with the description `This host was silently installed` (`-description` parameter). Again, the spaces in the description require the same syntax as in the installation directory name. For example: `-description=\"\"This host was silently installed\"\"`

Note

The examples below are shown on several lines for readability. When you enter the command, all parameters should be on the same line.

```
C:\> vee-fs-7.0.0-47-win64.exe /s /v" /qn
INSTALLDIR=\"\"C:\cte\custom dir\"\"
registerhostopts=\"my-key-mgr.example.com -agent=my-host.example.com
-token=12345 -description=\"\"This host was silently installed\"\"\""
```

Example: CTE-LDT, Hardware Acceleration

The following example specifies that:

- The agent will be installed in the default installation directory (the `INSTALLDIR` parameter is omitted).
- The CipherTrust Manager host name is `my-key-mgr.example.com`.
- The host will be registered using its IP address and not its host name (`-useip` parameter).
- The CTE-LDT (`-enableldt` parameter) and hardware association (`-usehwsig` parameter) features are enabled.

```
C:\> vee-fs-7.0.0-47-win64.exe /s /v" /qn  
registerhostopts=\"my-key-mgr.example.com -token=12345 -useip -enableldt -usehwsig\""
```

Silent Installation Using the MSI File

The following sections discuss how to install CTE for Windows silently and then register the CTE Agent with a CipherTrust Manager using the MSI file. To install silently using the exe file, see ["Silent Installation Using the exe File" on page 21](#).

Note

Thales supports installing or upgrading CTE agents with Microsoft System Center Configuration Manager (SCCM) using MSI installation binaries. For details on how to do that, see your SCCM documentation.

Prerequisites

Make sure you have the following information from the CM Administrator:

- The registration token for the CipherTrust Manager with which you plan to register the CTE Agent.
- The name of the profile you intend to assign to the client if you want to use a profile other than the default client profile.
- Optionally, the name of the host group you want this client to be a part of.

Procedure

1. Log on to the host as a Windows user with System Administrator privileges.
2. Copy the CTE installation `MSI` file onto the Windows system.
3. Run the installation exe file using the following syntax:

```
msiexe.exe /i <Installation_executable> /qn INSTALLDIR=\"install-dir\"  
REGISTERHOSTOPTS=\"REGISTERHOSTOPTS_Options\"
```

where:

- `/i` (required) enables CTE installation.
- `/qn` (required) specifies that the install should be non-interactive and that no GUI should be displayed.
- `INSTALLDIR=\"install-dir\"` is an optional parameter specifying the installation directory you want to use. If you omit this parameter, CTE installs in the directory `C:\Program Files\Vormetric\DataSecurityExpert\agent\`

Note: Thales recommends that you install CTE in the default directory if at all possible.

- `REGISTERHOSTOPTS=\"Options\"` (required if you want to register CTE) is a list of options that you want the installer to use. The common options are:

Parameter	Description
<i>CipherTrust Manager host name</i>	Required if you want to register CTE with a CipherTrust Manager.
-token	The registration token for the CipherTrust Manager with which you plan to register this client. Required for registration.
-profile	Specifies the client profile in the CipherTrust Manager that will be associated with this client. If this value is omitted, the CipherTrust Manager uses the default client profile.
-agent= <i>your.agent.name.com</i>	FQDN of the host on which the CTE Agent is being installed. If this value is not specified, the installer uses the host's IP address.
-keyagentpwd	The administrative password for the CTE Agent. Required if the CTE Agent is being registered with a CipherTrust Manager. This password allows users to access encrypted data on the client if it is disconnected from the CipherTrust Manager.
-useip	Use the IP address of the protected host instead of host name. Used when -agent is not supplied.
-description=" <i>description</i> "	Specifies a description for the host. This description is displayed in the DSM. If an entry for this host already exists in the DSM and the host already has a description, CTE does <i>not</i> overwrite the existing description even if this option is specified.
-port= <i>port</i>	Specifies the port number this CTE Agent should use.
-usehwsig	Specify this option when you want to associate this installation with the machine hardware for cloning prevention.
-enableldt	Specify this option to automatically enable and register CTE-LDT (Live Data Transformation) during silent install.

Example: Custom Install Directory and Host Description with Spaces

The following example specifies that:

- CTE will be installed in the custom directory `C:\cte\custom dir`. The spaces in the installation directory name require it to be in double-quotes. For example: `INSTALLDIR="C:\cte\custom dir"`.
- The CipherTrust Manager host name is `my-key-mgr.example.com`.
- The CipherTrust Manager registration token is `12345` (-token parameter).
- The host will be registered using the host name `my-host.example.com` (-agent parameter).
- The host will be registered with the description `This host was silently installed` (-description parameter). Because -description is inside a double-quoted string, you must escape the double-quotes `-description=\"This host was silently installed\"`

Note

The examples below are shown on several lines for readability. When you enter the command, all parameters should be on the same line.

```
C:\> msixexec.exe /i vee-fs-7.0.0-47-win64.exe /qn
INSTALLDIR="C:\cte\custom dir"
registerhostopts="my-key-mgr.example.com -agent=my-host.example.com -token=12345
-description=\"This host was silently installed\""
```

Example: CTE-LDT, Hardware Acceleration

The following example specifies that:

- The agent will be installed in the default installation directory (the INSTALLDIR parameter is omitted).
- The CipherTrust Manager host name is `my-key-mgr.example.com`.
- The host will be registered using its IP address and not its host name (`-useip` parameter).
- The CTE-LDT (`-enableldt` parameter) and hardware association (`-usehwsig` parameter) features are enabled.

```
C:\> msixexec.exe /i vee-fs-7.0.0-47-win64.exe /qn
registerhostopts="my-key-mgr.example.com -token=12345 -useip -enableldt -usehwsig"
```

Registering CTE After Installation is Complete

The following procedure describes how to register the CTE Agent after installation is complete. If you have not yet installed the CTE Agent, see ["Interactive Installation on Windows" on page 18](#).

1. Log on to the host as a Windows user with administrative privileges.
2. Launch the CTE Registration Wizard using one of the following methods:
 - In the system tray, right click the CipherTrust Lock icon and select **Register Host**.
 - Run `C:\Program Files\Vormetric\DataSecurityExpert\agent\shared\bin\register_host.exe`.
 - Reboot the system. CTE automatically displays the registration wizard if CTE is not already registered.
3. In the Register Host dialog box, verify the host's machine name and click **Next**.
4. On the *Gathering agent information* page, select the **File System** check box and click **Next**.
5. On the *Gathering Key Manager information* page, enter the FQDN or IP address of the primary CipherTrust Manager.

When you are done, click **Next**. CTE communicates with the selected CipherTrust Manager to validate what features have been licensed and are available to the CTE Agent.

6. On the *Gathering host name information* page:
 - Specify the host name or IP address of the client. You can select the host name from the drop-down list or type it in the field.
 - To enable cloning prevention, select the **Enable Hardware Association** check box. For details, see ["Hardware Association Feature" on page 17](#).
 - If you want to have CipherTrust Transparent Encryption - Live Data Transformation available on the client, select the **Enable LDT Feature** check box. For details on CTE-LDT, see *CTE-Live Data Transformation with CipherTrust Manager*.

When you are done, click Next.

7. On the *Gathering registration information* page, enter the following:
 - **Registration token:** The registration token for the CipherTrust Manager with which you want to register this host.
 - **Profile name:** The name of the profile that you want to associate with this host. This name must match exactly the name of the profile in the CipherTrust Manager. If you do not specify a profile name, the CipherTrust Manager associates the default client profile with this client.
 - **Host group** (optional): The name of the client group to which the client will be added.
 - **Host description** (optional): A user-defined description of the client. This description will be displayed in the CipherTrust Manager.

WARNING

The registration token, profile name, and client group name are case-sensitive. If any of these are entered incorrectly, the client registration will not succeed. If the registration fails, click Back in the installer and verify that the case is correct for all entries on this page.

When you are done, click **Register**. CTE contacts the CipherTrust Manager and attempts to register the client with the specified options. The Register Host dialog box displays a message with the results of the registration request.

If the registration completed successfully, click **Finish**.

8. Restart the client to complete the installation process on the client.
9. After the host has rebooted, you can verify the installation by checking CTE processes:
 - a. In the system tray of the protected host, right-click the CipherTrust Lock icon.
 - b. Select **Status**. Review the information in the **Status** window to confirm that the correct CTE version is installed and registered.
10. In CipherTrust Manager, change the client password using the manual password creation method. This password allows users to access encrypted data if the client is ever disconnected from the CipherTrust Manager. For details on changing the password, see the CipherTrust Manager documentation.

Guarding a Device with CipherTrust Manager

After you register a client with a CipherTrust Manager, you can create as many GuardPoints on the client as you need. These GuardPoints can protect an entire device or individual directories.

In order to guard a device or directory, you need to use the CipherTrust Manager Console to:

1. Access the CipherTrust Manager domain in which the client is registered.
2. Identify or create an encryption key that CTE will use to encrypt the data on the device or directory.
3. Identify or create a policy for the device or directory that specifies the access controls and the encryption keys to use for the device or directory.
4. Assign a GuardPoint to the device or directory.

The following example creates a simple policy and uses it to guard a directory on a registered client. For all of the following procedures, you must be logged into the CipherTrust Manager Console as a CipherTrust Manager Administrator, and you must be in the domain with which the client is registered.

For details about any of these procedures or the options for domains, encryption keys, policies, and GuardPoints, see the CipherTrust Manager documentation.

Access the CipherTrust Manager Domain

1. In a web browser, navigate to the URL of the CipherTrust Manager Console you want to use and log in with CipherTrust Manager Administrator credentials.
2. If the client you want to protect is registered to the default domain (root), proceed to ["Create an Encryption Key" below](#). If you need to change to a different domain, do the following:
 - a. In the top menu bar, click the user name **root/admin** on the right-hand side.
 - b. Select **Switch Domains**, then select the domain in which the client is registered.
 - c. The logged in user now shows the new domain name/user name.

Create an Encryption Key

1. In the Applications page of the CipherTrust Manager Console, select **Keys & Access Management**.
2. Above the Key table, click **Create a New Key**.
3. In the **Key Name** field, add a name for the key. This name must be unique. For example, Simple-Key.
4. In the **Key Metadata > Groups for Key sharing** section, do the following:
 - a. In the **Search** box, type "cte".
 - b. Add CTE Admins and CTE Clients to the key sharing groups by clicking the green **Add** button. The **Key Shared?** check box is automatically selected and the **Add** button changes to a **Remove** button.
 - c. Below the Groups table, click the **CTE Key Properties** check box.

CipherTrust Manager displays the following options for CTE keys:

- **CTE Versioned:** Specify whether the key is versioned. By default, the key is set as versioned.
For a standard policy, you should clear this check box. If you do not, the key will *not* appear in the keys list when you add the key rule to the standard policy.
- **Persistent on Client:** Specify whether the key is stored in persistent memory on the client.
When the check box is selected, the key is downloaded and stored (in an encrypted form) in persistent memory on the client.
When the check box is left clear, the key is downloaded to non-persistent memory on the client. Every time the key is needed, the client retrieves it from the CipherTrust Manager. This is the default setting.

- **Encryption Mode:** Encryption mode of the key. The options are:
 - CBC
 - CBC CS1
 - XTS

Encryption using the XTS and CBC CS1 keys is known as enhanced encryption. For details, see the *CTE Agent for Windows Advanced Configuration and Integration Guide*.

5. In the Key Behaviors section at the bottom of the page, clear the **Prevent this key from being exported** check box. If the key cannot be exported, the key will not appear in the keys list when you add the key rule to the policy.

6. Click **Create**. The new key appears in the Keys table.

Create a Standard Policy

1. In the Applications page of the CipherTrust Manager Console, select the **CTE** application.
2. In the sidebar on the Clients page, click **Policies**.
3. Click **Create Policy**. CipherTrust Manager displays the Create Policy Wizard.
4. On the General Info page, set the following options:

Field	Description
Name	A unique name for the policy. Make sure you use a name that is descriptive and easy to remember so that you can find it quickly when you want to associate it with a GuardPoint. This example uses "Simple-Policy".
Policy Type	The type of policy you want to create. In this example, we will create a Standard policy.

Field	Description
Description	A user-defined description to help you identify the policy later. For example: Standard policy for new GuardPoints
Learn Mode	Learn Mode provides a temporary method for disabling the blocking behavior of CTE/CTE-LDT policies. While useful for quality assurance, troubleshooting, and mitigating deployment risk, Learn Mode is not intended to be enabled permanently for a policy in production. This prevents the policy Deny rules from functioning as designed in the policy rule set. Ensure that the policy is properly configured for use in Learn Mode. Any Security Rule that contains a Deny effect must have Apply Key applied as well. This is to prevent data from being written in mixed states, resulting in the loss of access or data corruption. Apply Key will have no effect when combined with a Deny rule unless the policy is in Learn Mode.
Data Transformation	If you select Standard as the policy type, also select the the Data Transformation option to tell CTE that you want to change the current encryption key used on the data in the GuardPoint, or that you want to encrypt clear-text data for the first time. This option is only displayed for Standard policies.

When you are done, click **Next**.

5. On the Security Rules page, define the security rules you want to use.

CipherTrust Manager automatically adds a default security access rule with an action of `key_op` and the effects `Permit` and `Apply Key`. This rule permits key operations on all resources, without denying user or application access to resources. This allows it to perform a rekey operation whenever the encryption key rotates to a new version. This rule is required by CTE-LDT, so you cannot edit it, move it, or delete it.

To add additional security rules, click **Create Security Rule** and enter the requested information. For details about adding security rules, see the CipherTrust Manager documentation.

For this example, click **Create Security Rule** and:

- Set Action to `all_ops`.
- Set Effect to **Permit** and **Audit**.

When you are done, click **Next**.

6. On the Create Key Rule page, click **Create Key Rule** and enter the following information:

Field	Description
Resource Set	If you want to select a resource set for this key rule, click Select and either choose an existing resource set or create a new one. Resource sets let you specify which directories or files will either be encrypted with the key or will be excluded from encryption with this key.
Current Key Name	Click Select to choose an existing key or create a new one. If the data has not yet been encrypted, select clear_key . Otherwise select the name of the non-versioned key that is currently being used to encrypt the data. In this example, select clear_key .
Transformation Key Name	Click Select to choose an existing versioned key or to create a new one. CTE uses the versioned key specified in this field to encrypt the data in the GuardPoint. If the data is currently encrypted, CTE decrypts it using the key specified in the Current Key Name field and re-encrypts it using the key specified in this field.

When you are done, click **Next**.

7. On the Data Transformation page, click **Create Data Transformation Rule** and enter the following information:

Field	Description
Resource Set	If you want to select a resource set for this key rule, click Select and either choose an existing resource set or create a new one. Resource sets let you specify which directories or files will either be encrypted with the key or will be excluded from encryption with this key.
Transformation Key Name	Click Select to choose an existing key or to create a new one. CTE uses the key specified in this field to encrypt the data in the GuardPoint. If the data is currently encrypted, CTE decrypts it using the key specified in the Current Key Name field and re-encrypts it using the key specified in this field. For this example, select the key Simple-Key you created in "Create an Encryption Key" on page 27 .

When you are done, click **Next**.

8. Click **Next**.

- On the confirmation page, review the information for the policy and click **Save**.

Create Policy

Review the provided policy details.

General info

Name: Create Policy
Policy Type: Standard
Description: Standard policy for new GuardPoints

Security Rules

Resource Set	User Set	Privilege Set	Action	Effect	Browsing
			key_op	perm_encrypt	yes
			all_ops	perm_decrypt	yes

Key Rules

Resource Set: _____ Current key name: clear-key

Data Transformation Rules

Resource Set: _____ Transformation Key Name: encrypt-key

Back Save

Create a GuardPoint

- Stop all applications that are accessing the device you want to protect. In this example, we are going to protect the following directories with the same policy and encryption key:
 - C:\HR Files\
 - C:\Accounting Files\
 - C:\Shared Resources\HR\
 - C:\Shared Resources\Accounting\
- Tip:** If you want to encrypt data without taking the device offline, you must use CipherTrust Transparent Encryption - Live Data Transformation.
- In the Applications page of the CipherTrust Manager Console, select the **CTE** application.
 - In the Clients table, click on the name of the client you want to protect.
 - Above the GuardPoints table, click **Create GuardPoint**.
 - In the Create GuardPoint page:
 - In the **Policy** field, select the policy you created earlier.
 - In the **Type** field, select the type of device. You can guard a directory or a raw/block device. For this example, select **Auto Directory**.
 - In the **Path** field, enter the directories you want to protect with this policy or click **Browse** to select them from a explorer window.
If you want to enter multiple paths, put each path on its own line. For example:

- d. Click **Create**.
- e. If you want to use the same policy and GuardPoint type on another path, click **Yes** when prompted. Otherwise, click **No**. For this example, click No.

The CipherTrust Manager pushes the GuardPoint configuration to the client and CTE immediately begins transforming the data in the specified folders from clear-text to cipher-text.

6. When the data transformation has finished, applications can resume accessing the now-protected data.

Configuring CTE for Windows with a DSM

This section describes how to install and configure CTE on Windows computers and, optionally, registering CTE with a Vormetric Data Security Manager (DSM). If you want to register CTE with a CipherTrust Manager, see ["Configuring CTE for Windows with CipherTrust Manager" on page 16](#).

The installation and configuration process consists of three basic steps:

1. Gather the information needed for the install and set up your network as described in ["Installation and Registration Options and Prerequisites" on the facing page](#).
2. Install CTE on the protected host as described in ["Interactive Installation on Windows" on page 36](#) or ["Silent Installation on Windows" on page 40](#).
3. Register the protected host with the primary DSM and make sure that the CTE Agent and the DSM can communicate with each other. Registration can be done as part of the initial installation or at any point after the CTE Agent has been installed.

Assumptions

- The IP addresses, routing configurations, and DNS addresses allow connectivity between the key manager and all hosts on which the CTE Agent is installed.
- If the protected host is a virtual machine, the VM is deployed and running.

Requirements

- You must install CTE on the system drive. Do *not* install CTE on a network share volume.
- The host on which you want to install CTE *must* support AES-NI hardware encryption.

Installation and Registration Options and Prerequisites

CTE has the following installation prerequisites and provides the following installation and registration options. The options you choose determine the information you need to supply during the actual install procedure, so you should decide what options you want to use before you start the installation.

Installation Method Options

There are two methods for installing CTE:

- **Interactive installation:** This is the most common and recommended type of installation. Use this for installing CTE on one host at a time using a standard InstallShield installation and registration wizard. See ["Interactive Installation on Windows" on page 36](#).
- **Silent installation:** Create pre-packaged installations by providing information and answers to the installation questions. Use silent installations when installing on a large number of hosts. See ["Silent Installation on Windows" on page 40](#).

CTE Registration Method Options

You can register the protected hosts with a DSM using either the *Fingerprint method* or the *Shared Secret method*.

- **Fingerprint method** requires the DSM Administrator to add the FQDN, or IP address, of each protected host to the DSM before registering CTE.
During the registration, the DSM generates the certificate and passes it down to CTE along with the fingerprint. The security administrator must verify the fingerprint to make sure the certificate is valid.
- **Shared Secret method** requires the DSM Administrator to create a *shared secret* password—a case-sensitive string of characters—for auto-registering a domain or host group.
CTE installers use the shared secret to add and register protected hosts to the DSM for a domain or host group. The DSM Administrator can optionally add host names or IP addresses to the DSM. There is no need to verify that the protected host and DSM share valid certificates. You can add multiple protected hosts dynamically with a single shared secret password during CTE installation and registration.
After the DSM Administrator creates a shared secret for the domain or host group in which the new protected host will reside, obtain it and the validity period (one hour, day, week, or month) and register within that period.

Host Name Resolution Requirements

Host name resolution is the method of mapping a host name to an IP address. During this configuration process, enter either the FQDNs, or IP addresses, of your DSM and protected hosts. If you use FQDNs, your protected hosts must be able to resolve the DSM host names, and the DSM must be able to resolve its protected hosts.

Note

The exception to this requirement is if you plan to configure one-way communication between CTE and the DSM.

A Domain Name Service (DNS) server is the preferred method of host name resolution. If you use DNS, use the FQDNs for the DSM and hosts.

If you do *not* use a DNS, you can do one of the following:

- Use the IP addresses of the DSM and protected hosts.
- Add an entry for the DSM in the `C:\WINDOWS\system32\drivers\etc\hosts` file on each one of the Windows machines on which you want to install the CTE Agent.

- Add an entry in the `/etc/hosts` file on the DSM associated with the host. The administrator must use the CipherTrust CLI, and, in an HA environment, they must add an entry to *each* DSM in the cluster because entries in the `/etc/hosts` file are not replicated across the cluster.

Port Configuration Requirements

If a protected host must communicate with the DSM through a firewall, see the *DSM Administration Guide* to determine which of the ports must be opened through the firewall.

The default port for communication between the DSM and the CTE Agent is 7024. If this port is already in use, you can set the port to a different number during the CTE Agent installation.

One-way Communication Option

In some deployments, CTE might not be visible to the DSM through normal network communications. For example, when the host on which CTE is installed:

- is behind NAT.
- is behind a firewall.
- is not permanently connected to a communication channel to the DSM.
- is unable to resolve the host name to an IP address.

In these situations, CTE can initiate CTE-only communication to the DSM. This feature is called one-way communication and works by having CTE poll the DSM for any policy messages or changes, then downloading changes as required.

The downside of one-way communication is that the DSM cannot issue any queries to CTE. For example, the DSM Administrator cannot browse host directories or User IDs. To enable the full functionality of both CTE and the CipherTrust Manager, Thales recommends that you use two-way communication between them whenever possible.

Port Usage in One-Way Communications Mode

By default, polling from the agent host to the DSM when running in one-way communications mode uses HTTP via port 8080. If the CTE Agent is configured to use secure polling, then polling is performed using HTTPS via port 8448 (in suite B mode) or port 8445.

Hardware Association (Cloning Prevention) Option

CTE's hardware association feature associates the installation of CTE with the machine's hardware. When enabled, hardware association prohibits cloned or copied versions of CTE from contacting the key manager and acquiring cryptographic keys. Hardware association works on both virtual machines and hardware hosts.

You can enable hardware association during CTE registration process. You can disable hardware association by re-running the registration program.

To verify if hardware association (cloning prevention) is enabled on the protected host, access the Windows command line and run the `vmsec.exe hwok` command. The default location of `vmsec.exe` is `C:\Program Files\Vormetric\DataSecurityExpert\agent\vmd\bin`.

To change the status from enable to disable or vice versa:

1. Open the system tray and right-click on the CipherTrust Lock icon.
2. Select **Register Host**.
3. Follow the prompts to re-register CTE with the DSM.

4. Select **Enable hardware association** in the wizard.

To verify if hardware association (cloning prevention) is enabled on host, on the command line enter the following:

```
cat /opt/vormetric/DataSecurityExpert/agent/vmd/etc/access
```

If you see `usehw:true`, then hardware association is enabled. If you see `usehw:false`, it's disabled.

CTE Windows Installation Checklist

Use this table to verify prerequisites and collect the information you need for the installation.

Checklist item	Status
Get the CTE installation binary from Thales support, either self-extracting .exe file or MSI. The format for the self-extracting executable CTE file name is: vee-fs-<release>-<build>-<system>.exe Example: vee-fs-7.0.0-47-win64.exe The format for MSI CTE file name is: vee-<agent_type-build-system>.msi For example: vee-fs-7.0.0-47-win64.msi	
Get the Fully Qualified Domain Name (FQDN) of the DSM.	
Determine the Administrator password for the host.	
Determine if you want to do an interactive (InstallShield) or silent (command line) install.	
Determine if you want to register the CTE Agent with the DSM using the Shared Secret registration method or the Fingerprint registration method. For more information, see "CTE Registration Method Options" on page 33 .	
If using Shared Secret registration, obtain the following from the DSM Administrator: • Shared secret for the DSM. • The Domain in which this host should be registered. • (Optional) Host Group in which this host should be added.	
If using the Fingerprint registration, ask the DSM Administrator to add the host to the DSM with the Registration Allowed check box selected. After you verify the fingerprints, the DSM Administrator can select the Communication Enabled check box.	
Decide if you want to enable cloning prevention as described in "Hardware Association (Cloning Prevention) Option" on the previous page .	
Determine if you will register the IP address or the FQDN of the client. If you want to use the FQDN, make sure that there is a communication channel between the client and the DSM as described in "Host Name Resolution Requirements" on page 33 .	
Decide if your environment will only support client-initiated communication as described in "One-way Communication Option" on the previous page . Note: Thales recommends that you only use this option if your environment will not allow two-way communication between the CTE Agent and the CipherTrust Manager.	
Open the appropriate ports as described in "Port Configuration Requirements" on the previous page . The default CTE Agent port is 7024 for two-way communication.	
Synchronize host clock to DSM clock.	

Interactive Installation on Windows

The Windows typical install uses an interactive InstallShield wizard that asks you a series of questions during the installation. You can also install CTE using a silent installer which pre-packages the install information. This allows you to install CTE on a large number of hosts. (For more information, see ["Silent Installation on Windows" on page 40](#)).

After you install CTE, you are prompted to register it immediately with a DSM. CTE must be registered with a DSM before you can protect any of the devices on the host. However, you may postpone the registration if you plan to register CTE later.

The procedure for installing CTE depends on the registration method you want to use. The available methods are described in ["CTE Registration Method Options" on page 33](#). After you have selected your registration method, you can use one of the following procedures:

- ["Installing CTE and Registering Using the Shared Secret Registration Method" below](#)
- ["Installing CTE and Registering Using the Certificate Fingerprint Method" on page 38](#)
- ["Installing CTE with No Key Manager Registration" on page 15](#)

Installing CTE and Registering Using the Shared Secret Registration Method

The following procedure describes how to install the CTE Agent on the host and then register the CTE Agent with a DSM using the Shared Secret registration method. For more information about the available registration methods, see ["CTE Registration Method Options" on page 33](#).

For other installation options, see ["Installing CTE and Registering Using the Certificate Fingerprint Method" on page 38](#) and ["Installing CTE with No Key Manager Registration" on page 15](#).

Prerequisites

Make sure you know the following information from the DSM Administrator:

- The server name of the primary DSM as shown on the DSM Dashboard.
- The shared secret for the domain on the primary DSM with which you want to register the host.
- The name of the domain in the DSM with which you want to register the host.
- Optionally, the name of the host group in which this host should be included.

All of this information is case-sensitive and must exactly match the corresponding information in the DSM.

Note

If registration appears to freeze, verify that the DSM and CTE can communicate with each other over the network.

Procedure

1. Log on to the host as a Windows user with System Administrator privileges.
2. Copy the CTE installation file onto the Windows system.
3. Double-click the installation file. The InstallShield Wizard for CipherTrust Transparent Encryption opens.
4. Verify the version of CTE you are installing and click **Next**.
5. On the *License Agreement* page, accept the License Agreement and click **Next**.

6. On the *Destination Folder* page, click **Next** to accept the default folder or click **Change** to select a different folder. When you are done, click **Next**.

Notes

- Thales recommends that you install CTE in the default installation directory, `C:\Program Files\Vormetric\DataSecurityExpert\agent\`
- You must install the CTE Agent on the same drive as Windows. For example, if Windows is installed on the `C:` drive, you must install the CTE Agent on the `C:` drive.

7. On the *Ready to Install* page, click **Install**. When the installation is finished, the **Install Shield Wizard Completed** window opens.
8. On the *InstallShield Wizard Completed* page, make sure the **Register CipherTrust Transparent Encryption** **now** check box is selected and click **Finish**. The installer opens the Register Host wizard.
9. In the Register Host dialog box, verify the host's machine name and click **Next**.
10. On the *Gathering agent information* page, select the **File System** check box and click **Next**.
11. On the *Gathering Key Manager information* page, enter the FQDN of the Primary DSM. This name must match the name shown in the **Server name** field in the **Management Summary** section on the DSM **Dashboard** page.

When you are done, click **Next**. CTE communicates with the selected DSM to validate what features have been licensed and are available to the CTE Agent.

12. On the *Gathering host name information* page:
 - Specify the host name or IP address of the host. You can select the host name from the drop-down list or type it in the field. If you specify a host name, it must be resolvable by the DNS server (see ["Host Name Resolution Requirements" on page 33](#)).
 - To enable cloning prevention, select the **Enable Hardware Association** check box. For details, see ["Hardware Association \(Cloning Prevention\) Option" on page 34](#).
 - If you want to have CipherTrust Transparent Encryption - Live Data Transformation available on the host, select the **Enable LDT Feature** check box. For details on CTE-LDT, see the *CTE-Live Data Transformation with Data Security Manager*.
 - If you want to have the CTE-Efficient Storage feature available on the host, select the **Enable ES Feature** check box. For details about CTE-Efficient Storage, see the *CTE Agent for Windows Advanced Configuration and Integration Guide*.
 - Make sure the **Use Shared Secret Registration** check box is enabled.

When you are done, click **Next**.

Note: If you get the message "Only CTE-initiated communication is possible", make sure that the DSM and CTE can communicate over the network.

13. On the *Gathering shared secret registration information* page, enter the following:
 - **Shared secret:** The shared secret established for the domain in the DSM to which you intend to add this host. Contact the DSM Administrator for this value.
 - **Domain name:** The name of the DSM domain to which the host will be added. Contact the DSM Administrator for this information.
 - **Host group** (optional): The name of the host group to which the host will be added. Contact the DSM Administrator for this value.
 - **Host description** (optional): A user-defined description of the host to be registered.

WARNING

The shared secret, domain name, and host group are case-sensitive. If any of these are entered incorrectly, an error message displays. If you exceed the number of allowable login attempts to the DSM, you will be locked out of the DSM. For more information, talk to your DSM Administrator.

When you are done, click **Register**. CTE contacts the DSM and attempts to register the host with the specified options. The Register Host dialog box displays a message with the results of the registration request.

If the registration completed successfully, click **Finish**.

14. Restart the host to complete the installation process.
15. After the host has rebooted, you can verify the installation by checking CTE processes:
 - a. In the system tray of the protected host, right-click the CipherTrust Lock icon.
 - b. Select **Status**. Review the information in the **Status** window to confirm that the correct CTE version is installed and registered.

Installing CTE and Registering Using the Certificate Fingerprint Method

The following procedure describes how to install the CTE Agent on the host and then register the CTE Agent with a DSM using the Fingerprint registration method. For more information about the available registration methods, see ["CTE Registration Method Options" on page 33](#).

For other installation options, see ["Installing CTE and Registering Using the Shared Secret Registration Method" on page 36](#) and ["Installing CTE with No Key Manager Registration" on page 15](#).

Prerequisites

Make sure the DSM Administrator has added the the FQDN, or IP address, of this host to the domain in which you want to register the host. During the registration, the DSM generates the certificate and passes it down to CTE along with the fingerprint. You will then need to verify the certificate fingerprint as part of the registration procedure.

In the DSM Management Console, the entry for the host must have at least the **Registration Allowed Agents > FS** and **Communication Enabled** options selected.

When you register the host, the machine name you use must exactly match the one in the DSM.

Additionally, make sure you know the server name of the primary DSM as shown on the DSM Dashboard.

Note

If registration appears to freeze, verify that the DSM and CTE can communicate with each other over the network.

Procedure

On the *InstallShield Wizard Completed* page, make sure the **Register CipherTrust Transparent Encryption now** check box is selected and click **Finish**. The installer opens the Register Host wizard.

In the Register Host dialog box, verify the host's machine name and click **Next**.

Note: The machine name shown here does *not* need to match the one specified in the DSM. You will have an opportunity to select a different machine name later in this procedure.

On the *Gathering agent information* page, select the **File System** check box and click **Next**.

On the *Gathering Key Manager information* page, enter the FQDN of the Primary DSM. This name must match the name shown in the **Server name** field in the **Management Summary** section on the DSM **Dashboard** page.

When you are done, click **Next**. CTE communicates with the selected DSM to validate what features have been licensed and are available to the CTE Agent.

On the *Gathering host name information* page:

- Specify the host name or IP address of the host. You can select the host name from the drop-down list or type it in the field. If you specify a host name, it must be resolvable by the DNS server (see ["Host Name Resolution Requirements" on page 33](#)).

WARNING

The host name specified here must exactly match the host name specified in the DSM in order for the fingerprints to match.

- To enable cloning prevention, select the **Enable Hardware Association** check box. For details, see ["Hardware Association \(Cloning Prevention\) Option" on page 34](#).
- If you want to have CipherTrust Transparent Encryption - Live Data Transformation available on the host, select the **Enable LDT Feature** check box. For details on CTE-LDT, see the *CTE-Live Data Transformation with Data Security Manager*.
- If you want to have the CTE-Efficient Storage feature available on the host, select the **Enable ES Feature** check box. For details about CTE-Efficient Storage, see the *CTE Agent for Windows Advanced Configuration and Integration Guide*.
- Clear the **Use Shared Secret Registration** check box so that CTE will use the Fingerprint Registration Method.

When you are done, click **Register**.

Note: If you get the message "Only CTE-initiated communication is possible", make sure that the DSM and CTE can communicate over the network.

CTE displays the Register host status page and displays the EC CA Certificate that it received from the DSM. This fingerprinting should exactly match the fingerprint displayed on the DSM Dashboard page. For example:

If the fingerprints match, click **Yes**.

Click **OK** when CTE displays the fingerprint for the host's certificate.

The *Register host status* page shows the two fingerprints and displays a message about the registration status. If the registration completed successfully, click **Finish**.

Restart the host to complete the installation process.

After the host has rebooted, you can verify the installation by checking CTE processes:

1. In the system tray of the protected host, right-click the CipherTrust Lock icon.
2. Select **Status**. Review the information in the **Status** window to confirm that the correct CTE version is installed and registered.

Silent Installation on Windows

Silent install refers to using the command line to install CTE in a non-interactive session. Use silent install to roll out CTE installations or upgrades to large numbers of hosts or to reduce your time and interaction as an administrator.

Thales provides two types of installation binaries for silent installation:

- Self-extracting .exe
- Windows Installer Package (MSI).

Note: Thales supports installing or upgrading CTE agents with Microsoft System Center Configuration Manager (SCCM) using MSI installation binaries. For details, see your SCCM documentation.

For details, see one of the following procedures:

- "Silent Installation Using the exe File and Shared Secret Registration Method" on the facing page
- "Silent Installation Using the MSI File and Shared Secret Registration Method" on page 43
- "Silent Installation Using the exe File and Fingerprint Registration Method" on page 46

- ["Silent Installation Using the MSI File and Fingerprint Registration Method" on page 48](#)

For a combined list of all available silent install options for both the exe file and the MSI file, see ["Windows Silent Install Command Line Options" on page 50](#).

Silent Installation Using the exe File and Shared Secret Registration Method

The following sections discuss how to install CTE for Windows silently and then register the CTE Agent with a DSM using the exe file and the shared secret registration method. For a list of other available methods, see ["Silent Installation on Windows" on the previous page](#).

Prerequisites

Make sure you know the following information from the DSM Administrator:

- The server name of the primary DSM as shown on the DSM Dashboard.
- The shared secret for the domain on the primary DSM with which you want to register the host.
- The name of the domain in the DSM with which you want to register the host.
- Optionally, the name of the host group in which this host should be included.

All of this information is case-sensitive and must exactly match the corresponding information in the DSM.

Note

If registration appears to freeze, verify that the DSM and CTE can communicate with each other over the network.

Procedure

1. Log on to the host as a Windows user with System Administrator privileges.
2. Copy the CTE installation `exe` file onto the Windows system.
3. Run the installation exe file using the following syntax:

```
<Installation_executable> /s /v"/qn INSTALLDIR=\"install-dir\" REGISTERHOSTPTS=\"Options\"
```

where:

- `/s` (required) specifies that this is a silent install.
- `/v` (required) specifies that you want to pass command line options and values of public properties through to the installer.
- `/qn` (required) specifies that the install should be non-interactive and that no GUI should be displayed.
- `INSTALLDIR=\"install-dir\"` is an optional parameter specifying the installation directory you want to use. If you omit this parameter, CTE installs in the directory `C:\Program Files\Vormetric\DataSecurityExpert\agent\`

Note: Thales recommends that you install CTE in the default directory if at all possible.

- `REGISTERHOSTPTS=\"Options\"` (required if you want to register CTE) is a list of options that you want the installer to use. The common options are:

Parameter	Description
<i>DSM host name</i>	Required if you want to register CTE with a DSM.

Parameter	Description
<code>-secret=shared-secret</code>	Specifies the shared secret for the DSM. This value is required for shared secret registration.
<code>-agent=your.agent.name.com</code>	FQDN of the host on which the CTE Agent is being installed. If this value is not specified, the installer uses the host's IP address.
<code>-keyagentpwd</code>	The administrative password for the CTE Agent. This password allows users to access encrypted data on the host if it is disconnected from the DSM.
<code>-useip</code>	Use the IP address of the protected host instead of host name. Used when <code>-agent</code> is not supplied.
<code>-description="description"</code>	Specifies a description for the host. This description is displayed in the DSM. If an entry for this host already exists in the DSM and the host already has a description, CTE does <i>not</i> overwrite the existing description even if this option is specified.
<code>-port=port</code>	Specifies the port number this CTE Agent should use.
<code>-usehwsig</code>	Specify this option when you want to associate this installation with the machine hardware for cloning prevention.
<code>-enableldt</code>	Specify this option to automatically enable and register CTE-LDT (Live Data Transformation) during silent install.
<code>-enablees</code>	Specify this option automatically enable and register CTE-Efficient Storage during silent install.
<code>-log=%temp%\vor-agent-reg.log</code>	Specifies a log file particular to the registration. Useful for documenting why the registration failed (if it does).
<code>-onewaycomms</code>	Specify this option when CTE-initiated-only communication is required. Thales recommends that you use two-way communication between CTE and the key manager whenever possible.

Note: If you want to enter an option with spaces in any value, it must be surrounded in two double-quotes with an escape character (\) before each double-quote. If the syntax is incorrect, the installation will fail.

Example: Custom Install Directory and Host Description with Spaces

The following example specifies that:

- CTE will be installed in the custom directory `C:\cte\custom dir`. The spaces in the installation directory name require it to be double-quoted, with each quote preceded by the escape character (\). For example:
`INSTALLDIR=\"\"C:\cte\custom dir\"\"`.
- The DSM host name is `my-key-mgr.example.com`.
- The host will be registered using the host name `my-host.example.com` (`-agent` parameter).
- The shared secret is `MaCarena45#` (`-secret` parameter) and the associated domain is `my-domain` (`-domain` parameter).

- The host will be registered with the description `This host was silently installed` (`-description` parameter). Again, the spaces in the description require the same syntax as in the installation directory name. For example: `-description=\"\"This host was silently installed\"\"`

Note

The examples below are shown on several lines for readability. When you enter the command, all parameters should be on the same line.

```
C:\> vee-fs-7.0.0-47-win64.exe /s /v" /qn
INSTALLDIR=\"\"C:\cte\custom dir\"\"
registerhostopts=\"my-key-mgr.example.com -agent=my-host.example.com
-secret=MaCarena45# -domain=my-domain -description=\"\"This host was silently installed\"\""
```

Example: CTE-LDT, CTE-Efficient Storage, One-way Communication, Hardware Acceleration

The following example specifies that:

- The agent will be installed in the default installation directory (the `INSTALLDIR` parameter is omitted).
- The DSM host name is `my-key-mgr.example.com`.
- The host will be registered using its IP address and not its host name (`-useip` parameter).
- The CTE-LDT (`-enableldt` parameter), CTE-Efficient Storage (`-enableees` parameter), one-way communication (`-onewaycomms` parameter) and hardware association (`-usehwsig` parameter) features are enabled.
- The shared secret is `MaCarena45#` (`-secret` parameter) and the associated domain is `my-domain` (`-domain` parameter).

```
C:\> vee-fs-7.0.0-47-win64.exe /s /v" /qn
registerhostopts=\"my-key-mgr.example.com -useip -enableldt -enableees
-onewaycomms -usehwsig -secret=MaCarena45# -domain=my-domain\""
```

Silent Installation Using the MSI File and Shared Secret Registration Method

The following sections discuss how to install CTE for Windows silently and then register the CTE Agent with a DSM using the MSI file and the shared secret registration method. For a list of other available methods, see ["Silent Installation on Windows" on page 40](#).

Prerequisites

Make sure you know the following information from the DSM Administrator:

- The server name of the primary DSM as shown on the DSM Dashboard.
- The shared secret for the domain on the primary DSM with which you want to register the host.
- The name of the domain in the DSM with which you want to register the host.
- Optionally, the name of the host group in which this host should be included.

All of this information is case-sensitive and must exactly match the corresponding information in the DSM.

Note

If registration appears to freeze, verify that the DSM and CTE can communicate with each other over the network.

Procedure

1. Log on to the host as a Windows user with System Administrator privileges.
2. Copy the CTE installation `MSI` file onto the Windows system.
3. Run the installation exe file using the following syntax:

```
msiexec.exe /i <Installation_executable> /qn INSTALLDIR=\"install-dir\"  
REGISTERHOSTOPTS=\"REGISTERHOSTOPTS_Options\"
```

where:

- `/i` (required) enables CTE installation.
- `/qn` (required) specifies that the install should be non-interactive and that no GUI should be displayed.
- `INSTALLDIR=\"install-dir\"` is an optional parameter specifying the installation directory you want to use. If you omit this parameter, CTE installs in the directory `C:\Program Files\Vormetric\DataSecurityExpert\agent\`

Note: Thales recommends that you install CTE in the default directory if at all possible.

- `REGISTERHOSTOPTS=\"Options\"` (required if you want to register CTE) is a list of options that you want the installer to use. The common options are:

Parameter	Description
<i>DSM host name</i>	Required if you want to register CTE with a DSM.
<code>-secret=shared-secret</code>	Specifies the shared secret for the DSM. This value is required for shared secret registration.
<code>-agent=your.agent.name.com</code>	FQDN of the host on which the CTE Agent is being installed. If this value is not specified, the installer uses the host's IP address.
<code>-keyagentpwd</code>	The administrative password for the CTE Agent. This password allows users to access encrypted data on the host if it is disconnected from the DSM.
<code>-useip</code>	Use the IP address of the protected host instead of host name. Used when <code>-agent</code> is not supplied.
<code>-description="description"</code>	Specifies a description for the host. This description is displayed in the DSM. If an entry for this host already exists in the DSM and the host already has a description, CTE does <i>not</i> overwrite the existing description even if this option is specified.
<code>-port=port</code>	Specifies the port number this CTE Agent should use.
<code>-usehwsig</code>	Specify this option when you want to associate this installation with the machine hardware for cloning prevention.
<code>-enableldt</code>	Specify this option to automatically enable and register CTE-LDT (Live Data Transformation) during silent install.
<code>-enablees</code>	Specify this option to automatically enable and register CTE-Efficient Storage during silent install.

Parameter	Description
-log=%temp%\vor-agent-reg.log	Specifies a log file particular to the registration. Useful for documenting why the registration failed (if it does).
-onewaycomms	Specify this option when CTE-initiated-only communication is required. Thales recommends that you use two-way communication between CTE and the key manager whenever possible.

Example: Custom Install Directory and Host Description with Spaces

The following example specifies that:

- CTE will be installed in the custom directory `C:\cte\custom dir`. The spaces in the installation directory name require it to be in double-quotes. For example: `INSTALLDIR="C:\cte\custom dir"`.
- The DSM host name is `my-key-mgr.example.com`.
- The host will be registered using the host name `my-host.example.com` (`-agent` parameter).
- The shared secret is `MaCarena45#` (`-secret` parameter) and the associated domain is `my-domain` (`-domain` parameter).
- The host will be registered with the description `This host was silently installed` (`-description` parameter). Because `-description` is inside a double-quoted string, you must escape the double-quotes `-description=\"This host was silently installed\"`

Note

The examples below are shown on several lines for readability. When you enter the command, all parameters should be on the same line.

```
C:\> msixec.exe /i vee-fs-7.0.0-47-win64.exe /qn
INSTALLDIR="C:\cte\custom dir"
registerhostopts="my-key-mgr.example.com -agent=my-host.example.com -secret=MaCarena45#
-domain=my-domain -description=\"This host was silently installed\""
```

Example: CTE-LDT, CTE-Efficient Storage, One-way Communication, Hardware Acceleration

The following example specifies that:

- The agent will be installed in the default installation directory (the `INSTALLDIR` parameter is omitted).
- The DSM host name is `my-key-mgr.example.com`.
- The host will be registered using its IP address and not its host name (`-useip` parameter).
- The CTE-LDT (`-enableldt` parameter), CTE-Efficient Storage (`-enableees` parameter), one-way communication (`-onewaycomms` parameter) and hardware association (`-usehwsig` parameter) features are enabled.
- The shared secret is `MaCarena45#` (`-secret` parameter) and the associated domain is `my-domain` (`-domain` parameter).

```
C:\> msixec.exe /i vee-fs-7.0.0-47-win64.exe /qn
registerhostopts="my-key-mgr.example.com -useip -enableldt -enableees -onewaycomms -usehwsig
-secret=MaCarena45# -domain=my-domain"
```

Silent Installation Using the exe File and Fingerprint Registration Method

The following sections discuss how to install CTE for Windows silently and then register the CTE Agent with a DSM using the exe file and the fingerprint registration method. For a list of other available methods, see ["Silent Installation on Windows" on page 40](#).

Prerequisites

Make sure the DSM Administrator has added the the FQDN, or IP address, of this host to the domain in which you want to register the host. During the registration, the DSM generates the certificate and passes it down to CTE along with the fingerprint. You will then need to verify the certificate fingerprint as part of the registration procedure.

In the DSM Management Console, the entry for the host must have at least the **Registration Allowed Agents > FS** and **Communication Enabled** options selected.

When you register the host, the machine name you use must exactly match the one in the DSM.

Additionally, make sure you know the server name of the primary DSM as shown on the DSM Dashboard.

Note

If registration appears to freeze, verify that the DSM and CTE can communicate with each other over the network.

Procedure

1. Log on to the host as a Windows user with System Administrator privileges.
2. Copy the CTE installation `exe` file onto the Windows system.
3. Run the installation exe file using the following syntax:

```
<Installation_executable> /s /v"/qn INSTALLDIR=\"install-dir\" REGISTERHOSTPTS=\"Options\"
```

where:

- `/s` (required) specifies that this is a silent install.
- `/v` (required) specifies that you want to pass command line options and values of public properties through to the installer.
- `/qn` (required) specifies that the install should be non-interactive and that no GUI should be displayed.
- `INSTALLDIR=\"install-dir\"` is an optional parameter specifying the installation directory you want to use. If you omit this paramater, CTE installs in the directory `C:\Program Files\Vormetric\DataSecurityExpert\agent\`

Note: Thales recommends that you install CTE in the default directory if at all possible.

- `REGISTERHOSTPTS=\"Options\"` (required if you want to register CTE) is a list of options that you want the installer to use. The common options are:

Parameter	Description
<i>DSM host name</i>	Required if you want to register CTE with a DSM.
<i>-agent=your.agent.name.com</i>	FQDN of the host on which the CTE Agent is being installed. If this value is not specified, the installer uses the host's IP address.

Parameter	Description
-keyagentpwd	The administrative password for the CTE Agent. This password allows users to access encrypted data on the host if it is disconnected from the DSM.
-useip	Use the IP address of the protected host instead of host name. Used when -agent is not supplied.
-description="description"	Specifies a description for the host. This description is displayed in the DSM. If an entry for this host already exists in the DSM and the host already has a description, CTE does <i>not</i> overwrite the existing description even if this option is specified.
-port=port	Specifies the port number this CTE Agent should use.
-usehwsig	Specify this option when you want to associate this installation with the machine hardware for cloning prevention.
-enableldt	Specify this option to automatically enable and register CTE-LDT (Live Data Transformation) during silent install.
-enablees	Specify this option automatically enable and register CTE-Efficient Storage during silent install.
-log=%temp%\vor-agent-reg.log	Specifies a log file particular to the registration. Useful for documenting why the registration failed (if it does).
-onewaycomms	Specify this option when CTE-initiated-only communication is required. Thales recommends that you use two-way communication between CTE and the key manager whenever possible.

Note: If you want to enter an option with spaces in any value, it must be surrounded in two double-quotes with an escape character (\) before each double-quote. If the syntax is incorrect, the installation will fail.

Example: Custom Install Directory and Host Description with Spaces

The following example specifies that:

- CTE will be installed in the custom directory `C:\cte\custom dir`. The spaces in the installation directory name require it to be double-quoted, with each quote preceded by the escape character (\). For example:
`INSTALLDIR=\"\"C:\cte\custom dir\"\"`.
- The DSM host name is `my-key-mgr.example.com`.
- The host will be registered using the host name `my-host.example.com` (-agent parameter).
- The host will be registered with the description `This host was silently installed` (-description parameter). Again, the spaces in the description require the same syntax as in the installation directory name. For example: `-description=\"\"This host was silently installed\"\"`

Note

The examples below are shown on several lines for readability. When you enter the command, all parameters should be on the same line.

```
C:\> vee-fs-7.0.0-47-win64.exe /s /v" /qn
INSTALLDIR="\"C:\cte\custom dir\"\"
registerhostopts=\"my-key-mgr.example.com -agent=my-host.example.com
-description=\"\"This host was silently installed\"\"\""
```

Example: CTE-LDT, CTE-Efficient Storage, One-way Communication, Hardware Acceleration

The following example specifies that:

- The agent will be installed in the default installation directory (the INSTALLDIR parameter is omitted).
- The DSM host name is `my-key-mgr.example.com`.
- The host will be registered using its IP address and not its host name (`-useip` parameter).
- The CTE-LDT (`-enableldt` parameter), CTE-Efficient Storage (`-enableees` parameter), one-way communication (`-onewaycomms` parameter) and hardware association (`-usehwsig` parameter) features are enabled.

```
C:\> vee-fs-7.0.0-47-win64.exe /s /v" /qn
registerhostopts=\"my-key-mgr.example.com -useip -enableldt -enableees
-onewaycomms -usehwsig\""
```

Silent Installation Using the MSI File and Fingerprint Registration Method

The following sections discuss how to install CTE for Windows silently and then register the CTE Agent with a DSM using the MSI file and the fingerprint registration method. For a list of other available methods, see ["Silent Installation on Windows" on page 40](#).

Note

Thales supports installing or upgrading CTE agents with Microsoft System Center Configuration Manager (SCCM) using MSI installation binaries. For details on how to do that, see your SCCM documentation.

Prerequisites

Make sure the DSM Administrator has added the the FQDN, or IP address, of this host to the domain in which you want to register the host. During the registration, the DSM generates the certificate and passes it down to CTE along with the fingerprint. You will then need to verify the certificate fingerprint as part of the registration procedure.

In the DSM Management Console, the entry for the host must have at least the **Registration Allowed Agents > FS** and **Communication Enabled** options selected.

When you register the host, the machine name you use must exactly match the one in the DSM.

Additionally, make sure you know the server name of the primary DSM as shown on the DSM Dashboard.

Note

If registration appears to freeze, verify that the DSM and CTE can communicate with each other over the network.

Procedure

1. Log on to the host as a Windows user with System Administrator privileges.
2. Copy the CTE installation MSI file onto the Windows system.
3. Run the installation exe file using the following syntax:

```
msiexe.exe /i <Installation_executable> /qn INSTALLDIR=\"install-dir\"
REGISTERHOSTOPTS=\"REGISTERHOSTOPTS_Options\"
```

where:

- `/i` (required) enables CTE installation.
- `/qn` (required) specifies that the install should be non-interactive and that no GUI should be displayed.
- `INSTALLDIR="install-dir\"` is an optional parameter specifying the installation directory you want to use. If you omit this parameter, CTE installs in the directory `C:\Program Files\ Vormetric\DataSecurityExpert\agent\`

Note: Thales recommends that you install CTE in the default directory if at all possible.

- `REGISTERHOSTOPTS="Options\"` (required if you want to register CTE) is a list of options that you want the installer to use. The common options are:

Parameter	Description
<i>DSM host name</i>	Required if you want to register CTE with a DSM.
<code>-agent=your.agent.name.com</code>	FQDN of the host on which the CTE Agent is being installed. If this value is not specified, the installer uses the host's IP address.
<code>-keyagentpwd</code>	The administrative password for the CTE Agent. This password allows users to access encrypted data on the host if it is disconnected from the DSM.
<code>-useip</code>	Use the IP address of the protected host instead of host name. Used when <code>-agent</code> is not supplied.
<code>-description="description"</code>	Specifies a description for the host. This description is displayed in the DSM. If an entry for this host already exists in the DSM and the host already has a description, CTE does <i>not</i> overwrite the existing description even if this option is specified.
<code>-port=port</code>	Specifies the port number this CTE Agent should use.
<code>-usehwsig</code>	Specify this option when you want to associate this installation with the machine hardware for cloning prevention.
<code>-enableldt</code>	Specify this option to automatically enable and register CTE-LDT (Live Data Transformation) during silent install.
<code>-enablees</code>	Specify this option automatically enable and register CTE-Efficient Storage during silent install.
<code>-log=%temp%\vor-agent-reg.log</code>	Specifies a log file particular to the registration. Useful for documenting why the registration failed (if it does).
<code>-onewaycomms</code>	Specify this option when CTE-initiated-only communication is required. Thales recommends that you use two-way communication between CTE and the key manager whenever possible.

Example: Custom Install Directory and Host Description with Spaces

The following example specifies that:

- CTE will be installed in the custom directory `C:\cte\custom dir`. The spaces in the installation directory name require it to be in double-quotes. For example: `INSTALLDIR="C:\cte\custom dir"`.
- The DSM host name is `my-key-mgr.example.com`.
- The host will be registered using the host name `my-host.example.com` (`-agent` parameter).
- The host will be registered with the description `This host was silently installed` (`-description` parameter). Because `-description` is inside a double-quoted string, you must escape the double-quotes `-description=\"This host was silently installed\"`

Note

The examples below are shown on several lines for readability. When you enter the command, all parameters should be on the same line.

```
C:\> msixec.exe /i vee-fs-7.0.0-47-win64.exe /qn  
INSTALLDIR="C:\cte\custom dir"  
registerhostopts="my-key-mgr.example.com -agent=my-host.example.com -description=\"This host  
was silently installed\""
```

Example: CTE-LDT, CTE-Efficient Storage, One-way Communication, Hardware Acceleration

The following example specifies that:

- The agent will be installed in the default installation directory (the `INSTALLDIR` parameter is omitted).
- The DSM host name is `my-key-mgr.example.com`.
- The host will be registered using its IP address and not its host name (`-useip` parameter).
- The CTE-LDT (`-enableldt` parameter), CTE-Efficient Storage (`-enablees` parameter), one-way communication (`-onewaycomms` parameter) and hardware association (`-usehwsig` parameter) features are enabled.

```
C:\> msixec.exe /i vee-fs-7.0.0-47-win64.exe /qn  
registerhostopts="my-key-mgr.example.com -useip -enableldt -enablees -onewaycomms -usehwsig"
```

Windows Silent Install Command Line Options

The MSI and self-extracting `.exe` silent install methods require different command line options to specify a silent installation. However, the parameters specific to CTE installation are the same for both MSI and self-extracting `.exe` install methods. See the following tables for required and optional command line options.

For a specific silent install procedure, see one the following:

- ["Silent Installation Using the exe File and Shared Secret Registration Method" on page 41](#)
- ["Silent Installation Using the MSI File and Shared Secret Registration Method" on page 43](#)
- ["Silent Installation Using the exe File and Fingerprint Registration Method" on page 46](#)
- ["Silent Installation Using the MSI File and Fingerprint Registration Method" on page 48](#)

General Format for Self-extracting .exe Silent Install Commands

For self-extracting `.exe` silent installations, be sure to escape the quotes surrounding the parameters passed in `REGISTERHOSTOPTS_Options` using a backslash (`\`) as shown:

```
<Installation_executable> /s /v"/qn REGISTERHOSTOPTS=\"REGISTERHOSTOPTS_Options\"
```

For example:

```
vee-fs-7.0.0-47-win64.exe /s /v"/qn REGISTERHOSTPTS=\"SecSrv.demo.com -useip\""
```

General Format for MSI Silent Install Commands

Use the following syntax for MSI silent installations:

```
msiexe.exe /i <Installation_executable> /qn REGISTERHOSTPTS="REGISTERHOSTPTS_Options"
```

For example:

```
msiexec.exe /i vee-fs-7.0.0-47-win64.msi /qn REGISTERHOSTPTS=" SecSrv.demo.com -useip"
```

Command Line Options for MSI and .exe Silent Installations

Refer to the following tables for required and optional command line options for MSI and self-extracting .exe CTE silent installations.

The following table lists the command line options for self-extracting .exe binary types.

Windows Attribute	Description	Required?
/s	Run the installation in silent mode.	Yes
/v	Pass command-line options and values of public properties through to the installer.	Yes

The following table lists the command line options for MSI binary types.

Windows Attribute	Description	Required?
/i	Enable installation/configuration	Yes, for installation
REINSTALLMODE=voums	Required REINSTALLMODE codes for upgrades	Yes, for upgrade
REINSTALL=ALL	Required REINSTALL setting for upgrades	Yes, for upgrade
/x	Required for uninstallation. See Chapter 14: "Uninstalling CTE from Windows" on page 139 .	Yes, for uninstall

The following table lists the command line options common to both MSI and self-extracting .exe binary types.

Windows Attribute	Description	Required?
/qn	Run the command in non-interactive mode (no GUI).	Yes
REGISTERHOSTPTS	Options for registering CTE with the DSM. The full set of options is specified below.	No
INSTALLDIR	Specifies an alternate location for installing CTE. Notes: • If syntax is incorrect, silent install will fail. See examples. • The alternate location must be on the system drive.	No
REBOOT=ReallySuppress	By default, the machine reboots after installation. Supplying this option prevents that. However, a reboot is still required to fully install CTE.	No

The following table lists the REGISTERHOSTOPTS parameters that determine log settings and CTE configuration settings. The REGISTERHOSTOPTS parameters are common to both MSI and self-extracting .exe binary types.

Parameter	Description
<i>DSM host name</i>	Required if you want to register CTE with a DSM.
<i>-secret=shared-secret</i>	Specifies the shared secret for the DSM. This value is required for shared secret registration.
<i>-agent=your.agent.name.com</i>	FQDN of the host on which the CTE Agent is being installed. If this value is not specified, the installer uses the host's IP address.
<i>-keyagentpwd</i>	The administrative password for the CTE Agent. This password allows users to access encrypted data on the host if it is disconnected from the DSM.
<i>-useip</i>	Use the IP address of the protected host instead of host name. Used when <i>-agent</i> is not supplied.
<i>-description="description"</i>	Specifies a description for the host. This description is displayed in the DSM. If an entry for this host already exists in the DSM and the host already has a description, CTE does <i>not</i> overwrite the existing description even if this option is specified.
<i>-port=port</i>	Specifies the port number this CTE Agent should use.
<i>-usehwsig</i>	Specify this option when you want to associate this installation with the machine hardware for cloning prevention.
<i>-enableldt</i>	Specify this option to automatically enable and register CTE-LDT (Live Data Transformation) during silent install.
<i>-enableeas</i>	Specify this option automatically enable and register CTE-Efficient Storage during silent install.
<i>-log=%temp%\vor-agent-reg.log</i>	Specifies a log file particular to the registration. Useful for documenting why the registration failed (if it does).
<i>-onewaycomms</i>	Specify this option when CTE-initiated-only communication is required. Thales recommends that you use two-way communication between CTE and the key manager whenever possible.

Registering CTE with the Shared Secret Registration Method After Installation is Complete

The following procedure describes how to register the CTE Agent after installation is complete. If you have not yet installed the CTE Agent, see ["Installing CTE and Registering Using the Certificate Fingerprint Method" on page 38](#) or ["Installing CTE and Registering Using the Shared Secret Registration Method" on page 36](#).

1. Log on to the host as a Windows user with administrative privileges.
2. Launch the CTE Registration Wizard using one of the following methods:
 - In the system tray, right click the CipherTrust Lock icon and select **Register Host**.
 - Run `C:\Program Files\Vormetric\DataSecurityExpert\agent\shared\bin\register_host.exe`.

3. In the Register Host dialog box, verify the host's machine name and click **Next**.
4. On the *Gathering agent information* page, select the **File System** check box and click **Next**.
5. On the *Gathering Key Manager information* page, enter the FQDN of the Primary DSM. This name must match the name shown in the **Server name** field in the **Management Summary** section on the DSM **Dashboard** page.

When you are done, click **Next**. CTE communicates with the selected DSM to validate what features have been licensed and are available to the CTE Agent.

6. On the *Gathering host name information* page:
 - Specify the host name or IP address of the host. You can select the host name from the drop-down list or type it in the field. If you specify a host name, it must be resolvable by the DNS server (see ["Host Name Resolution Requirements" on page 33](#)).
 - To enable cloning prevention, select the **Enable Hardware Association** check box. For details, see ["Hardware Association \(Cloning Prevention\) Option" on page 34](#).
 - If you want to have CipherTrust Transparent Encryption - Live Data Transformation available on the host, select the **Enable LDT Feature** check box. For details on CTE-LDT, see the *CTE-Live Data Transformation with Data Security Manager*.
 - If you want to have the CTE-Efficient Storage feature available on the host, select the **Enable ES Feature** check box. For details about CTE-Efficient Storage, see the *CTE Agent for Windows Advanced Configuration and Integration Guide*.
 - Make sure the **Use Shared Secret Registration** check box is enabled.

When you are done, click **Next**.

Note: If you get the message "Only CTE-initiated communication is possible", make sure that the DSM and CTE can communicate over the network.

7. On the *Gathering shared secret registration information* page, enter the following:
 - **Shared secret:** The shared secret established for the domain in the DSM to which you intend to add this host. Contact the DSM Administrator for this value.
 - **Domain name:** The name of the DSM domain to which the host will be added. Contact the DSM Administrator for this information.
 - **Host group** (optional): The name of the host group to which the host will be added. Contact the DSM Administrator for this value.
 - **Host description** (optional): A user-defined description of the host to be registered.

WARNING

The shared secret, domain name, and host group are case-sensitive. If any of these are entered incorrectly, an error message displays. If you exceed the number of allowable login attempts to the DSM, you will be locked out of the DSM. For more information, talk to your DSM Administrator.

When you are done, click **Register**. CTE contacts the DSM and attempts to register the host with the specified options. The Register Host dialog box displays a message with the results of the registration request.

If the registration completed successfully, click **Finish**.

8. Restart the host to complete the installation process.
9. After the host has rebooted, you can verify the installation by checking CTE processes:
 - a. In the system tray of the protected host, right-click the CipherTrust Lock icon.
 - b. Select **Status**. Review the information in the **Status** window to confirm that the correct CTE version is installed and registered.

Registering CTE with the Fingerprint Registration Method After Installation is Complete

The following procedure describes how to register the CTE Agent after installation is complete. If you have not yet installed the CTE Agent, see ["Installing CTE and Registering Using the Certificate Fingerprint Method" on page 38](#) or ["Installing CTE and Registering Using the Shared Secret Registration Method" on page 36](#).

Prerequisites

Make sure the DSM Administrator has added the the FQDN, or IP address, of this host to the domain in which you want to register the host. During the registration, the DSM generates the certificate and passes it down to CTE along with the fingerprint. You will then need to verify the certificate fingerprint as part of the registration procedure.

In the DSM Management Console, the entry for the host must have at least the **Registration Allowed Agents > FS** and **Communication Enabled** options selected.

When you register the host, the machine name you use must exactly match the one in the DSM.

Additionally, make sure you know the server name of the primary DSM as shown on the DSM Dashboard.

Note

If registration appears to freeze, verify that the DSM and CTE can communicate with each other over the network.

Procedure

1. Log on to the host as a Windows user with administrative privileges.
2. Launch the CTE Registration Wizard using one of the following methods:
 - In the system tray, right click the CipherTrust Lock icon and select **Register Host**.
 - Run `C:\Program Files\Vormetric\DataSecurityExpert\agent\shared\bin\register_host.exe`.
3. In the Register Host dialog box, verify the host's machine name and click **Next**.

Note: The machine name shown here does *not* need to match the one specified in the DSM. You will have an opportunity to select a different machine name later in this procedure.

4. On the *Gathering agent information* page, select the **File System** check box and click **Next**.
5. On the *Gathering Key Manager information* page, enter the FQDN of the Primary DSM. This name must match the name shown in the **Server name** field in the **Management Summary** section on the DSM **Dashboard** page.

When you are done, click **Next**. CTE communicates with the selected DSM to validate what features have been licensed and are available to the CTE Agent.

6. On the *Gathering host name information* page:

- Specify the host name or IP address of the host. You can select the host name from the drop-down list or type it in the field. If you specify a host name, it must be resolvable by the DNS server (see ["Host Name Resolution Requirements" on page 33](#)).

WARNING

The host name specified here must exactly match the host name specified in the DSM in order for the fingerprints to match.

- To enable cloning prevention, select the **Enable Hardware Association** check box. For details, see ["Hardware Association \(Cloning Prevention\) Option" on page 34](#).
- If you want to have CipherTrust Transparent Encryption - Live Data Transformation available on the host, select the **Enable LDT Feature** check box. For details on CTE-LDT, see the *CTE-Live Data Transformation with Data Security Manager*.
- If you want to have the CTE-Efficient Storage feature available on the host, select the **Enable ES Feature** check box. For details about CTE-Efficient Storage, see the *CTE Agent for Windows Advanced Configuration and Integration Guide*.
- Clear the **Use Shared Secret Registration** check box so that CTE will use the Fingerprint Registration Method.

When you are done, click **Register**.

Note: If you get the message “Only CTE-initiated communication is possible”, make sure that the DSM and CTE can communicate over the network.

7. CTE displays the Register host status page and displays the EC CA Certificate that it received from the DSM. This fingerprinting should exactly match the fingerprint displayed on the DSM Dashboard page. For example:

If the fingerprints match, click **Yes**.

8. Click **OK** when CTE displays the fingerprint for the host's certificate.
The *Register host status* page shows the two fingerprints and displays a message about the registration status. If the registration completed successfully, click **Finish**.
9. Restart the host to complete the installation process.
10. After the host has rebooted, you can verify the installation by checking CTE processes:
 - a. In the system tray of the protected host, right-click the CipherTrust Lock icon.
 - b. Select **Status**. Review the information in the **Status** window to confirm that the correct CTE version is installed and registered.

Guarding a Device with the DSM

After you register a device with a DSM, you can create as many GuardPoints on the device as you need. These GuardPoints can protect the entire device or individual directories or files.

In order to guard a device, you need to use the DSM Management Console to:

1. Access the DSM domain in which the host is registered.
2. Identify or create an encryption key that CTE will use to encrypt the data on the device.
3. Identify or create a policy for the device that specifies the access controls and the encryption keys to use for the device.
4. Create a GuardPoint for the device.

The following example creates a simple policy with a single key rule and no access controls and uses it to guard several directories on a registered host. For all of the following procedures, you must be logged into the DSM Management Console as a DSM Administrator, and you must be in the domain with which the host is registered.

For details about any of these procedures or the options for domains, encryption keys, policies, and GuardPoints, see the *DSM Administration Guide*.

Access the DSM Domain

1. In a web browser, navigate to the URL of the DSM you want to use and log in with DSM Administrator credentials.
2. In the top menu bar of the DSM Management Console, select **Domains > Switch Domains**.
3. Select the domain with which the host you want to protect is registered and click **Switch to domain**.

Create an Encryption Key

1. In the top menu bar of the DSM Management Console, select **Keys**.
2. In the Key table, click **Add**
3. In the **Name** field, add a name for the key. This name must be unique. For example, Simple-Policy-Key.
4. Set any other desired options or use the defaults provided.
5. Click **Ok**.

Create a Standard Policy

1. In the top menu bar, select **Policies**.
2. In the Policy table, click **Add**.
3. In the Add Policy page:
 - a. Select a Policy Type. In this example, we will create a Standard policy.
 - b. Enter a name for the policy in the **Name** field. For example, Simple-Policy.
 - c. Enter a description for the policy in the **Description** field.
 - d. In the Key Selection Rules section, click **Add**.
 - e. In the Key field, click **Select**.
 - f. Select the key you created earlier and click **Select key**.
 - g. Click **Ok**.

4. Click **Ok** to create the policy.

Create a GuardPoint

1. Stop all applications that are accessing the device you want to protect. In this example, we are going to protect the following directories with the same policy and encryption key:
 - C:\HR Files\
 - C:\Accounting Files\
 - C:\Shared Resources\HR\
 - C:\Shared Resources\Accounting\

Tip: If you want to encrypt data without taking the device offline, you must use CipherTrust Transparent Encryption - Live Data Transformation.

2. In the top menu bar, click **Hosts**.
3. In the Hosts table, click on the name of the host you want to protect.
4. Click the **GuardPoints** tab.

5. In the GuardPoints table, click **Guard**.
6. In the Guard page:
 - a. In the **Policy** field, select the policy you created earlier.
 - b. In the Type field, select the type of device. You can guard a directory or a raw/block device. For this example, select **Directory (Auto Guard)**.
 - c. In the **Path** field, enter the directories you want to protect with this policy or click **Browse** to select them from a Windows-style explorer.

If you want to enter multiple paths, put each path on its own line. For example:

- d. Click **Ok**.

The DSM pushes the GuardPoint configuration to the host and CTE immediately begins transforming the data in the specified folders from clear-text to cipher-text.
7. When the data transformation has finished, applications can resume accessing the now-protected data.

Chapter 3: Special Cases for CTE Policies

This chapter describes some CTE-specific configuration tasks related to configuring policies in the DSM and contains the following sections:

More Information About Configuring CTE Policies	60
Re-Signing Executable Files on Secfs GuardPoints	60
Restricting Access Overrides from Unauthorized Identities	61
Behavior of Hard Links Inside and Outside of GuardPoints (Windows)	61

More Information About Configuring CTE Policies

This chapter describes some special cases that apply only to CTE agent policy configuration. See the DSM Administration Guide for general information about configuring policies. The following chapters in the *DSM Administration Guide* pertain specifically to the information in this chapter:

- “Creating and Configuring Signature Sets”
- “Configuring Hosts and Host Groups”
- “Configuring Policies”

Re-Signing Executable Files on Secfs GuardPoints

If any of your existing VTE for Windows hosts are running VTE versions prior to version 6.2.0, an issue affects signed executables in Live Data Transformation policies. In these older VTE versions, any executable that is part of either a host setting or a Signature set, and resides in a GuardPoint that uses a Live Data Transformation policy will have a different SHA signature after every LDT key rotation. After each LDT key rotation, the host settings executables will no longer be authenticated, or the Signature Set policy rules that include those executables will no longer match them as expected. This problem occurred because VTE generated an SHA signature of the encrypted executable which changes after each key rotation. To work around these issues on these older VTE versions, the DSM Security Administrator must manually re-sign each affected executable after each key rotation. This workaround is *not* needed for any VTE for Windows release version 6.2.0 or later.

The SHA signature is created from the unencrypted executable. This new SHA signature does not change with a key rotation.

If upgrading or installing a new machine using the same signature sets that you used previously, do the following:

1. Install the current release of the CTE Agent. The previous signatures will be used until the next key rotation.
2. Before the next key rotation, the security administrator must resign the binaries.
3. Do not remove the old signatures on the DSM or CipherTrust Manager until all agents have been upgraded to the latest CTE release. Refer to the *DSM Installation and Configuration Guide* for information on how to perform a manual re-sign.
4. After all agents have been upgraded, then you can remove the old signatures.

Note

In previous releases, if the executable was in a GuardPoint protected directory, but was the same as an unguarded executable, the administrator could restrict only the guarded executable. In the current release of CTE, the unguarded executable matches the guarded executable with regards to policies.

Restricting Access Overrides from Unauthorized Identities

In some setups, system administrators can use the host settings > `|authenticator|` feature with `su` to change identities and gain access to restricted data. Now, you can instruct CTE to not trust any authentication attempt performed by certain identities by assigning restricted users to a user shell that CTE can block from authenticating other processes.

Any executable path that is marked with a `|path_no_trust|` host setting marks the process, and all child processes, as not trusted. Non-trusted processes are treated as "User Not Authenticated" to prevent access on user-based policies.

CTE prevents overrides from other host settings authenticators, using the `|path_no_trust|` status. If a user runs the `su` command from a non-trusted shell, that new shell is still marked as `|path_no_trust|`, even if `|authenticator|/usr/bin/su` is specified in the host-settings. The `|path_no_trust|` feature overrides any and all authenticators under host settings.

To restrict access overrides in the DSM:

1. At the DSM Management Console, click **Hosts > Hosts**.
2. Click on an existing host name to edit the host.
3. Click **Host Settings** tab.
4. Add the following to the host settings:

```
|path_no_trust|<path of the binary>
```

For example:

```
|path_no_trust|/bin/ksh
```

The above example indicates that no process under the kshell executable will be authenticated.

5. Click **OK**.

To restrict access overrides in CipherTrust Manager:

1. In the CipherTrust Manager Applications Page, click **CTE > Clients**.
2. Click on an existing client name to edit the client.
3. Click **Client Settings** tab.
4. Add the following to the client settings:

```
|path_no_trust|<path of the binary>
```

For example:

```
|path_no_trust|/bin/ksh
```

The above example indicates that no process under the kshell executable will be authenticated.

5. Click **OK**.

Behavior of Hard Links Inside and Outside of GuardPoints (Windows)

When using hard links on Windows, all the hard links to a file must be within the boundary of a GuardPoint and must use the same key. The following scenarios provide additional details:

- If hard links to the same file are inside a GuardPoint and outside a GuardPoint, the effect on the file depends on what process accesses which hard link first. If the hard link within the GuardPoint is opened first, the file is transformed. If the hard link outside the GuardPoint is opened first, the file won't be transformed.

- If hard links to the same file exist in different GuardPoints with different keys, the file will be corrupted.
- If hard links to the same file exist in the same GuardPoint but with different keys, such as if folder-based rules are used, there will be a conflict in the key.

Chapter 4: Concise Logging

This chapter contains the following sections:

Overview of Concise Logging	63
Using Concise Logging	63

Overview of Concise Logging

Thales's standard operational logging sends audit messages for each file system operation. An audit message is sent each time a file is opened, read, updated, or written. Thales's standard logging can generate high volumes of log data. Most of these messages might not be useful or required by security administrators to monitor file system activity on the system.

Concise Logging allows you to focus on relevant audit messages and important actionable messages, such as errors and warnings. It can eliminate the repetitive and less important audit messages generated by read and write activity on a file, reading and writing directory attributes, and other file system activity.

Concise Logging eliminates the following types of messages:

- Duplicate audit messages for each and every block read by the user or application. With Concise Logging, CTE only sends an audit message the *first* time a user or application performs a read/write activity. Subsequent read/write activity by that user or application is not logged.
- Audit messages that read the attributes, read the basic information of file-set attributes, and other event-based messages.
- Audit messages for directory open, read directory attributes, and directory close.

Using Concise Logging

You can enable and disable the Concise Logging option from the DSM or CipherTrust Manager for the following:

- All registered hosts in all domains; see ["Configuring Global Concise Logging with the DSM" on the next page](#).
- A host that has registered with the DSM; see ["Configuring Concise Logging for a Registered Host with the DSM" on the next page](#).

Considerations

- Concise Logging changes the set of log messages that are sent to Security Information and Event Management (SIEM) software systems. If this results in loss of data required for customer reports, then disable Concise Logging.
- Concise Logging is only supported by CTE `secfs`.
- Enable and disable Concise Logging on the host. CTE applies it to all GuardPoints and for all users on the host for which it is selected. There is no finer-grained control, such as per GuardPoint, user, or message type.
- When you enable this setting at the DSM level, it applies to all hosts in all domains, that are added to the DSM, but does not apply to any existing hosts. Hosts added after this setting is enabled inherit this setting. The default global setting is off.
- Do not use Learn mode with Concise Logging.

Configuring Concise Logging for CTE Clients or Client Groups with CipherTrust Manager

In CipherTrust Manager, when you create a Client Profile, you can select to Enable Concise Logging. Then, you can apply that Client Profile to a specific client, or to all clients in a Client Group. To enable Concise Logging, see the chapter *Managing Profiles* in the *CTE Administrator Guide*.

Configuring Global Concise Logging with the DSM

You can enable or disable Concise Logging at any time. The DSM controls the function. Any change in the Concise Logging is reflected on any newly registered hosts and their domains.

To configure global Concise Logging:

1. Log in to the DSM with System Admin privileges.
2. Click **System > Log Preferences**. Your system may contain multiple log tabs.
3. Click on a **Log** tab.
4. In the Duplicate Message Suppression Settings field, click **Enable Concise Logging**.
5. Click **Apply**.
6. Repeat steps for any other logs, as appropriate.

The host sends the following message after the administrator has enabled Concise Logging for an individual host:

```
DAO00821: Administrator "voradmin" updated Security Server configuration "Concise Logging Enabled" from "true" to "false".
```

Configuring Concise Logging for a Registered Host with the DSM

You can enable Concise Logging for a host after you have registered it with the DSM. Hosts that are added to the DSM after enabling Concise Logging inherit the global settings from the DSM. This setting can be customized at any time.

To enable Concise Logging on the DSM for a registered host:

1. Log into your host with DSM Security Administrator privileges.
2. Select the host that you would like to customize.
3. Select a **Log** tab.
4. In the Duplicate Message Suppression Settings, click **Enable Concise Logging**.
5. Click **Apply**.

After you enable or disable Concise Logging, CTE generates a log message to record that event:

```
[CGA] [INFO] [CGA3201I] [11/11/2016 10:57:18] Concise logging enable  
[CGA] [INFO] [CGA3202I] [11/11/2016 10:57:27] Concise logging disabled
```

Chapter 5: Enhanced Encryption Mode

This chapter describes the enhanced AES-CBC-CS1 encryption mode for keys. It contains the following sections:

Compatibility	65
Disk Space	66
Encryption Migration	66
File Systems Compatibility	66
FileTable Support on Windows	67
Using the AES-CBC-CS1 Encryption Mode in DSM	67
Using the AES-CBC-CS1 Encryption Mode in CM	68
Exceptions and Caveats	68
Best Practices for AES-CBC CS1 Keys and Host Groups	68

The AES-CBC-CS1 encryption is superior to the existing AES-CBC mode because it uses a unique and unpredictable (random) IV (initialization vector) generated for each individual file. The per-file IV object is generated only at file creation time. It is stored as file metadata.

Note

AES-CBC-CS1 encryption does not require any additional license.

	AES-CBC	AES-CBC-CS1
Security Improvements		
Unique IV per-file	No	Yes
IV predictability	Yes	No
File System Support		
Local FS	NTFS/ReFS	NFS3/NFS4/CIFS
Remote FS	CIFS	CIFS (if the backend storage for the CIFS share is Windows-based storage).
Block Device Support (sevm)	Fully supported	No. When a policy contains a key with CBC-CS1 encryption mode, the guarding fails on the DSM, and an error message displays.

Compatibility

- Starting with VTE for Windows version 6.1.0, CTE is backward compatible with, and fully supports, the existing AES-CBC mode for both new and existing datasets.
- Starting with VTE for Windows version 6.1.0, CTE fully supports AES-CBC-CS1 encryption for LDT and offline data transformation on CTE Windows environments.
Versions of VTE prior to version 6.1.0 are *not* backwards compatible with AES-CBC-CS1 encryption. On these earlier versions, attempting to guard a device using a policy containing an AES-CBC-CS1 key will fail.
- Protected hosts supporting AES-CBC-CS1 encryption can be added to host groups.

Difference between AES-CBC and AES-CBC-CS1

The two encryption modes are completely different from a file format standpoint.

- AES-CBC-CS1 encryption only applies to file system directories; AES-CBC encryption applies to both files and block devices.

Notes

- If you attempt to use an AES-CBC-CS1 key to guard a block device or partition, the guarding fails with an error reported on the DSM or CipherTrust Manager, similar to: Raw or Block Device (Manual and Auto Guard) GuardPoints are incompatible with Policy "policy-xxx" that contains a key that uses the CBC-CS1 encryption mode."
 - While AES-CBC-CS1 encryption is supported on both Linux and Windows environments, the file formats are incompatible. An encrypted file created with a specific AES-CBC-CS1 key on Windows cannot be read on Linux, even if that specific key were to be used and vice versa.
- AES-CBC-CS1 uses cipher-text stealing to encrypt the last partial block of a file whose size is not aligned with 16 bytes.
 - Each file encrypted with an AES-CBC-CS1 key is associated with a unique and random base IV.
 - AES-CBC-CS1 implements a secure algorithm to tweak the IV used for each segment (512 bytes) of a file.

Disk Space

Files encrypted with AES-CBC-CS1 keys consume additional disk space in contrast to files encrypted with AES-CBC keys. This is because AES-CBC-CS1 encryption requires file IVs to be created and persistently stored in contrast to AES-CBC encryption which does not consume any additional disk storage.

Therefore, administrators need to plan and provision additional disk capacity prior to deploying AES-CBC-CS1 encryption.

	AES-CBC	AES-CBC-CS1
Local Windows FS	No change to file size. No ADS allocation.	Extra 4KB allocation (at minimum) in the form of an embedded header per file. With CTE guarding enabled, file size expansion is hidden.

Encryption Migration

You can use either LDT or offline dataxform to:

- Transform data encrypted by AES-CBC to AES-CBC-CS1 and vice versa.
- Transform AES-CBC-CS1 encrypted data to clear contents and vice versa.

File Systems Compatibility

On Windows, you can use AES-CBC-CS1 keys to guard currently supported file systems.

Note

The remote file system must have enough extra space to store the extra 4K bytes of the embedded header.

Storing Metadata

AES-CBC-CS1 encrypted files on Windows store the base IV of a file in a Windows ADS (Alternate Data Streams) associated with the file. The size required for saving the CS1 key depends on the allocation size of the file system. If the allocation size is set to 4k, then the new IV will require 4K of extra space on the disk. You can run the `fsutil fsinfo` tool to find out the allocation size of the file system.

The CS1 key is supported on following file systems:

- **NTFS**: Supported on all Windows platforms that are supported by CTE.
- **REFS**: Supported on Windows 2012 R2 and later.
- **CIFS**: Supported if the backend storage for the CIFS share is Windows-based storage.

Note

Some network storage servers do not support multiple ADS associated with a file.

To get the value of the base IV, type:

```
C:/>voradmin secfs iv get <file-name>
```

Note

The base IV of a file is protected. It cannot be set/modified/removed by commands and applications. However, if a GuardPoint is unguarded, the files in the GuardPoint are no longer protected. An adversary can then corrupt the content of the files, as well as the IVs.

AES-CBC-CS1 depends on the physical file system's support for extended attributes in a manner similar to the CipherTrust Transparent Encryption - Live Data Transformation feature.

Missing IV file

If the IV for a file is missing, or CTE is unable to read the IV, then CTE denies access to the file. This access denied message may trigger an application to display an error message. This message may vary from application to application.

	AES-CBC	AES-CBC-CS1
Local FS (Windows)	No change	Alternate Data Streams

FileTable Support on Windows

The CBC-CS1 key does not support FileTables. This is because FileTables do not support alternate data streams. The CS1 key requires the ability to write the per-file IV into an alternate data stream on each file.

Using the AES-CBC-CS1 Encryption Mode in DSM

Deploy AES-CBC-CS1 encryption by using a symmetric agent key type created in the DSM:

1. In the DSM, click **Keys > Agent Keys > Keys**.
2. Click **Add**.
3. In the Encryption Mode dropdown, select **CBC-CS1**.
4. In the Algorithm dropdown, select **AES128** or **AES256** to create an AES-CBC-CS1 key.

5. Edit or create a policy that will use the AES-CBC-CS1 key. In this policy:
 - If you are using NFS, in the **Security Rules** section, add a security rule that specifies:
Action: `f_rd_att`
Effect: `Permit, Apply Key`
This security rule allows CTE to read the base IV value in the file's embedded header over NFS. This rule is not needed if you are not using NFS.
 - In the **Key Selection Rules** section, click **Add** and select the AES-CBC-CS1 key.
6. Click **OK** to save the policy.
7. Push the policy to the GuardPoints that you want to use this encryption key.

Using the AES-CBC-CS1 Encryption Mode in CM

When you create a key in CTE, you enable Encryption Mode by selecting CTE Key Properties. See *Creating a New Key* in the "Managing Policies" chapter in the CTE Administrator Guide.

Exceptions and Caveats

Note the following when using AES-CBC-CS1 keys.

Guarding Existing Files Without Data Transformation

You must convert an existing file with clear text through offline data transformation or LDT. If you do not transform the file, then after you guard using an AES-CBC key, the file displays garbled characters.

If you use an AES-CBC-CS1 key, access to the file is blocked with an I/O error.

Best Practices for AES-CBC CS1 Keys and Host Groups

In a host group, do not deploy policies associated with AES-CBC and AES-CBC CS1 keys unless all hosts are running VTE for Windows version 6.1.0 or CTE version 7.0.0 or later.

Chapter 6: Utilities for CTE Management

Thales provides a variety of utilities that augment the standard Windows utilities. This combination of tools helps administrators manage CTE. The following utilities are described in this chapter:

voradmin secfs Commands	69
vmsec Utility	70
agenthealth Utility	71
agentinfo Utility	72

voradmin secfs Commands

The `voradmin secfs list` and `voradmin secfs status` commands display GuardPoint and policy information on the host.

voradmin secfs List Commands

The `voradmin secfs list` command has the following options:

voradmin secfs list Options

guardpoints	Displays all the GuardPoints on the host.
policy	Displays all the policies used on the host.
logger	Displays the logging details on the host.
status	Displays the authentication settings on the host.

For example, to view all the GuardPoints on the host, you would enter:

```
C:\>voradmin secfs list guardpoints
Guard Point:      1
Policy ID:        16553
Policy name:      ES-Standard-Policy
Directory:        esg-disk1-demo
Type:             rawdevice
Status:           guarded

Guard Point:      2
Policy ID:        18857
Policy name:      Accounting-IT-Access-Policy
Directory:        G:\Data
Type:             local
Status:           guarded

Guard Point:      3
Policy ID:        18985
Policy name:      LDT-Policy
Directory:        C:\LDT-Folder
Type:             local
Status:           guarded
```

To view just the policies in use on the host, you would enter:

```
C:\>voradmin secfs list policy
Policy:           1
Policy name:      LDT-Policy
```

```
Type:                LDT

Policy:              2
Policy name:         ES-Standard-Policy
Type:                ONLINE

Policy:              3
Policy name:         Accounting-IT-Access-Policy
Type:                ONLINE
```

voradmin secfs status Commands

The `voradmin secfs status` command has the following options:

voradmin secfs status Options

keys	Displays the current status of the keys on the host.
lock	Displays the status of any system or agent locks on the host.

For example:

```
C:\>voradmin secfs status keys
Encryption keys are available

C:\>voradmin secfs status lock
FS Agent Lock: Disabled
System Lock: Disabled
```

vmsec Utility

The `vmsec` utility allows you to manage the security aspect of the CTE Agent on the host. On Windows the `vmsec` utility is `<windows-agent-install-dir>\vmd\bin\vmsec.exe`. The default path is:

```
C:\Program Files\Vormetric\DataSecurityExpert\agent\vmd\bin\vmsec.exe
```

vmsec Syntax

check_install	Verifies that the kernel component is running. This command checks CTE services and reports if any of the services are not running.
challenge	Initiates challenge-response on the host. This command displays a File System Agent password challenge string and enter the response string when the DSM is not network accessible.
status	Displays kernel configuration.
vmdconfig	Displays the vmd configuration.
check_hwenc	Determines whether this system supports hardware crypto.
hwok	Reports status of hardware signature.
passwd [-p passwd]	Enters the host password when the DSM is not network accessible. User can unlock the GuardPoints with this password.
version	Displays the CTE version.

Displaying the CTE Challenge String

In addition to using `vmsec challenge` on Windows, you can also right-click the tray icon and select **Challenge...-> Response**. The *CTE Challenge/Response* window opens.

If no challenge string is displayed, the host password is static. If a challenge string displays, contact a DSM Administrator for the response string.

agenthealth Utility

The `agenthealth.ps` utility validates:

- Super-user privilege
- CTE Agent installation
- CTE registration to DSM Server
- CTE processes/modules that are running
- Available disk resources
- Current GuardPoints

Tests if the agent can reach the GuardPoints

- CTE log directory resource status

This directory contains pending CTE log files for upload. This utility reports the size and number of pending files for upload. These text files are logs that contain vmd/SecFS information. They are regenerated whenever secfs restarts. If the number of files is unexpectedly large, this can indicate a problem.

The Agent Health Check Script

The Agent health check script (`agenthealth.ps1`) is located in `C:\Program Files\Vormetric\DataSecurityExpert\agent\shared\bin\`

To run the Agenthealth check script:

1. Run the power shell command to enable self-signing for the system.
Before running agent-health script make sure power shell command has enough privileges to execute the Powershell script. Some Windows operating systems have default execution policy set as `restricted`.
Use the Powershell command `Set- Execution-policy Remote Signed` to change the execution policy if needed.
2. Open the Powershell prompt as administrator.
3. Type:
`.\agenthealth.ps1`

For example:

```
.\agenthealth.ps1
Log file is at C:\Program
Files\Vormetric\DataSecurityExpert\agent\log\agent_health.log
Checking super user privilege..... OK
Vormetric Agent installation..... OK
Vormetric policy directory..... OK
Registration to server..... OK
Kernel drivers are loaded..... OK
VMD is running..... OK
SECFSD is running..... OK
```

```
rhat26130.qal.com is resolvable..... OK
rhat26130.qal.com port 8446 is reachable..... OK
rhat26130.qal.com port 8447 is reachable..... OK
Can communicate to at least one server..... OK
VMD is listening on port 7024..... OK
Time of last update from server 2016-12-01      14:39:49.038
Checking available disk space..... OK
Checking logging space ..... OK
    Log directory is "/var/log/vormetric"
    File system for log data is "/", 32G free (17% full)
    Log directory contains 2 of maximum 200 files (1% full)
    Log directory contains 1 of maximum 100 Mbytes used (1% full)
Testing access to C:\GP2..... OK
```

agentinfo Utility

The `agentinfo` utility collects system logs, CTE agent logs, CTE agent trace information, and system information for diagnostic purposes. All this information is saved in the destination path and compressed into a zip file. The `agentinfo` utility is available as an `agentinfo.js` Java command and as an `agentinfo.ps1` PowerShell command.

agentinfo Utility (Java version)

The `agentinfo.js` utility is a JavaScript file. You can open it in a text editor to see specific functions.

The `agentinfo.js` support collection scripts reside in the following path on systems where the CTE agent is installed.

To run the `agentinfo` script on Windows, navigate to one of the following folders:

```
C:\Program
Files\Vormetric\DataSecurityExpert\agent\vmd\bin

or

C:\Program
Files\Vormetric\DataSecurityExpert\agent\shared\bin
```

then run the following script:

```
agentinfo.js
```

agentinfo Utility (PowerShell version)

The PowerShell version of `agentinfo` supports several parameters.

PowerShell version agentinfo parameters

Directory - Specify the directory where all the collection information is saved. By default, this information is saved in the current directory.

ZipFile - Specify the name of the compressed file, where all the collected information will be archived. By default, this information is saved in the current directory.

Logfile - Specify the name of the files where verbose logs will be saved. By default, this information is saved in the current directory.

Examples for using agentinfo utility (PowerShell version)

To save all the collection information in “c:\AgentLogs” folder, run the following command:

```
.\agentinfo.ps1 -Directory 'C:\AgentLogs'
```

To save all the collected information in “c:\AgentLogs” folder and verbose logs in “c:\temp\AgentInfo.log”, run the following command:

```
.\agentinfo.ps1 -Directory 'C:\AgentLogs' -LogFile 'c:\temp\AgentInfo.log'
```

To save all the collected information in “c:\AgentLogs” folder, verbose logs in “c:\temp\AgentInfo.log”, and create the “AgentInfo.zip” archive file, run the following command:

```
.\agentinfo.ps1 -Directory 'c:\AgentLogs' -LogFile 'c:\temp\AgentInfo.log' -ZipFile  
'C:\temp\AgentInfo.zip'
```

Note

PowerShell 5.1 or later is required. Use the `$PSVersionTable.PSVersion` command to confirm which PowerShell version you are using.

Chapter 7: Using CTE with Microsoft SQL

This chapter discusses using CTE with Microsoft SQL AlwaysOn and SQL File Tables. It contains the following sections:

Using CTE with SQL	74
Using LDT with SQL FILESTREAM	74
Using CTE with SQL FileTables	74
Installing CTE on Microsoft SQL AlwaysOn	76
Data Transformation (Encryption in place)	79
Copy/Restore	79
SQL Server Policy Tuning	79
Using LDT with SQL AlwaysOn	79

Using CTE with SQL

You must stop the SQL service before guarding the SQL DB. When this occurs, the SQL Server replication may become unsynchronized. When restarting, it may take a brief period of time for the SQL Server replication to resynchronize with the other node. The SQL Server issues a warning against any attempted failovers during that brief period.

Note

Minimizing the duration for which the SQL Server service is stopped is beneficial for reducing the resynchronization period.

Using LDT with SQL FILESTREAM

When applying a Live Data Transformation (LDT) GuardPoint to SQL Server with FILESTREAM enabled, a rekey may be triggered which never finishes. This can occur if SQL Server is renaming files when the GuardPoint is applied, which causes the rekey to start the scan process again. If the rekey seems to be taking a long time, stop the SQL service until the rekey finishes and then restart the SQL service.

Using CTE with SQL FileTables

SQL FileTables allows you to store files and documents in special tables in the SQL Server called FileTables, but access them from Windows applications as if they were stored in the file system, without making any changes to your client applications. For some of the use cases, you can use FileTables with CTE.

Considerations

- The CTE Agent must be installed on the same server where the FileTables reside. If the FileTables reside on your SQL server, then you should install the CTE Agent on your SQL server.
- If multiple servers access the SQL FileTables:
 - Install CTE agent on all of the servers.
 - Protect all of the FileTable folders with the same CTE policy.

**CAUTION**

Accessing the FileTable without CTE may corrupt the data.

- When you create a new FileTable, alter, or drop FileTables, this may require applying a new GuardPoint.
- Every FileTable has a separate FileTable Folder so you must apply separate GuardPoints for each FileTable.
- You must apply a unique GuardPoint to each VNN path.
For example, if you configure two FileTables on an SQL Server, then the remote SQL administrator system must apply one GuardPoint to each configured VNN name.
- Guarding on a VNN name is similar to guarding a network path with CTE.
- If you want to access the FileTables from multiple remote systems, you must install CTE agent on those systems and apply the GuardPoints.

**CAUTION**

LDT is not supported with SQL FileTables. Only use offline Data Transformation to transform the initial SQL data.

Advantages

- System administrator cannot see the data locally on the SQL server because no CTE Agent is installed on the SQL server.
- The data transferring between servers is also encrypted.

Supported FileTables Use Cases

CTE supports the following FileTables use cases:

CTE Data Transformation of existing files in FileTables

Configuration guidelines:

1. Install CTE agent on the remote server.
2. Create a new FileTable, or Identify the FileTable folder for the existing FileTable.
3. Create an offline Data Transformation policy and apply to the GuardPoint on the FileTable folder.
4. Run the Dataxform utility to transform the data.

Protect files in SQL FileTables with CTE

Configuration guidelines:

1. Install CTE agent on the remote server.
2. Create a new FileTable, or Identify the FileTable folder for the existing FileTable.
3. Create a production policy and apply the GuardPoint on the FileTable folder.
4. Once the GuardPoint is active, you can use the file table to load and access files.

Protect files with SQL AlwaysOn Availability Groups with CTE

When the database that contains the FILESTREAM, or FileTable data, belongs to an AlwaysOn availability group, the FILESTREAM and FileTable functions accept or return virtual network names (VNNs) instead of computer names.

Configuration guidelines:

1. Install CTE agent on the remote server.
2. Create a new FileTable, or Identify the virtual network names (VNNs) for the existing FileTable.
3. Create a production policy and apply the GuardPoint to the VNN name
4. Once the GuardPoint is active, you can use the FileTable to load and access files.
5. When you enable FILESTREAM on an instance of SQL Server, it creates an instance-level share to provide access to the FILESTREAM data. Access this share by using the computer name in the following format:
`\\<computer_name>\<filestream_share_name>`
6. In an AlwaysOn availability group, the computer name is virtualized by using a Virtual Network Name, (VNN). When the computer is the primary replica in an availability group, and databases in the availability group contain FILESTREAM data, then SQL creates a VNN-scoped share to provide access to the FILESTREAM data. Applications that use the file system APIs have to use the VNN-scoped share, which has a path in the following format:

`\\<VNN>\<filestream_share_name>`

Install CTE on remote systems and guard the SQL Server VNN names

In this use case, CTE is installed on the SQL administrator system (a separate system from where the SQL Server resides) and a GuardPoint is applied to the VNN name.

Unsupported FileTables Use Cases

CTE does not support the following use cases:

1. Install CTE agent on the SQL Server and locally apply the GuardPoint on the SQL Server storage.
2. Access FileTables with Transact-SQL.
3. Access FileTables with File I/O APIs on the SQL server. Perform all file I/O on the remote system running the CTE agent.

Installing CTE on Microsoft SQL AlwaysOn

This section describes how to implement CTE with Microsoft SQL AlwaysOn in a variety of configurations for primary and secondary replica servers, and assumes that you have a basic understanding of Microsoft SQL database.

You may want to keep the primary server decrypted to serve all users, and use the secondary database for running reports or backups.

- If the database is encrypted, then the Volume Shadow copy-related backups will snapshot and backup encrypted protected data.
- Administrators with the `apply_key` permission can run a query and pull down reports from the secondary database server without affecting the performance of the primary database server.
- The secondary server could be in a remote Data Recovery location. You may want to secure it with encryption.
- LDT is supported with SQL AlwaysOn. See ["Using LDT with SQL AlwaysOn" on page 79](#) for more information.

Methods for Initial Encryption

There are multiple methods for performing the initial encryption of the databases. Decide on which of the following methods best fits your environment. For more information on transforming data, see the *CTE-Live Data Transformation with Data Security Manager*.

- Data Transformation – Encrypt data in place.
- Backup and Restore to a GuardPoint.
- Copy and paste the data into a GuardPoint.

Configuration 1

- Databases on primary server and secondary replica servers require encryption
- Database name and location of secondary replica server are the same as the primary server

To perform the procedure:

1. Perform a full backup of the primary database.
2. Change the primary database to offline mode.
3. Confirm the creation of a data transformation and/or operational policy.
4. Guard the folder containing the primary database files with that policy:
 - a. If using 'Encrypt data in place' as the selected method of encryption, execute the data transformation and then apply the operational policy.
 - b. If using the 'Copy/Restore' method of encryption, apply the operational policy on an empty folder/device.
5. On the secondary server, create a new folder to store the replicated database.

Note: The folder name and the path must be the same as the primary server.

6. Guard the folder with the operational policy.
7. Perform step 4 above for additional secondary server(s).
8. Put the primary database back into online mode.
9. Setup SQL AlwaysOn High Availability group to perform FULL Data Synchronization.
This copies the primary database and replicates it to secondary replica servers.
10. Verify that the databases in the secondary server are in “Synchronized” mode.

Configuration 2

- Database on the primary server does not require encryption, but the secondary replica database requires it
- Database names and locations for the secondary replica servers are the same as the primary server

To perform the procedure:

1. Perform a full backup of the primary database.
2. Confirm the creation of a data transformation and/or operational policy.
3. On the secondary server, create a new folder to store the replicated database.

Note: The folder name and the path must be the same as the primary server.

4. Guard the folder with the operational policy.
5. Perform step 3 & 4 above for additional secondary server(s).
6. Setup SQL AlwaysOn High Availability group to perform **FULL Data Synchronization**.
This copies the primary database and replicates it to secondary replica servers.
7. Verify that the databases in the secondary server are in “Synchronized” mode.

Configuration 3

- Databases on the primary and secondary replica servers require encryption
- Database name is the same, but the location of the secondary replica server is in a different location from that of the primary server

To perform the procedure:

1. Perform a full backup of the primary database.
2. Change the primary database to offline mode.
3. Confirm the creation of a data transformation and/or operational policy.
4. Guard the folder containing the primary database files with that policy:
 - a. If using 'Encrypt data in place' as the selected method of encryption, execute the data transformation and then apply the operational policy.
 - b. If using the 'Copy/Restore' method of encryption, apply the operational policy on an empty folder/device.
5. On the secondary server, create a new folder to store the replicated database.

Note: The folder name and the path must be the same as the primary server.

6. Guard the folder with the encryption policy.
7. From secondary server, perform the restore to the primary database.
 - a. Select the options **Restore with norecovery** and **Relocate all files to folder**.
 - b. Specify the path of the new folder from step 5.
8. Repeat steps 4 & 5 above for any additional secondary server(s).
9. Setup SQL AlwaysOn High Availability group to perform **JOIN ONLY Data Synchronization**.
This joins the secondary database to the SQL Always High Availability Group. It also establishes replication of new data and logs from the primary to the secondary replicated server.
10. Verify that the databases in the secondary server are in **Synchronized** mode.

Configuration 4

- Database on the primary server does not require encryption, but the secondary replica database requires encryption
- Database name is the same, but the location on the secondary replica server is in a different location than that of the primary server

To perform the procedure:

1. Perform a full backup of the primary database.
2. Confirm the creation of a data transformation and/or operational policy.
3. On the secondary server, create new folder to store the replicated database.
4. Guard the folder with the operational policy.
5. From secondary server, perform restore the primary database:
 - a. Select the options **Restore with norecovery** and **Relocate all files to folder**.
 - b. Specify the path of the new folder from step.
6. Setup SQL AlwaysOn High Availability group to perform **JOIN ONLY Data Synchronization**.
Joins the secondary database to the SQL Always HA Group. It also establishes replication of new data and logs from the primary to the secondary replicated server.
7. Verify that the databases in the secondary server are in **Synchronized** mode.

Data Transformation (Encryption in place)

For more information on transforming and encrypting data-in-place, see the *CTE-Live Data Transformation with Data Security Manager*.

Copy/Restore

For more information on transforming data using the copy and replace method, see the *CTE Data Transformation Guide*.

SQL Server Policy Tuning

In this section, you created and defined a process set for SQL Server that grants certain executables –in this case `sqlservr.exe`– unrestricted access to the database files. The need may arise to allow other executables, and/or users, access to the files.

You can grant this access by:

- Adding to the existing process set
- Creating a new one

The best option depends on the access requirements. The key decision is whether or not to select the **Apply Key** effect along with **Permit** or not. Omitting **Apply Key** on a security rule that still contains **Permit** allows the specified user or process to access to the data, but does not apply the encryption key, so therefore only shows them the data in its encrypted, cypher-text format. This is useful for anti-virus or backup software that may need to scan or copy the file, but does not necessarily need to see the contents.

Using LDT with SQL AlwaysOn

To guard a directory with an LDT (Live Data Transformation) policy, you must temporarily close all files in that directory. In a SQL Server AlwaysOn environment, this may entail temporarily stopping the SQL Server service on the node that is being guarded. Once the directory is guarded, then you can start the SQL Server service immediately.

It is important to remember the SQL Server AlwaysOn replication standard operating procedures.

- If one SQL Server service is taken offline for any reason, then once it is brought back on line, it takes the SQL Server a moment to re-synchronize the database nodes.
- The longer that secondary service was down, and the more inserts/updates and deletes that occurred on the still active node during that downtime, then the longer the synchronization period takes.
- During that synchronization period, any attempted fail over results in the SQL Server warning that data loss may occur if the fail over continues. However, once the SQL Server has completed re-synchronizing that secondary node, then any fail over is safe and does not result in loss of data.

Chapter 8: Secure Start

This chapter describes encrypting an Microsoft Active Directory (AD) with the Secure Start feature. It contains the following sections:

- Secure Start Overview 81
- Prerequisites 81
- Encrypt by Moving the AD Service into a Guarded Directory 82
- Encrypt Data in Place with Offline Transformation 84
- Encrypt with an LDT Transformation Policy 84
- Configure the Time Out Failure 84
- Recover a Server After it Loses Connection to the DSM 85
- Other Use Cases 86
- Best Practices for Encrypting and Protecting the AD Service 86

Secure Start Overview

Secure Start offers data protection for applications which start earlier in the boot sequence than VMD (Vormetric Daemon). For example, the Microsoft Active Directory system service starts very early in the boot sequence. To determine if another application qualifies, contact Thales technical support.

Notes

- Secure Start is included with CTE v6.0.2. You do not have to purchase it separately.
- Secure Start is supported on Windows Server 2008 R2 and later versions.

In CTE v6.0.1 and below, CTE cannot encrypt the AD system service because it boots earlier in the boot sequence than the VMD agent service. After it boots, VMD makes a secure connection with the DSM and retrieves the encryption keys from the DSM. Therefore, since AD boots before that, the AD system service is not encrypted.

CTE offers Secure Start through a new type of GuardPoint. A Secure Start GuardPoint starts before the AD services, and can, therefore, encrypt those services.

There are three methods for encrypting the directory:

- "Encrypt by Moving the AD Service into a Guarded Directory" on the next page
- "Encrypt Data in Place with Offline Transformation" on page 84
- "Encrypt with an LDT Transformation Policy" on page 84

Prerequisites

Prior to using Secure Start to guard your AD database:

1. Backup your AD database:
 - a. Navigate to **Administrative Tools**.
 - b. Click **Windows Server Backup**.
 - c. Click **Action > Backup Once**.
 - d. Follow the instructions in the Backup Wizard to create a backup of the server in a local drive.

Note: When the backup operation completes, it saves the server backup in `<backup drive>:\WindowsImageBackup\<BackupComputerName>`.

2. Perform a system state backup.
3. Obtain the Microsoft DSRM (Data Services Restore Mode) password.
4. Ensure that your AD database is not in `c:\Windows\NTDS`.

WARNING

Do not put your AD database in `c:\Windows` or `c:\Program files`. Secure Start cannot encrypt or decrypt any files in those folders.

Encrypt by Moving the AD Service into a Guarded Directory

You can move the AD service into a directory protected by a standard or LDT production policy. This method does not require the initial data transformation step. When you move the AD service into this directory, CTE immediately encrypts the data with either policy.

Note

This step occurs when the system is in DSRM mode, so users have no access to the AD service.

Create the AD GuardPath directory

Create the directory in which the AD service will reside.

1. Log in to the Active Directory Server in DSRM mode using the DSRM password. User ID is Administrator.
2. Create a folder to which you will move the AD database.

Apply Secure Start GuardPoints to a Directory with the DSM

Access to a Secure Start GuardPoint is only permitted during the boot sequence and for a short period of time. Once the VMD is up and running, it performs the normal agent initialization and communicates with the DSM to access files within a GuardPoint location.

To apply Secure Start GuardPoints in **DSM**:

1. In the DSM, click **Hosts > Hosts > <hostName>**
2. In the General host information section, select the option: **Secure Start GuardPoint**.
3. Click **GuardPoints**.
4. Select the directory and click **Guard**.
5. In the Policy field, select an **LDT** or **Standard Production** policy.
6. Set Type to **Directory (Auto Guard)**.
7. Click **Browse** and navigate to the folder that you just created for the AD database.
8. Select the option: **Secure Start**.
9. Click **OK**.
10. Select the GuardPoint and click **Secure Start On**.

Apply Secure Start GuardPoints to a Directory with CipherTrust Manager

To apply Secure Start GuardPoints in **CM**:

1. In the CipherTrust Manager Applications Page, click **CTE > Clients > <clientName>**.
2. Click **Create GuardPoint**.
3. In the Policy field, select a policy.
4. Set Type to **Auto Directory**.
5. Click **Browse**, navigate to, and select, the folder that you just created for the AD database.
6. Select the option: **Secure Start**.
7. Click **Create**.
8. Click **No** to the question, "Would you like to use these GuardPoint settings on another GuardPoint with a different path?" because you are only guarding the AD database.

Verify the Secure Start GuardPoint with CLI

After the policy is pushed to the Active Directory Server, verify the GuardPoints.

To verify the GuardPoints, type:

```
> voradmin ss verify <GuardPoint_path>
Successfully completed the command verify
Success from kernel -Successfully verified the secure start GP
```

Move the AD Database into the Secure Start GuardPoint

Move your AD database from the default location (c:\windows\NTDS) to this newly created protected folder.

To move the AD database:

1. In DSRM mode, login using the DSRM password. User ID is Administrator.
2. Start NTDSUTIL utility, type:

```
> activate instance ntds
```
3. Type:

```
> files
```
4. Type:

```
> move db to \<GuardPoint>
```
5. Type:

```
> move logs to \<GuardPoint>
```
6. Exit NTDSUTIL utility.
7. Reboot the system into normal mode. The Active Directory Services automatically starts after rebooting.

Note

This step occurs when the system is in DSRM mode, so users have no access to the AD service.

Encrypt Data in Place with Offline Transformation

Encrypting the AD database with a standard (production), or offline policy is very similar to encrypting other data with a standard (production), or offline policy.

The advantage to encrypting data in place is that it saves space. When you copy/move a directory into a guarded directory, you will need twice as much space to store the data because you leave a copy of the data in the original folder, as a precaution, until the original directory has been successfully moved and encrypted. Once the data is transformed, then you can delete the directory that contains the decrypted/clear data.

Using this method, you perform an Initial Data Transformation using the `dataxform` command line utility. During this transformation, access to the GuardPoint data is blocked. After initial transformation, you remove the initial policy, and then apply a production policy, so users can access the data.

Notes

- This step occurs when the system is in DSRM mode, so users have no access to the AD service.
- If your AD service is installed in the default directory, `C:\Windows\NTDS`, you must move it to another directory before you can encrypt it. See ["Encrypt by Moving the AD Service into a Guarded Directory" on page 82](#) for more information.

To encrypt the data:

1. In DSRM mode, login using the DSRM password. User ID is Administrator.
2. Create and apply a `dataxform` policy to the GuardPoint directory.
3. Run the `dataxform` command.
4. Remove the `dataxform` policy on the GuardPoint and replace it with a production policy.
5. Reboot out of DSRM mode.

Encrypt with an LDT Transformation Policy

Encrypting the AD database with an LDT policy uses the same steps as encrypting with a standard production policy. The only difference is that you select an LDT policy instead of a standard one. See ["Encrypt by Moving the AD Service into a Guarded Directory" on page 82](#) for more information.

Note

If your AD service is installed in the default directory, `C:\Windows\NTDS`, you must move it to another directory before you can encrypt it.

Configure the Time Out Failure

During the initial access to a Secure Start GuardPoint, the CTE agent sets a timer. The default duration is 120 seconds, but you can configure the duration. Minimum duration is one second, maximum duration is 300 seconds.

Data inside the GuardPoint is accessible without DSM connectivity until the timeout is reached. VMD service activates and makes a secure connection to the DSM. After the VMD makes a secure connection, the agent verifies that it is connected to correct DSM. If the VMD fails to connect to the DSM, the timeout is reached, and if AD is installed, the agent shuts down the system for data security purposes.

Note

In DSRM mode, when the timeout occurs, CTE removes the keys from memory. However, CTE does not shut down the system.

In normal mode, CTE shuts down the AD server. For any other application, or if AD is not installed, Secure Start does not shut down the server. However, the data inside the GuardPoint becomes inaccessible until DSM connectivity is restored, or you issue a challenge/response, or password. After the timer has expired, CTE denies any further access to the Secure Start GuardPoint.

1. To configure the timeout duration in seconds, type:

```
C:\> voradmin ss settimeout <timeout>
```

```
C:\> voradmin ss settimeout 220
```

Successfully completed the command settimeout

Successfully set the Secure Start timeout value to 220 seconds

2. To verify the timeout duration, type:

```
C:\> voradmin ss gettimeout
```

Successfully set the Secure Start timeout value to 220 seconds

Recover a Server After it Loses Connection to the DSM

User must unlock the GuardPoint by entering the Challenge/Response or password to restore the DSM connectivity. Once the GuardPoint is unlocked, you can start the AD services manually.

Note

The challenge response pop up dialog does not display in DSRM mode when the host loses DSM connectivity.

To activate the challenge/response:

1. Navigate to:

```
C:\Program
```

```
Files\Vormetric\DataSecurityExpert\agent\shared\bin
```

2. Double-click `etray.exe` to start it manually.

If the AD server does not connect to the DSM, then the AD system automatically shuts down. The Administrator must enter DSRM mode and restore the DSM connectivity to recover the server.

Prerequisites

Before rebooting your active directory servers, ensure that DSM connectivity is strong. If it is not strong, restore the DSM connectivity.

Note

When trying to fix a DSM connectivity issue, you can log in to DSRM mode. In DSRM mode, there is no requirement to increase the timeout, because in DSRM mode, the AD system does not shut down after timeout expires.

DSRM Mode

The first method for recovering a server relies on manual DSM connection troubleshooting:

1. Boot into DSRM mode.
2. Attempt to resolve why the server is not connecting to the DSM.
3. Fix that DSM connectivity issue.

4. Reboot into normal mode.

Other Use Cases

Using Secure Start GuardPoints, you can also secure an SQL Server on Microsoft Azure in certain scenarios. SQL system services in Azure also boot earlier in the boot sequence than the VMD (Vormetric Daemon) agent service.

Note

To determine if another application qualifies, contact Thales technical support.

Boot a Windows Server in Azure

To move and guard the AD database, you must boot the AD server into DSRM mode.

To boot a Windows Server 2012/2016 Domain Controller into DSRM remotely in Azure:

Note

The Windows Server 2012/2016 domain controller must be running and accessible through Windows Remote Desktop.

1. Establish a Remote Desktop session on the domain controller.
2. Open an command prompt as Administrator and type:

```
> bcdedit /set safeboot dsrepair
```
3. Reboot the domain controller. The Remote Desktop session disconnects.
4. Wait a few minutes, then establish a new Remote Desktop session. The domain controller will be running in DSRM.
5. To reboot into normal mode, open an command prompt as Administrator and type:

```
> bcdedit /deletevalue safeboot
```
6. Reboot the domain controller.

Best Practices for Encrypting and Protecting the AD Service

Thales recommends the following best practices when using Secure Start with an AD service.

Access Control with Secure Start

User can setup a restricted access control policy with encryption to prevent the unauthorized access of AD database files. The restricted policy with Secure Start:

- Prevents a rogue user from logging into the system, and moving or copying the AD database files to another directory and tampering with it.
- Denies permissions, after you setup and guard files, so that no one can move a file from the guarded directory. Plus it restricts any other unwanted/unnecessary process or users from tampering with AD files.
- Provides permission for an authorized user who needs access to AD services and files.

Creating a Minimal Policy Required for AD with Access Control

When creating a normal, strict policy for access control, you must allow access to the following processes and directories for Active Directory.

Processes

```
secfsd.exe (C:\Program
Files\Vormetric\DataSecurityExpert\agent\secfs\ sec\bin\)
lsass.exe (C:\Windows\System32\)
vds.exe (C:\Windows\System32\)
vssvc.exe (C:\Windows\System32\)
wbengine.exe (C:\Windows\System32\)
ntoskrnl.exe (C:\Windows\System32\)
```

Users

```
NT AUTHORITY\SYSTEM
```

To create a minimal policy:

1. Create a User Set named **AD_Minimum_User_Set** with the following parameters:

ID	uname	osDomains
1	SYSTEM	NT AUTHORITY

2. Create a Process Set named: **AD_Process_Set** with the following parameters:

ID	Directory	Base Name
1	C:\Program Files\Vormetric\DataSecurityExpert\agent\secfs\sec\bin	secfsd.exe
3	c:\Windows\System32\	ntoskrnl.exe
4	c:\Windows\System32\	vds.exe
5	c:\Windows\System32\	vssvc.exe
6	c:\Windows\System32\	wbengine.exe
7	c:\Windows\System32\	lsass.exe

3. Create a Security rule set with the following parameters:

Order	User	Process	Action	Effect	Browsing
1	AD_Minimum_User_ Set	AD_Process_Set	all_ops	Audit, Permit, Apply key	Yes
2				Audit, Deny	Yes

Creating a Restricted Policy in DSRM Mode

Create the following policy for the initial transformation of an AD database in DSRM mode. The policy allows access to the local administrator.

In DSRM mode, you use the `NTDSUTIL` utility to perform maintenance for an Active Directory.

To create a restricted policy:

1. Create a User Set named **AD_Minimum_User_Set** with the following parameters:

ID	uname	osDomains
1	SYSTEM	NT AUTHORITY
2	Administrator	localhost

2. Create a Process Set named: **AD_Process_Set** with the following parameters:

ID	Directory	Base Name
1	C:\Program Files\Vormetric\DataSecurityExpert\agent\secfs\sec\bin	secfsd.exe
2	c:\Windows\System32\	ntdsutil.exe
3	c:\Windows\System32\	ntoskrnl.exe
4	c:\Windows\System32\	vds.exe
5	c:\Windows\System32\	vssvc.exe
6	c:\Windows\System32\	wbengine.exe
7	c:\Windows\System32\	lsass.exe

3. Create a Security rule with with the following parameters:

Order	User	Process	Action	Effect	Browsing
1	AD_Minimum_User_Set	AD_Process_Set	all_ops	Audit, Permit, Apply key	Yes
2				Audit, Deny	Yes

Guard Directories

The best practice for guarding a directory with a Secure Start GuardPoint is to:

1. Create a directory.
2. Guard that directory with a standard production or LDT policy. Follow the steps in ["Apply Secure Start GuardPoints to a Directory with the DSM" on page 82](#).
3. Move the AD service into that directory.

Perform Subsequent System State Backups

After you move an AD service into a guarded directory, or out of a guarded directory:

1. Perform another system state backup.
2. Save this subsequent backup to a different location.

Chapter 9: Exchange DAG

This chapter describes encrypting email databases using Microsoft Exchange database availability group (DAG). It contains the following sections:

- Exchange DAG Overview 89
- Recommendations 90
- Requirements 90
- Preparing your Exchange DAG Environment for Encrypting/Decrypting with CTE 91
- Encrypting with LDT in the Exchange DAG environment 92
- Decrypting with LDT in the Exchange DAG environment 93
- Encrypting with a Standard CTE Policy in the Exchange DAG Environment 94

Exchange DAG Overview

A DAG is a high-availability (HA) and data-recovery feature of the Microsoft Exchange Server. A DAG, which can consist of up to 16 Exchange mailbox servers, automates recovery at the database-level after a database, server or network failure. You can now use CTE for Windows to encrypt Exchange DAG mailboxes.

Figure 9-1: High Level Overview of Exchange DAG functions

You can encrypt the Exchange databases with a standard (offline) policy or an LDT policy. In an offline policy, users cannot access the database during initial data encryption. LDT is Live Data Transformation. It encrypts the data while users and applications are accessing files within it. LDT is used for Initial data transformation as well as transparent encryption/decryption.

Use Case tested and supported by Exchange DAG with CTE

Use CTE to encrypt Exchange DAGs in the following scenarios:

- Initial Data Transformation of Exchange Databases using:
 - Live Data Transformation
 - Standard Data Transformation

Note

For more information about LDT and Data Transform, request the guides for the software from Technical Support.

- Transparent Encryption/Decryption of the Exchange Database on DAG nodes
- Rotate the key using the Live Data Transformation policy

The following Exchange DAG operations were tested using the following use cases:

- Failover/Failback of databases from one node to another node and making both databases active on each node.
- Add new Databases to the existing nodes

Recommendations

To use Microsoft DAG Exchange:

1. Disable all antivirus software as suggested by Microsoft.
[https://technet.microsoft.com/en-us/library/bb332342\(v=exchg.160\).aspx](https://technet.microsoft.com/en-us/library/bb332342(v=exchg.160).aspx)
2. Disable Windows defender:
 - a. Type:
`> gpedit.msc`
 - b. Go to **Computer Configuration > Administrative Templates > Windows Components > Windows Defender**.
 - c. Double-click and then, in the context menu, click **Turn Off Windows Defender**.
For more information see <https://www.windowscentral.com/how-permanently-disable-windows-defender-windows-10>.
3. Only guard the Mailbox Database. Do not guard at a higher or lower directory.

State	Unapplied	Enabled	Disabled	Secure Start On	Secure Start Off	Transaction Support Required
Select Policy						
Database Mail - LDT/DTM Policy						
Host Group						
Protected Path						
End Group / Path						
Type						
Protect						
Secure Start						

4. Guard one host at a time. Do not apply GuardPoints to hostgroups.
5. Make sure that communication port 7024 is not blocked so that CTE agent can register with the host.

Requirements

The following is required for encrypting an Exchange DAG database with CTE :

- Windows Exchange Server 2016 Cumulative Patch 5
- Windows Server 2016 for Exchange Server nodes
- Windows 2016 Server as a file share witness
- Two nodes in the Exchange DAG configuration

- Both nodes on the same subnet

Note: Thales has not tested an environment with nodes on different subnets, but CTE supports this configuration. If you encounter any issues with different subnets, please contact Thales customer support.

- Use the same CTE Policy and keys on both nodes.
- You must enable Secure Start on the GuardPoints.
- All users must be offline when applying the initial GuardPoint, (even for CTE-LDT).

Note: Alternatively, you can choose to make all of the DBs active on one node and perform data transformation on the other node.

- Prepare your environment for suspending databases:
 1. Suspend the Exchange Database to stop replication and access to data.
 2. Disable replication between the nodes.

Note: No file access can happen within the target directory

Figure 9-2: Proper Configuration for Exchange DAG

- Create Keys and Policies for the system

Note: You must use the same Keys and Policies on each node. For more information on Keys and Policies, see the *CTE-Live Data Transformation with Data Security Manager* and the *DSM Administration Guide*

- Install CTE agent on the systems
- Register the agent with the DSM and make sure LDT is enabled, (if they are planning to use LDT. For more information on LDT, see the *CTE-Live Data Transformation with Data Security Manager*.)

Preparing your Exchange DAG Environment for Encrypting/Decrypting with CTE

The following describes how to prepare your environment for encrypting with Exchange.

To use Microsoft DAG Exchange with LDT to encrypt data:

1. In the **Exchange Admin Center**, make Exchange node 1 the primary node.
Make node 1 the active node and move all of the databases to that node.

WARNING

Make sure that all of the Exchange services in node 2 are down and not accessing the Exchange databases. All Exchange Services must be stopped. All databases must be suspended.

2. Make all of the databases active on node 1.
3. Suspend all databases on node 2.

Note

Wait for 2-3 minutes for the database to finish with replication so the database will be suspended.

Encrypting with LDT in the Exchange DAG environment

You can use LDT for initial data transformation as well as transparent encryption/decryption.

WARNING

You must guard the databases with the same Key/Policy on both nodes.

1. Make sure that you have prepared your environment properly. See ["Preparing your Exchange DAG Environment for Encrypting/Decrypting with CTE" on the previous page](#).
2. Make sure that the GuardPoint is active on the host. Live Data Transformation starts on the server as soon as the GuardPoint is established.
3. Guard the Mailbox Database directory and apply the Live Data Transformation policy to the directory on node 2.
4. Select the GuardPoint and click **Secure Start On**.

WARNING

Only guard the Mailbox Database. Do not guard at a higher or lower directory.

[illegible]

WARNING

Guard one host at a time. Do not apply GuardPoints to both nodes using hostgroups.

5. In the **Exchange Admin Center**, go to the Exchange Database tab and **Resume** all Passive database copy on node 2.

Note: It may take a few minutes for the Exchange Service to resync. Monitor the Exchange logs on the system and make sure that replication is working. Make sure that database replication finishes and databases are in a healthy state before proceeding.

6. Wait for 10-15 minutes more for the server to move to the healthy state. If not, wait for some more time for the Content Index state to change to Healthy.

7. In the **Exchange Admin Center**, move all of the databases from node 1 to node 2.
Now the databases on node 1 are mounted as passive. All databases on node 2 are mounted as active.
8. Repeat these steps on node 1.

Decrypting with LDT in the Exchange DAG environment

To use an LDT policy:

1. Make sure that the LDT state is set to REKEYED before unguarding.
2. Make sure that all of the files inside the GuardPoint are at the same version of the key.
 - a. Run the LDT report to find the version:

```
> voradmin ldt report <GuardPoint path> [<logfile>]
```
 - b. Run the Key map report to find the version:

```
> voradmin ldt key [report|map] <key_name, version> <GuardPoint path>
```

To use Microsoft DAG Exchange with LDT to decrypt data:

1. Make sure that all of the Exchange services in node 2 are down and not accessing the Exchange databases.

Note: Suspension can take 2-3 Minutes.

2. In the **Exchange Admin Center**, make Exchange node 1 the primary node.
This means that node 1 is mounted as the active node and node 2 is mounted as the passive node.
3. Make all of the databases active on Exchange node 1.
4. Go to the Exchange Database tab and suspend all databases on node 2.
5. Unguard the database folders that you previously guarded on node 2.
6. Delete all of the metadata on all of the database folders on node 2, type:

```
> voradmin ldt attr delete [<file name path> | <guard path>]
```
7. Guard with an LDT policy set for Encryption to Clear on node 2.

Note: You must clone the current version of the encryption key to use as the current key in the new LDT policy and clear key as the transformation key.

8. Go to the Exchange Database tab and resume all databases on node 2.

Note: After a few minutes, the databases should become healthy automatically. If not wait for the LDT process to decrypt the data. Make sure that all of the data is transformed back to clear and that the LDT state is set to **REKEYED**.

9. Move the database from node 1 to node 2.
 10. Repeat this procedure for node 1.
- After both nodes are rekeyed and transformed from encryption to clear, you can unguard them.

1. In the **Exchange Admin Center**, make Exchange node 1 the primary node.
This means that node 1 is mounted as the active node and node 2 is mounted as the passive node.
2. Make all of the databases active on Exchange node 1.
3. Go to the Exchange Database tab and suspend all databases on node 2.

4. Unguard the database folders that you previously guarded on node 2.

WARNING

Always ensure that you are unguarding a passive node.

5. Repeat this procedure for Node 1.

Encrypting with a Standard CTE Policy in the Exchange DAG Environment

Refer to the following sections to prepare for encrypting in the Exchange environment.

To use Microsoft DAG Exchange with CTE:

1. In the **Exchange Admin Center**, make Exchange node 1 the primary node.

This means that node 1 is mounted as the active node and node 2 is mounted as the passive node.

2. Make all of the databases active on Exchange node 1.
3. Go to the Exchange Database tab and suspend all database on node 2.

Make sure that all of the exchange database services in node 2 are down and not accessing the Exchange databases.

Note

Suspension can take 2-3 Minutes.

4. Guard the mailbox database directory with a data transform policy.
5. Run `dataxform.exe`, type:

```
dataxform --rekey --print_stat --gp <directory>
```

6. After the data transformation is finished, unguard the directory and guard with a Production policy. Apply a standard production data transformation policy on only the node 2 database folders.

Note

Use the same Key/Policy on both nodes.

See “Remove the dataxform policy and apply production policy” in the *CTE Agent DataXform* guide for more information.

7. In the **Exchange Admin Center**, go to the Exchange Database tab and resume all databases on node 2.
After a few minutes, all nodes should become Healthy.
8. In the **Exchange Admin Center**, try to move a database from node 1 to node 2. If the data move is successful: this means that node 2 is mounted as the active node and node 1 is mounted as the passive node.
9. Repeat the previous steps for node 1.

Unsupported Use Cases

The following scenarios are not supported:

- Using different encryption keys on Exchange DAG nodes; both nodes must use the same encryption key
- Adding a new node to the Exchange DAG Environment

- Using the new CBC-CS1 key (not tested for this release)
- Encryption of Exchange Binaries
- Using nodes in a different subnet, data center or site, (Thales is not testing this scenario, but we do not believe it will cause any issues)

Chapter 10: Storage Spaces Direct

This chapter describes how CTE integrates with Windows Storage Spaces Direct (S2D) hyper-converged clusters. It contains the following sections:

S2D Overview 96

S2D Overview

S2D uses industry-standard servers with local-attached drives to create high-availability (HA) software-defined storage. SD2 is included in Windows Server 2019 Datacenter and Windows Server 2016 Datacenter, both of which are supported by CTE.

S2D extends the stack of usable storage devices to storage devices such as SATA and SAS HDD's, SSD's and NVMe (Non-Volatile Memory Express) disks to create shared disk volumes. S2D supports clusters of a minimum of two nodes, and a maximum of 16 nodes and 400 drives. S2D aggregates the available storage into a Storage Pool.

The hyper-converged deployment option runs virtual machines on the servers providing the storage.

A complete description of the S2D product, and instructions on how to set up the S2D environment is available on the Microsoft website at <https://docs.microsoft.com/en-us/windows-server/storage/storage-spaces/storage-spaces-direct-overview>

Deployment Options

CTE supports S2D in a hyper-converged infrastructure where computing and storage components are in a single cluster as shown in the following figure.

Figure 10-1: Hyper-converged infrastructure

Hyper-converged with S2D and CTE virtual machines run on the servers providing the storage. In the following figure, CTE is installed inside 6 of the VMs to protect the data.

Figure 10-2: High-Level view of S2D

You can use all the capabilities of CTE to protect the data in the VMs in a S2D hyper-converged deployment. These capabilities are describe in ["Supported Use Cases" below](#).

Supported Use Cases

Thales tested only Hyper-converged deployments in the following scenarios.

- Initial Data Transformation of data using:
 - Live Data Transformation
 - Offline Data Transformation
- Transparent Encryption/Decryption of structure and unstructured data
- Key rotation using a Live Data Transformation policy

Chapter 11: Using CTE with Quantum StorNext

This chapter describes how to configure CTE and Quantum StorNext devices to interoperate to allow CTE policies to apply to storage managed by Quantum StorNext. This chapter contains the following sections:

Overview of using CTE with Quantum StorNext	98
CTE and Quantum StorNext Compatibility	98
Setting up CTE and Quantum StorNext Integration	100

Overview of using CTE with Quantum StorNext

Quantum StorNext Fibre Channel-connected devices provide shared file access to third party storage for workstation clients and are optimized for simultaneous access to very large files such as video files. The Quantum StorNext file system is known as SNFS or by its older name, CVFS.

You can encrypt and control access to SNFS files with DSM policies by installing CTE Agents on Windows clients that are configured for access to the SNFS file system. Some limitations apply to this integration, such as supported operating systems, supported SNFS features, concurrent read/write access by multiple clients, and GuardPoint settings (see the next section for more information about these limitations).

CTE and Quantum StorNext Compatibility

The following sections list the supported operating systems and CTE settings supported for use with Quantum StorNext file systems. Important unsupported configuration parameters are also listed.

Supported StorNext Server and Client Configurations

The CTE integration with SNFS file systems works only with certain SNFS versions, SNFS storage policies, and client operating systems.

Configuration parameter	Windows
StorNext (SNFS) operating system version	6.x
StorNext metadata controller (MDC) server OS type	Windows MDC supported
StorNext replication policy	Not supported
StorNext deduplication policy	Not supported
StorNext truncation	Supported
StorNext full and partial backup	Supported
StorNext expand filesystem	Supported
StorNext data migration	Supported
StorNext read-ahead cache	Disable for use with CTE
Client operating systems	Windows Server 2012 R2, Windows Server 2016
StorNext LAN client	DLC

Configuration parameter	Windows
StorNext mount method: locally mounted directory	Supported
StorNext mount method: Windows drive letter	Supported
StorNext mount method: CIFS	Not supported
StorNext mount method: NFS	Not supported

Supported GuardPoint and Key Settings for SNFS File Systems

When configuring CTE GuardPoints and keys for SNFS, keep in the mind the compatibility limitations listed in the following table.

Configuration element	Windows
Offline data transformation	Supported
Live Data Transformation (LDT)	Not supported
Key manager compatibility	See the <i>Compatibility Matrix for CTE Agent with Data Security Manager</i> or the <i>Compatibility Matrix for CTE Agent with Data Security Manager</i> for your CTE version
Guard unstructured data	Supported
Guard structured data	Not supported
GuardPoint type: Directory (including entire SNFS volume)	Supported
GuardPoint type: Raw device	Not supported
GuardPoint type: Block device	Not supported
GuardPoint mount option: manual guard	Not applicable
GuardPoint mount option: auto guard	Supported
GuardPoint mount option: automount	Not applicable
AES-CBC key type	Supported
AES-CBC-CS1 key type	Not supported

Supported Concurrent Access Read/Write Scenarios

If you want to allow access by multiple clients (users) to CTE-protected SNFS files under the same GuardPoint, just read-only access is supported. StorNext file locking is not implemented in CTE, so there is currently no way to prevent concurrent conflicting writes to the same file. As a result, Thales does not support write access to the same GuardPoint from multiple clients.

To enable read access to the same GuardPoint from multiple clients, ensure that all clients are configured to use the same policy and key.

Configuration parameter	Windows
Read/write access from a single LAN client to a GuardPoint	Supported
Read/write access from two or more LAN clients to the same GuardPoint	Not supported
Read-only access from one, two, or more LAN clients to the same GuardPoint	Supported

Setting up CTE and Quantum StorNext Integration

For the most part, CTE integration with Quantum StorNext is the same as for any standard file system. The next section provides an overview of the steps involved in making CTE work with SNFS. Later sections provide more information about the steps that are new or differ significantly from a typical CTE setup.

Integration Task Overview

The table below provides an overview of the steps involved in setting up SNFS and CTE to work together. As noted in the table, some of these tasks are described in the documentation for your selected key manager. Some of these steps may need to be performed by other staff members at your organization if you have divided the security administration duties as recommended by Thales and you don't have access to the key manager.

Task	Key configuration notes	For more information
Install and configure a Quantum StorNext MDC server for use with CTE	Disable the StorNext read-ahead cache. Only certain StorNext policies, features, and mount types are supported. See "Supported StorNext Server and Client Configurations" on page 98 .	See "Installing and Configuring a Quantum StorNext MDC Server for Use with CTE" on the next page .
Install and configure Quantum StorNext clients for use with CTE	Only certain operating systems are supported. See "Supported StorNext Server and Client Configurations" on page 98 .	See "Installing and configuring Quantum StorNext DLC Clients for Use with CTE" on the next page .
Create a domain for one or more SNFS hosts, or add them to an existing domain	No difference from standard CTE agent configuration.	See "Domain Management" in your key manager documentation.
Add the host to the key manager	No difference from standard CTE agent configuration.	See "Configuring Hosts and Host Groups" in your key manager documentation.
Install and register the CTE Agent on the host system	No difference in installation.	See Chapter 2: "Getting Started with CTE for Windows" on page 15
Create encryption keys (optional)	AES-CBC-CS1 keys are not supported on Windows. See the note in "Supported GuardPoint and Key Settings for SNFS File Systems" on the previous page .	See "Managing Keys" in your key manager documentation. For information about AES-CBC-CS1 keys, see Chapter 5: "Enhanced Encryption Mode" on page 65 .
Configure host groups containing one or more StorNext LAN clients (optional)	No difference from standard CTE agent configuration.	See "Configuring Hosts and Host Groups" in your key manager documentation.

Task	Key configuration notes	For more information
Configure policies (including user, process, and resource sets) to control access or enable encryption	No difference from standard CTE agent configuration.	See “Configuring Policies” in your key manager documentation.
Configure one or more GuardPoints	Some GuardPoint settings are not supported. See "Supported GuardPoint and Key Settings for SNFS File Systems" on page 99 .	See “Managing GuardPoints” in your key manager documentation

Installing and Configuring a Quantum StorNext MDC Server for Use with CTE

Install and configure a Quantum StorNext metadata controller (MDC) server using the [Quantum StorNext documentation](#) as a guide. The CTE integration works with Windows StorNext MDCs. Ensure that you configure the StorNext server to work with the settings supported by CTE as listed in ["Supported StorNext Server and Client Configurations" on page 98](#). For example, you must disable the StorNext read-ahead cache and only certain StorNext policies, features, and mount types are supported.

Installing and configuring Quantum StorNext DLC Clients for Use with CTE

Install and configure Quantum StorNext DLC clients using the [Quantum StorNext documentation](#) as a guide. The CTE integration works with Windows StorNext DLCs.

Ensure that you configure DLC clients to work with the settings supported by CTE as listed in ["Supported StorNext Server and Client Configurations" on page 98](#). For example, only certain operating systems are supported.

Note

Just read-only access is supported if multiple StorNext LAN clients will access files in the same GuardPoint. For more information, see ["Supported Concurrent Access Read/Write Scenarios" on page 99](#).

Choosing a Mounting Method

There are two methods for mounting a StorNext file system on Windows in the StorNext Client Configuration application:

- Map to Drive Letter
- Map to Directory

Both methods are supported in CTE. If you mount the StorNext file system using the Map to Directory method, you must create the directory on the Windows computer before assigning that directory in the Client Configuration application. For example, the default Map to Directory folder is `C:\Mount\snfs1`. If you use that default, you must create `C:\Mount\snfs1` before mounting the StorNext file system in the Client Configuration application.

If you change mounting methods (drive letter to directory or vice versa), you may need to close and reopen Windows Explorer or reboot the computer for the change to take effect.

Installing the CTE Agent on Each StorNext LAN client

Install a CTE Agent on each computer that is set up as a StorNext LAN client and for which you want to set policies. For supported operating systems, see the table in ["Supported StorNext Server and Client Configurations" on page 98](#).

Use any installation method supported for your operating system. For details, see [Chapter 2: "Getting Started with CTE for Windows" on page 15](#).

Chapter 12: CTE-Efficient Storage for Windows

Storage arrays offer features such as compression and deduplication for storage efficiency. They also provide simplistic encryption that fails to deliver the requisite levels of security. CipherTrust Transparent Encryption (CTE) offers a much higher level of security. However, in deployments where storage arrays receive encrypted data streams from hosts protected by a CTE instance (protected hosts), the encrypted data streams make the efficiency of storage array systems ineffective. This is because every block written by CTE is different resulting in zero deduplication and compression on these blocks.

CTE offers CTE-Efficient Storage as the solution to the storage efficiency challenge in storage arrays on Windows.

Note
Currently, this feature is only supported on the DSM. Support for this feature will be added to CipherTrust Manager in a future release.

This chapter contains the following sections:

Introduction to CTE-Efficient Storage	102
Guarding an Efficient Storage Device on Windows	108
Windows System and ES GuardPoint Administration	117
Changing the Encryption Key for a Windows ES GuardPoint	119
Resizing Guarded Efficient Storage Devices	123
Use Cases Involving Efficient Storage GuardPoints	124
Alerts and Errors on Windows	132

Introduction to CTE-Efficient Storage

CTE-Efficient Storage for Windows is a licensed feature available with CTE 7.0.0 or later. In addition, all CTE Agents must be registered with a Vormetric Data Security Manager (DSM) version 6.3 or later.

Note
All references to 'storage array' in this document assume storage array systems capable of supporting CTE-Efficient Storage functionality.

With CTE-Efficient Storage, CTE offers the same degree of security for the data stored on the arrays while offering a new type of encryption key and GuardPoint. The new type of key enables storage array systems to achieve storage efficiencies with encrypted data streams. The coordination between the storage array and CTE is essential for achieving storage efficiency with encrypted data.

In the context of this solution, a LUN exported from a storage array system to a CTE-managed host, is referred to as an *ES GuardPoint*. An ES GuardPoint is a guarded device configured with the CTE-Efficient Storage capability.

Requirements and Considerations

- CTE-Efficient Storage requires XTS-AES mode of the AES algorithm for encryption.
- CTE only supports CTE-Efficient Storage on servers with microprocessors integrated with Advanced Encryption Standard instruction set (AES-NI).
- CTE-Efficient Storage requires that the encryption keys be stored in the KMIP server on the DSM. Therefore, all hosts on which you want to create ES GuardPoints must be registered with a KMIP-enabled domain in the DSM.

CTE-Efficient Storage Enhanced Storage Arrays

CTE shares the encryption key associated with the LUN with a storage system that exports the LUN to a protected host. In this solution, the LUN is a device configured for CTE-Efficient Storage that can be guarded as an ES GuardPoint. When the device is guarded, the storage system and protected hosts coordinate operations for sharing the encryption key applied to the ES GuardPoint.

By sharing the key, the storage system decrypts the encrypted data streams that the protected host writes to the LUN, and then performs the data reduction process on the clear data before encrypting and storing the final encrypted data in the storage array system. The storage system does the reverse operations when the protected host reads data from Efficient Storage devices.

Storage Arrays Compatible with CTE-Efficient Storage

Currently, FlashArray from Pure Storage is the only storage system compatible with CTE-Efficient Storage ES GuardPoints.

FlashArray from Pure Storage is enhanced with CTE-Efficient Storage capabilities and inter-operates with CTE to provide CTE-Efficient Storage on Windows. The Pure Storage system is a client of the Vormetric Data Security Manager (DSM) and shares the encryption keys protecting the LUNs exported from the storage system to the protected hosts registered with the same DSM.

Note

See the EncryptReduce Installation Guide from Pure Storage for information on setting up interoperability with CTE.

Sharing Encryption Keys

CTE shares the encryption key for a LUN with the storage system using the KMIP protocol. In this solution, the DSM is the KMIP server, and the storage system is a KMIP client registered with the DSM. Any host accessing and protecting the LUNs from the storage system is a CTE managed host registered with the same DSM. The protected hosts register with the DSM using the `register_host` script executed on the protected hosts.

With the host and the storage system registered with the same DSM, the protected host continues enforcing policy and security rules on device and directory GuardPoints. The protected host stores an Efficient Storage Device Header, (ES Header) on each LUN configured as ES GuardPoint. The ES Header includes the UUID of the encryption key applied to the LUN and identifies the LUN as an ES GuardPoint to the storage array exporting the LUN. The storage array recognizes the ES Header on the LUN when the protected host writes the header, and then uses the UUID of the key from the header to retrieve the key attributes and material from the DSM (KMIP Server). This process enables the storage array and the protected host to share and apply the same key for encryption and decryption of data streams exchanged between them.

Note

The hosts accessing a shared LUN must be protected hosts registered with the same DSM as the storage array.

When the LUN is permanently de-configured as an ES GuardPoint, the ES Header must be removed. The storage array also detects the removal of the ES Header from the LUN and de-configures the LUN as an CTE-Efficient Storage device. Both the protected host and the storage array stop encryption and decryption of data streams exchanged between hosts and the storage array.

Storage Array Registration

The storage array administrator creates a certificate for the storage array and communicates the certificate to the DSM Administrator. The DSM Administrator produces a corresponding certificate specific to the array which is given to the storage array administrator. The DSM and the storage array system register both certificates and uses them each time they establish a secured session.

Note

See the EncryptReduce Installation Guide from Pure Storage for detailed instructions on registering the FlashArray as KMIP client with the DSM's KMIP server.

Efficient Storage Device Header and CTE Private Region

The key sharing aspect of an ES GuardPoint requires a small amount of disk space in the storage device reserved for CTE private use. The reserved space is where CTE shares information with the storage array that is exporting the device to the protected host. The reserved space starts the beginning of the device.

The protected host writes the ES Header to the device when the device is guarded for the first time. The storage array recognizes the header written to the LUN and begins the key sharing process and encrypting/decrypting data streams transferred between the protected host and the storage array on the LUN.

CTE allocates a small amount of storage space on each device configured as CTE-Efficient Storage. This region is reserved for exclusive use by CTE and is referred to as the CTE Private Region. The CTE Private Region is 64 megabytes.

CTE stores the ES Header and other metadata information to allow CTE and the storage array to exchange information. The ES Header occupies the first sector on the device. The method that CTE uses to claim the CTE Private Region on a device depends on whether the device is new (holds no data) or has existing data that you want to preserve. CTE writes the ES Header when guarding the device for the first time. The storage array recognizes the header written to the device and begins the key sharing process for exchange of encrypted data streams between the protected host and the storage array on the device.

Device Size

After you create the ES GuardPoint on the device, the device size reported to applications is the size of the device minus the space reserved for the CTE Private Region. This can lead to a discrepancy between the disk size reported by some applications versus the size reported by system utilities.

WARNING

Do not shrink ES GuardPoints. Due to relocation of user data from CTE Private Region, if you shrink the device, you may corrupt data on the device.

DSM Domain Enabled for KMIP

The KMIP protocol is the interface between the DSM and the storage arrays registered with the DSM. The Domain in the DSM for serving security requirements of storage arrays and protected hosts must be KMIP enabled. For deployment of CTE-Efficient Storage, you must create a new domain with the **Enable KMIP** option checked or modify an existing domain so that the **Enable KMIP** box is checked. This allows the DSM to make the keys for guarding CTE-Efficient Storage devices within the domain available to KMIP clients (storage arrays). Existing keys in a domain before checking **KMIP Enable** checkbox will not be accessible through KMIP.

A DSM domain can serve any number of FlashArrays as a KMIP client, but a FlashArray registered with a DSM domain *cannot* register with other domains in the DSM or with another DSM. This restriction forces the FlashArrays registered with a DSM domain to serve LUNs *only* to the CTE hosts registered with that specific DSM domain in that specific DSM.

Note

See the EncryptReduce Installation Guide from Pure Storage for detailed instructions on registering the FlashArray as KMIP client with the DSM's KMIP server.

ES GuardPoint Encryption Keys

ES GuardPoints must be encrypted using XTS-AES 256 keys. An XTS-AES 256 type key is a 512-bit key composed of two components:

- The first 256 bits of the key is the AES 256 encryption key component
- The second 256 bits is the tweak component

You create XTS keys on the DSM using the “Add Key” function, similar to non-XTS keys.

Note

You *must* check the **KMIP Accessible** check box on the “Add Agent Key” page to make the key available to KMIP clients through KMIP. If you do not check the **KMIP Accessible** option, storage arrays cannot get keys for CTE-Efficient Storage devices from the DSM (KMIP server) for sharing those keys with protected hosts.

The DSM also generates a UUID for a newly added key. The DSM provides the key and its attributes to the protected hosts for guarding the CTE-Efficient Storage device. The protected host for the device writes the ES Header to the device, including the UUID of the key, before the initial attempt to enable an ES GuardPoint. The storage array recognizes the ES Header written to the device, retrieves the UUID from the ES Header, and retrieves information and attributes of the AES 256 component of the XTS-AES 256 key from the DSM using KMIP.

Key Attributes - Example

The following figure illustrates the parameters you should specify to add a new XTS-AES 256 key named ESG_DEMO_KEY_1. Note the key algorithm and encryption mode specified for the key and the checked “KMIP Accessible” option.

The following figure illustrates the general properties of ESG_DEMO_KEY_1 after adding the key. Note the UUID of the key.

The following figure illustrates the attributes of ESG_DEMO_KEY_1 after adding the key. Note that this tab displays both the UUID of the key and the UUID of the tweak component.

The attribute “x-deactivation-date” represents the date on which ESG_DEMO_KEY_1 expires. When the expiration date is reached, the key is no longer valid. It is important to choose an expiration date that exceeds any data retention period imposed on the data stored in the protected LUNs where the key is used. Note that any snapshot of a protected LUN inherits the same key protecting the primary LUN, therefore, if the key expires before reaching the end of retention period, the LUN and its snapshots will not be accessible. More importantly, do not delete the key before the data retention period expires on the LUN. The data on the LUN and its snapshots cannot be decrypted if the key is deleted prior to the data retention period.

KMIP Key Object

The following figure shows the attribute of the KMIP object for the specified UUID. The UUID specified in the example is the UUID of ESG_DEMO_KEY_1.

The following figure shows the KMIP attributes of the KMIP objects associated with ESG_DEMO_KEY_1.

The following figure shows the KMIP attributes of the KMIP object associated with the tweak component of ESG_DEMO_KEY_1.

Policy Requirements for ES GuardPoints

Initializing an ES GuardPoint requires a Standard or In-place Data Transformation - Device policy with a KMIP-accessible XTS-AES 256 key as described in ["Initialize Windows CTE-Efficient Storage Devices" on page 111](#).

Rekeying an ES GuardPoint requires an In-place Data Transformation - Device policy with a KMIP-accessible XTS-AES 256 key as described in ["Changing the Encryption Key for a Windows ES GuardPoint" on page 119](#).

You may add security rules to restrict certain user/process access to protected devices. For suggestions about what security rules you may want to use, see ["Use Cases involving Efficient Storage GuardPoints" on page 124](#).

The following figure shows an example of a simple Standard policy that uses ESG_DEMO_KEY_1 key to guard devices.

Guarding an Efficient Storage Device on Windows

The following sections discuss how to guard an efficient storage device on Windows. If you want to guard an efficient storage Linux device, see the *CTE Agent for Linux Advanced Configuration and Integration Guide*.

In order to guard an efficient storage device, you need to:

1. Make sure the devices you intend to guard meet the requirements for Efficient Storage GuardPoints. For details, see ["Requirements for Efficient Storage GuardPoints on Windows" below](#).
2. Register the protected host with the DSM with Efficient Storage enabled. For details, see ["Register the Windows Host with DSM" on page 110](#).
3. Initialize the storage device to create a Private Region for the Efficient Storage Header. For details, see ["Initialize Windows CTE-Efficient Storage Devices" on page 111](#).
4. Log on to the DSM to apply the ES GuardPoint to the storage device. For details, see ["Guard the Windows Device with an ES GuardPoint" on page 115](#).

Requirements for Efficient Storage GuardPoints on Windows

Windows-specific requirements:

- The Windows host must be running one of the following:
 - Windows Server 2012 R2
 - Windows Server 2016
 - Windows Server 2019
- You can *only* protect data volumes with an ES GuardPoint. Protecting the boot volume with an ES GuardPoint is *not* supported.
- You must enable Secure Start on the protected host and in the ES GuardPoint in the DSM.

- Existing data LUNs must be increased in size by at least 128MB (64MB for the CTE private region plus an additional 64MB to allow enough space for the data to be shifted after the CTE private region has been created). For details, see ["Data Relocation on Existing Windows Devices" on page 116](#).

Note: If you create a new Windows device to be protected, do *not* initialize that device with the Windows Disk Manager until *after* you have created and assigned the ES GuardPoint. After the GuardPoint has been assigned through the DSM, you can manage the disk as normal using the standard Windows disk management tools.

A LUN must meet the following requirements before it can be protected as an ES GuardPoint:

- The storage array exporting the LUN to the protected host must be enhanced with the Efficient Storage capability. For details, see ["Storage Arrays Compatible with CTE-Efficient Storage" on page 103](#).
- The storage array exporting the LUN to the protected host must be a KMIP client registered with the same DSM as the protected host.
- The protected host must have direct physical access to the LUN through Fiber Channel Protocol (FCP) or iSCSI.
- The entire LUN must be protected as one and only one ES GuardPoint.
- In an ESXi environment, the LUN added to a virtual machine must be configured for Raw Device Mapping in physical mode, or:
 - The LUN must be part of a VVol datastore.
 - The LUN *cannot* be a VMDK or a disk in a datastore.
- In a HyperV environment, the LUN *cannot* be a virtual disk.

Limitations for ES GuardPoints on Windows

The current implementation of ES GuardPoints on Windows has the following limitations:

- CTE does not support dynamic disks or DFS/DFS-R.
- All applications that access the Pure Storage LUN directly must be shut down while the devices are being initialized, guarded, and encrypted. Once you begin this process, devices must not be accessed by any other applications until all data has been transformed. If other applications do access the device, CTE may not be able to successfully apply the ES GuardPoint and the user may have to reboot the device.
- If the disk is in a cluster:
 - The disk must be taken offline during the initial guarding process or while the disk is being rekeyed. You do *not* need to take any of the other disks in the cluster offline and you do *not* need to take the disk out of the cluster. But the disk itself must be offline.
 - Thales recommends that you do *not* include the disk in a host group because of the issues that can arise when CTE attempts to make changes to the same device through multiple hosts. These issues are compounded if you have multiple ES GuardPoints that are protected with different policies. In a cluster environment, it is better to manage each host individually through the DSM.
- Once the process has started, Administrators cannot use any Disk Management tools to manage the devices. All disk administration must wait until after the process is complete.
- When you unguard an ES GuardPoint, the files in that GuardPoint may still be accessible through the Windows File Explorer until Windows has updated the file cache. To update the cache immediately, you can do either of the following:
 - Issue the `voradmin esg status` command on the host.
 - Reboot the host.

Register the Windows Host with DSM

If the host is already registered with a DSM, you can initialize the devices you want to protect as ES GuardPoints as described in ["Initialize Windows CTE-Efficient Storage Devices" on the next page](#) as long as:

- The host is part of a DSM domain that has KMIP enabled.
- The DSM allows the host to register the File System component.
- A license for the CTE-Efficient Storage feature has been uploaded to the DSM.

To verify this, have the DSM Administrator check the host settings in the DSM.

If the host is not already registered with a DSM, you need to register it before you can protect the devices on that host. When you register the host with the DSM, you must have AES-NI available on the host, a current license for registering host, and a current license for CTE-Efficient Storage. The following procedure describes how to register the host using the CTE Agent GUI. If you want to register the host silently, see the *CTE Agent for Windows Quick Start Guide*.

1. If you are planning to use the fingerprint registration method, make sure the DSM Security Administrator has added the host to the appropriate domain and enabled at least File system and KMIP as registration options.
2. If necessary, install CTE on the host. Follow the installation prompts as until you get to the registration portion of the installation. If CTE is already installed, you can start the registration process by running `C:\Program Files\Vormetric\DataSecurityExpert\agent\shared\bin\register_host.exe`.
3. Follow the prompts to register the host with the DSM. During the registration process, make sure that you enable Efficient Storage support when you are selecting the features you want to register.

4. Complete the registration process as normal.
5. Reboot the machine after the registration process is complete.

- To verify that the host is properly registered with the Efficient Storage option enabled, have the DSM Administrator verify that **Efficient Storage** and **Secure Start GuardPoint** are checked for the host as shown below.

- After the host is registered with the DSM, initialize each device that you want to guard as described in the next section.

Initialize Windows CTE-Efficient Storage Devices

When you initialize a Windows CTE-Efficient Storage device, the process creates the CTE Private Region on the device so that CTE can write the Efficient Storage Device Header along with metadata that identifies the storage device as a guarded device. The CTE Private Region also contains the metadata for the initial transformation of clear-text data on device to cipher-text, and for the subsequent transformation of cipher-text on the device to another encryption key as needed. The initialization process also adds a user-defined label for the storage device that the DSM Administrator will use when referring to the device in the DSM.

Note

This user-defined label is maintained across system reboots, allowing CTE to always find the device regardless of any device name changes that may happen within Windows.

How you initialize the device depends on whether it is a new device or an existing device that already has data that needs to be transformed into cipher-text. For details, see:

- ["Initialize New Windows Devices" below](#)
- ["Initialize and Resize Existing Windows Devices" on page 113](#)

Initialize New Windows Devices

For each new device you want to initialize, run the `voradmin esg config new` command. The `new` option specifies that the device does not hold user data, and that CTE can reserve the first 64MB of storage on the device for the CTE Private Region. The remaining storage space is available for new user data. The device size reported to applications is the actual device size minus the CTE Private Region size.

WARNING

Do not use the `voradmin esg config new` command if the Windows disk has existing data that you want to keep. After you guard a device that has been initialized with this command, you will need to reformat the device and all existing data will be lost. To initialize a disk with existing data, see ["Initialize and Resize Existing Windows Devices" on the next page](#).

1. Log into the device as an Administrator and open PowerShell or Cmd (command prompt).
2. Close all applications, including any Windows disk management tools, that are using or mounting the device.
3. If this disk is part of a cluster, you must take the disk offline. You do *not* need to take any of the other disks in the cluster offline and you do *not* need to take the disk out of the cluster. But the disk itself must be offline during this procedure if it is part of cluster.
 - For an unstructured data cluster, open the Windows Failover Cluster Manager and go to **<cluster name> > Storage > Disks**, then select the disk and take it offline.
 - For a structured SQL database cluster, open the Windows Failover Cluster Manager and go to **Roles -SQL <cluster name> Role**. Stop the Role for the SQL instance or take the SQL server offline.
4. Make sure you know the Device Names of the devices that you want to protect.

To get a list of the Device Names for the available devices, use the `voradmin esg list disk` command and look in the **Device Name** column. Any new disk that is not a boot disk and that does not contain any data can be initialized by CTE as a new disk. For example:

C:\>`voradmin esg list disk`

Disk###	Device Name	Boot Disk	Size	Status	Partition	Read Only	SERIAL NUMBER
Disk0	\Device\Ide\IdeDeviceP0T0L0-0	Yes	127.0 GB	Online	MBR	No	6000c29d241599...
Disk1	\Device\00000032	No	49.9 GB	Online	MBR	No	6000c29b1d5a4c...
Disk2	\Device\00000033	No	50.9 GB	Online	MBR	Yes	6000c290582227...
Disk3	\Device\00000034	No	50.9 GB	Online	MBR	No	6000c290fd627b...

In the example above, the available Device Names are `\Device\00000032`, `\Device\00000033`, and `\Device\00000034`.

5. Run the `voradmin esg config new <device-name>=<label>` command, where:
 - `new` (required) indicates that the device contains no data (it is a new disk). CTE will create the CTE private region at the beginning of the disk and the rest of the disk will be available for user data.
 - `<device-name>=<label>` (required) is the device name and a user-defined label for the device. This label will be the path the DSM Administrator uses to specify to the device in the DSM. (For example, `\Device\00000033=NewESDisk`.) The label can be 1 to 32 ASCII characters. Do not use spaces or special characters in the label.

Make sure that the device you select does *not* contain any existing data. When CTE applies the GuardPoint to a new device, it removes the existing file system information from the device. That means the device will need to be reformatted and all existing data will be unrecoverable as soon as the GuardPoint is applied.

For example, if you want to initialize a new disk Windows device named `00000033` with the label "NewESDisk", you would specify:

```
PS C:> voradmin esg config new \Device\00000033=NewESDisk
Disk is initialized successfully with CTE ESG protection.
```

- To verify that the disk has been initialized, run the `voradmin esg status` command.

This command shows that the device label has been set and the Xform Status has been set to NA (not applicable). For example:

C:\>**voradmin esg status**

Disk###	Device Name	Boot Disk	ESG Device label	Guard Status	Xform Status
Disk0	\Device\Ide\IdeDeviceP0T0L0-0	Yes	NA	unguarded	
Disk1	\Device\00000032	No		unguarded	
Disk2	\Device\00000033	No	NewESDisk	unguarded	NA
Disk3	\Device\00000034	No		unguarded	

- At this point the DSM Administrator can protect the device as an ES GuardPoint through the DSM Management Console as described in ["Guard the Windows Device with an ES GuardPoint" on page 115](#).

Note: The initialization process prepares the devices to be guarded but does not actually guard them. You need to assign an ES GuardPoint to each device through the DSM before the devices are actually protected. In addition, the initialization process is only kept in memory until the devices are guarded or rebooted. If a device is rebooted before you guard it, you will need to perform the initialization procedure again.

Initialize and Resize Existing Windows Devices

If a Windows device has existing data, you need to use the `voradmin esg config xform` command to initialize the disk for CTE. This command tells CTE that the data on the device needs to be encrypted after an ES GuardPoint is assigned to the device through the DSM. After the CTE initialization is complete, you then need to resize the device before you can guard it with an ES GuardPoint.

The following procedure describes how to initialize existing devices for CTE. Note that the existing data is not altered in any way until after you perform this procedure and you guard the data with an ES GuardPoint. CTE does *not* begin transforming the data from clear-text to cipher-text until the ES GuardPoint has been applied and the encryption key has been pushed to the device through the GuardPoint Policy.

- Log into the device as an Administrator and open PowerShell or Cmd (command prompt).
- Close all applications, including any Windows disk management tools, that are using or mounting the device.
- If this disk is part of a cluster, you must take the disk offline. You do *not* need to take any of the other disks in the cluster offline and you do *not* need to take the disk out of the cluster. But the disk itself must be offline during this procedure if it is part of cluster.
 - For an unstructured data cluster, open the Windows Failover Cluster Manager and go to **<cluster name> > Storage > Disks**, then select the disk and take it offline.
 - For a structured SQL database cluster, open the Windows Failover Cluster Manager and go to **Roles -SQL <cluster name> Role**. Stop the Role for the SQL instance or take the SQL server offline.
- Make sure you know the Device Names of the devices that you want to protect.

To get a list of available devices on Windows, use the `voradmin esg list disk` command. The Disk Name column shows the names of the available disks. In the list, existing disks must *not* be boot disks and they must *not* be Read Only. In the following example, \Device\00000032 and \Device\00000034 show **No** in the **Boot Disk** and **Read Only** columns:

C:\>**voradmin esg list disk**

Disk###	Device Name	Boot Disk	Size	Status	Partition	Read Only	SERIAL NUMBER
Disk0	\Device\Ide\IdeDeviceP0T0L0-0	Yes	127.0 GB	Online	MBR	No	6000c29d241599...
Disk1	\Device\00000032	No	49.9 GB	Online	MBR	No	6000c29b1d5a4c...
Disk2	\Device\00000033	No	50.9 GB	Online	MBR	Yes	6000c290582227...
Disk3	\Device\00000034	No	50.9 GB	Online	MBR	No	6000c290fd627b...

- If you want to make sure the disk has not yet been initialized, used the `voradmin esg status` command. If the disk already has an ESG Device Label, then the disk has already been initialized. In the following example, Disk2 has already been initialized, but Disk1 and Disk3 have not:

C:\>**voradmin esg status**

Disk###	Device Name	Boot Disk	ESG Device label	Guard Status	Xform Status
Disk0	\Device\Ide\IdeDeviceP0T0L0-0	Yes	NA	unguarded	
Disk1	\Device\00000032	No		unguarded	
Disk2	\Device\00000033	No	NewESDisk	unguarded	NA
Disk3	\Device\00000034	No		unguarded	

- For each existing device you want to initialize, run the `voradmin esg config xform <device-name>=<label>` command, where:
 - `xform` (required) indicates that the device contains existing data. CTE will transform all existing data on the device from clear-text to cipher-text as soon as you guard the device. The device will be inaccessible until the transformation is complete, and the device must remain offline during the entire transformation process. No user access will be permitted until all data has been transformed.
 - `<device-name>=<label>` (required) is the device name and a user-defined label for the device. This label will be the path the DSM Administrator uses to specify to the device in the DSM. (For example, `\Device\00000032=ExistWinDisk1`.) The label can be 1 to 32 ASCII characters. Do not use spaces or special characters in the label.

For example, if you want to initialize a new disk Windows device named 00000032 with the label `ExistWinDisk1` and the device 00000034 with the label `ExistWinDisk2`, you would specify:

C:> **voradmin esg config xform \Device\00000032=ExistWinDisk1**

Disk is initialized successfully with CTE ESG protection. Disk must be Resized to at least 128MB before guarding as Efficient Storage GuardPoint

C:> **voradmin esg config xform \Device\00000034=ExistWinDisk2**

Disk is initialized successfully with CTE ESG protection. Disk must be Resized to at least 128MB before guarding as Efficient Storage GuardPoint

With Windows, you always need to increase the disk size on each device by at least 128MB, which provides enough space for the CTE Private Region as well as room to relocate the existing data. After you guard the disk, you can expand it again later but you cannot shrink it unless you remove the GuardPoint. For details about the data relocation, see ["Data Relocation on Existing Windows Devices" on page 116](#).

- To verify that the disks have been initialized, run the `voradmin esg status` command.

This command shows that the device labels have been set and the Xform Status has been set to Not Started. For example:

C:\>**voradmin esg status**

Disk###	Device Name	Boot Disk	ESG Device label	Guard Status	Xform Status
Disk0	\Device\Ide\IdeDeviceP0T0L0-0	Yes	NA	unguarded	
Disk1	\Device\00000032	No	ExistWinDisk1	unguarded	Not Started
Disk2	\Device\00000033	No	NewESDisk	unguarded	NA
Disk3	\Device\00000034	No	ExistWinDisk2	unguarded	Not Started

- At this point, you need to resize all initialized existing devices by increasing their volume size through the Pure Storage management interface. Make sure you increase the device size on each device by at least 128 MB. For details, see your Pure Storage documentation.

To verify that the disk size has been increased, use the `voradmin esg list disk` command.

C:\>**voradmin esg list disk**

Disk###	Device Name	Boot Disk	Size	Status	Partition	Read Only	SERIAL NUMBER
Disk0	\Device\Ide\IdeDeviceP0T0L0-0	Yes	127.0 GB	Online	MBR	No	6000c29d241599...
Disk1	\Device\00000032	No	50.1 GB	Online	MBR	No	6000c29b1d5a4c...
Disk2	\Device\00000033	No	50.9 GB	Online	MBR	Yes	6000c290582227...
Disk3	\Device\00000034	No	51.1 GB	Online	MBR	No	6000c290fd627b...

You cannot assign an ES GuardPoint to the devices until it they have been resized. If you do not resize the devices, the GuardPoint assignment will fail.

- After the devices have been resized, the DSM Administrator can protect the devices as ES GuardPoints through the DSM Management Console as described in ["Guard the Windows Device with an ES GuardPoint"](#) below.

Note

The initialization process prepares the devices to be guarded but does not actually guard them. You need to assign an ES GuardPoint to each device through the DSM before the devices are actually protected. In addition, the initialization process is only kept in memory until the devices are guarded or rebooted. If a device is rebooted before you guard it, you will need to perform the initialization procedure again.

Guard the Windows Device with an ES GuardPoint

Note

For details about how to create a GuardPoint, see the chapter, "Managing GuardPoints", in the *DSM Administration Guide*.

After the device has been initialized, you can guard the device as an ES GuardPoint from the DSM Management Console. For existing devices, as soon as the GuardPoint has been pushed to the host and the status changes to guarded, CTE begins transforming the data on the disk using the encryption key associated with the GuardPoint Policy.

- Log on to the DSM Management Console as an administrator of type Security with Host role permissions, type Domain and Security, or type All.
- Make sure that you know what Policy you want to associate with the GuardPoint or create a new policy if needed. The policy you use for CTE-Efficient Storage must be either a Standard policy or an In-place Data Transformation - Device policy, and it must use a KMIP-accessible XTS-AES 256 key in the key rule. For more information on key requirements, see ["ES GuardPoint Encryption Keys"](#) on page 105.
- Select **Hosts > Hosts** on the menu bar. The *Hosts* window opens.
- Click the target host in the **Host Name** column. The *Edit Host* window opens to the General tab for the selected host.
- Click the **GuardPoints** tab and then click **Guard**. The *Guard File System* window opens.
 - In the **Policy** field, select the Policy you identified or created earlier in this procedure. CTE will use the XTS-AES 256 key associated with this policy to encrypt the data on the device.
 - In the **Type** field, select **Raw or Block Device (Auto Guard)**.

When you select Auto Guard, CTE starts the guard process as soon as the policy is pushed to the host. You enable, disable, guard, and unguard the GuardPoint in the DSM.

- c. In the **Path** field, add the device label you assigned when you initialized the disk. For example, `ExistWinDisk1`.
If you specify multiple device labels in this field, all specified devices will be guarded and all will be encrypted with the encryption key specified in the selected policy.
- d. Make sure the **Secure Start** check box is checked.

6. When you are done, click **OK**.

The DSM pushes the policy and the GuardPoint configuration to the host and the CTE Agent on the host writes the ES Header into the CTE Private Region for the specified devices.

If this is a new device, the status changes to guarded and the disk is available for user access immediately. At this point you can use the Windows Disk Manager to perform any required disk management tasks and all data that gets written to the disk will be protected by CTE.

If there is existing data on the device, CTE begins transforming the data from clear-text to cipher-text as soon as the ES GuardPoint configuration is available and the device status changes to guarded. The device will remain inaccessible until this data transformation completes. The length of time required to transform the data depends on the size of the disk.

7. If this disk is part of a cluster, do the following:
 - a. If the disk has existing data, wait until the data transformation process has completed before you proceed. To verify the status of the process, use the `voradmin esg status` command.
 - b. After any required data transformation is complete, apply the same GuardPoint with the same policy to the disk on each one of the hosts that can access the disk. You must specify the same policy name and disk label on each host.

Tip: Thales recommends that you do *not* use a Host Group for clustered disks. Instead, you should apply the GuardPoint individually on each host.

- c. After you have created the GuardPoint on each host that can access the disk, you can bring the disk back online or restart the SQL Role/SQL server.

Data Relocation on Existing Windows Devices

When you add an ES GuardPoint to a device that has been initialized with the `xform` option, CTE shifts the existing data by 64MB, then it creates the CTE Private Region in the first 64MB on the device. This relocation occurs only once when the device is guarded for the first time.

Data Transformation on Existing Windows Devices

As the ES Header is written before data transformation begins, the data transformed to cipher-text and written back to the device during data transformation process is subject to data reduction process through the storage array.

Existing devices populated with data are transformed from clear-text to cipher-text using the encryption key applied to each device. Data transformation is also called CipherTrust InPlace Data Transformation (CTE-IDT).

CTE-IDT is not the same as the legacy offline data transformation. CTE-IDT is a block level data transformation with built-in resiliency to recover from system crashes during the data transformation process. CTE-IDT uses the CTE Private Region on the device to manage the entire transformation process. CTE-IDT partitions the data on a device in segments of 512KB in size and transforms one or multiple segments, up to 60 segments, in parallel. The CTE-IDT process preserves existing data in a segment during transformation in the private region of the device, and then transforms the data in-place. CTE-IDT also maintains the segments undergoing transformation in the private region. In the event of system crash, CTE-IDT will recover the segments undergoing transformation at the time of crash and then resume the transformation process.

Another advantage of CTE-IDT over legacy offline data transformation is that CTE-IDT does not require a separate policy for data transformation. With the same production policy applied to the device, CTE-IDT determines whether the device is in need of data transformation, per specification of `xform` option when device was initialized, and starts the CTE-IDT process when transformation is required. During the CTE-IDT process, access to the device is blocked until the CTE-IDT process completes.

To view the data transformation status, use the `voradmin esg status` command and look in the **Xform Status** column. In the following example:

- Disk1 has been guarded and the data transformation process has completed, so the device is guarded and ready to use.
- Disk2 was initialized as a new device, so no data transformation was required. The device is guarded and ready to use.
- Disk3 has been guarded but the data transformation process is still in progress. This device cannot be accessed until the data transformation process has completed.

```
C:\>voradmin esg status
```

Disk###	Device Name	Boot Disk	ESG Device label	Guard Status	Xform Status
Disk0	\Device\Ide\IdeDeviceP0T0L0-0	Yes	NA	unguarded	
Disk1	\Device\00000032	No	ExistWinDisk1	guarded	Completed
Disk2	\Device\00000033	No	NewESDisk	guarded	NA
Disk3	\Device\00000034	No	ExistWinDisk2	guarded	In-Progress

(18%)

CTE-IDT Recovery From Crash

CTE-IDT is fault tolerant in the event of system crashes. CTE-IDT keeps track of the transformation process over the entire device. In the event of a crash, CTE-IDT will automatically resume transformation from the point of failure as soon the GuardPoint is enabled after system startup.

If you find the transformation status set to **In-Progress** when the GuardPoint is not enabled, the **In-Progress** state reflects an earlier system crash after which the GuardPoint has not been enabled to recover from the interruption in the CTE-IDT process.

Windows System and ES GuardPoint Administration

The `voradmin` command is a command line utility for management of CTE specific configuration and status reporting. The `voradmin` command also supports configuration management related to ES GuardPoints (ESG).

Windows supports the following `voradmin esg` commands.

voradmin esg list disk

Command: `voradmin esg list disk`

Lists the disks available on the Windows host. The `Disk###` column matches the disk numbers in the Windows Disk Manager. The `Device Name` column shows the name of the disk that you need to use with other `voradmin` commands. In the following example, the `Device Name` for `Disk1` is `\Device\00000036`.

For example:

`C:\>voradmin esg list disk`

Disk###	Device Name	Boot Disk	Size	Status	Partition	Read Only	SERIAL NUMBER
Disk0	\Device\Ide\IdeDeviceP0T0L0-0	Yes	127.0 GB	Online	MBR	No	6000c29d241599...
Disk1	\Device\00000032	No	49.9 GB	Online	MBR	No	6000c29b1d5a4c...
Disk2	\Device\00000033	No	50.9 GB	Online	MBR	Yes	6000c290582227...
Disk3	\Device\00000034	No	50.9 GB	Online	MBR	No	6000c290fd627b...

voradmin esg config

Command: `voradmin esg config [new|xform] <device-name>=<device-label>`

Initializes a new or existing Windows device so that it can be protected as an ES GuardPoint through the DSM. For details on using this command, see ["Initialize New Windows Devices" on page 111](#) and ["Initialize and Resize Existing Windows Devices" on page 113](#).

voradmin esg status

Command: `voradmin esg status`

Displays the status of the disks on the host. The `Disk###` column matches the disk numbers in the Windows Disk Manager. The `Device Name` column shows the name of the disk that you need to use with other `voradmin` commands. In the following example, the `Device Name` for `Disk1` is `\Device\00000032`.

If the device has been initialized, the user-defined disk label appears in the `ESG Device Label` column. If the device has been protected with an ES GuardPoint through the DSM, the `Guard Status` column displays “guarded”. The `Xform Status` column displays the status of any data transformation processes run on the disk. NA means it was a new disk, so no data transformation was needed. For existing disks, the `Xform Status` can be Not Started, In Progress, or Completed.

For example:

`C:\>voradmin esg status`

Disk###	Device Name	Boot Disk	ESG Device label	Guard Status	Xform Status
Disk0	\Device\Ide\IdeDeviceP0T0L0-0	Yes	NA	guarded	
Disk1	\Device\00000032	No	ExistWinDisk1	guarded	Completed
Disk2	\Device\00000033	No	NewESDisk	guarded	NA
Disk3	\Device\00000034	No	ExistWinDisk2	guarded	Completed

voradmin esg status [xform] <device-label>

Displays the details of the device specified in `<device-label>`, where `<device-label>` is the ESG Device Label assigned to the device. If you use the optional `xform` parameter, the command displays the status of any data transformation processes running on the device.

For example:

```
C:\> voradmin esg status NewESDisk
```

```
Disk###           Disk2

```

voradmin esg delete

Command: voradmin esg delete <disk-label>, where:

<disk-label> is the user-defined label that was specified when the device was initialized. To view a list of disk labels, use the voradmin esg status command.

Removes the ES Header from the specified device. The device *cannot* be protected as an ES GuardPoint or this command will fail.

For example:

```
# voradmin esg delete NewESDisk
ES disk header deleted successfully.
```

Changing the Encryption Key for a Windows ES GuardPoint

To meet various compliance requirements, you may want to change the key that CTE has used to encrypt an GuardPoint. Thales refers to this changing of encryption keys as “Key rotation” or “Rekey”. Unlike the CipherTrust Transparent Encryption - Live Data Transformation product offered by Thales for file systems on traditional storage devices, to change the encryption key on an ES GuardPoint, the device must be taken offline. The data on the device will be inaccessible during the key rotation process.

The key rotation process involves the following:

- Creating a new policy for key rotation
- Preparing the ESG device for key rotation
- Applying the new policy to the ESG device on the DSM

See the following sections for details of key rotation. If your organization has separated security duties, some of the steps below may need to be completed by different people.

Requirements and Considerations

Rekeying a Windows ES GuardPoint requires an In-place Data Transformation - Device policy, which is available with the DSM version 6.4.2 and later. If the Windows host is registered with an older version of the DSM, you must upgrade the DSM to at least version 6.4.2 if you want to rekey a Windows ES GuardPoint.

Creating a New DSM Policy for Key Rotation

As part of rekeying the data on an ESG device, you must create a new In-place Data Transformation - Device policy with a key rule specifying the current key and the new key. The screenshot below shows a policy named ES-GP-Windows-Rekey that specified the current key as ES-GP-Key-1 and the new key as ES-GP-Key-2:

When this policy is pushed to the host from the DSM, the CTE Agent will decrypt the data on the device using the key ES-GP-Key-1 and then will reencrypt it using the key ES-GP-Key-2.

Rekeying the Windows Device

1. Shutdown any applications accessing the GuardPoint. This also includes unmounting the file system if the GuardPoint is a device mounted as a file system.

WARNING

During this procedure, you will have to disable the GuardPoint while the device is being rekeyed. Therefore it is critical that no file changes occur during the rekey process or the data may become corrupted.

2. If this disk is part of a cluster, you must check the ownership of the disk and then take the disk offline. You do *not* need to take any of the other disks in the cluster offline and you do *not* need to take the disk out of the cluster. But the disk itself must be offline during this procedure if it is part of cluster.

During this procedure, you need to log into the host that owns the disk in order to run the `voradmin esg rekey` command. If you want to do that on a host other than the current owner, change the disk ownership in the Windows Failover Cluster Manager.

After you have set the correct owner, take the disk offline:

- For an unstructured data cluster, open the Windows Failover Cluster Manager and go to **<cluster name> > Storage > Disks**, then select the disk and take it offline.
- For a structured SQL database cluster, open the Windows Failover Cluster Manager and go to **Roles -SQL <cluster name> Role**. Stop the Role for the SQL instance or take the SQL server offline.

3. In the DSM Management Console, unguard the ES GuardPoint.

If this disk is part of cluster, unguard the disk on each one of the hosts that can access the disk.

4. Log into the host with System Administrator privileges.

If this disk is part of a cluster, you need to log into the host that is the current owner of the disk.

5. Make sure that the device you intend to rekey is no longer guarded using the `voradmin esg status` command. In the following example, we are about to rekey the device NewESDisk:

```
C:\>voradmin esg status
```

Disk###	Device Name	Boot Disk	ESG Device label	Guard Status	Xform Status
Disk0	\Device\Ide\IdeDeviceP0T0L0-0	Yes	NA	Unguarded	
Disk1	\Device\Ide\IdeDeviceP0T1L0-1	No	NewESDisk	Unguarded	NA
Disk2	\Device\Ide\IdeDeviceP1T1L0-3	No	ExistWinDisk1	Guarded	NA

6. Use the `voradmin esg rekey` command to prepare the device to be rekeyed. For example:

```
C:\>voradmin esg rekey NewESDisk
```

```
Disk is initialized successfully with CTE ESG protection.
```

7. In the DSM Management Console, guard the device with the new policy you created in ["Creating a New DSM Policy for Key Rotation"](#) on page 120. Make sure that:
- You select **Raw or Block Device (Auto Guard)**.
 - You check the **Secure Start** check box.

In the following example, NewESDisk is guarded with the In-place Data Transformation - Device policy ES-GP-Windows-Rekey:

When you click **OK**, the DSM pushes the new policy to the ES GuardPoint and the CTE Agent rekeys the device.

8. During the rekey process, you can use the `voradmin esg status` command to track the rekey progress.

C:\>**voradmin esg status**

Disk###	Device Name	Boot Disk	ESG Device label	Guard Status	Xform Status
Disk0	\Device\Ide\IdeDeviceP0T0L0-0	Yes	NA	Unguarded	
Disk1	\Device\Ide\IdeDeviceP0T1L0-1	Unknown	NewESDisk	Guarded	In Progress (80%)
Disk2	\Device\Ide\IdeDeviceP1T1L0-3	No	ExistWinDisk1	Guarded	NA

When the rekey process has finished, the status changes to Completed.

C:\>**voradmin esg status**

Disk###	Device Name	Boot Disk	ESG Device label	Guard Status	Xform Status
Disk0	\Device\Ide\IdeDeviceP0T0L0-0	Yes	NA	Unguarded	
Disk1	\Device\Ide\IdeDeviceP0T1L0-1	Unknown	NewESDisk	Guarded	Completed
Disk2	\Device\Ide\IdeDeviceP1T1L0-3	No	ExistWinDisk1	Guarded	NA

9. If you want to verify that the GuardPoint is using the new key, use the `voradmin esg status xform <device-label>` command. For example:

```
C:\> voradmin esg status xform NewESDisk
```

```
ESG Rekey/Xform Status
```

```
-----
```

```
      Status      :NA
      Device Type  :New
```

```
Key Information:
```

```
      Key UUID      :cf242f18-de61-3f72-ba57-0b28a94a4f21
      KeyID         :48361
      KeyName       :ES-Rekey
      Old KeyID     :0
      Old KeyName   :ES_Key
```

```
Block information:
```

```
      Transformed   :0
      Remaining     :0
      Total         :0
```

10. If the disk is *not* part of a cluster, you can restore access to the disk at this point. If it *is* part of a cluster, do the following:
- After any required data transformation is complete, apply the same GuardPoint with the same policy to the disk on each one of the hosts that can access the disk. You must specify the same policy name and disk label on each host.
 - After you have created the GuardPoint on each host that can access the disk, you can bring the disk back online or restart the SQL Role/SQL server.

Resizing Guarded Efficient Storage Devices

Devices configured for Efficient Storage can be resized using the system-provided resizing utilities. If you are using a file system on the GuardPoint, you can mount the file system after resizing the device and then grow the file system to the new size using the native Windows disk management tools.

WARNING

Do not shrink ES GuardPoints. Due to relocation of user data from CTE private region, if you shrink the device, you may corrupt data on the device.

- Stop applications from accessing the GuardPoint.
 - Unmount the file system if the device is mounted.
 - Disable GuardPoints: auto-guard if is enabled on the DSM, or manual-guard if is enabled on the protected host.
- Use the native disk management tools to resize the device.
- After resizing the device, check the size of the device. On Windows you can use the `voradmin esg list disk` command.
- If the reported size does not match what you expect, you may need to rescan your storage devices using the command appropriate for the device's connection type.
- Once the expected size is achieved, enable the GuardPoint and restart your applications.

Use Cases involving Efficient Storage GuardPoints

ES GuardPoints support three use cases for managing customer's data in GuardPoints. This section describes those potential use cases.

Use Case 1: Single Encryption Key

Applications, such as an Oracle Database, store structured data in one or multiple LUNs guarded as an ES GuardPoint. In this use case, a LUN may be an independent datastore or a member of a disk group managed by an application, for example an Oracle ASM disk group. In this use case, the policy applied to the GuardPoints specifies one key rule for encryption. The policy may include access rules for user or process level access control.

Use Case 2: Device-Level GuardPoints

Protect structured or unstructured data stored in data files. The data files are organized inside one or more directories or folders within a file system namespace, such as NTFS or ReFS, without any protection on the folders or the file system namespace. In this use case, the file system resides in the device guarded as Efficient Storage using a policy with a key rule and *no user specified access rule*. Access rules are not applicable in this use case and should not be used.

Figure 12-1: File system resides in device guarded as ES GuardPoint

Example

In the following example, the Windows Administrator has created a new 10 MG VHD in the Windows Disk Management tool. This VHD is called Disk 3, and it has not yet been initialized.

The Windows Administrator then uses `voradmin esg list disk` to get the CTE device name for the new disk and initializes it using the `voradmin esg config new` command, as shown:

```
C:\>voradmin esg list disk
```

Disk###	Device Name	Boot Disk	Size	Status	Partition	Read Only	SERIAL NUMBER
Disk0	\Device\Ide\IdeDeviceP0T0L0-0	Yes	127.0 GB	Online	MBR	No	
Disk1	\Device\00000032	No	49.9 GB	Online	MBR	No	
Disk2	\Device\00000033	No	50.9 GB	Online	MBR	No	
Disk3	\Device\00000051	No	10.0 GB	Online	MBR	No	

```
C:\>voradmin esg config new \Device\00000051=NewDisk3
Disk is initialized successfully with CTE ESG protection.
```

The Administrator guards the new disk through the DSM, and uses the `voradmin esg status` command to make sure the new disk has been successfully guarded.

```
C:\>voradmin esg status
```

Disk###	Device Name	Boot Disk	ESG Device label	Guard Status	Xform Status
Disk0	\Device\Ide\IdeDeviceP0T0L0-0	Yes	NA	unguarded	
Disk1	\Device\00000032	No	esg-disk1-demo	guarded	Completed
Disk2	\Device\00000033	No	esg-disk2-demo	guarded	Completed
Disk3	\Device\00000051	No	NewDisk3	guarded	NA

After the device has been guarded, the Administrator returns to the Windows Disk Manager and selects **Action > Rescan Disks** to make sure the Windows Disk Manager is synchronized with CTE. They then initialize the disk, create a new volume for it, and format it. Notice that the new volume size is slightly smaller than the original 10 GB because CTE has reserved room for the CTE Private Region.

Use Case 3: Directory-Level GuardPoints

Protect structured or unstructured data stored in data files. The data files are organized inside one or multiple directories or folders within a file system namespace, such as NTFS or ReFS, where the entire file system namespace is guarded with one policy as a Directory GuardPoint. In this use case, the file system resides in a device guarded as ES GuardPoint.

Figure 12-2: All Data in file system Device Encrypted through an ES GuardPoint

In this use case, two policies are enforced to protect the data in the device. As stated, one policy protects the entire file system namespace guarded under the Directory GuardPoint, and the guarded directory is the mount point pathname of the mounted file system. The policy on the mount point directory must specify *clear_key* in the key rule. Specifying a key other than *clear_key* must be avoided because all the data in the file system device is encrypted through the ES GuardPoint corresponding to the file system device. The screen shot below represents a sample Linux policy over the file system mount point where the policy blocks root access to read/write files under the subdirectory *dir1* in the mounted file system. For Windows, the policy would be the same as shown below except that the user name would be *Administrator* instead of root.

The second policy protecting the device is the same policy as use case 2.

Example

In this example, Jane Doe is a member of the Accounting team and John Fredricks is a member of the IT team. There are two folders on the guarded disk called `G:\Data\Accounting-Specific-Files` and `G:\Data\IT-Specific-Files`. Even though the disk is protected by an Efficient Storage GuardPoint, both Jane and John can see the files in either folder. For example:

The DSM Administrator goes into the DSM and creates a standard policy that grants access to Jane Doe in the Accounting folder and grants access to John Fredricks in the IT folder. For the key rule, the policy must specify `clear_key`. For example:

Then the DSM Administrator applies the policy to `G:\Data`. For example:

Select All		View 50													
Guard		Unguard		Enable		Disable		Secure Start On		Secure Start Off		Transform Sparse Regions			
Select Policy		Host Group		Protected Path				Disk Group / Disk		Type		Domain		Auto Mount	
☐ ES-Standard-Policy				esg-disk1-demo						Raw or Block Device (Auto Guard)		ES		☐	
☐ ES-Standard-Policy				esg-disk2-demo						Raw or Block Device (Auto Guard)		ES		☐	
☐ ES-Standard-Policy				NewDisk3						Raw or Block Device (Auto Guard)		ES		☐	
☒ Accounting-IT-Access-Policy				G:\Data\						Directory (Auto Guard)		ES		☐	
Guard		Unguard		Enable		Disable		Secure Start On		Secure Start Off		Transform Sparse Regions			

Now when Jane Doe logs into the server, she can see the files in the Accounting-Specific-Files directory but she cannot access the files in the IT-Specific-Files directory, even if her account has Administrator-level access. For example:

Similarly, when John Fredricks logs in he will be able to access the files in the IT-Specific-Files directory but he will be unable to access the Accounting-Specific-Files directory.

Use Case 4: Full Device Protection

As shown in the previous use cases, administrators can add access control policies at the file system or directory level, thus controlling normal user access to the protected files. This does not, however, block users with Administrator privileges on the Windows machine from opening protected disks or volumes directly using Windows Administration tools such as DiskPart.

By opening the disks or volumes directly, Windows Administrators can read and write the clear text data from the device, bypassing any access controls. In order to prevent this, the DSM Security Administrator can include a *process set* in the policy associated with the device-level GuardPoint. The process set includes a white list of the processes that are allowed to run on the protected device. Any process not in the white list will be blocked by CTE.

Thales recommends adding at least the following system processes to your process set. These system processes are used to create snapshots and perform other standard disk management tasks. You can add other processes to your white list as required.

- Windows\System32\ntoskrnl.exe
- Windows\System32\svchost.exe
- Windows\System32\vds.exe

- Windows\System32\webm\WmiPrvSE.exe

For an additional layer of protection, you can create a *signature set* that contains the signature for each one of the processes that you want to add to your white list. If you include signature information in the process set, CTE uses that signature to verify the integrity of the process before it allows that process to access the protected data.

Note

Signature sets are host-specific, as the signature for a particular process may be different on different hosts. Therefore, if you add a signature set to a policy, you should only assign that policy to devices on the host associated with the signature set.

In the following example, we create a signature set that contains the four processes listed above, then we create a process set that references the signature set for each process. We then add the process set to a policy that we can use at the device level to protect the device.

1. Log into the DSM Management Console and switch to the appropriate domain.
2. To create the signature set:
 - a. In the top menu bar, click **Signatures**.
 - b. In the signature set table, click **Add**.
 - c. Enter a name for the signature set and click **OK**. For example, you could call the signature set "Win-WhiteList-Sigs".
 - d. Click on the name of the signature set you just created to edit the set.
 - e. Click the **Source** tab.
 - f. In the **Host** field, select the host whose processes you want to sign.
 - g. In the process table, click **Add**.
 - h. In the Add Sources dialog box, enter the processes you want to sign. You can either type the fully-qualified executable name or click **Browse** to select the process from an Explorer-styled interface. Make sure that each process is on its own line.

For example:

- i. Click **OK**.

- j. Click **Sign**.
- k. Click on the Signature tab to make sure that all processes now have a signature.

3. To create the process set:
 - a. In the DSM Management Console tool bar, select **Policies > Manage Policies > Process Sets**.
 - b. In the **Name** field, enter a name for the process set. For example, "Win-WhiteList-Proc-Set".
 - c. In the process set table, click **Add** and, for each process in the white list, fill out the following fields:
 - **Signature Set** — The name of the signature set you created in the previous step. For example, "Win-WhiteList-Sigs".
 - **Host** — The name of the host on which the process will run. You only need to specify the host if you want to **Browse** to the directory.
 - **Directory** — The directory in which the process resides. For example, "C:\Windows\System32\".
 - **File** — The process filename. For example, "vds.exe".

When you are done, there should be one entry for each process on the White List with the associated signature set.

- d. When you are done, click **OK**.

4. To add the process set to a policy:
 - a. Create a new policy or edit an existing policy.
 - b. In the **Security Rules** section, click **Add**.
 - c. In the Add Security Rule page, click the **Select** button associated with the **Process** field.
 - d. Select the process set you created in the previous step, then click **Select Process Set**.
 - e. Click the **Select** button associated with the **Action** field and select **all_ops**.
 - f. Click the **Select** button associated with the **Effect** field and select **Permit, Apply Key, and Audit**.
 - g. Click **OK**.
 - h. Add a second security rule with the effects **Audit** and **Deny**. Make sure that this rule comes *after* the process set rule.

- i. Save the policy.
5. Apply the policy to the appropriate device-level GuardPoints on the host associated with the signature set.

Alerts and Errors on Windows

ESG-ALERT: Data transformation failure on [GuardPoint]

This is an alert message to the DSM. It occurs when a protected host encounters an error transforming the data on the device during the IDT process.

Solution: Please contact Thales Support for troubleshooting and recovery.

ESG-INFO: Data transformation complete on [GuardPoint]

This message notifies the DSM Administrator that the protected host has completed the data transformation on the specified ES GuardPoint.

Disk label validation failed. Check your disk label and run command again.

This error occurs when you run the `voradmin esg config` command on an ESG device and you specify a disk label that is too long or that contains unsupported characters.

Solution: Check disk label and make sure that it meets the label name requirements.

Failed to get disk information

This error occurs when ESG found the device but cannot open it.

Solution: Please contact Thales Support for troubleshooting and recovery.

Boot partition is present on the disk. Disk or LUN can not be protected using CTE agent.

This message occurs when you run the `voradmin esg config` command on a disk that has a boot partition. ESG only supports protecting the data disks. You cannot use ESG to protect the system or boot disks.

The disk is dynamic disk. This disk or LUN can not be protected using CTE agent.

This message occurs when you run the `voradmin esg config` command on a dynamic disk. ESG does not support guarding dynamic disks.

Failed to initialize disk

This error message occurs when the `voradmin esg config` command fails to initialize the disk.

Solution: Please contact Thales Support for troubleshooting and recovery.

Disk is already initialized/guarded with CTE ESG protection

This message occurs when you run the `voradmin esg config` command on a disk is already protected by an ES GuardPoint or has already been initialized using the `voradmin esg config` command. The error message shows the disk label that was assigned to the device when it was initialized.

To determine the ESG status of all disks on the host, use the `voradmin esg status` command.

Failed to initialize disk with CTE ESG protection. Size must be greater than %xMB, Current size: %yMB

This error occurs when there is not enough free disk space to store the ES Header in the CTE private region on the disk.

Solution: Increase the disk size to at least the size shown in the error message.

Disk is initialized successfully with CTE ESG protection.

This notification indicates that CTE ESG protection has been successfully applied to the disk.

Disk is initialized successfully with CTE ESG protection. Disk must be Resized to at least 128MB before guarding as Efficient Storage GuardPoint

This message occurs after you use the `voradmin esg config xform` command on an existing disk. It indicates that the initialization was successful but that you must now increase the disk size by at least 128MB before you can apply the ES GuardPoint through the DSM.

Failed to initialize disk with CTE ESG protection. The specified disk does not exist or is not online.

This error message occurs when CTE cannot find the disk specified on the `voradmin esg config` command.

Solution: Check in the disk management utility to make sure the disk is available on the system. If it has gone offline, bring it back online and re-submit the `voradmin esg config` command. If the disk appears to be online and can be accessed by other applications but ESG still cannot find it, please contact Thales Support for troubleshooting and recovery.

Disk with specified label does not exist. Please select another disk.

This error occurs when the disk label specified on a `voradmin esg` command does not exist.

Solution: Check the disk label and resubmit the command. To see all available disk labels, use the `voradmin esg status` command.

Header deletion failed with error code

This error occurs when the Administrator enters the `voradmin esg delete <disk-label>` command for a valid ES disk but CTE cannot delete the ES Header from the specified disk.

Solution: Please contact Thales Support for troubleshooting and recovery.

Disk is protected with CTE ESG. Please unguard the disk before deleting ESG header.

This error occurs when the Administrator enters the `voradmin esg delete <disk-label>` command but there is still an ES GuardPoint assigned to the disk in the DSM.

Solution: Remove the ES GuardPoint through the DSM and then re-submit the `voradmin esg delete` command.

CTE ESG header deleted successfully.

This message indicates that CTE has successfully deleted the ESG header on the disk specified in the `voradmin esg delete <disk-label>` command.

CTE ESG header does not exist on the selected disk. Please select another disk

This message occurs when the Administrator enters the `voradmin esg delete <disk-label>` command but CTE cannot find an ES Header on the specified disk.

Solution: Check the disk label and resubmit the request. If the disk label is correct and the problem persists, please contact Thales Support for troubleshooting and recovery.

Chapter 13: Upgrading CTE on Windows

This chapter describes how to upgrade an existing VTE for Windows host to CipherTrust Transparent Encryption (CTE) for Windows.

Note

Currently, you can only upgrade a VTE for Windows host to CTE version 7.0.0.47 if you continue to use the DSM as your key manager. You cannot upgrade a VTE host to CTE and then register the upgraded CTE host with CipherTrust Manager. The migration path to CipherTrust Manager will be available in a future release.

This chapter contains the following sections:

- [To Upgrade in Windows Silently 135](#)
- [Verify the Windows Installation 135](#)
- [Resolving Problems that Prevent Silent Install 136](#)
- [CTE Scheduled Upgrade 136](#)
- [Workaround for MSI CTE Typical, Silent, and Scheduled Upgrades 137](#)

To Upgrade in Windows Silently

If you have already installed CTE on a Windows computer and want to upgrade it silently, use the appropriate command below for the type of installation binary that you are using.

Note

The protected host must be able to connect to the DSM that it is registered to or the upgrade will fail.

Upgrade using self-extracting .exe

```
vee-fs-7.0.0-47-win64.exe /s /v" /qn"
```

Upgrade using MSI

```
msiexec.exe /i vee-fs-7.0.0-47-win64.msi /qn REINSTALLMODE=voums REINSTALL=ALL
```

Before upgrading using MSI, you must rename the installation file to the name of the previously used MSI installation file. See ["Workaround for MSI CTE Typical, Silent, and Scheduled Upgrades" on page 137](#) for more information.

Note

For all types of upgrades, including interactive (GUI-based) and scheduled upgrades, the protected host must be able to connect to the DSM that it is registered to or the upgrade will fail.

Verify the Windows Installation

After running a silent install, verify the installation by checking CTE processes.

1. In the system tray, right-click the CipherTrust Lock icon.
2. Select **Status**. Review the information in the Status window to confirm the correct CTE are installed and registered.

Resolving Problems that Prevent Silent Install

If you encounter problems using MSI or self-extracting .exe silent install commands, first check the syntax of the command. To further investigate installation issues, you can use Microsoft diagnostics software:

- For desktop versions of Windows: [Microsoft Diagnostics Troubleshooting Wizard](#)
- For server versions of Windows: [Microsoft Automatic Troubleshooting Services](#) (MATS)

Refer to the Microsoft documentation on the linked pages for more information. See the *Compatibility Matrix for CTE Agent with Data Security Manager* for a list of versions of Windows that are supported for use with CTE.

CTE Scheduled Upgrade

Scheduled upgrade allows you schedule an upgrade of the CTE agent to occur after the next time the server hosting the agent reboots normally. Scheduled upgrade can minimize CTE service interruptions. Also, scheduled upgrade can reduce coordination issues in organizations where the security roles are separated.

Notes

- Install all Microsoft update patches before scheduling a CTE Agent upgrade. Otherwise, the upgrade will fail.
- The CTE scheduled upgrade feature is compatible with Windows Server 2008 R2 and higher versions.
- Currently, you can only upgrade a VTE for Windows host to CTE version 7.0.0.47 if you continue to use the DSM as your key manager. You cannot upgrade a VTE host to CTE and then register the upgraded CTE host with CipherTrust Manager. The migration path to CipherTrust Manager will be available in a future release.
- For all types of upgrades, including interactive (GUI-based) and scheduled upgrades, the protected host must be able to connect to the DSM that it is registered to or the upgrade will fail.

Scheduling a CTE Upgrade on the Command Line

To schedule CTE to upgrade the next time the system reboots, type:

```
> voradmin upgrade schedule <CTE setup executable path>
```

Self-extracting .exe Example

```
> voradmin upgrade schedule C:\6.0.3.15\vee-fs-7.0.0-47-win64.exe
```

MSI Example

```
> voradmin upgrade schedule C:\7.0.0.47\vee-fs-7.0.0-47-win64.msi
```

System Response

```
Creating and installing service to upgrade. CTE agent will be upgraded on next reboot.
```

WARNING

If you have scheduled an upgrade on reboot and the system crashes or is not shutdown gracefully, you must restart the system again to upgrade the agent.

Scheduling a CTE Upgrade Interactively (self-extracting .exe only)

When you open the self-extracting .exe CTE installation binary and a version of CTE is already installed, you have the option of upgrading immediately or initiating a scheduled upgrade. See the procedure below for details. This is an alternative to scheduling an update on the command line using `voradmin` (see ["Scheduling a CTE Upgrade on the Command Line" on the previous page](#)).

1. Move the self extracting .exe CTE installation binary to the computer on which you want to initiate the scheduled upgrade.
2. Double-click the self extracting .exe CTE installation binary to run it.
3. Click through the standard initial dialog boxes like the license dialog box.
4. On the **UPGRADE - Install now or Later** dialog box, click **Schedule Upgrade on next reboot** and then click **Next**.
5. Click **Schedule** on the confirmation dialog box.

The next time the computer reboots, the upgrade will occur.

This interactive method of scheduling an update is not available for MSI CTE installation binaries. You must use the `voradmin` command line scheduled upgrade method.

Show Scheduled CTE Upgrades

To display all scheduled CTE agent upgrades, type:

```
> voradmin upgrade show
```

System Response

```
Current version:      6.0.3.12
Target upgrade version: 6.0.3.15
Upgrade on reboot:    Enabled
```

Cancel a Scheduled CTE Upgrade

To cancel/cleanup a scheduled CTE agent upgrade, type:

```
> voradmin upgrade cancel
```

System Response

```
CTE agent upgrade canceled successfully.
```

Workaround for MSI CTE Typical, Silent, and Scheduled Upgrades

When performing an upgrade, Windows Installer Package (MSI) expects the name of the installation binary to be the same as the binary that you used to install CTE. Because Thales includes the software version and build number in the binary file name, you must rename the installation binary to the name of the previously used MSI installation binary before upgrading using MSI. This applies to any MSI CTE upgrade method: typical (interactive), silent upgrade, and scheduled upgrade. If the name does not match the previous binary file name, the upgrade will fail with error code 1316.

For example, let's say that you installed the CTE Agent using the following installation file:

```
vee-fs-6.3.1.38-win64.msi
```

If you used this binary to install or upgrade CTE, the next time you want to upgrade CTE the installation binary that you download from Thales might have the following file name:

vee-fs-7.0.0.47-win64.msi

To upgrade successfully using MSI, you would need to rename the new installation binary to the previous file name of vee-fs-6.3.1.38-win64.msi before upgrading.

Finding The Name Used For A Previous MSI Installation or Upgrade

If you want to upgrade CTE using an MSI installation binary but don't know the file name that you used during the previous installation or upgrade, you can look it up by using one of the following methods on the computer where you installed CTE:

MSI File Name Lookup Method 1: PowerShell

Run the following command in PowerShell:

```
PS> (Get-WmiObject Win32_Product | where { $_.Name -match "CipherTrust Encryption Expert File System Agent" }).PackageName
```

Rename the new CTE setup installation binary to the file name output from the PowerShell command and proceed with the upgrade.

MSI File Name Lookup Method 2: Windows Registry

Find the following registry entry:

```
HKEY_LOCAL_MACHINE\SOFTWARE\Classes\Installer\Product\  
905CB36BF7940894995701C86901D14F
```

Rename the new CTE installation binary to the file name in the registry and proceed with the upgrade.

Chapter 14: Uninstalling CTE from Windows

Considerations

- The CTE Agent must be removed from the Windows host before the host is removed from the key manager with which it is registered.
- Database applications like DB2 and Oracle can lock the user space while they run. If the uninstall fails because a GuardPoint is in use, determine which applications are using the files in the GuardPoint and stop them. Then run the uninstall again.

Procedure

1. Stop any application from accessing files in the GuardPoint.
2. In the key manager with which this host is registered, do the following:
 - Decrypt any data you want to use after uninstall. After the CTE Agent software is removed, access to data is no longer controlled. If data was encrypted, it will remain encrypted. If decrypted or copied out of the GuardPoint, the data is visible as clear text.

This decryption must be done on *every* GuardPoint on the host if you want to access all existing data on the host.
 - Make sure the Agent and System locks have been disabled for the host.
 - Thales recommends that you remove all GuardPoints from the host before you uninstall the CTE Agent.*Do not* remove the host from the key manager yet.
3. Log on to the host as with system administrator privileges.
4. Use one of the following methods to uninstall the CTE Agent:
 - Use the standard Windows Add/Remove program utility from the Control Panel to remove the CTE software.
 - If you installed the CTE Agent using the MSI file, you can uninstall it using the command line with the `msiexec.exe /x Installation_executable /qn` command. For example:

`C:\> msiexec.exe /x vee-fs-7.0.0-47-win64.msi /qn`
5. Reboot the system when prompted.
6. Remove the host record from the key manager.

Appendix 15: Troubleshooting and Best Practices

Windows Systems

CTE will not register with the DSM

- If there is a firewall between the DSM and CTE, configure `vmd.exe` as a firewall exception on CTE for Windows. Otherwise, the DSM is unable to browse CTE.
- If using a Windows XP or Windows 2003 system Firewall, select **Control Panel > Windows Firewall > Exceptions > Add Program...** and browse for `vmd.exe`. The default location is
`C:\Program Files\Vormetric\DataSecurityExpert\agent\vmd\bin\vmd.exe`
- If using a Windows 7 system Firewall, select **Control Panel > System and Security > Windows Firewall > Allowed Programs...** click **Change settings**, click **Allow another program** and browse for `vmd.exe`. The default location is
`C:\Program Files\Vormetric\DataSecurityExpert\agent\vmd\bin\vmd.exe`

CTE with NFSv4: Permission denied error

You may see a permission denied error if you try to access files on an NFSv4 file system that is guarded by CTE.

CTE imposes a restriction on NFSv4 file systems to prevent write-only permissions from being set on individual files. You can work around this restriction by configuring read and write permissions on the same files.

You can also add a policy that allows write permissions.

This restriction applies only in the case of files resident in guarded NFSv4 file systems.

CipherTrust Transparent Encryption

CTE-Live Data Transformation with CipherTrust Manager

Release 7.0.0

Document Version 1

September 22, 2020

The bottom half of the page features a dark blue background with abstract geometric shapes. On the left, there is a large, bright blue triangle pointing upwards. Below it, a smaller, darker blue triangle points upwards. In the bottom left corner, there is a blue circular shape with a dotted pattern. The right side of the page has a vertical gradient from dark blue at the top to a lighter blue at the bottom, with a dotted pattern at the very bottom.

Preface

CTE-Live Data Transformation with CipherTrust Manager describes how to configure and use CipherTrust Transparent Encryption - Live Data Transformation (CTE-LDT) when the host is registered to CipherTrust Manager. If you want to use a Vormetric Data Security Manager (DSM) as your key manager, see the *CTE-Live Data Transformation with Data Security Manager* guide.

CTE-LDT is an optional, separately licensed feature of CipherTrust Transparent Encryption (CTE). With CTE-LDT, a CipherTrust Manager Administrator can change the encryption key and re-encrypt GuardPoint data without suspending user or application access to the data.

Intended Audience

CTE-Live Data Transformation with CipherTrust Manager is for security teams who want to rekey the existing GuardPoint data, or who need to perform an initial encryption of their GuardPoint data.

Assumptions

CipherTrust Transparent Encryption - Live Data Transformation is an enhancement to existing functionality. This documentation assumes the reader is familiar with the following CipherTrust products and processes:

- CipherTrust Manager
- CipherTrust Transparent Encryption (CTE)
- Key management
- Data encryption

The CTE Agent Documentation Set

The following guides are available for CTE Agent:

- *CTE Agent for Linux Quick Start Guide*
- *CTE Agent for Linux Advanced Configuration and Integration Guide*
- *CTE Agent for Windows Quick Start Guide*
- *CTE Agent for Windows Advanced Configuration and Integration Guide*
- *CTE Agent for AIX Installation and Configuration Guide*
- *CTE-Live Data Transformation with Data Security Manager*
- *CTE-Live Data Transformation with CipherTrust Manager*
- *Compatibility Matrix for CTE Agent with CipherTrust Manager*
- *Compatibility Matrix for CTE Agent with Data Security Manager*
- *Compatibility Matrix for CTE Agent for AIX with CipherTrust Manager*
- *Compatibility Matrix for CTE Agent for AIX with Data Security Manager*
- *Release Notes for CTE for Linux Version 7.0.0.47*
- *Release Notes for CTE for Windows Version 7.0.0.47*
- *Release Notes for CTE for AIX Version 7.0.0.11*

Document Conventions

The document conventions describe common typographical conventions and important notice and warning formats used in Thales technical publications.

Typographical Conventions

This section lists the common typographical conventions for Thales technical publications.

Table 3-1: Typographical Conventions

Convention	Usage	Example
bold regular font	GUI labels and options.	Click the System tab and select General Preferences.
<i>bold italic monospaced font</i>	variables or text to be replaced	https://<Token Server name>/admin/ Enter password: <Password>
<code>regular monospaced font</code>	Command and code examples XML examples	Example: session start iptarget=192.168.253.102
<i>italic regular font</i>	GUI dialog box titles	The <i>General Preferences</i> window opens.
	File names, paths, and directories	/usr/bin/
	Emphasis	<i>Do not</i> resize the page.
	New terminology	<i>Key Management Interoperability Protocol (KMIP)</i>
	Document titles	See <i>CTE-Live Data Transformation with CipherTrust Manager</i> for information about CipherTrust Transparent Encryption.
quotes	File extensions Attribute values Terms used in special senses	“.js”, “.ext” “true” “false”, “0” “1+1” hot standby failover

Notes, tips, cautions, and warnings

Notes, tips, cautions, and warning statements may be used in this document.

A Note provides guidance or a recommendation, emphasizes important information, or provides a reference to related information. For example:

Note

It is recommended to keep tokenization keys separate from the other encryption/decryption keys.

A tip is used to highlight information that helps you complete a task more efficiently, such as a best practice or an alternate method of performing the task.

Tip

You can also use Ctrl+C to copy and Ctrl+P to paste.

Caution statements are used to alert you to important information that may help prevent unexpected results or data loss. For example:

CAUTION

Make a note of this passphrase. If you lose it, the card will be unusable.

A warning statement alerts you to situations that can be potentially hazardous to you or cause damage to hardware, firmware, software, or data. For example:

WARNING

Do not delete keys without first backing them up. All data that has been encrypted with deleted keys cannot be restored or accessed once the keys are gone.

Sales and Support

If you encounter a problem while installing, registering, or operating this product, please refer to the documentation before contacting support. If you cannot resolve the issue, contact your supplier or Thales Customer Support.

Thales Customer Support operates 24 hours a day, 7 days a week. Your level of access to this service is governed by the support plan arrangements made between Thales and your organization. Please consult this support plan for further information about your entitlements, including the hours when telephone support is available to you.

For support and troubleshooting issues:

- <https://supportportal.thalesgroup.com>
- (800) 545-6608

For Thales Sales:

- <https://cpl.thalesgroup.com/>
- CPL_Sales_AMS_TG@thalesgroup.com
- (888) 267-3732

Chapter 1: Introduction to CTE-LDT

This chapter contains the following sections:

Overview of CTE-LDT	11
Keys in CTE-LDT (Versioned Keys)	12
CTE-LDT Policies	12
CTE-LDT Runtime Flow	13
CTE-LDT Administrator Roles	14
Resiliency	15

Overview of CTE-LDT

CipherTrust Transparent Encryption - Live Data Transformation (CTE-LDT) is an optional, separately licensed feature of CipherTrust Transparent Encryption (CTE). With CTE-LDT, after enabling a GuardPoint, a CipherTrust Manager Administrator can encrypt, or rekey, GuardPoint data without blocking user or application access to the data. In CTE-LDT, *rekey* means decrypting data with the current cryptographic key and then encrypting it with a new cryptographic key. The concept of rekey, and how CTE-LDT rekeys data, is described in this document.

After enabling GuardPoints, CTE-LDT performs *initial* encryption or rekeying in the background, unnoticed by users. The data stays live and available. This accelerates CTE deployments and eliminates the need to block application and user access to data during encryption or rekey operations, which can seriously inconvenience users and affect operational efficiency.

With CTE-LDT, the CipherTrust Manager Administrator can create a single CTE-LDT policy for both initial encryption and subsequent rekeying. The same policy applies to production access and security rules without restricting user or application access to data. Applications have continuity of access to GuardPoint data during CTE-LDT.

WARNING

To prevent data loss or corruption, you must stop all applications and users that are accessing files inside a GuardPoint before enabling a Live Data Transformation encryption policy for that GuardPoint. Terminating the applications closes all files that are currently being accessed inside the GuardPoint.

Unlike non-Live Data Transformation policies, however, you do *not* need to keep the GuardPoint offline while data transformation takes place. Instead, you can restart all applications as soon as the GuardPoint has been applied to the host, and CTE will perform the data encryption in the background. This is the only application service downtime required when using CTE-LDT.

Use Cases

This section provides a summary of typical uses for CTE-LDT. The concepts mentioned in this section are described in more detail throughout the rest of this guide.

1. Encrypt unprotected data.

When protecting files in a directory, you must encrypt them. This process is called *initial data encryption*.

2. Convert non-CTE-LDT GuardPoints to CTE-LDT GuardPoints

Use when you have existing GuardPoints that are protected with policies created before you started using CTE-LDT.

3. Rekey process.

Changing the key from one version to another version of the same key provides more security. Using CTE-LDT, you can change the encryption keys to more secure keys.

4. Transform the encrypted data to clear data.

Keys in CTE-LDT (Versioned Keys)

CTE-LDT uses *versioned* keys. Each version of a particular versioned key has the same key name and encryption algorithm, but its own unique cryptographic material. That means that data encrypted with version 3 of a key named `LDT-Key` *cannot* be decrypted by *any* other version of `LDT-Key`, even though the key name remains the same.

Versioning allows you to add one key to your CTE-LDT encryption policy and then use different versions of that same key to periodically re-encrypt your data over time. CTE-LDT uses the new key material to transform data to the new key version, as part of the same Live Data Transformation policy that also protects the data. The process of re-encrypting data with a new version of the existing key is called *Key Rotation*.

In CipherTrust Manager, you can create a versioned key and then add that key to one or more Live Data Transformation policies. When you use CipherTrust Manager to create a new version of the key, CipherTrust Manager automatically pushes the new key version to any CTE clients associated with the Live Data Transformation policies that contain the key. As soon as the CTE Agent receives the new key, it begins transforming the data to the new key version in the background.

You can also create a Key Rotation Schedule in CipherTrust Manager that automatically rotates your keys periodically. When the scheduled rekey date is reached, CipherTrust Manager automatically creates a new key version and pushes it to any CTE clients that are associated with any policies that include the key. When CTE receives the new key version, it automatically starts the rekey process on the affected CTE-LDT GuardPoints.

Rekey | Key Rotation

In CTE-LDT, *rekeying* or *key rotation* means decrypting the data with a previous version of the key and re-encrypting it with a new version of the key. CTE-LDT allows users and applications to access data while CTE-LDT is rekeying the data. Rotating the key and re-encrypting the GuardPoint data with the new version of the key helps to maintain a high level of data security.

Most often, the rekey happens automatically based the Key Schedule defined in CipherTrust Manager, but you can also generate a new version of the key whenever you want to rekey the GuardPoints associated with that key.

CTE-LDT Policies

In CTE-LDT, you define a single policy for initial data encryption and subsequent rekeying. The policy specifies:

- **Current key**

Associated with data that you want to protect using CTE-LDT. This is either a non-versioned key from an earlier policy, or `clear_key`, which means that the data is not currently encrypted.

- **Transformation key**

The versioned key that CTE-LDT applies to transform the data from the key used for initial data transformation. When the transformation key rotates, it transforms the data from a previous version of the transformation key to a new version.

Note

Transformation key and versioned key are used interchangeably throughout this document.

As soon as CTE-LDT applies the policy to a GuardPoint and enables protection for it, CTE-LDT triggers an initial transformation from the current key to the transformation key.

When the transformation key expires, it generates the next version of the versioned key with new cryptographic material. The CipherTrust Manager then pushes the policy to the hosts. The policy now contains the new version of the key. This initiates a rekey process on the GuardPoint to transform data to the new version of the transformation key specified in the policy.

Users and applications can continue accessing data without any interruption during initial encryption and subsequent key transformations.

Note

During CTE-LDT policy creation, you must use the Apply Key effect in your policy. If you do not, then end users can see the clear text data until the file is transformed.

CTE-LDT Runtime Flow

This section presents an overview of how CTE-LDT works and what to expect when CTE-LDT is enabled and running in your environment. All of the tasks mentioned here are described in more detail later in this chapter.

First, the administrator completes CTE-LDT setup:

1. Upload the CTE-LDT license on the CipherTrust Manager.
2. Register CTE-LDT hosts with the CipherTrust Manager and be sure that the hosts are licensed for CTE-LDT.
3. Create one or more versioned keys.
4. Optionally create a Key Rotation Schedule or add your new keys to an existing schedule.
5. Define Live Data Transformation policies which use the versioned key(s) and contain rules governing CTE-LDT operations.
6. Optionally provide Quality of Service (QoS) settings for the CTE-LDT hosts. The QoS settings control the:
 - Window of time in which CTE-LDT operations are allowed to run.
 - Percentage of CPU resources that CTE-LDT can use, or the amount of data to transform according to the QoS setting per the CipherTrust Manager Administrator.

Note: Configuring the QoS settings is highly recommended as a best practice.

When these items are set up, CTE-LDT is ready to transform and encrypt data by applying policies to GuardPoints for live initial transformation and subsequent rekeys, as well as enforcement of security rules.

CTE-LDT goes through the following phases after the keys and Live Data Transformation policies are defined:

1. Initial data transformation starts

CTE-LDT begins when an Live Data Transformation policy is first applied to a GuardPoint or an LDT key is automatically rotated through a key rotation schedule in CipherTrust Manager. When a client that uses the associated policy contacts CipherTrust Manager, CipherTrust Manager sends the new policy, or the the key rotation notification, to the client. (If the same versioned key is used in multiple policies, *all* of the clients associated with the policies that contain the key are notified when the key changes.)

2. New key version triggers a rekey on the affected GuardPoints

On each client, CTE determines which GuardPoints are using the key that has just rotated to a new version. CTE starts an CTE-LDT rekey on each of those GuardPoints.

On Windows, you must wait for the current key rotation process to finish before you can launch another rekey request. On Linux, if another rekey is already underway on that GuardPoint, the new rekey is queued for later execution. For details, see ["Rotating Encryption Keys While a Rekey is in Progress \(Relaunch\)" on page 45](#).

3. Scan for files

On each GuardPoint where CTE has started a rekey, CTE-LDT determines which files to transform. CTE-LDT takes inventory of files encrypted with earlier versions of the rotated key and makes a persistent list of the files for transformation.

The scan phase might be interrupted, such as by a host reboot. In this case, when the host reboots and the GuardPoint is enabled again, the scan operation starts over from the beginning.

4. Rekey/Key Rotation

- a. Each file, from the persistent list of files, is decrypted using the old version of the key. The old key is applied to each file and then re-encrypted using the new version of the key. Note that new files created during the CTE-LDT process do not need to be rekeyed, as they inherit the new version of the key. Multiple files and multiple regions of files are rekeyed simultaneously.
- b. The CTE-LDT extended attribute of each file is updated. (For more about extended attributes, see ["CTE-LDT Metadata in Extended Attributes" on page 57](#).)
- c. You can suspend and resume the CTE-LDT rekey operation manually, or through the QoS schedule. This manages the impact CTE-LDT has on other applications and processes.

If system errors occur during rekeying, such as IO errors or crashes, CTE-LDT can manage and recover from them after the system error is fixed.

5. Finish

When all of the required files in the GuardPoint have been rekeyed, the system and storage resources used by CTE-LDT are released, except for the storage required for the extended attributes.

CTE-LDT creates a rekey report, listing all of the files that were rekeyed. For more information, see ["Obtaining a Rekey Report" on page 79](#).

Upon completion of rekey, the Rekey Status in the GuardPoint Status window of the CipherTrust Manager Console shows Rekeyed.

CTE-LDT Administrator Roles

Using CTE-LDT requires coordination and collaboration between several different administrators. Security, system, application performance and backup schedules are critical factors that affect planning. It is very important for the **CipherTrust Manager Administrator** to coordinate with the **system administrator** and the **backup administrators**. The following table describes the roles and responsibilities for these administrators.

CTE-LDT Administrators

Role	Responsibility	Actions
CipherTrust Manager Administrator	Administers CipherTrust Manager	Coordinates with system and backup administrators. Creates security policies, key rotation schedules, and rules for CTE-LDT. Defines Quality of Service settings for CTE-LDT, applications, and backups.

Role	Responsibility	Actions
System administrator	Administers servers on which CipherTrust Transparent Encryption (CTE) is deployed	Coordinates with the CipherTrust Manager Administrator to create Quality of Service schedule, taking into consideration the backup schedules.
Backup administrator	Manages data backups for data encrypted by CTE	Coordinates with the CipherTrust Manager Administrator to create Quality of Service schedule, taking into consideration the backup schedules.

Resiliency

CipherTrust Transparent Encryption - Live Data Transformation is resilient to many user actions and system occurrences. Since it is designed to run periodically without intervention, it includes various features to provide this resilience.

Before CTE-LDT enables a GuardPoint, it checks for any inconsistencies in files that were undergoing rekey at the time when system operations were interrupted. If it finds any inconsistencies, CTE-LDT corrects them before it enables the GuardPoint. It should only take a few seconds to identify and correct any inconsistency. On Windows, this process is delayed until applications access the affected files.

During rekey, if an issue such as an I/O problem or system crash occurs, the resiliency features of CTE-LDT ensures the consistency of user data. Such issues can cause an interruption in the middle of a rekey operation. When system operations resume, CTE-LDT corrects the problems and then resumes rekeying.

Chapter 2: Getting Started

This chapter contains the following sections:

Using CTE-LDT	16
Backup/Restore	17
Restrictions	17

Using CTE-LDT

Notes

- If you are new to CTE and CTE-LDT, read the CipherTrust Manager documentation first to familiarize yourself with the concepts of GuardPoints and Policies.
- Before installing CTE-LDT, see the *Compatibility Matrix for CTE Agent with CipherTrust Manager* to verify that your version of Linux is supported. Contact Thales Technical Support (<https://supportportal.thalesgroup.com>) for the matrix.

The following list contains the steps for successfully setting up and using CTE-LDT.

1. Install the CTE-LDT License on the CipherTrust Manager.
CipherTrust Transparent Encryption - Live Data Transformation is a separately-licensed feature of CTE. Before you can use it, you have to install the license to activate it. CTE-LDT is licensed for a specific number of hosts. For details about licensing, see the CipherTrust Manager documentation.
2. Install the CTE Agent and select the CTE-LDT feature during the install. For more information, see ["Installing and Registering the CTE Agent Software" on page 20](#).
If the client is already registered with CipherTrust Manager, you can enable CTE-LDT on the client through the CipherTrust Manager Console. For more information, see ["Enabling CTE-LDT on a Protected Host" on page 22](#).
3. Create Versioned Keys.
CTE-LDT uses *versioned keys*. A versioned key rotates to the next version of the key generating new key material automatically without policy change. CTE-LDT encrypts data with keys that use encryption standards like AES-256. This allows data to be re-encrypted without users having to edit the policy.
For more information, see ["Keys in CTE-LDT \(Versioned Keys\)" on page 12](#) and ["Creating and Viewing Versioned Keys" on page 24](#).
4. Optionally create a Key Rotation Schedule that will automatically rotate the versioned keys periodically. For more information, see ["Creating a Key Rotation Schedule" on page 39](#).
5. Create CTE-LDT Policies.
CTE-LDT uses a single Live Data Transformation policy to address both initial encryption and subsequent rekeying. The same policy applies to production access and security rules without restricting user or application access to data. Applications have continuity of access to GuardPoint data during CTE-LDT.
For more information, see ["Creating CTE-LDT Policies" on page 26](#).
6. Set QoS Settings.
QoS enables administrators to manage and control CTE-LDT impact to application workloads by monitoring and controlling the use of host system resources, such as memory or I/O utilization, during CipherTrust Transparent Encryption - Live Data Transformation. Administrators can also choose schedules for data transformation, or manually pause or resume transformation operations.
For more information, see ["Quality of Service" on page 29](#).

7. Create GuardPoints and Apply CTE-LDT policies to the GuardPoints

A GuardPoint is a directory in the file system hierarchy, where its contents have a CipherTrust data protection policy applied to it. The CTE Agent intercepts any attempt to access anything in the GuardPoint and uses the policies obtained from the CipherTrust Manager to grant or deny the access attempt. Typically data copied into a GuardPoint is encrypted, and only authorized users can decrypt and use that GuardPoint data.

For more information, see ["Create an CTE-LDT GuardPoint" on page 37](#).

Backup/Restore

Before you enable GP with CTE-LDT policies, make sure that you back up your data.

For more information, see ["Backing Up and Restoring CTE-LDT GuardPoints" on page 62](#).

Restrictions

Remember the following restrictions when using CTE-LDT:

- CTE-LDT does not support nested GuardPoints, where a GuardPoint is contained inside another GuardPoint.
- For HA clusters, CTE-LDT only supports the Asymmetric (active/passive) configuration. CTE-LDT does not support Symmetric (active/active) configuration.

Windows Only Limitations

CTE-LDT does not support GuardPoints on CIFS network shared directories.

Linux Only Limitations

- CTE-LDT does not support Linux automounted file systems.
- CTE-LDT does not support system hibernation (`pm-hibernate`) on Linux hosts where CTE-LDT is in use.
- CTE-LDT does not support GuardPoints on NFS shares and `secvm` configured devices.
- Do not use CTE-LDT on GuardPoints over XFS and VxFS file systems at the same time.
- You cannot use CTE-LDT and Docker container on the same host.
- You cannot use CTE-LDT and OpenShift container on the same host.

Chapter 3: Setting Up CTE-LDT

This chapter contains the following sections:

System Requirements	18
Installing the CTE-LDT License	19
Installing and Registering the CTE Agent Software	20
Setting the Linux Kernel Time Zone	22
Enabling CTE-LDT on a Protected Host	22

System Requirements

CipherTrust Transparent Encryption - Live Data Transformation (CTE-LDT) requires the following environment.

Note

See the latest *Compatibility Matrix for CTE Agent with Data Security Manager*, in the online support portal, for a list of CTE versions and supported operating systems.

CipherTrust Software Requirements

- CTE Agent version 7.0.0 or higher must be installed on every client that you want to protect.
- The CipherTrust Manager with which these clients are registered must be version 2.0.0 or higher.

CTE-LDT License Requirements

One CTE-LDT license is required for *each* protected host.

Host System Requirements

Memory requirements: Both Linux and Windows require a minimum of 8 GB memory on each protected host.

Disk space requirements: CTE-LDT requires a specific amount of disk space in the file system, over and above the space required for the guarded files themselves. CTE-LDT uses the additional space to store CTE-LDT metadata.

- For Linux, to estimate the amount of free file system disk space required by CTE-LDT on a Linux host, use the `voradmin ldt space` command.
- For Windows, the typical minimum space requirement for a GuardPoint is the number of files in the GuardPoint multiplied by 4K, plus 256MB. To estimate the amount of free space required for a GuardPoint, use the `voradmin ldt space <GuardPoint-name>` command.

Backup Requirements

The backup application must have the capability to back up user-extended attributes. For example, Thales tested CTE-LDT with NetBackup. You can also use other applications that can back up user-extended attributes.

Note

For Windows, the application must use Volume Shadow Copy service (VSS) for backup and restore.

Linux-Specific Requirements

To use CTE-LDT on an ext3 or ext4 file system, the block size **must** be 4K. Run `dumpe2fs` to determine the block size of the ext3 or ext4 file systems before using CTE-LDT. This limitation does not apply to XFS or VxFS file systems. You can use CTE-LDT on XFS with a block size of 1K or 2K.

For CTE-LDT to work properly, the underlying file system must support and enable user-extended attributes. All of the file systems supported by CTE-LDT support these attributes. If you are using CTE-LDT with ext3 or ext4 mount points, you must explicitly enable the extended attribute mount option by editing `/etc/fstab` and adding the `user_xattr` mount option. In the other file systems supported by CTE-LDT, user extended attributes are enabled by default, so you do not have to explicitly enable them.

Example `/etc/fstab` entry for ext3 on Red Hat 6 or SLES:

```
/dev/sdb1 /disk2 ext3 defaults,user_xattr 0 0
```

Example `/etc/fstab` entry for ext4 on Red Hat 6 or SLES 12 (ext4 is not supported on SLES 11):

```
/dev/sdc1 /disk3 ext4 auto,users,user_xattr,exec 0 0
```

For more information about extended attributes, see ["CTE-LDT Metadata in Extended Attributes" on page 57](#).

Supported Applications in Linux

For all of the supported operating systems for database applications, see the *Compatibility Matrix for CTE Agent with CipherTrust Manager*.

Replication

- `rsync`.
- Hardware/software based replication system.

SAP HANA Fibre Channel Systems

SAP HANA is compatible with CTE-LDT. See the *Compatibility Matrix for CTE Agent with CipherTrust Manager* and the *CTE Agent for Linux Advanced Configuration and Integration Guide*.

Installing the CTE-LDT License

CTE-LDT installs with the CTE Agent software, but it is a separately-licensed CTE feature. Before you can use it, you have to install the license on the CipherTrust Manager to activate CTE-LDT on any CTE clients. CTE-LDT is licensed for a specific number of clients.

1. Obtain an CTE-LDT license from Thales. You can purchase CTE-LDT along with the CipherTrust Manager software or you can add CTE-LDT later.
2. Install the license on the CipherTrust Manager.
For details, see the CipherTrust Manager documentation.

To confirm that the CTE-LDT license is in effect:

1. In the CipherTrust Manager Applications Page, open the **Admin Settings** application.
2. Click **Licensing** in the left-hand menu bar.
3. Expand the entry for **CTE - Live Data Transformation** in the License table. CipherTrust Manager shows the total number of client licenses in the **Total Clients** field and the total number of licenses used in the **Used Clients** field.

Installing and Registering the CTE Agent Software

Install the CTE Agent software with the CTE-LDT feature on each client you want to protect. The following procedure describes how to use the interactive installer to install CTE and register CTE-LDT. For additional registration options, see the *CTE Agent for Linux Advanced Configuration and Integration Guide* or the *CTE Agent for Windows Advanced Configuration and Integration Guide*.

Prerequisites

Make sure you have the following information from the CM Administrator:

- The registration token for the CipherTrust Manager with which you plan to register the CTE Agent.
- The name of the profile you intend to assign to the client if you want to use a profile other than the default client profile.
- Optionally, the name of the host group you want this client to be a part of.

Procedure

1. Log on to the host where you will install the CTE Agent as `root`. You cannot install the CTE Agent without `root` access.
2. Copy or mount the installation file to the host system. If necessary, make the file executable with the `chmod` command.
3. Install the CTE Agent. A typical installation uses the following syntax:

```
# ./vee-fs-<release>-<build>-<system>.bin
```

For example:

```
# ./vee-fs-7.0.0-47-rh8-x86_64.bin
```

To install the CTE Agent in a custom directory, use the `-d <custom-dir>` option. For example:

```
# ./vee-fs-7.0.0-47-rh8-x86_64.bin -d /home/my-cte-dir/
```

Note: If possible, Thales recommends that you use the default directory `/opt/vormetric`.

To view all installer options, use the `-h` parameter. For example:

```
# ./vee-fs-7.0.0-47-rh8-x86_64.bin -h
```

4. The Thales License Agreement displays. When prompted, type **y** and press Enter to accept.

The install script installs the CTE Agent software in either `/opt/vormetric` or your custom installation directory and then prompts you about registering the CTE Agent with a key manager.

```
Welcome to the CipherTrust Transparent Encryption File System Agent
Registration Program.
```

```
Agent Type: CipherTrust Transparent Encryption File System Agent
Agent Version: 7.0.0.47
```

```
In order to register the CipherTrust Transparent Encryption File System Agent
with a Vormetric Data Security Manager
```

- 1) you must know the host name of the machine running the DSM (the host name is displayed on the Dashboard window of the Management Console), and
- 2) unless you intend to use the 'shared secret' registration method, the agent's host machine must be pre-configured on the DSM as a host with the 'Reg. Allowed' checkbox enabled for this agent type on the Hosts window of the Management Console.

```
In order to register with a CipherTrust Manager you need a valid registration
token from the CM.
```

```
Do you want to continue with agent registration? (Y/N) [Y]:
```

5. Enter **y** to continue with the registration process. The install script prompts you to enter the host name or IP address of the CipherTrust Manager with which you want to register CTE. For example:

```
Do you want to continue with agent registration? (Y/N) [Y]: y
```

```
Please enter the primary key manager host name: 10.3.200.141
```

```
You entered the host name 10.3.200.141
Is this host name correct? (Y/N) [Y]: y
```

6. Enter the client host name when prompted.

```
Please enter the host name of this machine, or select from the following
list.
```

```
[1] sys31186.qa.com
[2] 10.3.31.186
```

```
Enter a number, or type a different host name or IP address in manually:
What is the name of this machine? [1]: 2
You selected "10.3.31.186".
```

7. Enter the CipherTrust Manager registration token, profile name, host group and host description. If you omit the profile name, CipherTrust Manager associates the default client profile with this client.

```
Please enter the registration token: 12345
Please enter the profile name for this host: My-Profile
Please enter the host group name for this host, if any:
Please enter a description for this host: RHEL7 system West Coast Datacenter
```

```
Token           : 12345
Profile name     : My-Profile
Host Group       : (none)
Host description : RHEL7 system West Coast Datacenter
Are the above values correct? (Y/N) [Y]: y
```

- At the hardware association prompt, select whether you want to enable the hardware association feature to prevent cloning. The default is **y** (enabled):

```
It is possible to associate this installation with the hardware of this
machine.  If selected, the agent will not contact the key manager or use any
cryptographic keys if any of this machine's hardware is changed.  This
can be rectified by running this registration program again.
Do you want to enable this functionality? (Y/N) [Y]: y
```

- At the LDT prompt, specify that you want this client to use CTE-LDT by typing **Y** and pressing Enter:

```
Do you want this host to have LDT support enabled on the server? (Y/N) [N]: y
```

- At the Cloud Object Storage (COS) prompt, specify whether you want this client to use CTE COS.

```
Do you want to configure this host for Cloud Object Storage? (Y/N) [N]:
```

- CTE finishes the installation and registration process.

```
Generating key pair for the kernel component...done.
Extracting SECFS key
Generating EC certificate signing request for the vmd...done.
Signing certificate...done.
Enrolling agent with service on 10.3.200.141...done.
Successfully registered the CipherTrust Transparent Encryption File System Agent with the
CipherTrust Manager on 10.3.200.141.
```

```
Installation success.
```

- In CipherTrust Manager, change the client password using the manual password creation method. This password allows users to access encrypted data if the client is ever disconnected from the CipherTrust Manager. For details on changing the password, see the CipherTrust Manager documentation.

Setting the Linux Kernel Time Zone

The Linux kernel contains an internal time structure that may or may not contain time zone information. On system configurations that do not contain time zone information, CTE-LDT stores and displays timestamps for rekey beginning and ending in UTC (Coordinated Universal Time) rather than the system's local time zone. If this occurs, the administrator can set the kernel's internal time zone to the local time zone if they desire timestamps in their local time zone.

To set the Linux Kernel time zone information, at boot time type:

```
# hwclock --systz
```

The command sets the kernel's time zone to the local time zone and resets the System Time based on the current time zone.

Note

On systems that do not set the time zone by default, existing timestamps for completed rekeys remain in UTC, even if you run `hwclock --systz`. Only timestamps for new rekeys display the local time zone.

Enabling CTE-LDT on a Protected Host

When you install CTE on a host, you can enable CTE-LDT during the registration process as described in "[Installing and Registering the CTE Agent Software](#)" on page 20. If you have already registered the host with CipherTrust Manager, you can enable CTE-LDT in the client entry in CipherTrust Manager.

Note

The CTE-LDT license is valid for a certain number of clients. Once you reach this limit, you can either purchase additional CTE-LDT licenses, or reclaim a license by removing a CTE-LDT client. For details, see ["Removing CTE-LDT and Security Encryption" on page 73](#).

You cannot disable CTE-LDT on a client once it has been enabled.

To enable CTE-LDT on an existing host:

1. In the CipherTrust Manager Applications Page, open the **CTE** application and click **Clients** in the left-hand menu bar.
2. Click on the name of the client on whom you want to enable CTE-LDT.
3. On the Client Details page, select the **Live Data Transformation** check box, then click **Apply** to enable CTE-LDT on the protected host.

Note: After CTE-LDT has been enabled for the host, the check box is greyed out because you cannot change this option once it has been set.

Chapter 4: Using CTE-LDT

Creating and Viewing Versioned Keys	24
Creating CTE-LDT Policies	26
Quality of Service	29
Create an CTE-LDT GuardPoint	37
Rotating Encryption Keys (Rekey)	39
File System Operations	45
Excluding Files or Directories from Rekey	48
Using CTE-LDT with SAP HANA Fibre Channel Systems (Linux Only)	56

Setting up keys, policies, and GuardPoints with CTE-LDT is very similar to performing the same tasks in CTE without CTE-LDT. However, there are some differences.

This chapter contains the steps, in order, for successfully setting up and using CTE-LDT.

Creating and Viewing Versioned Keys

For CTE-LDT, you create a versioned key that you can add to any number of Live Data Transformation policies. When you add a new key version, CipherTrust Manager pushes the new version to every CTE client that is associated with any of they Live Data Transformation policies that contain that key.

Use the **Keys & Access Management** application in the CipherTrust Manager Applications Page when creating or viewing versioned keys.

CAUTION

Make sure that all keys you create for CTE-LDT are Symmetric. CTE-LDT does not support asymmetric keys.

Creating a Versioned Key

1. Log into the CipherTrust Manager Console as an administrator.
2. Open the **Keys & Access Management** application.
3. Click **Create a New Key**.
4. Enter a Key Name so that you will be able to find this key easily when you want to rotate it. For example, LDT-Key-1.

Note

When CipherTrust Manager displays the list of available keys, you cannot filter the list by versioned vs. non-versioned. Therefore, it is especially important to name the key in such a way that you can easily search for it by name.

Using a standard naming convention will also help if you want to create an automatic key rotation schedule for all your CTE-LDT keys.

5. In the **Key Metadata > Groups for Key sharing** section, do the following:
 - a. In the **Search** box, type "cte".
 - b. Add CTE Admins and CTE Clients to the key sharing groups by clicking the green **Add** button. The **Key Shared?** check box is automatically selected and the **Add** button changes to a **Remove** button.

- c. Below the Groups table, click the **CTE Key Properties** check box.

CipherTrust Manager displays the following options for CTE keys:

- **CTE Versioned:** Specifies that this is a versioned key. Make sure this option is selected.
- **Persistent on Client:** Specifies whether the key is stored in persistent memory on the client.

If this option is selected, the key is downloaded and stored (in an encrypted form) in persistent memory on the client.

If this option is *not* selected, the key is downloaded to non-persistent memory on the client. Every time the key is needed, the client retrieves it from the CipherTrust Manager. This is the default setting.

- **Encryption Mode:** Encryption mode of the key. Choose one of the following for CTE-LDT keys:
 - CBC
 - CBC CS1

Encryption using CBC CS1 keys is known as enhanced encryption. For details, see the *CTE Agent for Linux Advanced Configuration and Integration Guide* or the *CTE Agent for Windows Advanced Configuration and Integration Guide*.

Note: XTS encryption is not supported for protecting directory-based GuardPoints. Do not select XTS as your encryption mode.

6. In the Key Behaviors section at the bottom of the page, clear the **Prevent this key from being exported** check box. If the key cannot be exported, the key will not appear in the keys list when you add the key rule to the policy. If you want the option to delete this key later on, clear the **Prevent this key from being deleted** check box. Use caution when deleting keys, as any data encrypted with that key will be inaccessible if you delete the encryption key.

7. Click **Create**. The new key appears in the Keys table.

Viewing Versioned Key Information

1. Log into the CipherTrust Manager Console as an administrator.
2. Open the **Keys & Access Management** application.
3. Click the **Latest Version Only** check box to show only one entry for each versioned key.
4. Find the key in the Keys table.

Tip: You can filter the list by key name using wildcard searches. For example, if you know that the key name contains "LDT", you can search for *ldt*. The search is *not* case sensitive.

If the **Version** for a key is 0, then this is the first version of the key and no key rotation has taken place. If the **Version** is greater than 0, the key has been rotated.

Note: When you create a CBC CS1 key, CipherTrust Manager automatically makes a second key called <key-name>_xts. This key is maintained and used by CipherTrust Manager, and it can be ignored when you are looking at your CTE-LDT keys.

5. To find all versions of a key, click the name of the key in the **Key Name** column. CipherTrust Manager displays the ID, version number, state, and date created information for each version of the key.

Creating CTE-LDT Policies

CTE-LDT uses a single Live Data Transformation encryption policy to address both data transformation and ongoing protection. In contrast, if you do not use CTE-LDT, you need a separate policy for initial data transformation, or rekey, and another policy to protect the data while it is in production use. For more information about CTE-LDT policies, see ["CTE-LDT Policies" on page 12](#).

To create an Live Data Transformation encryption policy:

1. In a web browser, navigate to the URL of the CipherTrust Manager you want to use and log in with CipherTrust Manager Administrator credentials.
2. If the client you want to protect is registered to the default domain (root), proceed to the next step. If you need to change to a different domain, do the following:
 - a. In the top menu bar, click the domain/user name (default: **root/admin**) on the right-hand side.
 - b. Select **Switch Domains**, then select the domain in which the client is registered.
 - c. The logged in user now shows the new domain name/user name.

3. In the CipherTrust Manager Applications Page, open the **CTE** application.
4. In the left-hand menu bar on the Clients page, click **Policies**.
5. Click **Create Policy**. CipherTrust Manager displays the Create Policy Wizard.
6. On the General Info page, set the following options:

Field	Description
Name	A unique name for the policy. Make sure you use a name that is descriptive and easy to remember so that you can find it quickly when you want to associate it with a GuardPoint. For example: LDT-Policy-West
Policy Type	Select Live Data Transformation.
Description	A user-defined description to help you identify the policy later. For example: LDT policy for the West Coast Datacenter.
Learn Mode	Learn Mode provides a temporary method for disabling the blocking behavior of CTE/CTE-LDT policies. While useful for quality assurance, troubleshooting, and mitigating deployment risk, Learn Mode is not intended to be enabled permanently for a policy in production. This prevents the policy Deny rules from functioning as designed in the policy rule set. Ensure that the policy is properly configured for use in Learn Mode. Any Security Rule that contains a Deny effect must have Apply Key applied as well. This is to prevent data from being written in mixed states, resulting in the loss of access or data corruption. Apply Key will have no effect when combined with a Deny rule unless the policy is in Learn Mode.

7. Click **Next**.

8. On the Security Rules page, define the security rules you want to use.

CipherTrust Manager automatically adds a default security access rule with an action of `key_op` and the effects `Permit` and `Apply Key`. This rule permits key operations on all resources, without denying user or application access to resources. This allows it to perform a rekey operation whenever the encryption key rotates to a new version. This rule is required by CTE-LDT, so you cannot edit it, move it, or delete it.

To add additional security rules, click **Create Security Rule** and enter the requested information. If you want to grant user and application access to files at all times, including during initial CTE-LDT and subsequent key rotations, add a security rule with the action `all_ops` and the effects `Permit` and `Audit`.

For details about adding security rules, see the CipherTrust Manager documentation.

9. On the Create Key Rule page, click **Create Key Rule** and enter the following information:

Field	Description
Resource Set	If you want to select a resource set for this key rule, click Select and either choose an existing resource set or create a new one. Resource sets let you specify which directories or files will either be encrypted with the key or will be excluded from encryption with this key.
Current Key Name	Click Select to choose an existing key or create a new one. If the data has not yet been encrypted, select clear_key . Otherwise select the name of the non-versioned key that is currently being used to encrypt the data.
Transformation Key Name	Click Select to choose an existing versioned key or to create a new one. CTE uses the versioned key specified in this field to encrypt the data in the GuardPoint. If the data is currently encrypted, CTE decrypts it using the key specified in the Current Key Name field and re-encrypts it using the key specified in this field.

When you are done specifying key rules, click **Next**.

10. On the Confirmation page, review the information you entered and click **Save** when you are ready to save the policy.

The following example shows a simple CTE-LDT policy that encrypts clear-text files using a versioned key named LDT-Key-1. The `key_op` and `all_ops` actions in the Security Rules panel grant user and application access to files at all times, including during initial CTE-LDT and subsequent key rotations.

1 General Info

Name: LDT-Policy-West

Policy Type: Live Data Transformation

Description: LDT policy for the West Coast Datacenter

2 Security Rules

Resource Set	User Set	Process Set	Action	Effect	Browsing
*			key_op	permit,applykey	No
*			all_ops	permit,audit	Yes

3 Key Rules

Resource Set	Current Key Name	Transformation Key Name	Exclusion Rule
	clear_key	LDT-Key-1_v1	No

Quality of Service

CTE-LDT runs in real time, while users actively interact with applications. This could impact performance. However, CTE-LDT is designed to not adversely affect application or system performance.

Purpose of QoS

Quality of Service (QoS) provides tools for an administrator to minimize the effect of CTE-LDT on system and application performance. It provides a set of parameters that administrators can set to control CTE-LDT use of system resources, primarily CPU and I/O bandwidth. When the QoS parameters are set appropriately, CTE-LDT stays within the defined boundaries to ensure that critical user applications are not adversely affected by CTE-LDT operations.

Manage CTE-LDT Impact

Administrators can pause or resume CTE-LDT operations to manage and control CTE-LDT impact to application workload. When data transformation occurs, either during initial or subsequent transformations, it requires substantial host CPU and I/O resources. This can cause contention for resources between the applications simultaneously running on the protected host. The administrator specifies QoS settings on each host, or at a host group level, that is using CTE-LDT. When CTE-LDT is running, QoS monitors CPU or rekey/scan rate on the host and enforces the QoS settings. QoS can also monitor and enforce an administrator imposed limit on the volume of data undergoing rekey per second. The QoS settings enable you to strike a balance between completing an CTE-LDT process and not interfering with host application performance.

Monitor and Control CPU Usage

QoS monitors and controls the use of host system resources during CTE-LDT, specifically, CPU usage and rekey/scan rate.

Note

You can control CPU usage or rekey/scan I/O rate, but not both. The CPU usage and rekey/scan I/O rate options are mutually exclusive.

Monitor and Control Rekey/Scan I/O Rate

You can choose Rekey I/O Rate as a threshold to control the CTE-LDT processing rate. When this threshold is entered, the Quality of Service continuously monitors CTE-LDT transformation and enforces the specified amount of data during:

- **Rekeying**—CTE-LDT is transforming the data on active GuardPoints based on the new key version.
- **Scanning**—CTE-LDT is analyzing files in GuardPoints. Scanning occurs:
 - Before initial transformation (Linux only)
 - Before a rekey (Linux only)
 - Following an interrupted rekey, such as a reboot on Linux or Windows, and also a directory rename or directory deletion on Windows

You can set the Rekey I/O Rate or CPU Threshold for multiple clients through the QoS Settings section in a CipherTrust Manager client profile. All clients associated with a given client profile will use the QoS thresholds set in that profile unless the thresholds are overridden locally on the individual client. (The default setting for Rekey I/O Rate in the client profile is 0 (zero), which means QoS will run full throttle.)

To set the QoS thresholds locally on a particular client, use the `voradmin ldt ior <iorate>` command on that client. When you do so, the `voradmin` setting overrides the Rekey I/O Rate or CPU Threshold set in the CipherTrust Manager client profile. If QoS was already set locally on this client and you use `voradmin` to set the Rekey I/O Rate, CTE-LDT ignores any CPU threshold previously set.

To resume using the client profile QoS values for a client, use `voradmin ldt ior 0` to set the Rekey I/O Rate to 0 (zero). When you do so, CTE returns to using the Quality of Service settings in the client profile.

A tolerance level is associated with the Rekey I/O Rate. Together, the tolerance and Rekey I/O Rate specify a range for the CTE-LDT processing rate. The Quality of Service selects a proper tolerance for a Rekey I/O Rate provided through the `voradmin` command, and maintains the CTE-LDT processing rate at the specified Rekey I/O Rate plus or minus the tolerance. The tolerance is selected as follows:

- When the Rekey I/O Rate is less than or equal to 10MB/sec, the tolerance is 3MB/sec.
- When the Rekey I/O Rate is greater than 10MB/sec. and less than 50MB/sec, the tolerance is 4MB/sec.
- When the Rekey I/O Rate is at 50MB/sec or higher, the tolerance is 10% of the specified Rekey I/O Rate.

To set or reset Rekey I/O Rate on a single host, use the `voradmin` command as follows:

- To set the threshold of 50 MB/sec., use the following command:

```
# voradmin ldt ior 50
```

- To reset the current threshold:

```
# voradmin ldt ior 0
```

For more information about setting the Rekey I/O Rate using `voradmin`, see ["Select and Set Rekey I/O Rate" on page 35](#).

QoS Scheduling During Backup/Restore

QoS scheduling plays an important role when backing up/restoring data without the *Apply Key* rule applied to the backup/restore process. During backup/restore, you **must** pause CTE-LDT operations before taking backups. QoS scheduling allows the administrator to enter the schedule for QoS aligned with the backup schedule, and pause the CTE-LDT processes for the duration of the backup. The schedule specifies which days of the week, and what times of day, CTE-LDT is permitted to run. CTE-LDT cannot run at any time that is not permitted by the QoS schedule. QoS suspends CTE-LDT operations at all times outside of the schedule.

When setting a QoS schedule, consider your system and application peak demand periods during the day and week. Also consider your schedule for data backups. Schedule CTE-LDT to pause when you need all available system resources for other tasks, such as meeting peak user demand or performing data backups.

Note

On Windows, if your backup applications are using VSS, then you do not need to pause CTE-LDT on Windows.

How to Set QoS

To set QoS for a host to enforce a threshold on CTE-LDT based on CPU percentage:

1. Log into the CipherTrust Manager Console as an administrator.
2. Open the **CTE** application.
3. In the left-hand menu, select click **Profiles**.
4. If you want to add a new profile, click **Create Profile** and specify a profile name and description.

5. Click the profile name in the **Profiles** table.
6. Click the Quality of Service Configuration section heading to open the QoS options and select one of the following radio buttons:
 - **Rekey by Rate** — Specifies that you want to set a Rekey I/O Rate threshold. Enter a value between 0 and 100 in the associated **LDT QoS Rekey Rate** field. If you specify 0, CTE does not throttle the CTE-LDT rekey or scanning processes.
 - **Rekey by CPU**— Specifies that you want to set a CPU Rate threshold. Enter a value between 0 and 99 in the associated **CPU Percentage** field.

If you select this option, CTE-LDT applies a tolerance of +/- 2% on CPU threshold settings up to 7%. For threshold over 7%, CTE-LDT applies a tolerance of +/- 4%.

If CPU% is set to 0, QoS stops monitoring CPU usage and CTE-LDT operations run at maximum rekey rate within the available system resources. Setting CPU percentage to 0 does not affect CTE-LDT schedules, so CTE-LDT operations are suspended and resumed per QoS schedule.

If you do not enter CPU threshold percentage, CTE-LDT applies CPU threshold of 5% capped by default.

If CPU% is set to a very high value, such as 25%, the rekey process competes with other applications to use as many CPU cycles as it can. As a best practice, start with a setting of 10%, and increase or decrease it slowly by 5% until it reaches a reasonable level that does not adversely affect the performance of user applications. The higher the percentage, the more quickly CTE-LDT completes its processing. However, this speed causes increased competition for resources, which can significantly degrade the performance of other applications using this host.

CAUTION

Do not set CPU% to a very high value in an attempt to force faster data transformation. This can potentially exhaust other system resources.

When you select **Rekey by CPU**, the **Cap CPU Allocation** check box becomes available. Check this box to specify that the CPU allowance must never exceed the percentage set in CPU%. If **Cap CPU Allocation** is not checked, and additional CPU resources are available on the host, CTE-LDT consumes part of the available resources for rekey above the CPU threshold. Exceeding the threshold may impact your production workload as your production CPU resource consumption fluctuates over time.

For example, if CPU% is set to 10%, but **Cap CPU Allocation** is not set, the rekey process continues consuming available CPU cycles after reaching 10% CPU utilization, at which point the rekey process starts contending with applications for CPU cycles.

7. In the QoS Schedules section, select the schedule you want to use from the **LDT QoS Schedule** drop-down list. This list includes the following options:
 - ANYTIME
 - WEEKNIGHTS
 - WEEKENDS
 - CUSTOM

If you select anything other than CUSTOM, CipherTrust Manager displays the time ranges in which CTE-LDT can run in the **Time Ranges** column. If you select CUSTOM, you can then click the **Create New QoS Schedule** button to create a custom schedule. Add one custom schedule entry for each time range in which you want QoS to run.

By limiting CTE-LDT to periods of low application usage, you minimize the potential for resource contention between applications and CTE-LDT.

The following example shows a profile with the CPU threshold capped at 10%. The QoS schedule is set for 1 am to 4 am on Mondays, Wednesdays, and Fridays.

CUSTOM	Friday 1:00 AM - Friday 4:00 AM	...

QoS Best Practices

This section gives tips and examples to help you set QoS parameters for the best results.

General Best Practices for QoS

- Use Rekey I/O Rate threshold to limit CTE-LDT impact, if any, to your production workloads. Rekey I/O Rate approach is a simpler method for a CipherTrust Manager Administrator or system administrator to enforce a limit on the volume of data that CTE-LDT should rekey per second. You can choose a threshold, in units of MBs per second, which is a small percentage of peak IOPS from your production workload.
- You will see the effects of QoS settings only if the number and/or types of files in the GuardPoints stress the rekey or scan processes. On hosts with a relatively small number of files, the rekey or scan process may complete quickly without hitting a threshold and causing throttling to occur.

- Use QoS CPU parameters as an alternate method for controlling the effect CTE-LDT has on application performance.

Set limits on CTE-LDT CPU usage whenever runtime monitoring shows that user applications are affected by CTE-LDT. Start by setting the CPU parameter to 10%, then increase or decrease in 5% intervals, as needed, to tune the CPU allocation. When an acceptable level is reached, and CTE-LDT is not noticeably affecting user applications, leave the QoS CPU parameters at a constant setting.

- Use monitoring tools.

Monitor host CPU utilization with tools like `vmstat`, `top`, and `iotop` on Linux and `perfmon` on Windows.

You can also monitor and obtain statistics with the `voradmin ldt stats` command.

For more information about `voradmin ldt stats`, see ["Obtaining CTE-LDT Statistics at the Command Line" on page 78](#).

- Select CPU resource allocation for CTE-LDT from 1% to the available limit minus 5%.

If the monitoring tools indicate system CPU usage, without CTE-LDT, it is at N%, available CPU resource is M%, where $M = 100 - N$. Select a percentage within 1 - (M - 5) to allocate to CTE-LDT CPU usage. However, remember that QoS tolerates 2% - 4% leeway in the actual CPU usage, so adjust your selection by 2 - 4%.

- Do not set CPU resources to 0% or 99% in an attempt to minimize or stop CTE-LDT

A CPU% value of 0 or 99 is reserved for disabling the QoS CPU monitoring function. This does not stop CTE-LDT or minimize its resource usage; rather the opposite. It enables CTE-LDT to run with its maximum rekey rate. Note that when CPU % is not set, CTE-LDT clients enforce a 5% CPU threshold by default.

- Cap the CPU allocation.

QoS provides a **CAP CPU Allocation** parameter. Set this parameter to **True**. This ensures that CTE-LDT resource usage never exceeds the allocated percentage.

Example: Setting QoS before starting CTE-LDT

You can be proactive and set up QoS parameters before enabling GuardPoints that are protected with CTE-LDT policies. This ensures QoS starts monitoring and controlling CTE-LDT resource usage from the start. The following graph shows an example where 10% of the CPU is assigned to CTE-LDT. QoS makes sure that CTE-LDT is restricted to use only 10% of the CPU. There is a tolerance level of +/- 4%, so actual CTE-LDT usage can range between 5% and 15% of CPU. In the following example, applications use 75% of the CPU resources. As the graph shows, when CTE-LDT starts, application CPU utilization drops for a moment, because CTE-LDT exceeds the CPU threshold. QoS immediately reduces CTE-LDT's CPU usage to 12%, which is within tolerance levels for a 10% setting, and the application CPU share returns to normal.

Figure 4-1: QoS makes visible improvement immediately when CTE-LDT starts

The graph above was obtained on a Linux system running sysbench.

- To find the amount of CPU resources currently in use by applications, type:

```
# top -n 1 -b | grep sysbench | awk 'BEGIN {cpu=0} {cpu += $9} END {print cpu}'
```

- To find the amount of CPU currently in use by the CTE-LDT-protected host, type:

```
# top | grep Cpu
```

- To find the amount of CPU currently in use by CTE-LDT, type:

```
# voradmin ldt stats | grep CPU
```

Example: Monitoring and controlling resource usage during CTE-LDT

Suppose that CTE-LDT has started with CPU set to 25%, and users realize their applications are affected. For example, there might be a higher than expected level of CTE-LDT I/O operations. To return application performance to normal, reduce the CPU allocation for CTE-LDT.

1. Set the **CPU parameter** to a lower value, such as 10%.
2. Select the **Cap CPU Allocation** option.

QoS restricts CTE-LDT CPU usage to 10%. The application user should monitor their application. If the application's performance is still affected, reduce the CPU parameter further, such as to 5%. Repeat this procedure until application performance returns to a satisfactory level.

The following graph shows an example where QoS is not enabled to monitor and control CTE-LDT CPU usage from the start. When CTE-LDT starts, application CPU usage drops from 65% to 20%. By setting the QoS CPU parameter to 10%, application usage is greatly improved.

Figure 4-2: CPU usage allocation before and after QoS CPU parameter is set

Example: How QoS CPU settings affect I/O bandwidth

Controlling CPU utilization indirectly controls I/O bandwidth. When CTE-LDT is consuming less CPU resources, it is usually performing fewer operations of all kinds, including input and output.

The following graph shows how an application's I/O throughput is affected by CTE-LDT, and how QoS can reduce this effect through monitoring and controlling the CTE-LDT CPU resource usage.

This graph is from the same system described in ["Example: Monitoring and controlling resource usage during CTE-LDT" above](#). No QoS parameters are set at first. When CTE-LDT starts, application I/O drops from more than 600 MB per second to below 30 MB per second. By setting the QoS CPU parameter to 10%, the CTE-LDT I/O operations drop to below the application's ability to perform so application I/O operations is greatly improved.

Figure 4-3: I/O operations before and after QoS CPU limit is set

To obtain the data for this graph:

- Use `iotop` and benchmarking tools on an RHEL system to obtain application I/O throughput.
- Use `voradmin ldt stats` to obtain the CTE-LDT I/O throughput and rekey rate.

Select and Set Rekey I/O Rate

You can choose to set the Rekey I/O Rate to control I/O operations from CTE-LDT to minimize CTE-LDT impact to your production workload. It's assumed that you already know the maximum IOPS on your host system during your production workload. With this information, you can choose a threshold for Rekey I/O Rate and enforce the selected threshold during CipherTrust Transparent Encryption - Live Data Transformation. The work flow is as follows:

1. Set **Rekey I/O Rate** threshold using `voradmin` or in the CipherTrust Manager Console.
2. QoS retrieves the threshold and starts monitoring and controlling CTE-LDT according to the specified threshold and the tolerance factor corresponding to the threshold.
3. The selected threshold will be in effect within 2 to 4 minutes after entering the threshold.

When Rekey I/O Rate and CPU or IOWAIT thresholds are set, QoS will monitor and control the CTE-LDT processing rate based on the Rekey I/O Rate threshold. The CPU threshold will be ignored.

Set Rekey I/O Rate Threshold

1. Set **Rekey I/O Rate** threshold by using `voradmin`:

```
# voradmin ldt ior 10
```

You can also set the Rekey I/O Rate for one or more managed hosts using the Quality of Service section in a client profiles. For more information about using this method, see ["How to Set QoS" on page 30](#).

In the `voradmin` example above, QoS enforces the threshold of 10MB/sec with the tolerance of +/- 3MB/second. Effectively, CTE-LDT attempts to rekey the amount of data in the range of 7MBs/second to 13MB/second.

On Linux and Windows, you can use `voradmin ldt ior` to report the current threshold setting without specifying a value for threshold:

```
# voradmin ldt ior
QoS Rekey I/O rate threshold: 10 MB/sec
QoS Rekey I/O tolerance: 3 MB/sec
```

2. Be sure the threshold you enter is appropriate for your production workload. To verify this:

- a. Observe the Rekey I/O Rate for a few minutes using `voradmin`.

On Linux, you can do this using:

```
# voradmin ldt stats
Host level statistics:
File stats: rekeyed=202390, passed=0, created=0, removed=0
Data stats: rekeyed=6.2GB, truncated=0.0MB
QoS: IOR threshold=10MB/sec, tolerance=3MB/sec
current_rekey_rate=2MB/sec, current_iow=0ms
load_factor=50, delay_factor=0, delay_scan=0
```

On Windows, you can do this using:

```
voradmin ldt monitor
Host Stats:
Total number of Guard Points      = 1
Rekey Status                      = Rekey done (Finished rekey on 1 out of 1 GP's)
Total files to be transformed     = 0
Total files transformed           = 0
Total files in progress           = 0
Total transformation threads      = 0

Current rekey rate                = 0 KB/s
Rekey IO rate threshold           = 1000 MB/s
Rekey IO rate tolerance           = 4 MB/s
```

- b. Set an appropriate threshold. Do not set the threshold value too high, as QoS might not be able to achieve it because of other resource bottlenecks.

3. Check the QoS controlling rekey rate.

QoS will monitor and control CTE-LDT utilization using the specified threshold. The following figure shows an example of how QoS monitors and controls CTE-LDT utilization. In this example, the threshold is 30 MB/sec. Throughput of CTE-LDT was nearly 130 MB/sec. QoS brings it down to within the range of 30 MB/second.

4. Disable QoS.

QoS will not monitor and control resources when all the thresholds, CPU, Rekey I/O rate, and IOWAIT are set to 0. When Rekey I/O Rate and IOWAIT are not explicitly set, it is considered to be set to 90 MB/second.

QoS continues to apply its schedules for suspending CTE-LDT operations at certain days and times regardless of what values are set for CPU, Rekey I/O Rate, and IOWAIT thresholds.

Summary of QoS Resources

The following table summarizes the available thresholds and the actions of QoS module to enforce the set thresholds:

Scenario	QoS Action
Only Rekey I/O Rate threshold is set	Monitor and control the CTE-LDT processing rate based on Rekey I/O Rate
Rekey I/O Rate and CPU threshold are set	Monitor and control the CTE-LDT processing rate based on Rekey I/O Rate. CPU threshold is ignored.

Create an CTE-LDT GuardPoint

After you have installed the license and registered the CTE-LDT host (see [Chapter 3: "Setting Up CTE-LDT" on page 18](#)), you can create an CTE-LDT GuardPoint on the host. When you create the CTE-LDT GuardPoint, you select a Live Data Transformation policy and apply that policy with its transformation keys to that GuardPoint. CTE automatically gets the Quality of Service settings from the associated Client Profile in CipherTrust Manager.

This section describes two scenarios:

- ["Create an CTE-LDT GuardPoint for an Unguarded Directory" below](#)
- ["Converting a Non-CTE-LDT GuardPoint to an CTE-LDT GuardPoint" on the facing page](#)

Create an CTE-LDT GuardPoint for an Unguarded Directory

To create an CTE-LDT GuardPoint on what was previously an unprotected/unguarded directory:

1. Create an Live Data Transformation policy that transforms data from clear text to a versioned key. In the policy, set Current Key to `clear_key` and Transformation Key to the versioned key. For details, see ["Creating CTE-LDT Policies" on page 26](#).
2. Set, or modify, the Quality of Service (QoS) parameters in the Client Profile associated with the CTE client to account for CTE-LDT on all GuardPoints on this client. For details see ["Quality of Service" on page 29](#).
3. In the CipherTrust Manager Applications Page, select the **CTE** application.
4. In the Clients table, click on the name of the client you want to protect.
5. Above the GuardPoints table, click **Create GuardPoint**.

6. In the Create GuardPoint page:
 - a. In the **Policy** field, select the CTE-LDT policy you created earlier.
 - b. In the **Type** field, select the type of device. For CTE-LDT, you can select **Auto Directory** or **Manual Directory**.
 - c. In the **Path** field, enter the directories you want to protect with this policy or click **Browse** to select them from a Windows-style explorer.

If you want to enter multiple paths, put each path on its own line.
 - d. Keep the **Preserve Sparse Regions** option selected if you want CTE to ignore sparse regions during data transformation.

A *sparse region* is a region within the file size that has not yet been written to. Therefore, it is not allocated with disk blocks. Any attempt to read a sparse region reads stream of zeros as data. A file may have one or more sparse regions, or an entire file may be sparse.

If you select **Preserve Sparse Regions**, CTE-LDT detects and skips transforming sparse regions. Therefore, it does not change the number of blocks utilized in the file system. This is the default.

If you disable **Preserve Sparse Regions**, CTE-LDT transforms a file without checking or skipping sparse regions, if they exist. Consequently, as CTE-LDT operations transform and fill sparse regions with encrypted stream of zeros, sparse regions are allocated with disk blocks. This increases the number of disk blocks utilized in the file system.
 - e. Click **Create**.
 - f. If you want to use the same policy and GuardPoint type on another path, click **Yes** when prompted. Otherwise, click **No**.

The CipherTrust Manager pushes the GuardPoint configuration to the client and CTE immediately begins transforming the data in the specified folders from clear-text to cipher-text.
7. When the data transformation has finished, applications can resume accessing the now-protected data.

Converting a Non-CTE-LDT GuardPoint to an CTE-LDT GuardPoint

After enabling CTE-LDT on a client, you can change a non-LDT GuardPoint to a CTE-LDT GuardPoint. CTE-LDT GuardPoints provide the advantage of allowing users to access all files in the GuardPoints while encryption is occurring. There is no downtime for the user except for the time needed to apply the GuardPoint.

1. Write a new CTE-LDT policy that transforms data from the non-CTE-LDT/non-versioned key used in the existing GuardPoint, to an CTE-LDT versioned key. See ["Creating CTE-LDT Policies" on page 26](#).
2. Make sure there is no application activity within the GuardPoint.

CAUTION

This step is critical. Do not skip it. Make sure there is no application activity within the GuardPoint.

3. Remove the current GuardPoint.
 - a. Open the **CTE** application and click **Clients** in the left-hand menu bar.
 - b. Click on the name of the client whose GuardPoint you want to change.
 - c. Find the GuardPoint you want to change in the GuardPoints table, then click the (...) button at the end of the row and select **Remove**.
4. Guard the directory again using the new CTE-LDT policy. Use the steps in ["Create an CTE-LDT GuardPoint for an Unguarded Directory" on the previous page](#), but choose the policy that starts from the non-versioned/non-LDT key rather than a policy that starts from `clear_key`.

Rotating Encryption Keys (Rekey)

The following sections describe procedures related to encrypting an existing GuardPoint with a new key (also called rekeying).

Manual Key Rotation

If you need to rekey your GuardPoint prior to the expiration of the current key version, you can manually start a rekey process.

On Windows, you cannot rotate a key until all current data transformations that use the same key have completed, whether those transformations are an initial data transformation or a rekey. On Linux, you can rotate the key at any time. For details, see ["Rotating Encryption Keys While a Rekey is in Progress \(Relaunch\)"](#) on page 45.

1. In the CipherTrust Manager Applications Page, open the **Keys & Access Management** application.
2. Click **Keys** in the left-hand menu bar.
3. In the Keys table, click on the name of the key that you want to rotate.
4. On the Key Detail page, click the Add button (+) above the table to add a new version.

The new version appears in the Versions table.

Creating a Key Rotation Schedule

In CipherTrust Manager, you can create an automatic key rotation schedule that will automatically rotate all of the keys included in the schedule on a periodic basis. As soon as CipherTrust Manager creates a new version of a key, it pushes the new version to any clients associated with the policies that use the key. If the policy is a Live Data Transformation policy, CTE automatically begins rekeying the data in the CTE-LDT GuardPoint with the new version of the key.

1. In the CipherTrust Manager Applications Page, open the **Admin Settings** application.
2. Click **Schedules** in the left-hand menu bar.

CipherTrust Manager displays the existing key rotation and backup schedules that have been defined in the system. Thales strongly recommends that you look at any existing key rotation schedules to make sure that the keys you want to rotate are *not* already included in one of those existing schedules.

If the existing key rotation schedules do not include the keys you want to rotate, continue with this procedure to create a new schedule.

3. On the **Schedules** page, click **Add Schedule**.
4. On the **Select Schedule Type** page, click **Key Rotation** and click **Next**.
5. Add a schedule name and description. Make sure you name the schedule as descriptively as possible so that other users can tell at a glance what keys that schedule includes. For example, you could name the schedule "Rotate-LDT-Keys" and use the description "Rotates all keys with "LDT" in their name on a yearly basis."

When you are done, click **Next**.

6. On the **Schedule Config** page, enter the following information:
 - **Duration**. Enter the day and time on which CipherTrust Manager should start using the key rotation schedule in the **Schedule Starts** field. When this day and time is reached, CipherTrust Manager looks at the date in the **Frequency** section and automatically creates a new version on that date.

Enter the day the schedule should end in the **Schedule Ends** field, or select the **Never** check box to tell CipherTrust Manager there is no end date for this key rotation schedule. If you select a date in this field, CipherTrust Manager automatically stops creating new key versions when that day and time are reached.

- **Frequency**. Select the **Basic** radio button to specify the frequency (daily, weekly, monthly, or yearly) and the UTC time at which CipherTrust Manager should automatically rotate the key after the schedule starts.

Select the **Raw (Cron)** radio button to create a cron job to control the key rotation schedule. Specify cron format in the following order:

minute, hour, day of month, month, and day of week

These five values indicate when the job should be executed. These values are mandatory and must be specified in the order given. The allowable values are:

Field	Allowed Values
minute	0-59 or * / , -
hour	0-23 or * / , -
day of month	1-31 or * / , -
month	1-12 or JAN-DEC or * / , - This field is case in-sensitive, so JAN, Jan, or jan are all equally valid.
day of week	0-6 or SUN-SAT or * / , - This field is case in-sensitive, so SAT, Sat, or sat are all equally valid.

Examples:

- December 31 at 2:35 AM UTC could be specified as: 35 2 31 Dec *
- On the 25th of every April, August, and December at midnight UTC could be specified as:
0 25 APR,Aug,dec *.
- Every Monday, Wednesday, and Friday at 8:00 PM UTC could be specified as: 0 20 * * 1,3,5

When you enter a **Duration** and a **Frequency**, CipherTrust Manager displays the next several times the key rotation will be run under the **Frequency** field. Make sure the key rotation will be done on the days you expect.

Note: While the specified time is in UTC, the scheduled run times are shown in your local time. Therefore there may not be an exact match between the time set in the **Frequency** field and the displayed run time.

When you are done, click **Next**.

7. On the **Key Rotation Page**, specify the selection criteria you want CipherTrust Manager to use when it selects the keys it will rotate.

CAUTION

Make sure you are extremely careful when you specify the selection criteria so that you do not accidentally rotate keys that should not be rotated using this schedule. Whenever a new key is added to CipherTrust Manager, CipherTrust Manager compares its name and details to the filters set in all key rotation schedules defined in the Admin Settings application, and it automatically adds the new key to ALL key rotation schedules where it matches the selection criteria.

If your selection criteria is too broad, you could accidentally rotate keys that should not be rotated by this key rotation schedule.

You can enter a key name in the **Name** field, or select any of the available filters from the drop-down lists. The Selected Keys table shows the keys that will be rotated by this schedule.

CipherTrust Manager displays the current list of keys that match this criteria in the **Selected Keys** table. Make sure you go through this list carefully so that you do not rotate keys you do not want to rotate.

For example, you can rotate all keys with "ldt" anywhere in their name by specifying `*ldt*` in the **Name** field:

Add Key Rotation Schedule

1 Select Schedule Type 2 General Info 3 Schedule Config 4 Key Rotation Query

A key rotation query is an object that specifies the keys that need to be rotated. All keys are rotated when it is not provided.

Name

Filters ☒ Basic ☐ Raw

Types Size Status Dates

☒ Latest Version Only

Name: *ldt* Version: latest

Selected Keys

Key Name	Ver	Modified	Type	Alg	Size
LDT-Key-West-Coast	2	08 Sep 2020, 10:10	Symmetric	AES	256
LDT-Key-East-Coast	3	08 Sep 2020, 10:10	Symmetric	AES	256
My_LDT_Key	0	08 Sep 2020, 10:07	Symmetric	AES	256

Back Save

If you only want to rotate the keys whose names begin with "ldt", use the query `ldt*` in the **Name** field. In the example above, that removes `My_LDT_Key` from the list of keys that will be rotated.

The search is case insensitive, so "ldt" will also match `LDT`, `ldT`, `ldT`, or any variation thereof.

When you are certain the list of keys to be rotated is accurate, click **Save**.

Checking the Rekey Status

During a rekey, you can check the progress in the CipherTrust Manager Console, however GuardPoint status is not relayed to the CipherTrust Manager in real time. A delay of several minutes before the CipherTrust Manager displays events on the client is likely. When the number of GuardPoints on the managed host is high, for example 100+, the delay in relaying GuardPoint status is due to delays in scheduling and the execution of CTE-LDT operations on the managed host for GuardPoints.

To see the progress of a rekey and the estimated completion time:

1. In the CipherTrust Manager Applications Page, open the **CTE** application.
2. Click **Clients** in the left-hand menu bar.
3. Click the **Client Name** of the client whose CTE-LDT status you want to check in the Clients table.

4. Find an active CTE-LDT GuardPoint and click **Active** in the **Status** column.

CipherTrust Manager displays the GuardPoint Health page, which includes transformation status information such as the basic status (Rekeyed or Rekeying), the last transformation completion time, the last transformation start time, and the estimated rekey completion time.

Obtaining Information About Keys Applied to Files

Key Report Option

In the following command, you can use the `report` option of the `voradmin` command to obtain information about all of the keys in use on the GuardPoint. The report lists all keys used in the GuardPoint. For each key, it gives the key name and key version number. It lists each unique key name and version combination only once, no matter how many files use the key.

The following example shows three keys used in the GuardPoint `/oxf-fs1/gp1`:

```
# voradmin ldt key report /oxf-fs1/gp1
LDT_KEY1,1
LDT_KEY2,2
LDT_KEY3,5
```

For an overview of `voradmin ldt`, see ["CTE-LDT Command-Line Administration: voradmin command" on page 71](#).

Key Map Option

In the `voradmin ldt key [report|map] <key_name> <guard_path>` command, you can use the `map` option to obtain information about which files in a GuardPoint were transformed with a specific key, where:

- `<key_name>` is the name of the key.
- `<guard_path>` is the path of the GuardPoint where the key was used.

For example, to view information about the key `LDT_KEY2` in the GuardPoint `/oxf-fs1/gp1`, you would enter:

```
# voradmin ldt key map LDT_KEY2 /oxf-fs1/gp1
/oxf-fs1/gp1/file12345.dat10
/oxf-fs1/gp1/file12345.dat10
/oxf-fs1/gp1/file12345.dat10
/oxf-fs1/gp1/file12345.dat10
/oxf-fs1/gp1/file12345.dat10
```

Keys without a version number are used by files in an exclusion key rule or files that have yet to undergo initial key rotation. Use `voradmin ldt key map` in conjunction with `voradmin ldt attr get` to determine if a file using a key without a version number is part of an exclusion key rule or awaiting initial key rotation.

Showing GuardPoints During Rekey (Linux)

Use the following command to display a list of known CTE-LDT metadata stores and any associated GuardPoints currently undergoing transformation.

```
# voradmin ldt list all
MDS_1:  type=file, nguards=0, name=/disk2/::vorm:mds::
        Guard Table: version 1 nentries 0
MDS_2:  type=file, nguards=0, name=/disk3/::vorm:mds::
        Guard Table: version 1 nentries 0
MDS_3:  type=file, nguards=0, name=/disk4/::vorm:mds::
        Guard Table: version 1 nentries 0
```

For an overview of `voradmin ldt` commands, see ["CTE-LDT Command-Line Administration: voradmin command" on page 71](#).

Suspending and Resuming Rekey and/or Scan Phase

The QoS schedule specifies certain time windows when CTE-LDT operations must be stopped temporarily. However, you can also suspend or resume CTE-LDT at the client level at any time.

To suspend CTE-LDT through the CipherTrust Manager Console:

1. Open the **CTE** application.
2. Click **Clients** in the left-hand menu bar.
3. Click the **Client Name** of the client on which you want to pause CTE-LDT in the Clients table.
4. In the Client Details area, click the **Suspend** button next to the Live Data Transformation field to suspend all CTE-LDT operations on the client.

After you pause CTE-LDT, the button turns into a Play button so that you can resume CTE-LDT operations when ready.

Considerations

- Disabling, or unguarding, an CTE-LDT GuardPoint where a rekey is in progress automatically suspends the CTE-LDT rekey operation.
- You can also use the `voradmin suspend/resume` command in Windows Powershell to suspend and resume the rekey. However, if you use the `voradmin ldt suspend` command to pause the rekey process, the CTE-LDT suspended state is not retained when the system reboots. If you want to retain the state after reboot, suspend the rekey from the CipherTrust Manager.
- On Linux, you can pause CTE-LDT during the scan phase of CTE-LDT. When paused during scan, CTE-LDT suspends operations that traverse through the namespace of GuardPoints in the scan phase of transformation. Suspending CTE-LDT during scan stops file lookup operations of CTE-LDT. This eliminates performance impact to I/O intensive production workloads, such as file serving type workloads, that access large number of files.

Automatic Suspend and Resume of CTE-LDT Operations Due to Insufficient Disk Space (Linux)

CTE-LDT requires adequate storage space headroom to perform CTE-LDT operations such as rekeying on GuardPoints. On Linux, if available storage space drops below the threshold required for CTE-LDT operations to continue, the CTE-LDT operations are automatically suspended. Once additional storage space is available in the file

system, CTE-LDT operations automatically resume.

As available space approaches the threshold for automatic suspension, CTE-LDT sends an alert to the CipherTrust Manager to notify you that you should free up more storage space before CTE-LDT operations are suspended. The alert on the CipherTrust Manager is:

Low space on guard point [GuardPoint], increase free space or CTE-LDT will be suspended.

Behavior of Automatic Suspend and Resume of CTE-LDT Operations on ext4 File Systems

By default, ext4 file systems reserve a portion of the storage space for use only by privileged processes to prevent running out of storage space in file systems. In this situation, non-privileged processes are automatically blocked from writing to the file system until the free disk space level reaches the minimum threshold. As CTE-LDT operates in privileged mode, CTE-LDT operations continue without blockage even if the free disk space threshold is low. Because of this ext4 feature, CTE-LDT operations on ext4 file systems may not be suspended due to low available storage space, even when the `df` command reports storage is 100% allocated.

Rotating Encryption Keys While a Rekey is in Progress (Relaunch)

On Linux, if a key is rotated (either manually or automatically when a key version expires) while CTE-LDT is in progress on a GuardPoint, the key rotation is processed and queued, and the GuardPoint is marked for relaunch. Relaunch indicates the need to restart CTE-LDT after the current transformation completes. If the GuardPoint has been rekeyed and is flagged for relaunch, CTE-LDT launches as soon as the GuardPoint is enabled.

Files already undergoing transformation at the time of the new key rotation complete rekey to the key version already in progress. Files that start transformation after the new key rotation request are rekeyed to the new key version. Once the current CTE-LDT of the GuardPoint is complete, CTE-LDT automatically relaunches to transform any files that are not rekeyed to the latest key version.

For example:

```
# voradmin ldt attr get /oxf-fs1/gp1
LDT stats: version=2, rekey_status=rekeying,relaunch
  Number of times rekeyed:          1 time
  Rekey start time:                 2020/03/18 16:54:00
  Last rekey completion time:       2020/03/18 16:53:38
  Estimated rekey completion time:  0 days 0 hours 6 minutes
  Policy key version:               344
  Data stats:
    total=9.8GB, rekeyed=0.0MB
    truncated=0.0MB, sparse=0.0MB
  File stats:
    total=1000, rekeyed=0, failed=0
    passed=0, skipped=0, created=0, removed=0, excluded=0
```

Note

Relaunch is supported on Linux only. It is not supported on Windows.

File System Operations

The following sections describe the file system operations that may require attention from the CipherTrust Manager Administrator.

Renaming Files and Folders

On both Linux and Windows hosts, you can rename files during initial transformation or rekey operations.

- On Linux, you cannot rename folders (directories) in a GuardPoint during a rekey operation. Any attempt to rename a directory is rejected with the error EAGAIN (try again) while CTE-LDT is in progress including the period during which transformation is suspended.
- On Windows, CTE-LDT stops if it is transforming the contents of a folder and a user attempts to rename/move that folder.

You can change the stopping behavior of CTE-LDT using the configuration parameter `oxf_stop_on_rename`.

Using the Registry Editor, or the Windows command line, add a registry entry in `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\services\Vmmgmt\Parameters` for `oxf_stop_on_rename`.

Registry Name	Values	Comments
<code>oxf_stop_on_rename</code>	0 - Disabled	CTE-LDT does not stop if there is contention.
	1 - Enabled	CTE-LDT stops if there is contention. Default: Enabled

For the target folder in rename operation, CTE-LDT is never stopped.

Deleting a File

When a file is removed before it is rekeyed, the file is not included in the total number of files transformed in the GuardPoint Health dialog box. Any discrepancy between total number of files to transform and those transformed is due to the removal of files from GuardPoints during CTE-LDT.

The `voradmin` command provides more detailed file level statistics related to rekey operations on the host. You can run `voradmin` to get file level statistics:

```
# voradmin ldt stats <guard_path>
```

File Handling (Windows Only)

It is critical that you understand how the CTE-LDT process handles read-only, binary (executable), NTFS encrypted and NTFS compressed files.

The CTE-LDT process is subjected to all of the File System policies and attributes set on the files. In some cases, this prevents CTE-LDT from encrypting a file. If users or applications are accessing files while CTE-LDT is in progress, CTE-LDT cannot change the attributes of the files and encrypt the file. It is critical that you understand how CTE-LDT handles various types of files:

- **NTFS Encryption and Compression**

If NTFS encryption and compression is enabled on a file or folder, the CTE-LDT process cannot encrypt these files. To maintain the data coherency, CTE-LDT skips the encryption of these files. These files display as “passthrough” files in the CTE-LDT statistics.

- **Read-Only Files**

When CTE-LDT encounters read-only files, it rekeys the file by resetting the read-only attribute and then setting the attributes back again when the rekey completes. If a file is open, CTE-LDT skips this file.

1. If the file is not opened, CTE-LDT changes the attributes of the file and stores the original attributes in the file metadata.
2. CTE-LDT starts Rekey on this file.
3. If a user requests to open a file for writing while rekey is in progress, access is denied. User can only open files for reading.
4. CTE-LDT restores the attributes once rekey is done.

- **Executable Files**

If an executable is running, or files are exclusively locked by the application, the CTE-LDT process cannot encrypt those files as it is unable to acquire the required locks on the files. CTE-LDT skips these files and changes to the INCOMPLETE state.

Enabling GuardPoints in Read-Only mounted file systems (Linux)

Access to a GuardPoint enabled in a read-only mounted file system is restricted to read operations. You cannot modify data in such file systems, therefore, you cannot perform CTE-LDT operations on GuardPoints in read-only file systems. For this reason, CTE-LDT automatically suspends operations when GuardPoints are enabled on read-only file systems. CTE-LDT ignores all attempts to resume CTE-LDT operations until the underlying file system is remounted with read/write access.

WARNING

You must disable a GuardPoint before changing the read/write mount options of the underlying file system. After changing the mount options, you can re-enable the GuardPoint. CTE-LDT operations adapt to the read/write options of the underlying file system when you enable the GuardPoint. Changing the mount options while a GuardPoint is enabled is unsupported and may result in unexpected errors.

Copying Files Into a GuardPoint

If you copy a file into a GuardPoint without an Apply Key rule, make sure that the file was previously copied from the same GuardPoint, or a GuardPoint protected with the same policy/versioned key. A copy operation, without an Apply Key rule, is the same as a backup or restore of a file from/to an CTE-LDT protected GuardPoint.

CTE enforces key rules of an CTE-LDT policy while a GuardPoint is enabled. CTE cannot enforce the key rules while a GuardPoint is disabled. Modifying or adding data/files inside a disabled GuardPoint is not only unsupported, but it also results in unrecoverable data corruption.

WARNING

Do not add new files or modify existing files inside CTE-LDT protected GuardPoints while the GuardPoint is not enabled. This results in unrecoverable data corruption and/or files that cannot be accessed when the GuardPoint is enabled.

Behavior of Hard Links Inside and Outside of GuardPoints (Windows)

When using hard links on Windows, all the hard links to a file must be within the boundary of a GuardPoint and must use the same key. The following scenarios provide additional details:

- If hard links to the same file are inside a GuardPoint and outside a GuardPoint, the effect on the file depends on what process accesses which hard link first. If the hard link within the GuardPoint is opened first, the file is transformed. If the hard link outside the GuardPoint is opened first, the file won't be transformed.
- If hard links to the same file exist in different GuardPoints with different keys, the file will be corrupted.
- If hard links to the same file exist in the same GuardPoint but with different keys, such as if folder-based rules are used, there will be a conflict in the key.

Excluding Files or Directories from Rekey

When you add a resource set to a key rule in a policy, you can select the **Exclude Rule** option. That tells CipherTrust Manager that the directories and/or files in the resource set should use a different key than the rest of the data in the CTE-LDT GuardPoint. If you specify `clear_key` for the key rule, then the directories and/or files in the resource set will be left unencrypted. Otherwise, you can select any non-versioned key to apply to those directories and/or files.

Examples of Exclusion Key Rules

This section describes some examples of how to use an exclusion key rule.

Encrypt Files With Exclusion Property a Non-Versioned Key

The following exclusion key rule applies the non-versioned key, `Key_TextFiles`, to any *new* files that are created with a `*.txt` extension.

Note

Existing `*.txt` files in the GuardPoint during the initial CTE-LDT data transformation process are assumed to be already encrypted with the same key that you specify in the exclusion key rule. These existing files are *not* transformed during the initial encryption or during any subsequent rekeys. The key you specify in the exclusion key rule is applied to new `*.txt` files only.

In the Policy, do the following:

1. Add a Key Rule.
2. In the **Resource Set** field, click **Select**.
3. Select a resource set that specifies *.txt in the **File** field and click the **Exclude Rule** option.

4. Click **Select**. CipherTrust Manager displays the resource set name in the Resource Set field with an icon indicating that this is an Exclusion Rule.
5. Select the `Key_TextFiles` key in the **Current Key Name** field.
6. Click **Add**.
7. Add any other key rules or exclusion key rules to the policy that you want. You must add at least one non-exclusion key rule that specifies the current encryption key and the versioned encryption key that you want to use with this Live Data Transformation policy.

For example, you could add another exclusion key rule that specifies all **.doc** files should be encrypted with the key `Key_DocFiles`, or one that specifies all **.zip** files should be left unencrypted by specifying the key `clear_key`.

Exempt Excluded Files from Encryption (Set to `clear_key`)

The following exclusion key rule sets all files in the resource set `/oxf-fs1/gp1/Clear_Files_Folder` (Linux) or `\oxf-fs1\gp1\Clear_Files_Folder` (Windows) to `clear_key` (in other words, not encrypted). Files in other directories that match other key rules in the same policy may be encrypted. This could allow unrestricted access to the files in `/oxf-fs1/gp1/Clear_Files_Folder` (Linux) or `\oxf-fs1\gp1\Clear_Files_Folder` (Windows) while access may be restricted to files in parallel directories.

- Linux Exclusion Key Rule: The Resource Set **Directory** field should contain `/oxf-fs1/gp1/Clear_Files_Folder`, and the **Key** should be `clear_key`.
- Windows Exclusion Key Rule: The Resource Set **Directory** field should contain `\oxf-fs1\gp1\Clear_Files_Folder`, and the **Key** should be `clear_key`.

Requirements for Exclusion Key Rules

Keep in mind the following requirements when configuring exclusion key rules:

- Before adding an exclusion key rule to an existing policy, you must disable all GuardPoints protected with the policy. Log on to the CipherTrust Manager to disable the GuardPoint.
- You cannot choose a versioned key for the key in an exclusion key rule. Only non-versioned keys or `clear_key` (no encryption) are valid for exclusion key rules.
- All exclusion key rules must be *above* all CTE-LDT transformation key rules in the **Key Rules** area in the policy.

Usage Notes and Limitations for Configuring Exclusion Key Rules

Keep in mind the information in the following sections when configuring an exclusion key rule.

Adding an Exclusion Key Rule to an Existing Policy with Versioned Keys (Linux)

When adding an exclusion key rule to an existing policy, the exclusion rule only applies to newly created files. Existing files that match the exclusion key rule remain encrypted with the same versioned key(s) specified in the non-exclusion key rule in the policy and will be rekeyed to the key in the exclusion key rule when the versioned key(s) rotates.

To force an existing file that matches an exclusion key rule to be transformed to the key in the exclusion key rule (non-versioned in this example), use one of the following methods:

- Rotate the versioned key specified in the policy to initiate rekey operations on the GuardPoint.
- Copy the existing file within the GuardPoint. The new file will be associated with the resource set in the exclusion key rule and will be encrypted with the non-versioned key. You can then delete the original file.

To perform a similar conversion on Windows, see ["Changing a Folder or Files from Versioned to Non-Versioned Key \(Windows\)" on page 52](#).

Adding an Exclusion Key Rule That is Part of an Active GuardPoint (Linux)

To edit and/or add an exclusion key rule to an CTE-LDT policy, all GuardPoints using the policy must first be disabled before the new key rule can be added.

Changing an Exclusion Key Rule That is Part of an Active GuardPoint (Windows)

Changes that you make to an exclusion key rule that is part of an existing policy in an active GuardPoint do not take effect until the GuardPoint that the exclusion key rule is part of is disabled and enabled again.

Conflicting Keys as the Result of Rename Operations

Do not attempt to move or rename a file encrypted with a versioned key to a name associated with an exclusion key rule with `clear_key`. If you attempt such a move or rename, the original file is unaffected but following error is output on Linux systems and a log entry is created:

```
<command name>: setting attribute 'user::secfs:xattr:' for 'user::secfs:xattr:': Invalid argument
<command name>: failed to close '<filename>': Invalid argument
```

No error is displayed on Windows systems. The target moved or renamed file is corrupted and should be deleted. The target file is also flagged with the `xattr_error` flag on Linux and `Rekey Status Excluded` on Windows. This flag prevents subsequent read/write access to the file. You can check the CTE-LDT attributes for the presence of this flag. See ["About the Exclusion Attribute for Files Matching an Exclusion Key Rule" on page 53](#).

Also, a log entry is sent to the CipherTrust Manager on Linux systems when this occurs. For example, if you moved the versioned file `/gp/foo.txt` into the GuardPoint `/gp/subdir/foo.txt` with an exclusion key rule that excludes matching files with the `clear_key`, the following log message would be created on the CipherTrust Manager:

```
[CGA] [WARN ] [29261] [CGS3268W] LDT-ALERT: encrypted data detected in filename [foo.txt] inode [35720037] in guard point [/gp] under clear exclusion key rule
```

Overlapping Exclusion Key Rules

Multiple exclusion key rules in the same policy may overlap each other. For example on Linux, if the non-versioned key `Key_A` is associated with resource `/oxf-fs1/gp1/Folder_Enc_With_KEY_A` and the non-versioned key `Key_B` is associated with resource `*.txt`, placement of the file `/oxf-fs1/gp1/Folder_Enc_With_KEY_A/foo.txt` overlaps the two key rules. In such a case, the first rule in the policy is enforced on `/oxf-fs1/gp1/Folder_Enc_With_KEY_A/foo.txt` when the file is created and in subsequent file access.

On Windows, if the non-versioned key `Key_A` is associated with resource `c:\oxf-fs1\gp1\Folder_Enc_With_KEY_A` and the non-versioned key `Key_B` is associated with resource `*.txt`, then they would overlap on the file `c:\oxf-fs1\gp1\Folder_Enc_With_KEY_A\foo.txt`. In such a case, the first rule in the policy is enforced on `c:\oxf-fs1\gp1\Folder_Enc_With_KEY_A\foo.txt` when the file is created and in subsequent file access.

Caution About Applications That Create Temporary Files (Windows)

Some applications on Windows create a temporary file version of the original file when you open and modify a file. This behavior can affect how you implement exclusion key rules.

If you have an exclusion key rule that uses a file extension to exclude files that may be opened and modified by such an application, exclude the temporary file name extension also. If you don't exclude the temporary file, the temporary file may be encrypted by another policy that matches the temporary file extension. Then the original file, which is copied from the temporary file, will be unreadable. Also keep in mind that other applications that may create temporary files with the same file extension and consider what policies should affect those temporary files.

This situation can happen with Microsoft Office files such as the `.docx` files used by Microsoft Word. When you open and modify a `.docx` file, Word creates a `.tmp` file version of that file. So for Microsoft Word you should add `*.tmp` to the exclusion key rule resource set if you add `*.docx`.

Rename Operations Crossing Key Rules (Linux)

On Linux, when a rename operation crosses key rules, the rename operation copies the source file to a new file using the new name and removes the original file. If the source file is flagged for exclusion key rule property, the target new file is disassociated with the exclusion key rule if the new name no longer matches the resource set associated with exclusion key rule. For more information, see ["About the Exclusion Attribute for Files Matching an Exclusion Key Rule" on page 53](#).

Using Linked Files with Exclusion Key Rules (Linux)

On Linux, do not create multiple hard links to the same target file such that the pathname of each hard link is associated with a resource set of an exclusion key and the key rules have different keys. Accessing the file through the pathname of each hard link results in a different key to be applied to the file resulting in data corruption in the target file due to application of multiple keys to the same data.

If you must create hard links, be sure the pathnames of hard links and the target file are within the same resource set.

Changing a Folder or Files from Versioned to Non-Versioned Key (Windows)

Exclusion key rules provide a way to convert a subset of guarded files or the contents of a folder from being encrypted by a versioned key to being encrypted by a non-versioned key. After this conversion, the excluded files or directory contents will be encrypted at the last version of the versioned key but the encryption keys for those items will not rotate to a new version when the keys for other non-excluded files are rotated. In other words, the excluded files or folder contents will be encrypted by a non-versioned key.

Follow these steps to change selected files or folder contents to a non-versioned key:

1. In the CipherTrust Manager, clone the versioned key that is used in the policy that you plan to edit. Cloning a key creates a non-versioned copy of the existing version of the versioned key.
2. In the CipherTrust Manager, disable the GuardPoint. Disabling the GuardPoint is required before modifying a policy applied in that GuardPoint.
3. Configure one or more resource sets to match the files that you want to exclude. For example, the resource set `star-dot-text` could contain `*.txt` and the resource set `sales-folder` could contain `\sales\*`.
4. Add one or more exclusion key rules to convert matching files to a non-versioned key. In the following example, files matching `*.txt` and files in the `sales` folder (as defined in resource sets) will be converted from the current version of the versioned key `AES256_versioned` to `AES256_clone`, assuming `AES256_clone` is a clone of `AES256_versioned`.

Order	Resource	Current Key	Transformation Key	Exclusion Rule
1	star-dot-txt	AES256_clone	AES256_clone	Y
2	sales-folder	AES256_clone	AES256_clone	Y
3		clear_key	AES256_versioned	N

Exclusion key rules must be ordered before other rules.

5. On the command line, run the following command to remove the CTE-LDT metadata from the files that you want to convert from versioned key to non-versioned key encryption:

```
voradmin ldt attr delete <path_to_files>
```

To recursively delete the CTE-LDT metadata from all files matching a pattern in all subfolders, use the following form, including `*` as a wildcard where needed:

```
voradmin ldt attr delete <path_to_files> -filter <filename>.<extension>
```

Note: Be careful when deleting the CTE-LDT metadata from files. If you delete the metadata from a file that does not match an exclusion key rule policy, the file will be unreadable after the next rekey.

Given the example exclusion key rule described in step 4, you would need to run this command on all files with the extension `.txt` (first example below) and on the files in `\sales` (second example below).

```
voradmin ldt attr delete c:\gp1 -filter *.txt  
voradmin ldt attr delete c:\gp1\sales
```

For more information about using `voradmin` on CTE-LDT metadata, run `voradmin ldt attr /?` on the command line.

6. In the CipherTrust Manager, re-enable the GuardPoint that includes the new exclusion key rule.
7. In the CipherTrust Manager, rotate the key for the policy that includes the new exclusion key rule.

Using the example exclusion key rule in step 4, after completing this procedure, files matching `*.txt` and files in the `sales` folder will have the exclusion attribute set and will be excluded from rekeying (see ["About the Exclusion Attribute for Files Matching an Exclusion Key Rule" on the next page](#)). Files not matching the exclusion key rule will be rekeyed to the next version of the `AES256_versioned` key.

To perform a similar conversion on Linux, see ["Adding an Exclusion Key Rule to an Existing Policy with Versioned Keys \(Linux\)" on page 50](#).

About the Exclusion Attribute for Files Matching an Exclusion Key Rule

Files matching an exclusion key rule have the status `rekey_excluded` in the CTE-LDT attribute. For more information about CTE-LDT attributes, see ["CTE-LDT Metadata in Extended Attributes" on page 57](#). To check for the exclusion attribute on a file, see ["Determining if a File is Included in an Exclusion Key Rule" below](#).

The Exclusion Attribute is Persistent

Exclusion from rekey is a persistent property. A file excluded from rekey is not rekeyed regardless of changes that may seem to disassociate the file from the exclusion key rule. For example, if you rename a file to a new name within the same GuardPoint that no longer matches the exclusion key rule that the original name matched, the file with the new name retains the encryption type (non-versioned key or `clear_key`) of the exclusion key rule. To remove the exclusion attribute from a file you must copy the file rather than move or rename it (see ["Removing the Exclusion Attribute From a File" below](#)).

Determining if a File is Included in an Exclusion Key Rule

Use the `voradmin ldt attr get <path to file>` command to check whether a file is associated with an exclusion key rule.

- On Linux, an excluded file will include the status `rekey_excluded` in the `voradmin` output. For example:

```
# voradmin ldt attr get /oxf-fs1/gp1/foo.txt
CTE-LDT attributes: rekeyed_size=0, rekey_status=rekey_excluded
```

- On Windows, an excluded file will include the attribute `Rekey Status Excluded` in the `voradmin` output. For example:

```
C:\> voradmin ldt attr get c:\gp1\foo.txt
CTE-LDT attributes:
Rekey Status Excluded
Initial Rekeyed Size 9 Bytes
Data Transformed 0 Bytes

Key:
Current Key Name/Version (Clear_Key)
New Key Name/Version (Clear_Key)
```

Removing the Exclusion Attribute From a File

To disassociate a file from an exclusion key rule, you must copy the file to a new file not associated with the resource set of the same or another exclusion key rule as the source file. You can then remove the original file. The new file is created under the default key rule of whatever policy applies to the new file. Moving or renaming a file does not disassociate a file from an exclusion key rule (see ["The Exclusion Attribute is Persistent" above](#)).

For example, assume the following exclusion key rule where `Key_TextFiles` is a non-versioned key:

Exclusion Key Rule: Resource set = *.txt, Key = `Key_TextFiles`

If you copy the file `test1.txt` to `test1.foo`, `test1.foo` is created with whatever key is specified in the policy that matches the new file. The key for the new file could be a non-versioned key, versioned key, `clear_key`, or, no key at all if the new file is outside of a GuardPoint. The original file `test1.txt` remains unchanged and encrypted with the `Key_TextFiles` non-versioned key because the file remains in the exclusion key rule.

Rename and Restore Operations (Linux)

The effect of rename or backup/restore operations involving files associated or not associated with exclusion key rules is mixed and somewhat confusing. In some cases, the operations to restore or rename cause conflicts between the key associated with the source file and the key associated with the target file. For example, the result of a rename operation involving a source file not associated with an exclusion key rule and target file name associated with a resource set of an exclusion key rule is different from the result of the same operation when target file name is associated with the resource set of an exclusion key rule with clear_key.

Note

Be sure to review the effect of the operations below and avoid administrative operations that cross associations of files across multiple resource sets with conflicting key rules.

Backup/Restore

The table below illustrates the status and the key effect of restore operations involving mixed keys associated with source files from backup image and existing target files inside GuardPoint.

Key Applied to File in Backup	Key Applied to existing file in GuardPoint	Key Effect of Restore Operation on Existing file
Versioned	Versioned	Versioned
Versioned	Exclusion key	xattr_error (failed)
Versioned	Exclusion clear key	xattr_error (failed)
Exclusion key	Versioned	Exclusion key
Exclusion key	Exclusion key	Exclusion key
Exclusion key	Exclusion clear key	xattr_error (failed)
Exclusion clear key	Versioned	Exclusion clear key
Exclusion clear key	Exclusion key	xattr_error (failed)
Exclusion clear key	Exclusion clear key	Exclusion clear key

The table below illustrates the status and the key effect of restore operations involving mixed keys associated with source files from backup image and new target files not present inside GuardPoint.

Key Applied to File in Backup	Key Applied to existing file in GuardPoint	Key Effect of Restore Operation on Existing file
Versioned	Versioned	Versioned
Versioned	Exclusion key	xattr_error (failed)
Versioned	Exclusion clear key	xattr_error (failed)
Exclusion key	Versioned	Exclusion key
Exclusion key	Exclusion key	Exclusion key
Exclusion key	Exclusion clear key	xattr_error (failed)
Exclusion clear key	Versioned	Exclusion clear key

Key Applied to File in Backup	Key Applied to existing file in GuardPoint	Key Effect of Restore Operation on Existing file
Exclusion clear key	Exclusion key	xattr_error (failed)
Exclusion clear key	Exclusion clear key	Exclusion clear key

Rename Operation

The table below illustrates the status and the key effect of rename operations for different combinations of versioned, exclusion key, and exclusion clear key.

Key Applied to File in Backup	Key Applied to existing file in GuardPoint	Key Effect of Restore Operation on Existing file
Versioned	Versioned	Versioned
Versioned	Exclusion key	Exclusion key
Versioned	Exclusion clear key	xattr_error (failed)
Exclusion key	Versioned	Exclusion key
Exclusion key	Exclusion key	Exclusion key
Exclusion key	Exclusion clear key	Exclusion key
Exclusion clear key	Versioned	Exclusion clear key
Exclusion clear key	Exclusion key	Exclusion clear key
Exclusion clear key	Exclusion clear key	Exclusion clear key

Listing All Files Included in an Exclusion Key Rule (Linux)

Determining the files that match an exclusion key rule involves two steps. You list all the keys in a GuardPoint, choose the key that you're interested in, and then run a command to list the files that match that key. This process works for both standard key rules and exclusion key rules.

1. Decide on the GuardPoint that you want to check for excluded files. For example, for the GuardPoint `/oxf-fs1/gp1`, type the following on the command line:

```
# voradmin ldt key report /oxf-fs1/gp1
LDT_KEY1,1
LDT_KEY2,2
LDT_KEY3,5
NON_VERSIONED_KEY
```

The number after the comma is the key version number. See ["Key Report Option" on page 43](#) for more information about the `voradmin` key report.

2. From the key report output, choose the key rule for which you want to list matching files. For example, to see the files associated with the NON_VERSIONED_KEY in the previous step, you would type:

```
# voradmin ldt key map NON_VERSIONED_KEY /oxf-fs1/gp1
/oxf-fs1/gp1/file1.dat10
/oxf-fs1/gp1/file2.dat10
/oxf-fs1/gp1/file3.dat10
/oxf-fs1/gp1/file4.dat10
/oxf-fs1/gp1/file5.dat10
```

See ["Key Map Option" on page 43](#) for more information about the `voradmin` key map report.

Listing All Files Included in an Exclusion Key Rule (Windows)

Determining the files that match an exclusion key rule involves two steps. You list all the keys in a GuardPoint, choose the key that you're interested in, and then run a command to list the files that match that key. This process works for both standard key rules and exclusion key rules.

1. Decide on the GuardPoint that you want to check for excluded files. For example, for the GuardPoint `c:\gp1`, type the following on the command line:

```
C:\> voradmin ldt key report c:\gp1
Keys used for GP, c:\gp1 :
clear_key,0
CS1-CTE-LDT-AES256,11
```

The number after the comma is the key version number. The `clear_key` key is not versioned, so the version number is 0.

2. From the key report output, choose the key rule for which you want to list matching files. For example, to show the files associated with the `clear_key` listed above, you would type:

```
C:\> voradmin ldt key map c:\gp1 clear_key,0
Files rekey with key (clear_key,0)-
c:\gp1\file1.txt
c:\gp1\file2.txt
c:\gp1\file3.txt
c:\gp1\file4.txt
c:\gp1\file5.txt
```

Using CTE-LDT with SAP HANA Fibre Channel Systems (Linux Only)

You must add additional CTE commands to the HANA administrator entry. To do so, edit the `/etc/sudoers` with a text editor and add entries for `/usr/bin/voradmin` and `/usr/bin/vmsec`. For example:

```
# hanadm ALL=NOPASSWD:
/usr/bin/secfsd,/usr/bin/voradmin,/usr/bin/vmsec,/sbin/multipath,/sbin/multipathd,/etc/init.d/m
ultipathd,/usr/bin/sq_
persist,/bin/mount,/bin/umount,/bin/kill,/usr/bin/lsof,/sbin/vgchange,/sbin/vgscan
```

If you are using an ext3 file system, you must mount it with extended attributes. To do so, edit the storage section of the `global.ini` file using a text editor and add the following lines:

```
partition_*_data__mountOptions = -o user_xattr
partition_*_log__mountOptions = -o user_xattr
```

Note

See the *CTE Agent for Linux Advanced Configuration and Integration Guide* or the *CTE Agent for Windows Advanced Configuration and Integration Guide* for more information about SAP HANA.

Chapter 5: CTE-LDT Administration

This chapter contains the following sections:

CTE-LDT Metadata in Extended Attributes	57
DFSR and Replication (Windows)	61
Multi-Node Configuration and Operation	62
Backing Up and Restoring CTE-LDT GuardPoints	62
CTE-LDT Command-Line Administration: voradmin command	71
Moving a CTE-LDT GuardPoint from One CTE-LDT Policy to Another	72
Removing CTE-LDT and Security Encryption	73
Uninstalling the Agent while CTE-LDT is Rekeying GuardPoints	77

CTE-LDT Metadata in Extended Attributes

An *extended attribute* is a name/value pair permanently associated with a file or directory stored in a file system. CipherTrust Transparent Encryption (CTE) creates and maintains its own user extended attributes on CTE-LDT GuardPoint directories and files. The extended attributes are used to store metadata related to each file or directory that is protected using an CTE-LDT policy.

On Linux, CTE-LDT sets extended attributes on GuardPoint directories. The CTE-LDT attribute of an CTE-LDT GuardPoint stores the following metadata:

- Current key version.
- Rekey status.
- Rekey start and end times.
- Estimated completion time.
- Total amount of data transformed.
- Total number of files transformed.
- Current key signature and applied key signature.

On both Linux and Windows, CTE-LDT sets extended attributes on files. The CTE-LDT attribute of a file stores the following metadata:

- Name of the current key.
- Name of the versioned key.
Also referred to in the CipherTrust Manager Console and product documentation as the new key or the transformation key.
- Version number of the versioned key.
- CTE-LDT rekey status of the file.

In most cases, the current and new key names are the same. The exception is during initial transformation from a legacy policy to an CTE-LDT policy, when the file has been encrypted with the current key and is being transformed to the current version of the transformation key.

Note

Before you set up a GuardPoint for CTE-LDT, ensure that there is sufficient disk space available in your file system for CTE-LDT metadata. The amount of disk space you need depends on the number of files in your GuardPoint. For more information about the disk space requirement, see ["Planning for CTE-LDT Attribute Storage" on page 60](#).

The state of a file changes during CTE-LDT operations. The extended attributes are continually updated to reflect the current file status, which falls into one of the following categories:

- Rekeyed to the current version of the key.
- Rekeyed to the previous version of the key, or the initial key state (before the first CTE-LDT rekey has been performed).
- Partially rekeyed, where some regions of the file are rekeyed to the new key version and other regions are still keyed to the previous key version or the initial key.

Listing Extended Attributes

You can list extended attributes by using native operating system commands, or system calls. As part of GuardPoint administration, CTE can modify or delete extended attributes.

In Linux, CTE-LDT attributes are set on GuardPoint directories and regular files in GuardPoint directories protected with CTE-LDT policies. The CTE extended attribute name is `::secfs:xattr:.`

The following example uses the native Linux operating system command `attr` to display the CTE-LDT attribute for the GuardPoint `/oxf-fs1/gp1` and the file `/oxf-fs1/gp1/File_1.txt`.

Example 1:

```
# attr -l /oxf-fs1/gp1/File_1.txt
Attribute "::secfs:xattr:" has a 1044 byte value for /oxf-fs1/gp1/File_1.txt
Attribute "selinux" has a 37 byte value for /oxf-fs1/gp1/File_1.txt
```

Example 2:

```
# attr -l /oxf-fs1/gp1
Attribute "::secfs:xattr:" has a 1044 byte value for /oxf-fs1/gp1
Attribute "selinux" has a 37 byte value for /oxf-fs1/gp1
```

Example 3:

In the following example, the file `/oxf-fs1/gp1/File_1.txt` has the same name for current and new keys at the same key version. In the following example, if the versioned key `LDT_KEY` is at version 755, the file is rekeyed to the latest key version under the CTE-LDT policy.

```
# voradmin ldt attr get /oxf-fs1/gp1/File_1.txt
CTE-LDT attributes: rekeyed_size=4096, rekey_status=none
Key:    name=LDT_KEY, version=755
```

Example 4: (Linux)

The following is example of an CTE-LDT attribute on a GuardPoint directory on Linux:

```
# voradmin ldt attr get /oxf-fs1/gp1
LDT stats: version=1, rekey_status=rekeying
  Number of times rekeyed:      3 times
  Rekey start time:             2018/08/04 16:24:45
  Last rekey completion time:   2018/07/04 16:24:04
  Estimated rekey completion time: N/A
  Policy key version:           2043
```

```
Data stats:
    total=3.3GB, rekeyed=1.5GB, truncated=0.0MB
File stats:
    total=4307, rekeyed=1181,
    passed=2, skipped=0, created=0, removed=0
```

Example 5: (Windows)

The attribute for the GuardPoint `c:\GP 1` contains the status (rekeyed) and statistics specific to the GuardPoint and CTE-LDT. Following is sample output of `voradmin` command on Windows for statistics on a file:

```
C:\> voradmin ldt attr get c:\GP\Test.txt
LDT attributes:
    Rekey Status          Rekeyed
    Initial Rekeyed Size  10 Bytes
Key:
    Key Name/Version      (LDT_KEY, 28)
```

The attribute for GuardPoint `C:\GP` contains the status (rekeyed) and statistics specific to the GuardPoint and CTE-LDT:

```
C:\> voradmin ldt attr get c:\gp\
LDT Stats
-----
    Rekey Status          LDT_ST_REKEYED
    Last rekey completion time    10/2/2017 4:26:50
    Rekey Start time            10/2/2017 4:26:17
    Estimated rekey completion time    000:00:00

File Stats:
    Total      444
    Rekeyed    444
    Skipped    0
    Errored    0
    Passed     0
    Removed    0

Data Stats:
    Total      11 GB (12649143417 Bytes)
    Rekeyed    11 GB (12649143417 Bytes)
    Truncated  0 Bytes
```

MDS File (Linux)

In addition to CTE-LDT attributes, the CTE-LDT process on Linux requires persistent storage for additional metadata related to encrypting, or rekeying, files in GuardPoints. CTE-LDT allocates the storage space as soon as the CTE-LDT process starts on a GuardPoint. It maintains this storage space during the entire transformation process, until the GuardPoint is completely transformed.

Storage for this metadata is allocated and managed in a special file, called the MDS (metadata store) file. The MDS file resides inside a GuardPoint directory so each GuardPoint has its own MDS file.

The MDS file is a CTE protected file with the name `::vorm:mds::`. For example:

```
# ls -l /oxf-fs1/gp1/::vorm:mds::
-rwxr-xr-x. 1 root  root 31754474496 Dec  8 09:09 /oxf-fs1/::vorm:mds::
# du -B 1024 /oxf-fs1/gp1/::vorm:mds::
25056    /oxf-fs1/::vorm:mds::
```

As shown above, the MDS file is sparse. In the example, the file size is approximately 30GB, however the file is allocated with approximately 25MB of disk storage. CTE-LDT automatically creates the MDS file the first time the CTE-LDT process starts on any GuardPoint in the file system namespace. It populates the MDS file with all of the metadata for the GuardPoint at the beginning of the CTE-LDT process. Disk space allocated to the MDS file is freed and the MDS file in the GuardPoint directory is removed when the CTE-LDT process completes on the GuardPoint.

WARNING

The MDS file is protected. You cannot remove it unless the administrator runs the `voradmin` command to manually remove the MDS file once it is no longer needed. See ["Deleting CTE-LDT Metadata \(Linux\)" on page 76](#) for more information.

CTE-LDT automatically allocates and deallocates disk space for the MDS file as part of the CTE-LDT process. Deallocation of disk space for a GuardPoint does not change the MDS file size, although it frees the disk blocks. MDS files are sparse and very large in size. With no GuardPoint undergoing CTE-LDT, the minimum allocation of an MDS file is approximately 25MB.

Planning for CTE-LDT Attribute Storage

Before a GuardPoint is enabled for CTE-LDT, make sure that there is sufficient free disk space in the file system to which the GuardPoint belongs. Free space is required for CTE-LDT attributes (CTE extended attributes) and (in Linux) metadata in the MDS file. CTE-LDT attributes are created during initial encryption and are never freed until the GuardPoint is permanently unguarded and removed from the protection of an CTE-LDT policy. In contrast, disk space for metadata in the MDS file is temporary, kept only during the live transformation process.

When planning how much free disk space to reserve for CTE-LDT on a GuardPoint, consider the following:

- Number of files in the GuardPoint
- (Linux) Average length of absolute pathnames of files in the GuardPoint

The CTE-LDT process pre-allocates disk space for the Linux MDS file based on a minimum of 200K files with an average pathname of 1024 bytes per GuardPoint. The minimum space amounts to 325MB of disk space for the MDS file for each GuardPoint, even if file count is very low. (In Windows, CTE-LDT reserves the space when the file is rekeyed.)

Using `voradmin` To Estimate Disk Space Required for CTE-LDT (Linux)

In Linux, you can use the `voradmin ldt space` command to estimate the amount of disk space required for CTE-LDT attributes and the MDS file. The result is rounded to the nearest MB. The syntax of the command is:

```
# voradmin ldt space <guard path>
```

The following example shows how to estimate the required disk space to perform CipherTrust Transparent Encryption - Live Data Transformation on 1501 files in the GuardPoint `/oxf-fs1/gp1`. Estimate the disk space before protecting `/oxf-fs1/gp1` using an CTE-LDT policy. For example:

```
# voradmin ldt space /oxf-fs1/gp1
/oxf-fs1/gp1: found 1501 files without CTE-LDT extended attributes
CTE-LDT disk space requirements: total 169MB (CTE-LDT attributes=6MB, MDS=163MB)
```

The `voradmin` command reports that 1501 files in `/oxf-fs1/gp1` without CTE-LDT attributes. These files are new to CTE-LDT. 6MB of space is required for the CTE-LDT extended attributes and 163MB for metadata in the MDS file.

The following example shows the output of the same command after encryption completes. This estimates the additional disk space needed for the next CTE-LDT rekey operation. For example:

```
# voradmin ldt space /oxf-fs1/gp1
/oxf-fs1/gp1: found 0 files without CTE-LDT extended attributes
CTE-LDT disk space requirements: total 163MB (CTE-LDT attributes=0MB, MDS=163MB)
```

The voradmin command still reports on the same 1501 files, but because encryption has occurred using CTE-LDT, the files all have their CTE-LDT attributes. No additional space is required for CTE-LDT extended attributes on the next run. However, since the MDS file is transient and deletes after it finishes encrypting the GuardPoint, it requires additional space for the next key rotation.

Note

Windows estimates space using the following equations:

- Permanent Space = Number of Files * 4K
- Temporary Space = 128K * (Number of CPU * 2)

Displaying Metadata

Use the following command to see CTE-LDT file attributes or GuardPoint attributes:

```
# voradmin ldt attr get [<file name path> | <guard path>]
```

For an overview of voradmin ldt, see ["CTE-LDT Command-Line Administration: voradmin command" on page 71](#).

Verifying Metadata (Windows only)

Use the following command to verify if the metadata is corrupt:

```
# voradmin ldt attr verify [<file name path> | <guard path>]
```

For an overview of voradmin ldt, see ["CTE-LDT Command-Line Administration: voradmin command" on page 71](#).

DFSR and Replication (Windows)

The Distributed File System Replication (DFSR) service is a multi-master replication engine used to maintain synchronized folders on multiple servers. Replicating data to multiple servers increases data availability and provides users in remote sites with fast, reliable access to files.

If you are creating GuardPoints in a DFSR environment, you must first add the DFSR private folder guard path to the exclusion list in the Windows Registry. CTE-LDT should not attempt data transformation on this read-only directory.

1. Using the Registry Editor, or the Windows command line, add a registry entry in: `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\services\Vmmgmt\Parameters` named "LDTEExclusionGPList" of type REG_MULTI_SZ.
2. Add the `DfsrPrivate` directory path to the `LDTEExclusionGPList`.
For example, if the DFSR private directory path is `D:\data\DfsrPrivate`, add this string in `LDTEExclusionGPList`.
3. Reboot the system to make the change take effect.

Note

CTE-LDT does not perform a rekey on the DFSR private directory. Its rekey status is always "N/A".

If an application, or user, is performing a rename or a delete folder operation inside a GuardPoint with an CTE-LDT policy, this may restart the rekey process. Files which are already rekeyed will not be rekeyed again.

- If a rename or a delete operation is already performed on rekeyed files/folder, then the rekey process does not restart.
- If a rename or delete operation is performed in a folder where a rekey is in progress, CTE-LDT needs to stop the rekey process and restart the rekey again.

Multi-Node Configuration and Operation

This section describes what to expect at runtime when CTE-LDT operates in a multi-node cluster environment.

CTE-LDT Behavior on Failover

In a multi-node cluster, CTE-LDT runs in active-passive mode. A GuardPoint is only enabled on the active node, and CTE-LDT only runs on the active node. On the CipherTrust Manager Console, you can only view statistics for the active host.

If the active host fails over, and the standby host takes control, CTE-LDT also fails over to the second host. On the CipherTrust Manager Console, CTE-LDT statistics now appear on the other host.

Veritas Cluster Server

In an HA environment with Veritas Cluster Server, manual failover of service to a stand-by host may require manual intervention. If any GuardPoint is in the scan phase at the time of the manual failover, the failover process fails with the error "UNABLE to OFFLINE". The reason for the failure may be the scan state of a GuardPoint that cannot be suspended. CTE-LDT suspends CTE-LDT operations during the rekey state of transformation. Because CTE-LDT scan operations cannot be suspended, the Veritas Cluster Server fails to suspend CTE-LDT on GuardPoints in the scan phase of CTE-LDT operation. This state of CTE-LDT operation prevents Veritas Cluster Server to manually offline the service for fail-over.

Backing Up and Restoring CTE-LDT GuardPoints

This section describes procedures and considerations related to backing up and restoring data in CTE-LDT GuardPoints.

In addition to the files in a GuardPoint, CTE-LDT stores metadata in extended file attributes. These CTE-LDT attributes contain information that is required for decrypting the files and for the proper operation of CTE-LDT. Therefore, it is critical that your backup application also backs up the extended attributes of the files along with file data.

Clear Text Backup and Restore

A policy that applies a Security Rule with the Apply Key effect on backup/restore operations does not require any special rules for data access by backup applications. Under such a policy, backup applications always read clear data and store clear data in backup media. The backup application is not required to back up the CTE-LDT extended attributes, and a QoS schedule is not required to suspend CTE-LDT during backups.

Encrypted Backup and Restore

When a policy does not enforce a Security Rule with the Apply Key effect on backup/restore operations, the policy does not decrypt data on I/O operations from that backup application. Under such a policy, the backup application stores encrypted data and the CTE-LDT extended attributes of the file on the backup media.

In Linux, CTE-LDT operations must be suspended during backup. Suspending CTE-LDT completes the ongoing rekey operations on regions of files before starting the backup. During live transformation, CTE-LDT first preserves those regions of a file to be rekeyed in the MDS file. Then it updates some of the metadata in order to update the status of the data preserved in the MDS file in preparation for the rekey. Then it starts rekeying and updating those regions in the underlying file.

Suspending CTE-LDT waits for ongoing rekey operations to complete, and saves the metadata in the CTE-LDT extended attribute section of the MDS file. Suspending CTE-LDT ensures that the rekey status stored in the CTE-LDT extended attribute accurately reflects the rekey status of the data in the entire file during backup.

Note

This requirement does not apply to CTE-LDT for Windows.

The following table summarizes the state of the data in files in backup media:

CTE-LDT State of File	Security Policy	Backup Metadata or Alternate Data Streams Along with File data	Effect
Not rekeyed	Permit	Yes	Data in backup may be in clear format or encrypted with older key version.
Rekey in progress	Permit	Yes	File in backup storage is partially rekeyed. Some parts are in clear format or encrypted with older key version, and other parts are encrypted with current key version.
Rekey complete	Permit	Yes	File in backup storage is in the encrypted format with new key version.

CTE-LDT Policy for Encrypted Backup and Restore

Suppose you have an CTE-LDT policy allowing a backup user, or a backup process, to perform an encrypted backup. The backup user, or the backup process, reads encrypted data from files and stores the same encrypted data in backup media.

For example, suppose you wanted to back up GuardPoint `/oxf-fs1/gp1` protected by `My_LDT_Policy_1`. The key version before the key rotation is 8. The following steps occur:

1. Key version 8 expires and is rotated to version 9.
2. Rotating the encryption key triggers CTE-LDT to start running on the data under the GuardPoint.
3. The QoS schedule suspends CTE-LDT because a backup process is running.
4. The backup process begins, runs and later ends.
5. The QoS schedule resumes CTE-LDT.
6. CTE-LDT on the GuardPoint completes.

Note

Although the backup/restore scenarios and examples described in the rest of this section are specific to CTE-LDT on Linux platform, the concepts also apply to CTE-LDT on the Windows platform.

Consider the state of the three files in the GuardPoint during the CTE-LDT process, right after CTE-LDT is suspended in preparation for the backup. You can obtain the state of each file through the `voradmin ldt attr get` command, which examines the CTE-LDT state of each file captured in the CTE-LDT extended attributes of those files. (For an overview of `voradmin CTE-LDT`, see ["CTE-LDT Command-Line Administration: voradmin command" on page 71](#)).

- **File_1.dat** is rekeyed/encrypted to completion. The applied and new key versions are at version 9 of the key.

```
# voradmin ldt attr get /oxf-fs1/gp1/data_files/file_1.dat
LDT attributes: rekeyed_size=1440743424, rekey_status=none
Key:      name=LDT_AES256_KEY, version=9
```

- **File_2.dat** is partially rekeyed/encrypted. The applied key version is at version 8 and the transformation key is at version 9.

```
# voradmin ldt attr get /oxf-fs1/gp1/data_files/file_2.dat
LDT attributes: rekeyed_size=1440743424, rekey_status=rekeying,state_saved
Current Key:      name=LDT_AES256_KEY, version=8
New Key:          name=LDT_AES256_KEY, version=9
```

- **File_3.dat** has not been rekeyed/encrypted. The applied key and transformation key are both at version 8, which is the version before the current key rotation.

```
# voradmin ldt attr get /oxf-fs1/gp1/data_files/file_3.dat
LDT attributes: rekeyed_size=1440743424, rekey_status=none
Key:      name=LDT_AES256_KEY, version=8
```

While CTE-LDT is suspended on the GuardPoint, the backup process starts and archives these three files, including extended attributes, in the backup media.

```
# my_backup --preserve=xattr /oxf-fs1/gp1/data_files/file_1.dat \
    /backup-media/oxf-fs1/gp1/data_files/file_1.dat
# my_backup --preserve=xattr /oxf-fs1/gp1/data_files/file_2.dat \
    /backup-media/oxf-fs1/gp1/data_files/file_2.dat
# my_backup --preserve=xattr /oxf-fs1/gp1/data_files/file_3.dat \
    /backup-media/oxf-fs1/gp1/data_files/file_3.dat
```

Notes

- On Linux platforms, you must perform backups on a GuardPoint during periods when CTE-LDT is not actively transforming data in the GuardPoint. You must schedule backups in conjunction with CTE-LDT schedules or during periods when CTE-LDT is paused. Make sure to coordinate with the backup administrator and schedule accordingly.
- If the preferred method of backup is to create device level snapshots of the file system on the managed host or in the storage array subsystem, you must ensure that the schedule for creating snapshots pauses CTE-LDT before a snapshot is created.

Backup/Restore of Metadata Store File (MDS) in GuardPoints Undergoing Rekey

Backing up an entire GuardPoint using commands such as `cp`, `tar`, or `rsync`, or even commercial backup products that sweep the file system namespace for backing up files is supported. This method of backup performed while live transformation is in progress over GuardPoint poses some challenges when files in GuardPoint are backed up in encrypted format. The challenge with this method of backup is existence of the CTE-LDT Metadata Store file (MDS) in GuardPoint during backup or restore process and strict protection enforced on MDS files preventing deletion or modification to MDS files. Second, your backup utility must backup and restore extended attributes of files, and because CTE-LDT extended attributes are also protected similar to MDS files, your backup must be enabled to restore extended attribute of files. To overcome both restrictions, your policy on GuardPoint must include a security rule without Apply Key Effect to enable your backup utility to replace MDS file and CTE-LDT extended attribute of files as

part of backup/restore operations. Additionally, your backup utility must be signed with a signature set from the CipherTrust Manager for added security, and be executed with the option to preserve extended attribute options available with the standard Linux utilities.

The following table lists the supported backup utilities, required options to preserve extended attributes, and supported versions of the utilities.

Command	Required options	Supported version
cp	--preserve=all	OS default
tar	--xattrs	OS default
rsync	-vapIXWP --inplace	OS default
netbackup	overwrite existing files	v7.6.1 and v7.7.3

You can also backup and restore GuardPoint data, including the MDS file, if the requirements listed above on the backup utility are satisfied. GuardPoints associated with an MDS file located outside of GuardPoint namespace cannot be backed up or restore using this method of backup.

Note

You must suspend CTE-LDT on GuardPoint before performing backup or restore.

You can check your GuardPoint to determine if you can use this method of backup. If the directory of your GuardPoint is a mount point, MDS files reside inside your GuardPoint and this method of backup can be used for backing up or restoring your GuardPoint. However, GuardPoint directories below file system mount points must be checked and verified to use this method of backup. To verify, you can run the `voradmin` command to determine the MDS file associated your GuardPoint.

For example:

```
# voradmin ldt list all
MDS_1:  type=file, nguards=1, name=/oxf-fs1/gp1/:vorm:mds::

Guard Table: version 1 nentries 1
Guard 0: type=GP, state=REKEYING SUSPENDED (vadm), flags=GP LOCKED, gp=/oxf-fs1/gp1
File List: count 4308
```

The report on `/oxf-fs1/gp1` GuardPoint indicates association of the MDS file `/oxf-fs1/gp1/:vorm:mds::` with the GuardPoint. As the MDS file resides inside the GuardPoint directory, you can use this method of backup to backup and restore this GuardPoint.

Before restoring the GuardPoint, you must suspend CTE-LDT operations on the GuardPoint if live transformation is in progress. Failure to do so will fail to restore the MDS file in the backup image. Failure to restore MDS file affects partially rekeyed files restored to the GuardPoint. In such a situation the restored data is invalid, and you must remove all the files restored to the GuardPoint and repeat the restore operation after suspending CTE-LDT.

Restoring a GuardPoint from a Backup

To properly restore GuardPoint along with the MDS file, the following steps must be done in order:

1. Verify if live transformation is in progress on the GuardPoint and suspend the CTE-LDT operations. (Skip this step if no live transformation is occurring.)
2. With the same tool that was used for backup, restore to the GuardPoint.

3. Once restore is complete, GuardPoint needs to be disabled and enabled again. Run the `voradmin` command as shown below to determine how the GuardPoint was suspended at the time of backup. For manual GuardPoint, run the `secfsd` command as shown below. For auto-guards, disable and enable GuardPoints on CipherTrust Manager.

```
# secfsd -unguard <GuardPoint>
# secfsd -guard <GuardPoint>
```

4. Since GuardPoint was in suspended state during the time of backup, it will be restored in suspended state. You must resume CTE-LDT to complete CTE-LDT on the restored GuardPoint. You must resume CTE-LDT on the CipherTrust Manager if CTE-LDT was suspended on the CipherTrust Manager at the time of backup, otherwise you will resume CTE-LDT using `voradmin` command.

Run the `voradmin` command below to determine if CTE-LDT must be resumed on CipherTrust Manager or through `voradmin`. If the tag string next to SUSPENDED state of GuardPoint is `vadm`, run `voradmin` command to resume CTE-LDT, otherwise the tag value is `qos` and CTE-LDT must be resumed on CipherTrust Manager. In the example below, GuardPoint `/oxf-fs1/gp1` was suspended using `voradmin`, and it must be resumed after restore using `voradmin` command.

```
# voradmin ldt list all
MDS_1: type=file, nguards=1, name=/oxf-fs1/gp1::vorm:mds::
Guard Table: version 1 nentries 1
Guard 0: type=GP, state=REKEYING SUSPENDED (vadm), flags=GP LOCKED, gp=/oxf-fs1/gp1
File List: count 4308
# voradmin ldt resume /oxf-fs1/gp1
```

5. Wait for CTE-LDT completion on GuardPoint.
6. We strongly recommend that you disable and re-enable the GuardPoint once more.

The restore is now complete and files in your GuardPoint can be accessed.

The CTE Agent sends the following alert message to CipherTrust Manager if the restore operation is rejected:

```
LDT-ALERT: Restore of LDT protected file <GuardPoint> not allowed by policy
```

Potential Warnings During Restore Operation

When using `cp` for backup/restore, the `cp` command may report a failed attempt to preserve permissions on the Metadata Store File (MDS) during a restore. If you encounter the below message, continue to proceed with the restore steps since this will not affect the MDS file or dataset that is being restored.

```
cp: preserving permissions for '/oxf-fs1/gp1::vorm:mds::': Permission denied
```

When using `rsync` for backup/restore, the `rsync` command may report a failed attempt to set extended attribute when restoring the MDS file on system with selinux configured in enforced mode. If user encounters the below message, continue to proceed with the restore steps since this will not affect the MDS file or dataset that is being restored.

```
rsync: copy_xattrs: lsetxattr("/oxf-fs1/gp1::vorm:mds::", "security.selinux") failed:
Permission denied (13)
rsync: rsync_xal_set: lsetxattr("/oxf-fs1/gp1::vorm:mds::", "security.selinux") failed:
Permission denied (13)
```

Restore an Encrypted Backup

This section illustrates restoration of the three files from the backup media to the same GuardPoint, `/oxf-fs1/gp1`. The files are restored to a different directory under the GuardPoint.

Restore a File Fully Rekeyed to the Latest Key Version

Recall that *file_1.dat* was archived in the backup media when it was fully rekeyed to version 9 of the key. As the current version of the key is also 9, *file_1.dat* is restored from backup without any changes. After restoring the file, the state of the restored file and its applied and current key versions remain unchanged, as compared to the original file that was backed up.

```
# my_backup --preserve=xattr /backup-media/oxf-fs1/gp1/data_files \ /file_1.dat /oxf-fs1/gp1/restored_files/file_1.dat

# voradmin ldt attr get /oxf-fs1/gp1/restored_files/file_1.dat
LDT attributes: rekeyed_size=1440743424, rekey_status=none
Key:      name=LDT_AES256_KEY, version=9

# voradmin ldt attr get /oxf-fs1/gp1/data_files/file_1.dat
LDT attributes: rekeyed_size=1440743424, rekey_status=none
Key:      name=LDT_AES256_KEY, version=9
```

Restore a Partially Rekeyed/encrypted File

Recall that *file_2.dat*, archived in the backup media, was partially rekeyed between versions 8 and 9. As the current version of the key was 9 at the time of backup, *file_2.dat* is restored to the GuardPoint with the same version of the key from the time of backup. The file is flagged for *lazy rekey*, meaning that a background rekey operation is scheduled to transform the file to the latest key version the next time an application tries to access the file.

At the completion of restoration, the file is fully transformed to the key version (v9). The key version is also the latest one in the policy. Although the file is flagged for lazy rekey (LAZY_RK), the file does not need to be transformed to the latest key version because it's already there. Had the file been partially rekeyed from version 7 to version 8 of the key at the time of backup, the restored file would have completed rekeying to version 8 at the end of the restoration. Therefore, the LAZY_RK flag would initiate a background transformation to update the key version to the latest key version when the file is accessed.

If this file is not accessed by any application, the file remains unchanged in the GuardPoint. It is not transformed to the latest key version. To trigger a rekey, either re-push the CTE-LDT policy from the CipherTrust Manager, or access the file with an application, such as a file explorer.

```
# my_backup --preserve=xattr /backup-media/oxf-fs1/gp1/data_files/\ file_1.dat /oxf-fs1/gp1/restored_files/file_2.dat

# voradmin ldt attr get /oxf-fs1/gp1/restored_files/file_2.dat
LDT attributes: rekeyed_size=1440743424, rekey_status=lazy_rekey
Key:      name=LDT_AES256_KEY, version=9

# voradmin ldt attr get /oxf-fs1/gp1/restored_files/file_2.dat
LDT attributes: rekeyed_size=1440743424, rekey_status=none
Key:      name=LDT_AES256_KEY, version=9
```

Restore a File Not Rekeyed/encrypted with an Older Key Version

Recall *file_3.dat* was archived in the backup media when it was keyed to version 8 of the key, one version below the latest version at the time of backup. At completion of the restoration, *file_3.dat* is restored from backup to the same version, version 8, that it was keyed to when it was backed up.

However, the file is flagged for lazy rekey. After restoring the file, it is keyed to version 8 and flagged for lazy rekey (LAZY_RK). The file is rekeyed to the latest key version, version 9, as soon as an application accesses the file. If this file is not accessed by any application, the file remains unchanged in the GuardPoint.

```
# my_backup --preserve=xattr /backup-media/oxf-fs1/gp1/data_files \ /file_3.dat /oxf-  
fs1/gp1/restored_files/file_3.dat  
  
# voradmin ldt attr get /oxf-fs1/gp1/restored_files/file_3.dat  
LDT attributes: rekeyed_size=1440743424, rekey_status=lazy_rekey  
Key:      name=LDT_AES256_KEY, version=8  
  
# sum /oxf-fs1/gp1/restored_files/file_3.dat  
39994 1406976  
  
# voradmin ldt attr get /oxf-fs1/gp1/restored_files/file_3.dat  
LDT attributes: rekeyed_size=1440743424, rekey_status=none  
Key:      name=LDT_AES256_KEY, version=9
```

Restoring Non-CTE-LDT Backup Data to an CTE-LDT GuardPoint

This section describes how to restore data encrypted with a non-versioned key to an CTE-LDT GuardPoint.

If the backup was performed with the Apply Key effect, the backup files are in clear text. Simply restore the clear text files to the CTE-LDT GuardPoint with the Apply Key effect. All files will be encrypted with the versioned key.

If the backup of the non-CTE-LDT GuardPoint was performed without the Apply Key effect, the backup is encrypted, and you must do the following:

Note

The following example is for a manual guarding. The steps may differ slightly if your GuardPoint is configured for auto guard.

1. Create a temporary directory for restoring the files, type:

```
# mkdir -p /oxf-fs1/tmp_restore
```
2. Restore the encrypted backup files into the temporary directory, type:

```
# cp -pr /backup-media/oxf-fs1/gp1/data_files/* /oxf-fs1/tmp_restore
```
3. Create a Standard Policy with the Apply Key effect for all operations, using the same key as the policy applied on the GuardPoint at the time of backup.
4. Create and enable a new GuardPoint for the temporary directory using the Standard Policy just created.

```
# secfsd -guard /oxf-fs1/tmp_restore
```
5. Ensure that the temporary GuardPoint and CTE-LDT GuardPoint are both enabled.

```
# secfsd -status guard
```

GuardPoint	Policy	Type	ConfigState	Status	Reason
-----	-----	----	-----	-----	-----
/oxf-fs1/gp1	LDT_AES256	manual	guarded	guarded	N/A
/oxf-fs1/tmp_restore	AES256	manual	guarded	guarded	N/A
6. Move the restored files from the temporary folder to the GuardPoint enabled with the CTE-LDT policy. The CTE agent encrypts the files in the CTE-LDT GuardPoint using the current key version in effect for the CTE-LDT policy.

```
# mv /oxf-fs1/tmp_restore/* /oxf-fs1/gp1
```
7. Disable the temporary GuardPoint and remove the temporary restore directory.

```
# secfsd -unguard /oxf-fs1/tmp_restore  
# rm -fr /oxf-fs1/tmp_restore
```
8. Delete the temporary GuardPoint on the CipherTrust Manager.

Using fsfreeze (Linux only)

If you use the `fsfreeze` command to quiesce access to the file system before creating a snapshot, refer to the `fsfreeze` section in CTE Admin Guide in the Linux Utilities chapter on how to run the `fsfreeze` command to quiesce access to both the file system and the GuardPoint(s).

WARNING

Do not use CTE-LDT schedules and do not pause CTE-LDT to align backup schedules with CTE-LDT. Instead, use the `fsfreeze` command.

- Running `fsfreeze -f` on the GuardPoint directory pauses CTE-LDT operations in-progress and freezes access to both the GuardPoint and the underlying file system.
- Running `freeze -u` reverses `freeze -f`, allowing access to underlying file system and resuming CTE-LDT operations.

CTE-LDT Backups Using a File System or Storage-Level Snapshot Tool

You can make a file system snapshot using a Logical Volume Manager service or mirroring/splitting storage level LUNs of a file system inside the storage subsystem. CTE-LDT does not have requirements for where and how you create a file system snapshot. However, it is required that you **suspend CTE-LDT processes before you take the file system snapshot**. Suspending CTE-LDT ensures data and metadata consistency between files and CTE-LDT extended attributes.

You may choose to suspend CTE-LDT manually on the managed host using `voradmin ldt suspend` command or `fsfreeze -f`, or suspend CTE-LDT on the CipherTrust Manager.

Note

Be aware that suspending CTE-LDT on the CipherTrust Manager suspends CTE-LDT on the entire host.

After creating a file system snapshot, you can resume CTE-LDT processes on the GuardPoint using `voradmin ldt resume`, or `fsfreeze -u`, or resuming CTE-LDT on the CipherTrust Manager. Do not mix the use of `fsfreeze` and `voradmin ldt suspend` to pause and resume CTE-LDT. CTE suspends or resumes CTE-LDT processes during live transformation when freezing or unfreezing GuardPoint access using `fsfreeze -f` or `-u` option. See the *CTE Agent for Linux Advanced Configuration and Integration Guide* on the use of the `fsfreeze` command on a GuardPoint.

Note

You can make sure CTE-LDT is suspended at backup time by setting the QoS schedule.

You can mount a file system snapshot for data recovery. Configuration for GuardPoints must be duplicated over the mount point of the snapshot file system. Make sure to use the same CTE-LDT policy. Enabling GuardPoints over or under the snapshot mount point provides access to the protected files for recovery. You can choose to manually resume key rotation on the GuardPoints of the snapshot file system, although this is not necessary.

Following is an example of the `fsfreeze` command used to freeze access to the file system `/oxf-fs1` in order to create a snapshot of the file system device. This examples illustrates three GuardPoints enabled inside the file system namespace, `/oxf-fs1/gp-1`, `/oxf-fs1/gp-2`, and `/oxf-fs1/gp-3`. Executing the command `fsfreeze -f` targets any of the GuardPoints in the `/oxf-fs1` mount point and suspends CTE-LDT processes on all of the GuardPoints. Then it freezes access to the file system.

```
# fsfreeze -f /oxf-fs1/gp-1
# voradmin ldt list all
MDS_1:  type=file, nguards=1, name=/oxf-fs1/gp-3/:vorm:mds::
        Guard Table: version 1 nentries 1
        Guard 0: type=GP, state=REKEYING SUSPENDED (vadm), flags=GP LOCKED,
```

fs1/gp-3

File List: count 4308

MDS_2: type=file, nguards=1, name=/oxf-fs1/gp-2/::vorm:mds::

Guard Table: version 1 nentries 1

Guard 0: type=GP, state=REKEYING DIRTY, flags=GP LOCKED, gp=/oxf-fs1/gp-2

File List: count 4308

MDS_3: type=file, nguards=1, name=/oxf-fs1/gp-1/::vorm:mds::

Guard Table: version 1 nentries 1

Guard 0: type=GP, state=REKEYING SUSPENDED (vadm), flags=GP LOCKED, gp=/oxf-fs1/gp-1

File List: count 4308

After the file system snapshot is created, executing the `fsfreeze -u` command on any of the GuardPoints in the file system namespace unfreezes access to the file system and resumes CTE-LDT processes on all of the GuardPoints.

```
# fsfreeze -u /oxf-fs1/gp-1
```

```
# voradmin ldt list all
```

MDS_1: type=file, nguards=1, name=/oxf-fs1/gp-3/::vorm:mds::

Guard Table: version 1 nentries 1

Guard 0: type=GP, state=REKEYING DIRTY, flags=GP LOCKED, gp=/oxf-fs1/gp-3

File List: count 4308

MDS_2: type=file, nguards=1, name=/oxf-fs1/gp-2/::vorm:mds::

Guard Table: version 1 nentries 1

Guard 0: type=GP, state=REKEYING DIRTY, flags=GP LOCKED, gp=/oxf-fs1/gp-2

File List: count 4308

MDS_3: type=file, nguards=1, name=/oxf-fs1/gp-1/::vorm:mds::

Guard Table: version 1 nentries 1

Guard 0: type=GP, state=REKEYING DIRTY, flags=GP LOCKED, gp=/oxf-fs1/gp-1

File List: count 4308

Windows Backup and Snapshots

On Windows, most backup applications use Volume Snapshot Service (VSS) for the backup. Using VSS is required for backing up files in CTE-LDT GuardPoints. VSS service provides a consistent view of the data to backup and restore applications by taking a snapshot of the volume. Windows Backup uses the snapshot volume, while other applications can continue using the original volume for normal I/O operations. VSS snapshot volume uses a “Copy on write” mechanism to provide a consistent view of the data. Some of the high-level steps of the Windows backup process are:

1. Backup application takes a snapshot of the volume using the VSS service.
2. Backup application mounts this VSS volume to read the data to be backed up.
3. The CTE Agent uses the same policy as that of the original volume to protect these snapshots.
4. The CTE Agent applies the policy and rules to all the I/O requests coming from the backup and restore applications.

CTE-LDT Backup and Restore Troubleshooting

Restored files to a GuardPoint protected with conflicting key rules

When restoring an encrypted file from backup media to an CTE-LDT protected GuardPoint without the Apply Key effect, and the file in the backup media does not have an CTE-LDT extended attribute, the file restored to the GuardPoint is set with an CTE-LDT extended attribute that specifies the current key version of the key in the policy

associated with the data in the restored file. As the key and key version in the policy do not match the key that was applied to the data at the time of backup, the file restored to the CTE-LDT protected GuardPoint is unreadable.

When restoring an encrypted file from backup media to an CTE-LDT protected GuardPoint without Apply Key effect, and the key specified in the CTE-LDT extended attribute of the file in backup media conflicts with the key rules of the policy on the GuardPoint, the restore operation fails and flags the restored file in error. You can only remove the file, or truncate it, to clear the error status on the file. Access to such files, except remove or truncate, fail with an EINVAL error.

CTE-LDT Command-Line Administration: voradmin command

Use the `voradmin` utility to gather statistics and administer CTE-LDT on a client. It has slightly different syntax and command capabilities depending on whether the client is running Linux or Windows.

Note

Refer to the `voradmin` man page for `voradmin` usage in Linux.

To use `voradmin`:

1. Log in to the host running the CTE Agent with CTE-LDT enabled.
2. At the command line, type `voradmin`.
3. Follow the usage outputs onscreen to find the available commands and their syntax. The general syntax is:

```
# voradmin ldt <command> [args]
```

Command	Description
<code>voradmin ldt attr get delete <guard path> <object path></code>	Get or delete attributes for a GuardPoint or Object path.
<code>voradmin ldt key <report map <key> > <guard path></code>	Creates a report, or map, containing statistics after each key rotation on a GuardPoint.
<code>voradmin ldt list all</code>	(Linux only) List all MDS files and GuardPoints undergoing CTE-LDT processing.
<code>voradmin ldt monitor [interval]</code>	(Windows only) Monitor CTE-LDT progress. If an interval is specified (in units of seconds), it continually updates the monitoring output at the specified interval.
<code>voradmin ldt rekey report <guard path> [output file]</code>	Generate a rekey report manually for a Guardpath.
<code>voradmin ldt resume <guard path> all</code>	Resume guarding the GuardPoint directory.
<code>voradmin ldt space <guard path></code>	Estimates disk space needed for metadata and mds store information.
<code>voradmin ldt stats [<guard path>] [<interval>]</code>	Obtains transformation CTE-LDT statistics such as: • Current rekey status • Start time • Estimated completion time • Percentage completed • Total data • Amount of data transformed • Total files • Number of files transformed • Number of files skipped • Number of files remaining for rekey

Moving a CTE-LDT GuardPoint from One CTE-LDT Policy to Another

To change the CTE-LDT policy that an CTE-LDT GuardPoint uses, complete the following steps to ensure that the GuardPoint is migrated properly from one CTE-LDT policy to another CTE-LDT policy.

Scenario

The GuardPoint is currently attached to LDT-Policy-1, which rekeys from `clear_key` to `LDT-Key-1`. The objective is to migrate the data in the GuardPoint to another versioned key, `LDT-Key-2`. Migration to `LDT-Key-2` requires detaching the GuardPoint from `LDT-Policy-1`, and then attaching it to `LDT-Policy-2`, assuming `LDT-Key-2` is the versioned key specified in `LDT-Policy-2`. This is a two step migration:

1. Migrate a GuardPoint out of the CTE-LDT policy to protection under a standard policy.
The step requires cloning `LDT-Key-1` to a non-versioned key, and migrating the GuardPoint out of the CTE-LDT policy. Because the cloned key and the the current version of `LDT-Key-1` have the same key material, the data in the GuardPoint directory remains encrypted to the same key after migration of the GuardPoint out of CTE-LDT.
2. Migrate a GuardPoint protected under a standard policy to protection with an CTE-LDT policy.

Note that you may set the transformation key to `clear_key` instead of `LDT-Key-2` in the second policy (`LDT-Policy-2`). The effect of `clear_key` is transformation of the data in the GuardPoint directory to clear text. Although the transformation key in CTE-LDT policies must be a versioned key, `clear_key` is an exception. It allows CTE-LDT GuardPoints to be transformed to clear using the CTE-LDT process.

To properly move the GuardPoint from LDT-Policy-1 to LDT-Policy-2:

Note

Ensure that no active processes or users are accessing files in the GuardPoint, or its subdirectories, until all steps have been completed.

1. Follow the instructions for, ["Converting a GuardPoint from an CTE-LDT policy to a non-CTE-LDT policy" on the facing page](#).
2. Assuming the current version of the `LDT-Key-1` is version 5, then clone version 5 of the key to `Cloned-LDT-Key-1v5`.
 - a. In the CipherTrust Manager Applications Page, open the **Keys & Access Management** application.
 - b. Click the name of the versioned key that you want to clone.
 - c. In the Key Details area, find the version that you want to clone.
 - d. Click the (...) button at the end of the row and select **Clone** to clone the selected version of the key.
3. Follow the instructions for ["Using voradmin To Estimate Disk Space Required for CTE-LDT \(Linux\)" on page 60](#).
4. Follow instructions for ["Converting a GuardPoint from an CTE-LDT policy to a non-CTE-LDT policy" on the facing page](#) using the cloned key (`Cloned-LDT-Key-1v5`) as the Initial Key and `LDT-Key-2` as the key for the new CTE-LDT policy. The files are now rekeyed from `Cloned-LDT-Key-1v5` to `LDT-Key-2`.

Removing CTE-LDT and Security Encryption

If you want to stop using CTE-LDT on a GuardPoint or on a whole client, follow the instructions in the following sections.

Migrating a GuardPoint Out of CTE-LDT

Migrating a GuardPoint from CTE-LDT removes the security encryption. It also provides a CipherTrust Manager Administrator with the flexibility to relax the compliance requirement, when strict compliance for frequent key rotation on specific data is no longer mandatory. The following sections describe how to migrate a GuardPoint from CTE-LDT to a non-CTE-LDT policy, or to remove encryption protection from it.

Converting a GuardPoint from an CTE-LDT policy to a non-CTE-LDT policy

If you want to do more than just change the policy on a GuardPoint from an CTE-LDT policy to a non-CTE-LDT policy, see ["Deleting CTE-LDT Metadata \(Linux\)" on page 76](#) or ["Deleting CTE-LDT Metadata \(Windows\)" on page 76](#).

1. Clone the versioned key associated with the CTE-LDT GuardPoint to a non-versioned key.
The clone function creates a new key with the same cryptographic encryption material as the current version of the cloned versioned key.
This allows CTE-LDT to use the cloned key in a non-CTE-LDT policy to convert the GuardPoint from an CTE-LDT to a non-CTE-LDT managed policy.
 - a. In the CipherTrust Manager Applications Page, open the **Keys & Access Management** application.
 - b. Click the name of the versioned key that you want to clone.
 - c. In the Key Details area, click the (...) button at the end of the row showing the current version of the key and select **Clone** to clone the current version.
 - d. Enter a new name for the key in the **Key Name** field. Do *not* select the **CTE Versioned** option for the clone.
 - e. Click **Clone**.
2. Open the **CTE** application and click **Clients** in the left-hand menu bar.
3. Click on the name of the client whose GuardPoint you want to migrate.
4. Find the GuardPoint you want to migrate in the GuardPoints table, then click the (...) button at the end of the row and select **Disable**.
5. After CTE-LDT disables the GuardPoint, click the (...) button at the end of the row and select **Remove**.
6. (Linux only) Ensure that the GuardPoint is removed on the managed host:

```
# secfsd -status guard
No GuardPoints configured
```
7. CTE-LDT creates extended attributes for every file under the GuardPoint as well as the GuardPoint directory. Now that the CTE-LDT policy does not manage the GuardPoint, you must remove the extended attributes for every file in the GuardPoint, type:

```
# voradmin ldt attr delete /<GuardPoint>
```
8. The command may take some time depending on the number of files in the GuardPoint.

Note: For all of the file system mount points that contain an CTE-LDT protected GuardPoint, you must clean up the metadata first. See ["Deleting CTE-LDT Metadata \(Linux\)" on page 76](#).

9. Create a non-CTE-LDT policy using the cloned key you created earlier in this procedure.
 - a. In the **CTE** application, click **Policies** in the left-hand menu bar and then click **Create Policy**.
 - b. Enter a name for the policy in the **Name** field.
 - c. In **Policy Type**, choose **Standard**.
 - d. Click **Next**.
 - e. On the Security Rules page, click **Next** to skip adding a security rule.
 - f. On the Key Selection Rules, click **Create Key Rule**.
 - g. In the **Key Name** field, select the cloned key you created earlier.
 - h. Click **Add**.
 - i. Click **Next**.
 - j. Confirm that the key rule is correct and click **Save**.
10. Apply the non-CTE-LDT policy to the GuardPoint.

CAUTION

Make sure that you have removed all of the CTE-LDT metadata from the GuardPoint before applying the non-CTE-LDT policy.

- a. Open the **CTE** application and click **Clients** in the left-hand menu bar.
- b. Click on the name of the client whose GuardPoint you want to migrate.
- c. Click **Create GuardPoint**.
- d. In the *Create GuardPoint* dialog box, select the Policy that you just created in the **Policy** field.
- e. Select the **Type: Auto Directory** or **Manual Directory**.
- f. In the **Path** field, and enter or browse to the directory to protect.
- g. When you are done, click **Create**.

Remove Protection from a GuardPoint

When compliance may no longer require protecting data in a GuardPoint, you may choose to unprotect/decrypt it. Before removing protection from your GuardPoint, you must decrypt the data in your GuardPoint by setting it to clear. You have two options to decrypt your data:

- While a GuardPoint is protected and enabled under an CTE-LDT policy, you can use copy or backup/restore commands to save files in your GuardPoint to a location outside of your GuardPoint.
- Use the `dataxform` command to transform your GuardPoint to clear in an offline transformation process.

Copying Files to Decrypt Them

If you choose to copy your files, you must create a directory outside of the GuardPoint and then copy the files into the GuardPoint directory. After finishing copying, complete the following steps:

1. Open the **CTE** application and click **Clients** in the left-hand menu bar.
2. Click on the name of the client whose GuardPoint you want to remove.
3. Find the GuardPoint you want to remove in the GuardPoints table, then click the (...) button at the end of the row and select **Disable**.
4. After CTE-LDT disables the GuardPoint, click the (...) button at the end of the row and select **Remove**.

5. (Linux only) Ensure that the GuardPoint is removed on the managed host:

```
# secfsd -status guard  
No GuardPoints configured
```

This completes removal of the GuardPoint under an CTE-LDT policy. You can now remove the original files and data within the GuardPoint namespace.

Using Dataxform Command to Transform the Files

If you choose to use the dataxform command to transform data in your GuardPoint to clear, use the `voradmin` command to verify that earlier versions of the versioned key are not in use on your GuardPoint. Complete the following steps to clear all metadata in your GuardPoint. Then, transform your GuardPoint to clear.

1. Clone the versioned key associated with the CTE-LDT GuardPoint to a non-versioned key.
 - a. In the CipherTrust Manager Applications Page, open the **Keys & Access Management** application.
 - b. Click the name of the versioned key that you want to clone.
 - c. In the Key Details area, click the (...) button at the end of the row showing the current version of the key and select **Clone** to clone the current version.
 - d. Enter a new name for the key in the **Key Name** field. Do *not* select the **CTE Versioned** option for the clone.
 - e. Click **Clone**.
2. Create a Standard policy using the cloned key you just created.
 - a. In the **CTE** application, click **Policies** in the left-hand menu bar and then click **Create Policy**.
 - b. Enter a name for the policy in the **Name** field.
 - c. In **Policy Type**, choose **Standard**.
 - d. Enable the **Data Transformation** option.
 - e. Click **Next**.
 - f. On the Security Rules page, click **Next** to skip adding a security rule.
 - g. On the Key Selection Rules, click **Create Key Rule**.
 - h. In the **Key Name** field, select the cloned key you created earlier.
 - i. Click **Add**, then click **Next**.
 - j. On the Data Transformation page, click **Create Data Transformation Rule**.
 - k. In the **Transformation Key Name** field, select `clear_key`.
 - l. Click **Add**, then click **Next**.
 - m. Confirm that the key rule and data transformation rule are correct and click **Save**.
3. Click **Clients** in the left-hand menu bar.
4. In the Clients table, click on the name of the client whose GuardPoint you want to remove.
5. Find the GuardPoint you want to remove in the GuardPoints table, then click the (...) button at the end of the row and select **Disable**.
6. After CTE-LDT disables the GuardPoint, click the (...) button at the end of the row and select **Remove**.

Before you apply the offline data transformation policy to your GuardPoint, you must clean up the CTE-LDT metadata from your GuardPoint. CTE-LDT creates extended attributes for every file under the GuardPoint, as well as the GuardPoint directory. Now that the CTE-LDT policy does not manage the GuardPoint, you can remove the extended attributes for every file in the GuardPoint.

7. Remove the extended attributes of files in a GuardPoint, type:

```
# voradmin ldt attr delete <GuardPoint>
```

The command may take some time depending on the number of files in the GuardPoint. After metadata deletion is complete, you can apply the offline transformation policy on the GuardPoint.

8. CipherTrust Manager, guard and enable the GuardPoint with the Standard policy you created earlier.
9. After enabling your GuardPoint, run the `dataxform` command on the managed host to transform the GuardPoint to a `clear_key`, type:

```
# dataxform --rekey --gp /<GuardPoint>/ --preserve_modified_time --preserve_access_time --cleanup_on_success
```
10. After completion of `dataxform`, unguard the GuardPoint.
11. Remove the GuardPoint from the `dataxform` policy in CipherTrust Manager.

Deleting CTE-LDT Metadata (Linux)

To remove the metadata associated with the GuardPoint, you must run the `voradmin` command on the managed host to remove the CTE-LDT metadata associated with the GuardPoint.

WARNING

Before you attempt to remove an MDS file, make sure that no CTE-LDT-protected GuardPoints remain configured under the file system mount point.

In the following example:

- `/oxf-fs1` is the mount point
- `/oxf-fs1/gp1` is the CTE-LDT-protected GuardPoint

To delete the metadata associated with the GuardPoint:

1. Ensure that the GuardPoint is not enabled on the host. Run the command below and verify that the GuardPoint pathname does not appear in the output of the `secfsd` command, type:

```
# secfsd -status guard
```

2. Run the `voradmin` command to remove CTE-LDT attributes on the GuardPoint, type:

```
# voradmin ldt attr delete <GuardPoint path>
```

For example:

```
# voradmin ldt attr delete /oxf-fs1/gp1  
LDT metadata has been removed from all files in GuardPoint /oxf-fs1/gp1
```

Deleting CTE-LDT Metadata (Windows)

Use the following command to delete the CTE extended attribute for a file or a GuardPoint. This is useful when removing a GuardPoint from under an CTE-LDT policy (see ["Migrating a GuardPoint Out of CTE-LDT" on page 73](#)).

```
# voradmin ldt attr delete [<file name path> | <guard path>]
```

For an overview of `voradmin ldt`, see ["CTE-LDT Command-Line Administration: voradmin command" on page 71](#).

Removing CTE-LDT from a Host

Once you have registered a host and enabled CTE-LDT, you cannot disable the CTE-LDT feature by unchecking the CTE-LDT box. You must unregister the host from the CipherTrust Manager, then register it again without CTE-LDT. When you remove the CTE-LDT feature from a host entirely, the host's CTE-LDT license becomes available for use on another host.

1. Stop all applications from accessing data in CTE-LDT GuardPoints on the host.
2. Migrate data in every CTE-LDT GuardPoint using the steps described in the section ["Remove Protection from a GuardPoint" on page 74](#).

WARNING

Potential data loss. Ensure that you have decrypted the data and, optionally, copied it out of the GuardPoint. Once the CTE Agent software is removed, access to data is no longer controlled by CTE. If the data was encrypted, it remains encrypted, and there is no way to read it.

3. Remove the GuardPoints on the host from the CipherTrust Manager.
 - a. Remove the CTE-LDT metadata from those GuardPoints.
 - b. Remove the MDS files associated with those GuardPoints, if necessary. See ["Deleting CTE-LDT Metadata \(Linux\)" on the previous page](#) for more information.
4. Remove the host from the CipherTrust Manager. For details, see the *CTE Agent for Linux Advanced Configuration and Integration Guide* or the *CTE Agent for Windows Advanced Configuration and Integration Guide*.
5. Re-install the agent on the host.
6. Register the host with the CipherTrust Manager. This time, do not select the CipherTrust Transparent Encryption - Live Data Transformation option. See ["Enabling CTE-LDT on a Protected Host" on page 22](#).

Uninstalling the Agent while CTE-LDT is Rekeying GuardPoints

You cannot uninstall the CTE Agent if CTE-LDT is rekeying any GuardPoints on that client.

If you want to uninstall the CTE Agent from a client that contains CTE-LDT GuardPoints, you must first unencrypt the files on each CTE-LDT GuardPoint using the steps noted in the previous sections.

Chapter 6: Troubleshooting CTE-LDT

Monitoring and Statistics	78
Protecting CTE-LDT GuardPoints against Failure in Underlying Filesystems (Linux)	80
Alerts Playbook	81
Error Messages	85
Warning and Info Messages	87
Recommendations and Considerations	88

The CTE-LDT administrator needs to monitor and respond to runtime statistics and alerts.

Monitoring and Statistics

This section describes how to find the runtime status of CTE-LDT and how to get statistics about its operation.

Note

When you check GuardPoint status on the CipherTrust Manager, be aware that the status is not relayed in real time. There can be a delay of several minutes before the CipherTrust Manager becomes aware of events on the host. When you configure the host and v for one-way communication, the delay is longer, up to an hour, because CTE-LDT sends statistics to the CipherTrust Manager only once per hour.

To find out when the CipherTrust Manager last received a status update from the host, check the Last Status Update timestamp in the GuardPoint Health dialog (for information about how to display this dialog, see ["Obtaining Statistics in the CipherTrust Manager with GuardPoint Status" below](#)). For the most up-to-date statistics, inspect the client. Run the `voradmin` command on the managed hosts to retrieve status and statistics pertaining to GuardPoints.

Obtaining Statistics in the CipherTrust Manager with GuardPoint Status

During and after data transformation, you can view statistics about any GuardPoint on any client in your system. Either use the CipherTrust Manager, as described in this section, or use the `voradmin` command, as described in ["Obtaining CTE-LDT Statistics at the Command Line" below](#).

To display the GuardPoint status in CipherTrust Manager:

1. Open the **CTE** application and click **Clients** in the left-hand menu bar.
2. Click on the name of the client whose GuardPoint you want to view.
3. Click the Status of the GuardPoint you want to view in the GuardPoints table.
CipherTrust Manager displays the GuardPoint Health dialog box with various statistics about the GuardPoint.

Obtaining CTE-LDT Statistics at the Command Line

You can obtain CTE-LDT statistics from the command line using the following command:

```
# voradmin ldt stats <guard path> [interval]
```

This command displays transformation statistics for a GuardPoint, or for all GuardPoints, if none are specified. If you specify an interval (in units of seconds), the command continually updates the statistics on the given interval. If no GuardPoint is specified, the command returns the aggregate statistics at the host level, including specific statistics related to QoS. If a GuardPoint is specified, statistics include:

- Current rekey status
- Rekey Start time
- Last rekey completion time
- Estimated Rekey completion time
- Data Statistics including the amount of data transformed
- File statistics including:
 - Number of files transformed
 - Number of files skipped
 - Number of files remaining for rekey

Obtaining a Rekey Report

CTE-LDT generates a report automatically after completion of a key rotation. The report lists the files in the GuardPoint and the key and version of the key applied to each file. This kind of report may be a common compliance requirement.

The administrator can also request a rekey report during rekey, if the need to see the partial transformation results so far.

About the rekey report

On Linux hosts, CTE-LDT writes rekey reports to a local file on the agent host in `/var/log/vormetric/`. The file name begins with `ldaudit-log-`. It is followed by the file system directory name, GuardPoint directory name, and a timestamp. For example, for a GuardPoint at `/oxf-fs2/gp2` with rekey completed on November 19, 2016, just after 2:00 p.m. (hour 14), the rekey report file name would be `ldaudit-log-_oxf-fs2_gp2-2016111914917`.

The report includes:

- Total number of files in the GuardPoint
- Number of files transformed
- Rekey start and end times
- List of all files transformed
- Applied key and key version for each file (for example, files in different resource sets might have used different keys)

Manually generating a rekey report

To generate a rekey report manually, use the following command:

```
# voradmin ldt rekey report <GuardPoint> [<logfile>]
```

In `<GuardPoint>`, type the GuardPoint path. In `<logfile>`, you can optionally direct the output to a file. If no logfile is specified, the report displays on `stdout`.

Monitoring Ongoing CTE-LDT Operations at the Command Line (Windows only)

Use the following syntax to monitor CTE-LDT progress. If an interval is specified (in units of seconds), it continually updates the monitoring output at the specified interval.

```
C:\> voradmin ldt monitor [interval]
```

For an overview of `voradmin ldt`, see ["CTE-LDT Command-Line Administration: voradmin command" on page 71](#).

Protecting CTE-LDT GuardPoints against Failure in Underlying Filesystems (Linux)

CTE-LDT Recovery Challenges

The main challenge with CTE-LDT recovery is a failure to access files or specific blocks in files inside a GuardPoint. Before CTE-LDT runs the recovery process on a GuardPoint, the underlying file system was recovered before file system was mounted. File system recovery may create orphan files in the `lost+found` directory inside the mount point. If an orphan file belongs to the GuardPoint, CTE-LDT cannot recover the file as the file is no longer in the same directory as it was prior to the crash while it was undergoing rekey.

CTE-LDT Recovery Enhancement

CTE-LDT has been improved for handling inconsistencies in the underlying file system during execution of CTE-LDT recovery. When enabling a GuardPoint after a system crash, CTE-LDT performs consistency checks on the files undergoing rekey at the time of crash before enabling GuardPoint. If the CTE-LDT recovery process is unable to recover any of the affected files, the GuardPoint will not be enabled and CTE-LDT will send the following alert to the CipherTrust Manager:

```
[CGS3266E] LDT-ALERT: Cannot enable guard point [GuardPoint] due to inconsistencies in
underlying file system encountered during LDT recovery.
```

You can check the status of a GuardPoint and the reason for failing to enable a GuardPoint using the `seccfsd -status guard` command. For example, the GuardPoint `/mnt/gp` failed to guard because Guard point needs LDT recovery as reported in the `Reason` column for the following example GuardPoint.

GuardPoint	Policy	Type	ConfigState	Status	Reason
/mnt/gp	LDT220	manual	guarded	not guarded	Guard point needs LDT recovery

Details on the specific issues encountered, including any files that could not be recovered, are reported to a log file in the `/var/log/vormetric` directory. The log file name is in the format:

```
ldt_recovery_log:<guardpoint_name>:<timestamp>.txt
```

The log file name starts with `ldt_recovery_log`, followed by the GuardPoint pathname and the date and time of the recovery attempt. The GuardPoint pathname and date and time are separated with `:"`. For example:

```
/var/log/vormetric/ldt_recovery_log:_mnt_gp:2018-12-08-14:6:12.txt
```

Refer to the issues listed in the log file, and resolve those issues before enabling the GuardPoint again. A GuardPoint cannot be enabled in subsequent guard attempts until those issues are resolved. Each attempt generates a new log file. Check the CTE-LDT log file for missing files whose inode numbers match inode numbers of orphan files in `lost+found`. If there is a match, restore the file from `lost+found` to the pathname specified in the CTE-LDT recovery log file. Be sure to run the `mv` command to restore the file to the original location, do not run the `cp` command. After resolving all or some of the reported issues, you must run the command `voradmin ldt recover <GuardPoint>` to repeat the recovery process.

```
voradmin ldt recover <GuardPoint>
```

Running this command resolves the problems that can be corrected and clears the failed recovery status on the GuardPoint, allowing the GuardPoint to enable automatically within 30 seconds. If the GuardPoint does not enable, you can enable it using `secfsd -guard` command, if manual guard, or enable it on the CipherTrust Manager, if auto-guard. Note that if you are unable to resolve all of the reported issues, you accept the loss of some data or files, as reported in the latest recovery log file for the GuardPoint, when you run the command `voradmin ldt recover <GuardPoint>`.

Recovery Alerts

CTE-LDT sends two alerts to CipherTrust Manager if CTE-LDT fails to resolve the issues encountered during recovery.

The alert below is an error report sent to the CipherTrust Manager whenever CTE-LDT encounters failure during recovery prior to enabling GuardPoint. This alert also reports the GuardPoint specified in the message is not enabled:

```
[CGS3266E] LDT-ALERT: Cannot enable guard point [GuardPoint] due to inconsistencies in  
underlying file system encountered during LDT recovery.
```

The alert below is a warning report sent to the CipherTrust Manager only if `voradmin ldt recover` encounters errors and continues anyway. This alert reports the GuardPoint specified in the message has been enabled with some files in error status.

```
[CGS3267W] LDT-ALERT: LDT manual recovery on guard point [GuardPoint] completed with [#]  
errors.
```

The full message body does not currently appear in the logs on the CipherTrust Manager. At this time, the CipherTrust Manager shows the message ID without the message body.

Alerts Playbook

This section lists the CTE-LDT alerts and describes what to do in each case. CTE-LDT generates alerts when issues arise that require attention from the CipherTrust Manager Administrator. Without prompt attention, alerts can delay the rekey process or cause the process to remain incomplete.

Failure to Suspend or Resume CTE-LDT Operation

- **LDT-ALERT: Failed to suspend rekey on GuardPoint [GuardPoint]**

Solution: An I/O error is the most common cause of failure when updating the persistent state of a GuardPoint. For I/O errors, you must fix the problem at the host OS or storage level.

The appropriate corrective action depends on when this problem occurs and the reason for the suspension. If the suspend request was at the host level as part of a QoS schedule, or it was initiated by a user on the CipherTrust Manager, the failure occurred at the host level rather than the specified GuardPoint.

Otherwise, the source is probably the initiation of a suspension on a specific GuardPoint before backup. If the backup operation is in progress when this alert message occurs, you must fix the cause of the suspension failure and then restart the backup. If the backup has already completed when the alert message occurs, the backup image on the GuardPoint may have inconsistent data and CTE-LDT metadata. Discard this backup image and do a fresh backup.

If you cannot find and fix the host OS or storage issue, contact Thales Support for troubleshooting and recovery.

- **LDT-ALERT: Failed to resume rekey on GuardPoint [GuardPoint]**

- **LDT-ALERT: Failed to resume rekey on all GuardPoints**

Solution: An I/O error is the most common cause of failure when updating persistent state of a GuardPoint. For I/O errors, you must fix the problem at the host OS or storage level.

The appropriate corrective action depends on when this problem occurs and the source of the problem. If the resume request was at the host level as part of a QoS schedule, or the resume request was initiated by a user on the CipherTrust Manager, the failure occurred at the host level rather than the specified GuardPoint.

Otherwise, the source is probably initiation of a resume operation on a specific GuardPoint after a backup is completed.

If you cannot find and fix the host OS or storage issue, contact Thales Support for troubleshooting and recovery.

Insufficient Resources

The following alerts trigger when there are not enough resources for CTE-LDT operations.

- **LDT-ALERT: Aborting rekey of file [FileName] due to insufficient disk space**

The key rotation process was stopped on a GuardPoint because there was not enough available disk space.

Solution: Resize or free up space in the file system where the PathName resides. Key rotation automatically starts again when sufficient free space becomes available.

- **LDT-ALERT: Failed to launch transformation on [GuardPoint]**

CTE-LDT failed to launch the data transformation process on the specified GuardPoint.

Solution: The most common causes of this failure are:

- Low amount of system resources, such as free disk space.
- Check the system logs for insufficient free space in underlying file systems. You can free up space by removing older files or resizing your underlying file system. You may resize the file system on-line or off-line.

For other issues, contact Customer Support.

- **LDT-ALERT: QoS failed to start**

The Quality of Service subsystem failed to launch QoS services due to lack of system resources.

Solution: A low amount of available memory is the most common cause of this failure.

Contact Customer Support.

- **LDT-ALERT: Skipped key rotation on GuardPoint [GuardPoint] due to insufficient disk space**

- **LDT-ALERT: MDS file [PathName] exceeded disk space quota on gp [GuardPoint]**

There was not enough storage space in one or more file systems containing GuardPoints undergoing rekey.

Solution: Check the file systems where your GuardPoints reside to see how much space it is using. Add more storage space as needed. After the condition is corrected and disk space is available, CTE-LDT operations resume automatically.

- **LDT-ALERT: Low space on guard point [GuardPoint], increase free space or LDT will be suspended.**

Available storage space in the file system containing the GuardPoint is nearing the threshold below which CTE-LDT rekeying cannot continue. If available space does drop below that threshold, rekeying will be automatically suspended.

Solution: Check the file system where your GuardPoint resides to see how much space is available. Make more free space available if necessary. After the condition is corrected and storage space is available, rekeying resumes automatically.

Failed to Update CTE-LDT Attribute

The following alerts trigger when CTE-LDT extended attributes are not properly updated.

- **LDT-ALERT: Failed to update LDT attribute on GuardPoint [GuardPoint]. Error: [ErrorNumber]**

Solution: I/O error is the most common cause of failure when updating CTE-LDT extended attributes. For I/O errors, fix the problems at the host OS or storage level. In Linux, if you experience an I/O error, identify the file that had the error, and restore it from backup. See ["Backing Up and Restoring CTE-LDT GuardPoints" on page 62](#).

In Windows, you can recover a file that has corrupt metadata as follows:

- If the file is fully encrypted, remove the metadata. Type:

```
# voradmin ldt attr delete <file name path>
```

Then apply the same policy that was used to encrypt the data.

- If the file was only partially rekeyed, restore the file from a backup.

If you cannot find and fix the underlying host OS or storage issue that is causing corrupt metadata, contact Customer Support for troubleshooting and recovery.

- **LDT-ALERT: Failed to update LDT attribute**

CTE-LDT failed to create or update an CTE-LDT extended attribute of a file in a GuardPoint.

Solution: An I/O error is the most common cause of failure when updating an CTE-LDT extended attribute. For I/O errors, fix the problem at the host OS or storage level.

If you cannot find and fix the host OS or storage issue, contact Customer Support for troubleshooting and recovery.

Rekey Stopped

The following alert is specific to Windows and is triggered when rekey is stopped before it completes normally.

LDT-ALERT: Suspending rekey of binary file [PathName] during its execution

CTE-LDT operations encountered an executable file that is running.

CTE-LDT cannot rekey a running executable file until the execution of the binary file stops.

Solution (Windows)

1. Obtain the name of the executable file from the alert message.
2. Stop execution of the binary file.

Incomplete Key Rotation

- **LDT-ALERT: Failed to rotate key on GuardPoint [GuardPoint]. Another rekey operation is already in progress** (Windows only)
- **LDT-ALERT: Key rotation failed on GuardPoint [GuardPoint]**

CTE-LDT failed to complete the key rotation process on the specified GuardPoint. On Windows, this may occur if a key rotation process is already in progress on the GuardPoint. This pre-existing rekey operation could be active, or it could be in a suspended state, either because of the QoS schedule or a manual pause initiated by the administrator. See ["Suspending and Resuming Rekey and/or Scan Phase" on page 44](#).

Solution

1. On Linux, you can run the following command to see whether key rotation is in progress on the GuardPoint.

```
# voradmin ldt list all
```
2. On Linux or Windows, check the rekey status of GuardPoints in the CipherTrust Manager Console.
3. If key rotation is already in progress on a Windows GuardPoint, wait for the key rotation to complete.

Contact Customer Support if this error occurs on Linux or if the cause of key rotation failure on Windows is not a key rotation in progress.

Skipped Key Rotation

The following alerts trigger when CTE-LDT skips key rotation.

- **LDT-ALERT: Skipped key rotation on GuardPoint [GuardPoint]. It is on a read-only file system**

Key rotation is skipped on a specified GuardPoint because the mount point where the GuardPoint resides does not permit write operations.

Solution:

1. Remount the file system where the GuardPoint resides, and change the mount option to read/write.
 2. On the GuardPoint page on the CipherTrust Manager, press **Re-push Policies** to manually re-push the policies to the host to initiate key rotation on GuardPoints ready for key rotation.
- **LDT-ALERT: Failed to rotate key on GuardPoint [GuardPoint] during pre-commit**
 - **LDT-ALERT: Failed to rotate key on GuardPoint [GuardPoint] during commit**
 - **LDT-ALERT: Skipped key rotation on GuardPoint [GuardPoint]. Error: [ErrorNumber]**
 - **LDT-ALERT: Failed to update LDT attribute on GuardPoint [GuardPoint]. Error: [ErrorNumber]**

CTE-LDT failed to start a key rotation process on a GuardPoint during a guard operation or when processing a key rotation notification from the CipherTrust Manager. For [ErrorNumber], a Linux error number is substituted, such as `errorcode 17`.

Solution: The host returns error code 17 during CTE-LDT key rotation if it cannot perform the key rotation because there is already a rekey in progress. This pre-existing rekey operation could be active, or it could be in a suspended state, either because of the QoS schedule or a manual pause initiated by the administrator. See ["Suspending and Resuming Rekey and/or Scan Phase" on page 44](#).

An I/O error is the most common cause of failure when updating the persistent state of a GuardPoint. For I/O errors, fix the problem at the host OS or storage level.

If you cannot find and fix the host OS or storage issue, contact Customer Support for troubleshooting and recovery.

Failed to Update CTE-LDT Metadata During Scan Phase

CTE-LDT triggers the following alerts when CTE-LDT cannot properly update metadata during the scan phase. (See ["CTE-LDT Runtime Flow" on page 13](#) for information about the scan phase.)

- **LDT-ALERT: Scan error on [GuardPoint] removing MDS guard for relaunching dataxform**

CTE-LDT failed to update metadata when restarting a scan on the specified GuardPoint.

Solution: An I/O error is the most common cause of failure when updating CTE-LDT metadata. For I/O errors, fix the problem at the host OS or storage level and then restart operations.

If you cannot find and fix the underlying host OS or storage issue that is causing the error, contact Thales Support for troubleshooting and recovery.

- **LDT-ALERT: Online Dataform failed during post scan stage on [GuardPoint]**

CTE-LDT failed to update metadata when transitioning from scan to rekey phase on the specified GuardPoint.

Solution: An I/O error is the most common cause of failure when updating CTE-LDT metadata. For I/O errors, the problem must be fixed at the host OS or storage level and the operation restarted.

If you cannot find and fix the underlying host OS or storage issue that is causing the error, contact Customer Support for troubleshooting and recovery.

File system inconsistencies after system crash

CTE-LDT sends two alerts to the CipherTrust Manager if CTE-LDT fails to resolve the issues encountered during recovery.

The alert below is an error report sent to the CipherTrust Manager whenever CTE-LDT encounters failure during recovery prior to enabling GuardPoint. This alert also reports the GuardPoint specified in the message is not enabled:

- **LDT-ALERT: Cannot enable guard point [GuardPoint] due to inconsistencies in underlying file system encountered during LDT recovery**

The alert below is a warning report sent to the CipherTrust Manager only if `voradmin ldt recover` encounters errors and continues anyway. This alert reports the GuardPoint specified in the message has been enabled with some files in error status.

- **LDT-ALERT: LDT manual recovery on guard point [GuardPoint] completed with [#] errors.**

Solution: See ["Protecting CTE-LDT GuardPoints against Failure in Underlying Filesystems \(Linux\)" on page 80](#).

Error Messages

This section describes runtime error messages. For information about other types of runtime messages, see ["Alerts Playbook" on page 81](#) and ["Warning and Info Messages" on page 87](#).

Failed to Transform File During Rekey

CTE-LDT could not complete transformation on a file.

Related Messages:

- **LDT: Rekey failed for file [PathName] on GuardPoint [GuardPoint]**
- **LDT: Extended attribute of inode [InodeNumber] is corrupted under GuardPoint [GuardPoint]**

Solution: An I/O error is the most common cause of failure when updating CTE-LDT metadata. For I/O errors, fix the problem at the host OS or storage level, and then restore the file from a backup.

If you cannot find and fix the underlying host OS or storage issue that is causing the error, contact Customer Support for troubleshooting and recovery.

Failure to Suspend CTE-LDT

A request to stop CTE-LDT processing did not succeed. The suspend request was at the host level as part of a QoS schedule, or the suspend request was initiated by a user on the CipherTrust Manager.

Related Messages:

- **LDT: Failed to suspend rekey on all GuardPoints**
- **LDT operations could not be suspended on the host**

Solution: An I/O error is the most common cause of failure when updating the persistent state of a GuardPoint. For I/O errors, fix the problem at the host OS or storage level.

If a backup operation is in progress when this message occurs, you must fix the cause of the suspend failure and then restart the backup. If the backup has already completed when the alert message occurs, the backup image on the GuardPoint may have inconsistent data and CTE-LDT metadata. Discard this backup image and do a fresh backup.

If you cannot find and fix the host OS or storage issue, contact Customer Support for troubleshooting and recovery.

Failure to Start or Stop Transformation

The following general messages are recorded when there are errors attempting to start or stop CTE-LDT:

- **LDT: Failed to abort key rotation on GuardPoint [GuardPoint]**
- **LDT: Failed to start**
- **LDT: Failed to stop**
- **LDT: Failed to exit**

Solution: Examine system logs for additional information as to the cause. If you cannot find and fix the underlying host OS or storage issue that is causing the error, contact Customer Support for troubleshooting and recovery.

Failure to Restart Transformation

The following message is recorded when an attempt to restart transformation after a system reboot fails because the file system is mounted as read-only. Transformation on the specified GuardPoint cannot continue until the file system is mounted with write permission.

- **LDT: Skipped LDT recovery on read-only file system [GuardPoint]**

Solution: Re-mount the file system with write permissions.

Temporary Failure to Start Transformation on a File

The following messages are recorded when there are communication issues or lack of resources on the host. Once the condition is corrected, transformation of the file continues automatically:

- **LDT: Insufficient memory condition encountered during LDT on GuardPoint [GuardPoint]**
- **LDT: Encryption key for file [PathName] unavailable for LDT, possibly due to loss of communication to CipherTrust Manager**
- **LDT: Aborting rekey of file [PathName] due to lack of free memory. Try closing other application to resolve the issue**

Solution: Resolve the communication issues or increase the available resources, then verify that CTE-LDT has resumed processing.

Transient Condition while enabling GuardPoint

The following messages are recorded when a request is made to guard an CTE-LDT GuardPoint when GuardPoint initialization is already in progress. During the GuardPoint initialization, the system initializes MDS file associated with the GuardPoint in preparation for CTE-LDT. Initialization of the MDS file can take a few minutes. During this time, if

the system retries the guard operation, one of the following messages displays.

Related Messages:

- **Not re-guarding path *[path]* (Reason: GuardPoint initialization already in progress)**
- **Not re-guarding path *[path]* from container *[container]* (Reason: GuardPoint initialization already in progress)**

Solution: Wait for the current GuardPoint initialization to complete and then resubmit the new GuardPoint initialization request if desired.

Failed to transform passthrough files for AD database files (Windows Only)

CTE-LDT skipped the transformation of passthrough files for all AD database files. The problem occurs when the AD database remains in the default folder location.

Related Messages:

- **Skipping transformation of passthrough file *[filename]*. The file resides in the boot directory. CTE cannot encrypt boot directory files.**
- **Skipping transformation of passthrough file *[filename]*. CTE cannot encrypt these files. They are already encrypted using NTFS encryption or compressed.**
- **Skipping transformation of passthrough file *[filename]*. File is not in a GuardPoint directory.**

Solution: To fix this issue, move the AD database to any folder other than `c:\windows` or `c:\program files`.

Warning and Info Messages

This section describes runtime error messages. For information about other types of runtime messages, see ["Alerts Playbook" on page 81](#) and ["Error Messages" on page 85](#).

Stopping Transformation of a File on Volume Dismount (Windows only)

The following warning message is recorded when transformation of a file is stopped because the containing volume is dismounted.

- **LDT: Volume dismounted. Aborting transformation at file *[PathName]***

Issues with Policy or System Configuration

The following warning messages are recorded when CTE cannot perform CTE-LDT on the GuardPoint, because there are errors in the policy associated with the GuardPoint, or the file system containing the GuardPoint is not supported by CTE-LDT. Files in the GuardPoint can still be accessed, but no CTE-LDT encryption occurs.

- **LDT: The GuardPoint *[GuardPoint]* does not have a valid transformation policy, there is no new key rule**
- **LDT: The GuardPoint *[GuardPoint]* does not have a valid transformation policy, there is no key_op rule**
- **LDT: The GuardPoint *[GuardPoint]* does not support online rekey, only file operations from the offline data transform process will be allowed**

Failure to Enable GuardPoint During Cleanup

CTE-LDT records the following informational message when a user attempts to enable a newly added GuardPoint. This message displays if the GuardPoint directory was previously guarded with an CTE-LDT policy and the CTE-LDT metadata cleanup is in progress when user is guarding under the new policy.

- **LDT: Cannot enable GuardPoint [GuardPoint] during LDT clean-up process**

Solution: Retry the operation once the cleanup completes.

General CTE-LDT Operations

The following informational messages are recorded during various CTE-LDT operations. No action is required.

- **LDT: Successfully suspended rekey on GuardPoint [GuardPoint]**
- **LDT: Successfully suspended rekey on all GuardPoints**
- **LDT: Successfully resumed rekey on GuardPoint [GuardPoint]**
- **LDT: Successfully resumed rekey on all GuardPoints**
- **LDT: Rekey operation completed on GuardPoint [GuardPoint]**

Missing CTE-LDT extended attribute

The following warning message reports that the file with the specified inode number in the specified GuardPoint directory does not have an CTE-LDT extended attribute, therefore, access to the file is denied.

- **LDT: Extended attribute of inode [InodeNumber] is missing under GuardPoint [GuardPoint]**

Solution: CTE-LDT cannot determine the encryption key associated with the data in the file, therefore, you can only remove the file.

Locking Contention

The following messages are recorded during the rekey process on a file. When user access to the file is very high, it causes a high degree of locking contention between the rekey process and user access. The second message reports when the contention is no longer in effect and the rekey process has resumed accessing file to rekey.

- **LDT: Exclusive access for rekey delayed on inode [InodeNumber]**
- **LDT: Exclusive access for rekey granted after delay on inode [InodeNumber]**

Initiation and completion of CTE-LDT metadata cleanup

The following messages are recorded at the beginning and completion of CTE-LDT metadata cleanup through voradmin command.

- **LDT: Metadata will start getting removed from all files in GuardPoint [GuardPoint]**
- **LDT: Metadata has been removed from all files in GuardPoint [GuardPoint]**

Recommendations and Considerations

The following information provides guidance for a better user experience.

All Platform Recommendations and Considerations

Binary Re-signing

Any executable that is part of either a Signature set or a Host setting, and that resides in a GuardPoint that uses an CTE-LDT policy, will use different signatures for an CTE-LDT key rotation. The result is that the Host Settings binaries will no longer be authenticated, or that the Signature Set policy rules will no longer trigger for those binaries.

To prevent these issues, the Security Administrator must manually re-sign each affected binary after each key rotation.

Alternatively, CTE can generate unencrypted signatures of binaries inside GuardPoints to avoid these problems. For details, see the CipherTrust Manager documentation.

Check for available disk space for CTE-LDT metadata

Before launching CTE-LDT on a GuardPoint:

1. Check the available free disk space in the file system where your GuardPoint resides.
2. Type the following command to check the disk space requirement of CTE-LDT on a target GuardPoint:

```
# voradmin ldt space /oxf-fs1/gp1
/oxf-fs1/gp1: found 1501 files without LDT extended attributes
LDT disk space requirements: total 169MB (LDT attributes=6MB, MDS=163MB)
```

In this example, the output shows that CTE-LDT requires 169MB of available disk space to launch and execute CTE-LDT on /oxf-fs1/gp1.

Note

Make sure that the free space in your file system exceeds the disk space requirement for CTE-LDT.

CTE-LDT Requirements for Backup

CTE offers the option to backup encrypted data from files through a security rule, which skips the Apply Key function when reading encrypted files by backup applications or processes. Such files can also be restored from backup streams, to the same or a different GuardPoint, without Apply Key. If you choose to restore to another GuardPoint, the target GuardPoint must be protected with the same key and security rules as the source GuardPoint.

If you backup encrypted data from files inside GuardPoints with CTE-LDT policies, CTE-LDT imposes a hard requirement on the backup application, or process, to backup or restore CTE-LDT metadata. The CTE-LDT metadata is stored as an extended attribute on Linux and as alternate data streams on files on Windows platforms. If the backup process cannot backup the metadata, then CTE-LDT protected GuardPoints must be backed up in clear key.

Customers are required to verify their backup application, or process, to ensure extended attributes (on Linux) or alternate data streams (on Windows) are backed up and restored through their backup/restore processes.

Note

Make sure that you suspend CTE-LDT operations before you start the backup process, and resume them after the backup process completes.

Learn Mode

Learn Mode provides a temporary method for disabling the blocking behavior of regular CTE or CTE-LDT policies. While useful for quality assurance, troubleshooting, and mitigating deployment risk, Learn Mode is not intended to be enabled permanently for a policy in production. This prevents the policy Deny rules from functioning as designed in the policy rule set.

Ensure that the policy is properly configured for use in Learn Mode. Any Security Rule that contains a Deny effect must have Apply Key applied as well. This is to prevent data from being written in mixed states, resulting in the loss of access or data corruption.

Note

Apply Key will have no effect when combined with a Deny rule unless the policy is in Learn Mode.

Quality of Service (QoS)

By default, the QoS component of CTE-LDT does not monitor live transformation operations unless you enable QoS on your host by entering QoS parameters in the CipherTrust Manager profile associated with the client. To avoid overhead of CTE-LDT on your production system, you must select QoS parameters suitable to your production environment. For information on tuning QoS, see ["Quality of Service" on page 29](#). It is critical that you understand the impact of CTE-LDT on your system and how to manage this impact using QoS.

Upgrade to CTE 7.0.0

Since the first release of the CTE-LDT feature, Thales has made several improvements in the areas of error handling, interoperability with applications, and Quality of Service (QoS). Thales strongly recommends that new deployments use version 7.0.0 (or later) of CTE. Thales further recommends that customers who have already deployed the CTE-LDT feature upgrade to version 7.0.0.

Windows Recommendations and Considerations

File Handling

The CTE-LDT process is subjected to all of the File System policies and attributes set on the files. In some cases, this prevents CTE-LDT from encrypting a file. If users or applications are accessing files while CTE-LDT is in progress, CTE-LDT cannot change the attributes of the files and encrypt the file. It is critical that you understand how CTE-LDT handles various types of files:

- **NTFS Encryption and Compression**

If NTFS encryption or compression is enabled on a file or folder, the CTE-LDT process cannot encrypt these files. To maintain the data coherency, CTE-LDT skips the encryption of these files. These files display as "passthrough" files in the CTE-LDT statistics.

- **Read-Only Files**

As the CTE-LDT process performs a read-encrypt-write operation on a file, it cannot encrypt read-only files. The CTE-LDT process skips these files and changes to the INCOMPLETE state.

- **Executable Files**

If an executable is running or files are exclusively locked by the application, the CTE-LDT process cannot encrypt those files as it is unable to acquire the required locks on the files. CTE-LDT skips these files and changes to the INCOMPLETE state.

File Modification

The CTE-LDT process performs a read-encrypt-write operation on the files that need to be encrypted, (also known as rekeying). Previously, file modification and access dates were changed when CTE-LDT was processing. In order to maintain compatibility for applications, we addressed this issue by saving a copy of the original access and modification times, and restoring them after the encryption completed. Preserved timestamps are updated during the rekey process, if an application/user accesses the files during rekey.

Note

Thales strongly recommends that you upgrade to the newly released v6.1.0 so that the access time and modification time is restored correctly.

CTE-LDT Limitations

- CTE-LDT on CIFS is not supported.
- CTE-LDT on a ReFS file system runs slowly because of limited support from the Extended Attributes on the ReFS file system.

Note

Customers running older versions of ReFS.sys on Windows Server 2012 R2 should be aware of the memory growth issue encountered by the Thales engineering team. This issue seems to occur only when CTE-LDT is running on a large number of files. As the system memory consumption by REFS file system increases, it can eventually make the system unresponsive. This issue does not occur with the recent versions of ReFS file system drivers available on Windows Server 2016. After consulting with Microsoft, they suggest that all customers migrate to Windows Server 2016 if they are using ReFS file.

Logical Sector Size

CTE-LDT Windows transformation is supported if the **logical sector size** is more than 512 Bytes. (A logical sector size of 4K is supported.) To find the logical sector size of the file system, type:

```
> fsutil fsinfo ntfsInfo <volume pathname>
```

For example:

```
> fsutil fsinfo ntfsInfo C:
NTFS Volume Serial Number :      0x5092568a92567506
NTFS Version      :              3.1
LFS Version      :              2.0
Number Sectors :      0x000000001c004eeb
Total Clusters :      0x00000000038009dd
Free Clusters  :      0x00000000008bb274
Total Reserved :      0x0000000000001864
Bytes Per Sector :              512
.
.
.
```

CTE-LDT Limitations on Linux

- CTE-LDT on NFS share is not supported.
- CTE-LDT support is limited to `ext3`, `ext4`, `XFS`, and `VxFS` file systems when `user_xattr` mount option is enabled.

CipherTrust Transparent Encryption

CTE-Live Data Transformation with Data Security Manager

Release 7.0.0

Document Version 1

September 22, 2020

The bottom half of the page features a dark blue background with abstract geometric shapes. On the left, there is a large, bright blue triangle pointing upwards. Below it, a smaller, darker blue triangle points upwards. In the bottom left corner, there is a blue circular shape with a dotted pattern. The right side of the page has a vertical gradient bar and a dotted pattern at the bottom.

Nothing herein shall be construed as implying or granting to you any rights, by license, grant or otherwise, under any intellectual and/or industrial property rights of or concerning any of Thales DIS France S.A. and any of its subsidiaries and affiliates (collectively referred to herein after as "Thales") information.

This document can be used for informational, non-commercial, internal and personal use only provided that:

- The copyright notice below, the confidentiality and proprietary legend and this full warning notice appear in all copies.
- This document shall not be posted on any network computer or broadcast in any media and no modification of any part of this document shall be made.

Use for any other purpose is expressly prohibited and may result in severe civil and criminal liabilities.

The information contained in this document is provided "AS IS" without any warranty of any kind. Unless otherwise expressly agreed in writing, Thales makes no warranty as to the value or accuracy of information contained herein.

The document could include technical inaccuracies or typographical errors. Changes are periodically added to the information herein. Furthermore, Thales reserves the right to make any change or improvement in the specifications data, information, and the like described herein, at any time.

Thales hereby disclaims all warranties and conditions with regard to the information contained herein, including all implied warranties of merchantability, fitness for a particular purpose, title and non-infringement. In no event shall Thales be liable, whether in contract, tort or otherwise, for any indirect, special or consequential damages or any damages whatsoever including but not limited to damages resulting from loss of use, data, profits, revenues, or customers, arising out of or in connection with the use or performance of information contained in this document.

Thales does not and shall not warrant that this product will be resistant to all possible attacks and shall not incur, and disclaims, any liability in this respect. Even if each product is compliant with current security standards in force on the date of their design, security mechanisms' resistance necessarily evolves according to the state of the art in security and notably under the emergence of new attacks. Under no circumstances, shall Thales be held liable for any third party actions and in particular in case of any successful attack against systems or equipment incorporating Thales products. Thales disclaims any liability with respect to security for direct, indirect, incidental or consequential damages that result from any use of its products. It is further stressed that independent testing and verification by the person using the product is particularly encouraged, especially in any application in which defective, incorrect or insecure functioning could result in damage to persons or property, denial of service or loss of privacy.

Preface

CTE-Live Data Transformation with Data Security Manager describes how to configure and use CipherTrust Transparent Encryption - Live Data Transformation (CTE-LDT) when the host is registered to a Vormetric Data Security Manager (DSM). If you want to use CipherTrust Manager as your key manager, see the *CTE-Live Data Transformation with CipherTrust Manager* guide.

CTE-LDT is an optional, separately licensed feature of CipherTrust Transparent Encryption (CTE). With CTE-LDT, a DSM Administrator can change the encryption key and re-encrypt GuardPoint data without suspending user or application access to the data.

Intended Audience

CTE-Live Data Transformation with Data Security Manager is for security teams who want to rekey the existing GuardPoint data, or who need to perform an initial encryption of their GuardPoint data.

Assumptions

CipherTrust Transparent Encryption - Live Data Transformation is an enhancement to existing functionality. This documentation assumes the reader is familiar with the following CipherTrust products and processes:

- Vormetric Data Security Manager (DSM)
- CipherTrust Transparent Encryption (CTE)
- Key management
- Data encryption

The CTE Agent Documentation Set

The following guides are available for CTE Agent:

- *CTE Agent for Linux Quick Start Guide*
- *CTE Agent for Linux Advanced Configuration and Integration Guide*
- *CTE Agent for Windows Quick Start Guide*
- *CTE Agent for Windows Advanced Configuration and Integration Guide*
- *CTE Agent for AIX Installation and Configuration Guide*
- *CTE-Live Data Transformation with Data Security Manager*
- *CTE-Live Data Transformation with CipherTrust Manager*
- *Compatibility Matrix for CTE Agent with CipherTrust Manager*
- *Compatibility Matrix for CTE Agent with Data Security Manager*
- *Compatibility Matrix for CTE Agent for AIX with CipherTrust Manager*
- *Compatibility Matrix for CTE Agent for AIX with Data Security Manager*
- *Release Notes for CTE for Linux Version 7.0.0.47*
- *Release Notes for CTE for Windows Version 7.0.0.47*
- *Release Notes for CTE for AIX Version 7.0.0.11*

Document Conventions

The document conventions describe common typographical conventions and important notice and warning formats used in Thales technical publications.

Typographical Conventions

This section lists the common typographical conventions for Thales technical publications.

Table 3-1: Typographical Conventions

Convention	Usage	Example
bold regular font	GUI labels and options.	Click the System tab and select General Preferences.
<i>bold italic monospaced font</i>	variables or text to be replaced	https://<Token Server name>/admin/ Enter password: <Password>
<code>regular monospaced font</code>	Command and code examples XML examples	Example: session start iptarget=192.168.253.102
<i>italic regular font</i>	GUI dialog box titles	The <i>General Preferences</i> window opens.
	File names, paths, and directories	/usr/bin/
	Emphasis	<i>Do not</i> resize the page.
	New terminology	<i>Key Management Interoperability Protocol (KMIP)</i>
	Document titles	See <i>CTE-Live Data Transformation with Data Security Manager</i> for information about CipherTrust Transparent Encryption.
quotes	File extensions Attribute values Terms used in special senses	"js", ".ext" "true" "false", "0" "1+1" hot standby failover

Notes, tips, cautions, and warnings

Notes, tips, cautions, and warning statements may be used in this document.

A Note provides guidance or a recommendation, emphasizes important information, or provides a reference to related information. For example:

Note

It is recommended to keep tokenization keys separate from the other encryption/decryption keys.

A tip is used to highlight information that helps you complete a task more efficiently, such as a best practice or an alternate method of performing the task.

Tip

You can also use Ctrl+C to copy and Ctrl+P to paste.

Caution statements are used to alert you to important information that may help prevent unexpected results or data loss. For example:

CAUTION

Make a note of this passphrase. If you lose it, the card will be unusable.

A warning statement alerts you to situations that can be potentially hazardous to you or cause damage to hardware, firmware, software, or data. For example:

WARNING

Do not delete keys without first backing them up. All data that has been encrypted with deleted keys cannot be restored or accessed once the keys are gone.

Sales and Support

If you encounter a problem while installing, registering, or operating this product, please refer to the documentation before contacting support. If you cannot resolve the issue, contact your supplier or Thales Customer Support.

Thales Customer Support operates 24 hours a day, 7 days a week. Your level of access to this service is governed by the support plan arrangements made between Thales and your organization. Please consult this support plan for further information about your entitlements, including the hours when telephone support is available to you.

For support and troubleshooting issues:

- <https://supportportal.thalesgroup.com>
- (800) 545-6608

For Thales Sales:

- <https://cpl.thalesgroup.com/>
- CPL_Sales_AMS_TG@thalesgroup.com
- (888) 267-3732

Chapter 1: Introduction to CTE-LDT

This chapter contains the following sections:

Overview of CTE-LDT	12
Keys in CTE-LDT (Versioned Keys)	13
CTE-LDT Policies	14
CTE-LDT Runtime Flow	14
CTE-LDT Administrator Roles	16
Resiliency	17

Overview of CTE-LDT

CipherTrust Transparent Encryption - Live Data Transformation (CTE-LDT) is an optional, separately licensed feature of CipherTrust Transparent Encryption (CTE). With CTE-LDT, after enabling a GuardPoint, a DSM Administrator can encrypt, or rekey, GuardPoint data without blocking user or application access to the data. In CTE-LDT, *rekey* means decrypting data with the current cryptographic key and then encrypting it with a new cryptographic key. The concept of rekey, and how CTE-LDT rekeys data, is described in this document.

After enabling GuardPoints, CTE-LDT performs *initial* encryption or rekeying in the background, unnoticed by users. The data stays live and available. This accelerates CTE deployments and eliminates the need to block application and user access to data during encryption or rekey operations, which can seriously inconvenience users and affect operational efficiency.

With CTE-LDT, the DSM Administrator can create a single CTE-LDT policy for both initial encryption and subsequent rekeying. The same policy applies to production access and security rules without restricting user or application access to data. Applications have continuity of access to GuardPoint data during CTE-LDT.

WARNING

To prevent data loss or corruption, you must stop all applications and users that are accessing files inside a GuardPoint before enabling a Live Data Transformation encryption policy for that GuardPoint. Terminating the applications closes all files that are currently being accessed inside the GuardPoint.

Unlike non-Live Data Transformation policies, however, you do *not* need to keep the GuardPoint offline while data transformation takes place. Instead, you can restart all applications as soon as the GuardPoint has been applied to the host, and CTE will perform the data encryption in the background. This is the only application service downtime required when using CTE-LDT.

Use Cases

This section provides a summary of typical uses for CTE-LDT. The concepts mentioned in this section are described in more detail throughout the rest of this guide.

1. Encrypt unprotected data.

When protecting files in a directory, you must encrypt them. This process is called *initial data encryption*.

2. Convert non-CTE-LDT GuardPoints to CTE-LDT GuardPoints

Use when you have existing GuardPoints that are protected with policies created before you started using CTE-LDT.

3. Rekey process.

Changing the key from one version to another version of the same key provides more security. Using CTE-LDT, you can change the encryption keys to more secure keys.

4. Transform the encrypted data to clear data.

Keys in CTE-LDT (Versioned Keys)

CTE-LDT uses *versioned* keys. Each version of a particular versioned key has the same key name and encryption algorithm, but its own unique cryptographic material. That means that data encrypted with version 3 of a key named `LDT-Key` *cannot* be decrypted by *any* other version of `LDT-Key`, even though the key name remains the same.

Versioning allows you to add one key to your CTE-LDT encryption policy and then use different versions of that same key to periodically re-encrypt your data over time. CTE-LDT uses the new key material to transform data to the new key version, as part of the same Live Data Transformation policy that also protects the data. The process of re-encrypting data with a new version of the existing key is called *Key Rotation*.

When you create a versioned key in the DSM, you set its *life span*. The life span is the duration (in days) of the versioned key. You also define an *initial expiration date*. When the key reaches its expiration date, it automatically rotates to a new version. After that it rotates every time its life span ends. For example, if you set an initial expiration date of October 10, 2021 and a life span of 10 days, the data will be automatically rekeyed first on October 10th and then on October 20th, October 30th, and so on.

Versioned keys all have the same properties as non-versioned keys, plus three additional required properties:

- **Automatic Key Rotation:** Always select this option to make the key automatically rotate. Selecting this option tells the DSM that the key is a versioned key.
- **Key Version Life Span (days):** Frequency of key rotation in days. Applies only if Automatic Key Rotation is selected.
- **Expiration Date:** CTE-LDT uses the initial version of the key until this date occurs. On the expiration date, CTE-LDT creates a new key version. Subsequently, it creates new versions based on the Key Version Life Span.

WARNING

You *must* specify the Expiration Date. Without an Expiration Date, a versioned key never rotates from the initial key version, and consequently, never triggers CTE-LDT.

Rekey | Key Rotation

In CTE-LDT, *rekeying* or *key rotation* means decrypting the data with a previous version of the key and re-encrypting it with a new version of the key. CTE-LDT allows users and applications to access data while CTE-LDT is rekeying the data. Rotating the key and re-encrypting the GuardPoint data with the new version of the key helps to maintain a high level of data security.

Most often, the rekey happens automatically, because each versioned key has a Key Version Life Span that specifies the lifespan of the key. In addition to this automatic key version rotation, you can manually generate a new version of the current key if a new version is required.

For more information, see:

- ["Creating and Viewing Versioned Keys" on page 27](#)
- ["Rotating Encryption Keys \(Rekey\)" on page 44](#)

CTE-LDT Policies

In CTE-LDT, you define a single policy for initial data encryption and subsequent rekeying. The policy specifies:

- **Current key**

Associated with data that you want to protect using CTE-LDT. This is either a non-versioned key from an earlier policy, or `clear_key`, which means that the data is not currently encrypted.

- **Transformation key**

The versioned key that CTE-LDT applies to transform the data from the key used for initial data transformation. When the transformation key rotates, it transforms the data from a previous version of the transformation key to a new version.

Note

Transformation key and versioned key are used interchangeably throughout this document.

As soon as CTE-LDT applies the policy to a GuardPoint and enables protection for it, CTE-LDT triggers an initial transformation from the current key to the transformation key.

Note

With DSM 6.1 or later, you may select current or transformation keys for CBC or CBC-CS1 encryption modes.

When the transformation key expires, it generates the next version of the versioned key with new cryptographic material. The DSM then pushes the policy to the hosts. The policy now contains the new version of the key. This initiates a rekey process on the GuardPoint to transform data to the new version of the transformation key specified in the policy.

Users and applications can continue accessing data without any interruption during initial encryption and subsequent key transformations.

Note

During CTE-LDT policy creation, you must use the Apply Key effect in your policy. If you do not, then end users can see the clear text data until the file is transformed.

CTE-LDT Runtime Flow

This section presents an overview of how CTE-LDT works and what to expect when CTE-LDT is enabled and running in your environment. All of the tasks mentioned here are described in more detail later in this chapter.

First, the administrator completes CTE-LDT setup:

1. Upload the CTE-LDT license on the DSM.
2. Register CTE-LDT hosts with the DSM and be sure that the hosts are licensed for CTE-LDT.
3. Create one or more versioned keys.
For each key, specify **Automatic Key Rotation**, the **Expiration Date**, and the **Key Version Life Span**.
4. Define Live Data Transformation policies which use the versioned key(s) and contain rules governing CTE-LDT operations.

5. Optionally provide Quality of Service (QoS) settings for the CTE-LDT hosts. The QoS settings control the:
 - Window of time in which CTE-LDT operations are allowed to run.
 - Percentage of CPU resources that CTE-LDT can use, or the amount of data to transform according to the QoS setting per the DSM Administrator.

Note: Configuring the QoS settings is highly recommended as a best practice.

When these items are set up, CTE-LDT is ready to transform and encrypt data by applying policies to GuardPoints for live initial transformation and subsequent rekeys, as well as enforcement of security rules.

The following figure shows the sequence of events during ongoing usage of CTE-LDT.

Figure 1-1: Phases of CTE-LDT runtime operation after keys and policies are defined

1. Initial data transformation starts or key expires

CTE-LDT begins when an Live Data Transformation policy is first applied to a GuardPoint or when a current key version expires. The DSM pushes the new policy, or the notification of a key version change, to the hosts that are protected by the policy. (If the same versioned key is used in multiple policies, *all* of the hosts associated with the policies that contain the key are notified when the key changes.)

2. New key version triggers a rekey on the affected GuardPoints

On each host, CTE determines which GuardPoints are using the key that has just rotated to a new version. CTE starts an CTE-LDT rekey on each of those GuardPoints.

On Windows, you must wait for the current key rotation process to finish before you can launch another rekey request. On Linux, if another rekey is already underway on that GuardPoint, the new rekey is queued for later execution. For details, see ["Rotating Encryption Keys While a Rekey is in Progress \(Relaunch\)" on page 47](#).

3. Scan for files

On each GuardPoint where CTE has started a rekey, CTE-LDT determines which files to transform. CTE-LDT takes inventory of files encrypted with earlier versions of the rotated key and makes a persistent list of the files for transformation. During this phase, the Rekey Status in the GuardPoint Status window of the DSM Management Console displays Starting, then Scanning.

The scan phase might be interrupted, such as by a host reboot. In this case, when the host reboots and the GuardPoint is enabled again, the scan operation starts over from the beginning.

4. Rekey/Key Rotation

- a. Each file, from the persistent list of files, is decrypted using the old version of the key. The old key is applied to each file and then re-encrypted using the new version of the key. Note that new files created during the CTE-LDT process do not need to be rekeyed, as they inherit the new version of the key. Multiple files and multiple regions of files are rekeyed simultaneously.
- b. The CTE-LDT extended attribute of each file is updated. (For more about extended attributes, see ["CTE-LDT Metadata in Extended Attributes" on page 59.](#))
- c. You can suspend and resume the CTE-LDT rekey operation manually, or through the QoS schedule. This manages the impact CTE-LDT has on other applications and processes.

During this phase, the Rekey Status in the GuardPoint Status window of the DSM Management Console shows Rekeying or Suspended.

If system errors occur during rekeying, such as IO errors or crashes, CTE-LDT can manage and recover from them after the system error is fixed.

5. Finish

When all of the required files in the GuardPoint have been rekeyed, the system and storage resources used by CTE-LDT are released, except for the storage required for the extended attributes.

CTE-LDT creates a rekey report, listing all of the files that were rekeyed. For more information, see ["Obtaining a Rekey Report" on page 83.](#)

Upon completion of rekey, the Rekey Status in the GuardPoint Status window of the DSM Management Console shows Rekeyed.

CTE-LDT Administrator Roles

Using CTE-LDT requires coordination and collaboration between several different administrators. Security, system, application performance and backup schedules are critical factors that affect planning. It is very important for the **DSM Security Administrator** to coordinate with the **system administrator** and the **backup administrators**. The following table describes the roles and responsibilities for these administrators.

CTE-LDT Administrators

Role	Responsibility	Actions
DSM Security Administrator	Administers Vormetric Data Security Manager (DSM)	Coordinates with system and backup administrators. Creates security policies and rules for CTE-LDT. Defines Quality of Service settings for CTE-LDT, applications, and backups.
System administrator	Administers servers on which CipherTrust Transparent Encryption (CTE) is deployed	Coordinates with the DSM Security Administrator to create Quality of Service schedule, taking into consideration the backup schedules.
Backup administrator	Manages data backups for data encrypted by CTE	Coordinates with the DSM Security Administrator to create Quality of Service schedule, taking into consideration the backup schedules.

The following process is recommended for coordination between the various administrators in order to achieve optimal QoS schedule settings and allocation of CPU resources when using CTE-LDT.

Resiliency

CipherTrust Transparent Encryption - Live Data Transformation is resilient to many user actions and system occurrences. Since it is designed to run periodically without intervention, it includes various features to provide this resilience.

Before CTE-LDT enables a GuardPoint, it checks for any inconsistencies in files that were undergoing rekey at the time when system operations were interrupted. If it finds any inconsistencies, CTE-LDT corrects them before it enables the GuardPoint. It should only take a few seconds to identify and correct any inconsistency. On Windows, this process is delayed until applications access the affected files.

During rekey, if an issue such as an I/O problem or system crash occurs, the resiliency features of CTE-LDT ensures the consistency of user data. Such issues can cause an interruption in the middle of a rekey operation. When system operations resume, CTE-LDT corrects the problems and then resumes rekeying.

Chapter 2: Getting Started

This chapter contains the following sections:

Using CTE-LDT	18
Backup/Restore	19
Restrictions	19

Using CTE-LDT

Notes

- If you are new to CTE and CTE-LDT, read the *DSM Administration Guide* first to familiarize yourself with the concepts of GuardPoints and Policies.
- Before installing CTE-LDT, see the *Compatibility Matrix for CTE Agent with Data Security Manager* to verify that your version of Linux is supported. Contact Thales Technical Support (<https://supportportal.thalesgroup.com>) for the matrix.

The following list contains the steps for successfully setting up and using CTE-LDT.

1. Install the CTE-LDT License on the DSM.
CipherTrust Transparent Encryption - Live Data Transformation is a separately-licensed feature of CTE. Before you can use it, you have to install the license to activate it. CTE-LDT is licensed for a specific number of hosts. For details about licensing, see the *DSM Administration Guide*.
2. Install the CTE Agent and select the CTE-LDT feature during the install. For more information, see ["Installing and Registering the CTE Agent Software" on page 22](#).
If the host is already registered, you can enable CTE-LDT through the DSM Management Console. For details, see ["Enabling CTE-LDT on a Protected Host" on page 25](#).
3. Create Versioned Keys.
CTE-LDT uses *versioned keys*. A versioned key rotates to the next version of the key generating new key material automatically without policy change. CTE-LDT encrypts data with keys that use encryption standards like AES-128 and AES-256. This allows data to be re-encrypted without users having to edit the policy.
For more information, see ["Keys in CTE-LDT \(Versioned Keys\)" on page 13](#) and ["Creating and Viewing Versioned Keys" on page 27](#).
4. Create CTE-LDT Policies.
CTE-LDT uses a single Live Data Transformation policy to address both initial encryption and subsequent rekeying. The same policy applies to production access and security rules without restricting user or application access to data. Applications have continuity of access to GuardPoint data during CTE-LDT.
For more information, see ["Creating CTE-LDT Policies" on page 29](#).
5. Set QoS Settings.
QoS enables administrators to manage and control CTE-LDT impact to application workloads by monitoring and controlling the use of host system resources, such as memory or I/O utilization, during CipherTrust Transparent Encryption - Live Data Transformation. Administrators can also choose schedules for data transformation, or manually pause or resume transformation operations.
For more information, see ["Quality of Service" on page 30](#).

6. Create GuardPoints and Apply CTE-LDT policies to the GuardPoints

A GuardPoint is a directory in the file system hierarchy, where its contents have a CipherTrust data protection policy applied to it. The CTE Agent intercepts any attempt to access anything in the GuardPoint and uses the policies obtained from the DSM to grant or deny the access attempt. Typically data copied into a GuardPoint is encrypted, and only authorized users can decrypt and use that GuardPoint data.

For more information, see ["Create an CTE-LDT GuardPoint" on page 41](#).

Backup/Restore

Before you enable GP with CTE-LDT policies, make sure that you back up your data.

For more information, see ["Backing Up and Restoring CTE-LDT GuardPoints" on page 64](#).

Restrictions

Remember the following restrictions when using CTE-LDT:

- CTE-LDT does not support nested GuardPoints, where a GuardPoint is contained inside another GuardPoint.
- For HA clusters, CTE-LDT only supports the Asymmetric (active/passive) configuration. CTE-LDT does not support Symmetric (active/active) configuration.

Windows Only Limitations

CTE-LDT does not support GuardPoints on CIFS network shared directories.

Linux Only Limitations

- CTE-LDT does not support Linux automounted file systems.
- CTE-LDT does not support system hibernation (`pm-hibernate`) on Linux hosts where CTE-LDT is in use.
- CTE-LDT does not support GuardPoints on NFS shares and `secvm` configured devices.
- Do not use CTE-LDT on GuardPoints over XFS and VxFS file systems at the same time.
- You cannot use CTE-LDT and Docker container on the same host.
- You cannot use CTE-LDT and OpenShift container on the same host.

Chapter 3: Setting Up CTE-LDT

This chapter contains the following sections:

System Requirements	20
Installing the CTE-LDT License	21
Installing and Registering the CTE Agent Software	22
Setting the Linux Kernel Time Zone	25
Enabling CTE-LDT on a Protected Host	25

System Requirements

CipherTrust Transparent Encryption - Live Data Transformation (CTE-LDT) requires the following environment.

Note

See the latest *Compatibility Matrix for CTE Agent with Data Security Manager*, in the online support portal, for a list of CTE versions and supported operating systems.

CipherTrust Software Requirements

Platform	CTE Agent Version	DSM Version
Linux	VTE Agent version 6.0.0 or higher or CTE Agent version 7.0 or higher installed on each protected host.	DSM version 6.0 or higher.
Windows	VTE Agent version 6.1.0 or higher or CTE Agent version 7.0 or higher installed on each protected host.	DSM version 6.1.x or higher.

CTE-LDT License Requirements

One CTE-LDT license is required for *each* protected host.

Host System Requirements

Memory requirements: Both Linux and Windows require a minimum of 8 GB memory on each protected host.

Disk space requirements: CTE-LDT requires a specific amount of disk space in the file system, over and above the space required for the guarded files themselves. CTE-LDT uses the additional space to store CTE-LDT metadata.

- For Linux, to estimate the amount of free file system disk space required by CTE-LDT on a Linux host, use the `voradmin ldt space` command.
- For Windows, the typical minimum space requirement for a GuardPoint is the number of files in the GuardPoint multiplied by 4K, plus 256MB. To estimate the amount of free space required for a GuardPoint, use the `voradmin ldt space <GuardPoint-name>` command.

Backup Requirements

The backup application must have the capability to back up user-extended attributes. For example, Thales tested CTE-LDT with NetBackup. You can also use other applications that can back up user-extended attributes.

Note

For Windows, the application must use Volume Shadow Copy service (VSS) for backup and restore.

Linux-Specific Requirements

To use CTE-LDT on an ext3 or ext4 file system, the block size **must** be 4K. Run `dumpe2fs` to determine the block size of the ext3 or ext4 file systems before using CTE-LDT. This limitation does not apply to XFS or VxFS file systems. You can use CTE-LDT on XFS with a block size of 1K or 2K.

For CTE-LDT to work properly, the underlying file system must support and enable user-extended attributes. All of the file systems supported by CTE-LDT support these attributes. If you are using CTE-LDT with ext3 or ext4 mount points, you must explicitly enable the extended attribute mount option by editing `/etc/fstab` and adding the `user_xattr` mount option. In the other file systems supported by CTE-LDT, user extended attributes are enabled by default, so you do not have to explicitly enable them.

Example `/etc/fstab` entry for ext3 on Red Hat 6 or SLES:

```
/dev/sdb1 /disk2 ext3 defaults,user_xattr 0 0
```

Example `/etc/fstab` entry for ext4 on Red Hat 6 or SLES 12 (ext4 is not supported on SLES 11):

```
/dev/sdc1 /disk3 ext4 auto,users,user_xattr,exec 0 0
```

For more information about extended attributes, see ["CTE-LDT Metadata in Extended Attributes" on page 59](#).

Supported Applications in Linux

For all of the supported operating systems for database applications, see the *Compatibility Matrix for CTE Agent with Data Security Manager*.

Replication

- `rsync`.
- Hardware/software based replication system.

SAP HANA Fibre Channel Systems

SAP HANA is compatible with CTE-LDT. See the *Compatibility Matrix for CTE Agent with Data Security Manager* and the *CTE Agent for Linux Advanced Configuration and Integration Guide*.

Installing the CTE-LDT License

CTE-LDT installs with the CTE Agent software, but it is a separately-licensed CTE feature. Before you can use it, you have to install the license on the DSM to activate CTE-LDT on the CTE host. CTE-LDT is licensed for a specific number of hosts.

1. Obtain an CTE-LDT license from Thales. You can purchase CTE-LDT along with the DSM software or you can add CTE-LDT later.
2. Install the license on the DSM.
If you purchase CTE-LDT with the DSM, it includes the CTE-LDT license in the same license file with the DSM license, so there is only a single file to install.
If you add the CTE-LDT license later, you need to install an additional license file. For details, see the *DSM Installation and Configuration Guide*

To confirm that the CTE-LDT license is in effect:

1. Ask the DSM Administrator to log on to the DSM Management Console and click **System > License**.
2. In the **Agent Type** column, find the row labeled **FS**. The number of host licenses displays in the **LDT License** column of this row.

Installing and Registering the CTE Agent Software

Install the CTE Agent software with the CTE-LDT feature on each host you want to protect. The following procedure describes how to use the interactive installer to install CTE and register CTE-LDT using the shared secret registration method. For additional registration options, see the *CTE Agent for Linux Advanced Configuration and Integration Guide* or the *CTE Agent for Windows Advanced Configuration and Integration Guide*.

Prerequisites

Make sure you know the following information from the DSM Administrator:

- The server name of the primary DSM as shown on the DSM Dashboard.
- The shared secret for the domain on the primary DSM with which you want to register the host.
- The name of the domain in the DSM with which you want to register the host.
- Optionally, the name of the host group in which this host should be included.

All of this information is case-sensitive and must exactly match the corresponding information in the DSM.

Note

If registration appears to freeze, verify that the DSM and CTE can communicate with each other over the network.

Procedure

1. Log on to the host where you will install the CTE Agent as `root`. You cannot install the CTE Agent without `root` access.
2. Copy or mount the installation file to the host system. If necessary, make the file executable with the `chmod` command.
3. Install the CTE Agent. A typical installation uses the following syntax:

```
# ./vee-fs-<release>-<build>-<system>.bin
```

For example:

```
# ./vee-fs-7.0.0-47-rh8-x86_64.bin
```

To install the CTE Agent in a custom directory, use the `-d <custom-dir>` option. For example:

```
# ./vee-fs-7.0.0-47-rh8-x86_64.bin -d /home/my-cte-dir/
```

Note: If possible, Thales recommends that you use the default directory `/opt/vormetric`.

To view all installer options, use the `-h` parameter. For example:

```
# ./vee-fs-7.0.0-47-rh8-x86_64.bin -h
```

4. The Thales License Agreement displays. When prompted, type **y** and press Enter to accept.

The install script installs the CTE Agent software in either `/opt/vormetric` or your custom installation directory and then prompts you about registering the CTE Agent with a key manager.

```
Welcome to the CipherTrust Transparent Encryption File System Agent
Registration Program.
```

```
Agent Type: CipherTrust Transparent Encryption File System Agent
Agent Version: 7.0.0.47
```

In order to register the CipherTrust Transparent Encryption File System Agent with a Vormetric Data Security Manager

- 1) you must know the host name of the machine running the DSM (the host name is displayed on the Dashboard window of the Management Console), and
- 2) unless you intend to use the 'shared secret' registration method, the agent's host machine must be pre-configured on the DSM as a host with the 'Reg. Allowed' checkbox enabled for this agent type on the Hosts window of the Management Console.

In order to register with a CipherTrust Manager you need a valid registration token from the CM.

Do you want to continue with agent registration? (Y/N) [Y]:

5. Enter **y** to continue with the registration process. The install script prompts you to enter the name of the DSM with which you want to register the host. This name must match the name shown in the **Server name** field in the **Management Summary** section on the DSM **Dashboard** page.

For example:

Do you want to continue with agent registration? (Y/N) [Y]: **y**

Please enter the primary key manager host name: **dsm630-121079.i.vormetric.com**

You entered the host name dsm630-121079.i.vormetric.com

Is this host name correct? (Y/N) [Y]: **y**

6. Enter the host name when prompted. If the Shared Secret registration in your DSM is configured to require an existing host entry, his name must match the name used on the **Add Host** page of the DSM Management Console.

Please enter the host name of this machine, or select from the following list. If using the "fingerprint" registration method, the name you provide must precisely match the name used on the "Add Host" page of the Management Console.

```
[1] host14.i.example.com
[2] Host-RHEL-14.i.example.com
[3] 10.3.14.90
```

Enter a number, or type a different host name or IP address in manually:
What is the name of this machine? [1]: **3**
You selected "10.3.14.90".

7. When prompted for the registration method, enter **s** for shared secret registration and then enter the required information about the domain, optional host group, and optional host description. For example:

Would you like to register to the DSM using a
registration shared secret (S) or using fingerprints (F)? (S/F) [S]: **S**

What is the registration shared secret?
Please enter the domain name for this host: **west-coast-domain**
Please enter the host group name for this host, if any:
Please enter a description for this host: **West Coast Data Center server 5**

```
Shared secret      : *****
Domain name       : west-coast-domain
Host Group        : (none)
Host description   : West Coast Data Center server 5
Are the above values correct? (Y/N) [Y]: Y
```

8. At the hardware association prompt, select whether you want to enable the hardware association feature that prevents a clone of this machine from accessing keys in the DSM. The default is **y** (enabled):

It is possible to associate this installation with the hardware of this machine. If selected, the agent will not contact the key manager or use any cryptographic keys if any of this machine's hardware is changed. This can be rectified by running this registration program again.
Do you want to enable this functionality? (Y/N) [Y]: **Y**

9. At this point, the install script asks you about some of the optional CTE features you may want to enable. Make sure you select **Y** for LDT.

For example:

Do you want this host to have docker support enabled on the server? (Y/N) [N]:

Do you want this host to have Efficient Storage support enabled on the server? (Y/N) [N]:

Do you want this host to have LDT support enabled on the server? (Y/N) [N]: **Y**

Do you want to configure this host for Cloud Object Storage? (Y/N) [N]:

Make sure you enter **Y** for LDT support.

10. At this point the installation script completes the installation and indicates that it successfully registered the host with the DSM.

```
Generating certificate signing request for the kernel component...done.  
Signing certificate...done.  
Generating EC certificate signing request for the vmd...done.  
Signing certificate...done.  
Generating EC certificate signing request for the vmd...done.  
Signing certificate...done.  
Successfully registered the CipherTrust Transparent Encryption File System Agent with the  
Vormetric Data Security Manager on dsm630-121079.i.vormetric.com.
```

11. Verify the installation by checking the CTE processes on the host:

- Run `vmd -v` to check the version of CTE.
- Run `vmsec status` to display the CTE processes.
- Look at the log files in `/var/log/vormetric/install.fs.log.<date>`, especially `vorvmd_root.log`.

Setting the Linux Kernel Time Zone

The Linux kernel contains an internal time structure that may or may not contain time zone information. On system configurations that do not contain time zone information, CTE-LDT stores and displays timestamps for rekey beginning and ending in UTC (Coordinated Universal Time) rather than the system's local time zone. If this occurs, the administrator can set the kernel's internal time zone to the local time zone if they desire timestamps in their local time zone.

To set the Linux Kernel time zone information, at boot time type:

```
# hwclock --systz
```

The command sets the kernel's time zone to the local time zone and resets the System Time based on the current time zone.

Note

On systems that do not set the time zone by default, existing timestamps for completed rekeys remain in UTC, even if you run `hwclock --systz`. Only timestamps for new rekeys display the local time zone.

Enabling CTE-LDT on a Protected Host

When you install CTE on a host, you can enable CTE-LDT during the registration process as described in ["Installing and Registering the CTE Agent Software" on page 22](#). If you have already registered the host with the DSM, you can enable CTE-LDT in the host entry in the DSM.

Note

The CTE-LDT license is valid for a certain number of hosts. Once you reach this limit, you can either purchase additional CTE-LDT licenses, or reclaim a license by removing a CTE-LDT host. For details, see ["Removing CTE-LDT and Security Encryption" on page 76](#).

You cannot disable CTE-LDT on a host once it has been enabled.

To enable CTE-LDT on an existing host:

1. In the DSM Management Console, click **Hosts > Hosts**.
2. In the Hosts table, click on the host name of the protected host.
3. On the Edit Host page, select the **Live Data Transformation** check box, then click **OK** or **Apply** to enable CTE-LDT on the protected host.

Note: After CTE-LDT has been enabled for the host, the check box is greyed out because you cannot change this option once it has been set.

Chapter 4: Using CTE-LDT

Creating and Viewing Versioned Keys	27
Creating CTE-LDT Policies	29
Quality of Service	30
Create an CTE-LDT GuardPoint	41
Rotating Encryption Keys (Rekey)	44
File System Operations	48
Excluding Files or Directories from Rekey	50
Using CTE-LDT with SAP HANA Fibre Channel Systems (Linux Only)	58

Setting up keys, policies, and GuardPoints with CTE-LDT is very similar to performing the same tasks in CTE without CTE-LDT. However, there are some differences.

This chapter contains the steps, in order, for successfully setting up and using CTE-LDT.

Creating and Viewing Versioned Keys

In CTE-LDT, you create a *versioned* key for a Live Data Transformation policy and define the *life span* of the key. The life span is the duration (in days) of the versioned key. You also define an *initial expiration date*. When the key reaches its expiration date, it automatically rotates to a new version.

Although an CTE-LDT policy specifies the same key name, when the key rotates, the rotation of the key automatically starts CTE-LDT on the data in the GuardPoints protected with the CTE-LDT policy. There is no need to change the policy. However, you can manually rotate the key if circumstances require it.

Use the **Add Agent Key** page in the DSM Management Console when creating versioned keys.

CAUTION

Make sure that you are working in the Symmetric tab. CTE-LDT does not support asymmetric keys.

Creating a New Versioned Key for CTE-LDT

1. Add a new key as described in the *DSM Administration Guide*. This procedure explains all of the steps and settings, including those related to versioned keys.
2. Set the following required fields:
 - **Expiration Date:** CTE-LDT uses the initial transformation key specified in the CTE-LDT policy until this date occurs. On the expiration date, CTE-LDT creates a new version of the transformation key. Thereafter, it creates new versions based on the **Key Version Life Span**.
 - **Expiration Date:** You must specify an expiration date. Without an Expiration Date, a versioned key is always viewed as the initial key version. This means that it does not trigger CipherTrust Transparent Encryption - Live Data Transformation during initial transformation or subsequent key rotations.
 - **Automatic Key Rotation:** When checked, this makes the key a versioned key. You can only use versioned keys for CTE-LDT.
 - **Key Version Life Span (Days):** Frequency of key rotation, in days, that determines how often the DSM automatically generates a new version of the key, after the initial expiration. This triggers CipherTrust Transparent Encryption - Live Data Transformation on all GuardPoints using the key. Applies only if **Automatic Key Rotation** is selected.

Note

It is important to understand the interaction between the Expiration Date and the Key Version Life Span. CTE-LDT uses the initial version of the key until the Expiration Date. The Life Span has no effect until after the Expiration Date passes. Unless an administrator forces a rekey manually, there is no key version rotation and no CipherTrust Transparent Encryption - Live Data Transformation until the Expiration Date arrives.

When creating or modifying a versioned key, set the key version life span with care. The rekey process uses system resources, and it may contend with host applications that also require these resources. The more often you rekey, the more often the CTE-LDT process requires system resources. Determining the life span is a balance between security, compliance, and convenience. If you have no contention problems between the CTE-LDT process and your host applications, you can rekey frequently. If you do encounter contention problems, then you may want to choose a longer interval between key versions.

The following figure shows an example of adding a versioned key. The key name is LDT_key_1, it expires on April 30, 2021, and it has a key version life span of 180 days. That means the DSM generates a new version of this key on April 30, 2021, which kicks off the CTE-LDT process for the first time. The DSM then generates a new key version every 180 days and automatically starts the CTE-LDT process over again.

The screenshot shows the 'Add Agent Key' dialog box with the following fields and values:

Field	Value
Name	LDT_key_1
Description	LDT versioned key
Template	Default SQL Symmetric Key Template
Expiration Date	4/30/2021
Algorithm	AES256
Encryption Mode - for VTE agents only	CBC_CS1
Key Type	Cached on Host
Unique to Host	☐
Key Creation Method	Generate
Key Refresh Period - for VAE keys only (minutes)	10080
Automatic Key Rotation	☒
Key Version Life Span (days)	180

For information about how versioned keys are rotated throughout the lifetime of the CTE-LDT policies that use them, see ["CTE-LDT Runtime Flow" on page 14](#). For information about how to manually rotate a versioned key at any time, see ["Rotating Encryption Keys \(Rekey\)" on page 44](#).

Viewing Versioned Key Information

To obtain information about keys, use the DSM Management Console. For example, you might use this procedure to:

- Find out which keys are versioned keys, and therefore available for use in CTE-LDT policies.
- Locate a past key version so you can use it to decrypt old data.

To view keys in the DSM Management Console:

1. In the DSM Management Console, click **Keys > Agent Keys > Keys**.
The currently defined keys display. You can filter the list by key name using the **Search** box.
2. To find your versioned keys, look for a checked box in the **Versioned** column.
If the **Current Version** for a key is 0, then this is the first version of the key and no key rotation has taken place. If the **Current Version** is greater than 0, the key has been rotated. Either the key version expired, which triggered an automatic rotation, or a DSM Administrator manually initiated a rekey as described in ["Manual Key Rotation" on page 44](#).
3. To find all versions of a key, click the name of the key in the **Name** column.
 - The **General** tab shows the most recent version of the key.
 - The **Versions** tab shows the key versions in reverse chronological order (most recent first). If the key has been rotated many times, the list takes up multiple pages. Click the arrow buttons to move from page to page.

Creating CTE-LDT Policies

CTE-LDT uses a single Live Data Transformation encryption policy to address both data transformation and ongoing protection. In contrast, if you do not use CTE-LDT, you need a separate policy for initial data transformation, or rekey, and another policy to protect the data while it is in production use. For more information about CTE-LDT policies, see ["CTE-LDT Policies" on page 14](#).

To create an Live Data Transformation encryption policy:

1. Select **Policies > Manage Policies > Manage Policies**.
2. Click **Add**.
3. In **Policy Type**, choose **Live Data Transformation**.

A default security access rule is automatically added in Security Rules. The action is `key_op`, and the effects are Permit and Apply Key. This rule permits key operations, for the policy, on all resources, without denying user or application access to resources. This allows it to perform a rekey operation whenever the encryption key rotates to a new version. This rule is required by CTE-LDT, so you cannot edit it, move it, or delete it.

4. Fill in the other fields as appropriate for an CTE-LDT policy. Some of the fields have special considerations when you use CTE-LDT:

- **Policy Type:** Must be Live Data Transformation.
- **Learn Mode:** Learn Mode provides a temporary method for disabling the blocking behavior of CTE/CTE-LDT policies. While useful for quality assurance, troubleshooting, and mitigating deployment risk, Learn Mode is not intended to be enabled permanently for a policy in production. This prevents the policy Deny rules from functioning as designed in the policy rule set.

Ensure that the policy is properly configured for use in Learn Mode. Any Security Rule that contains a Deny effect must have Apply Key applied as well. This is to prevent data from being written in mixed states, resulting in the loss of access or data corruption.

Apply Key will have no effect when combined with a Deny rule unless the policy is in Learn Mode.

- **Security Rules:** The Security Rules panel contains the policy rules for the production workload. One default rule is added automatically to every CTE-LDT policy, as described above. After this default rule, the other security rules are specified in the same way, whether or not CTE-LDT is in use.

If you set the **"When"** clause of `key_op` rules in CTE-LDT and a time period is set, it affects user I/O operations, not CTE-LDT I/O operations. CTE-LDT starts rekeying the GuardPoint regardless of the value in the `key_op` rule's When clause. CTE-LDT performs rekey operations according to the QoS schedule assigned to the host.

- **Key Selection Rules, Current Key:** Indicates the state of the data before the CTE-LDT policy is applied to the GuardPoint. The data might be clear text, or it might already have been encrypted using a non-versioned key.

Specify *clear_key* in Current Key if the data has not yet been encrypted. Otherwise, specify the name of the non-versioned key that was used to encrypt the data into its current state.

- **Key Selection Rules, Transformation Key:** The **Transformation Key** is the versioned key that is applied to the data for its initial transformation. After the initial transformation, it rotates every time its life span ends. When the key rotates, all of its properties, including the key name and cryptographic algorithm, remain unchanged, except for the key material for encryption. Specify the versioned key name in the **Transformation Key** column. You can enter *clear_key* to transform your data to clear using CTE-LDT. *clear_key* is an exception to a non-versioned key in Transformation Key.
- **Key Selection Rules, Resource:** Allows you to add or edit a resource set. A resource set is a named collection of directories, files, or both, to which a user or process is permitted or denied access.

Note: Thales strongly recommends limiting the number of resource sets in CTE-LDT policies to 50 resources or less.

The following example shows a simple CTE-LDT policy that encrypts clear-text files using a versioned key named LDT-Key-33-100, as shown in the Key Selection Rules panel. The example *key_op* and *all_ops* actions in the Security Rules panel grant user and application access to files at all times, including during initial CTE-LDT and subsequent key rotations.

Figure 4-1: CTE-LDT Policy that encrypts clear-text files

Quality of Service

CTE-LDT runs in real time, while users actively interact with applications. This could impact performance. However, CTE-LDT is designed to not adversely affect application or system performance.

Purpose of QoS

Quality of Service (QoS) provides tools for an administrator to minimize the effect of CTE-LDT on system and application performance. It provides a set of parameters that administrators can set to control CTE-LDT use of system resources, primarily CPU and I/O bandwidth. When the QoS parameters are set appropriately, CTE-LDT stays within the defined boundaries to ensure that critical user applications are not adversely affected by CTE-LDT operations.

Manage CTE-LDT Impact

Administrators can pause or resume CTE-LDT operations to manage and control CTE-LDT impact to application workload. When data transformation occurs, either during initial or subsequent transformations, it requires substantial host CPU and I/O resources. This can cause contention for resources between the applications simultaneously running on the protected host. The administrator specifies QoS settings on each host, or at a host group level, that is using CTE-LDT. When CTE-LDT is running, QoS monitors CPU or rekey/scan rate on the host and enforces the QoS settings. QoS can also monitor and enforce an administrator imposed limit on the volume of data undergoing rekey per second. The QoS settings enable you to strike a balance between completing an CTE-LDT process and not interfering with host application performance.

Monitor and Control CPU Usage

QoS monitors and controls the use of host system resources during CTE-LDT, specifically, CPU usage and rekey/scan rate.

Note

You can control CPU usage or rekey/scan I/O rate, but not both. The CPU usage and rekey/scan I/O rate options are mutually exclusive.

Monitor and Control Rekey/Scan I/O Rate

Starting with VTE version 6.1.2 and onwards, you can choose Rekey I/O Rate as a threshold to control the CTE-LDT processing rate. When this threshold is entered, the Quality of Service continuously monitors CTE-LDT transformation and enforces the specified amount of data during:

- **Rekeying**—CTE-LDT is transforming the data on active GuardPoints based on the new key version.
- **Scanning**—CTE-LDT is analyzing files in GuardPoints. Scanning occurs:
 - Before initial transformation (Linux only)
 - Before a rekey (Linux only)
 - Following an interrupted rekey, such as a reboot on Linux or Windows, and also a directory rename or directory deletion on Windows

The Rekey I/O Rate is either 0, or greater than 0. By specifying 0, Quality of Service resets the previously specified Rekey I/O Rate, if any, and then stops monitoring the LDT rekey/scan processing rate.

When the Rekey I/O Rate is set, Quality of Service ignores the CPU and/or the iow (IOWAIT) thresholds previously set. After resetting the Rekey I/O Rate to 0, the Quality of Service will resume enforcing the CPU and/or the iow thresholds, provided one or both are set.

To rekey at full throttle, you can set the Rekey I/O Rate, the CPU, and IOWAIT thresholds to 0.

Note

IOWAIT has been deprecated on Linux, and it is not supported on Windows. Instead, use Rekey IO Rate to control the CTE-LDT I/O utilization on both Linux and Windows.

With the DSM version 6.2.0 and later, you can set the Rekey Rate or CPU threshold for all of the CTE-LDT GuardPoints on a host, or for all of the GuardPoints in a given host group, on the **GuardPoints** tab in the DSM.

You can override the DSM settings locally on a single host using the `voradmin ldt ior <iorate>` command on that host. When you do so, the `voradmin` setting overrides the Rekey I/O Rate or CPU Threshold set in the DSM.

A tolerance level is associated with the Rekey I/O Rate. Together, the tolerance and Rekey I/O Rate specify a range for the CTE-LDT processing rate. The Quality of Service selects a proper tolerance for a Rekey I/O Rate provided through the `voradmin` command, and maintains the CTE-LDT processing rate at the specified Rekey I/O Rate plus or minus the tolerance. The tolerance is selected as follows:

- When the Rekey I/O Rate is less than or equal to 10MB/sec, the tolerance is 3MB/sec.
- When the Rekey I/O Rate is greater than 10MB/sec. and less than 50MB/sec, the tolerance is 4MB/sec.
- When the Rekey I/O Rate is at 50MB/sec or higher, the tolerance is 10% of the specified Rekey I/O Rate.

To set or reset Rekey I/O Rate on a single host, use the `voradmin` command as follows:

- To set the threshold of 50 MB/sec., use the following command:

```
# voradmin ldt ior 50
```

- To reset the current threshold:

```
# voradmin ldt ior 0
```

For more information about setting the Rekey I/O Rate using `voradmin`, see ["Select and Set Rekey I/O Rate " on page 39.](#)

Monitor and Control I/O Wait Time (Linux only)

CAUTION

The Linux I/O wait option has been deprecated in favor of Rekey I/O Rate. Support for the I/O wait option will eventually be removed from CTE. If you are currently using I/O wait time option with QoS, please plan on switching from I/O Wait Time to Rekey I/O rate.

You can choose to add **I/O wait time** for monitoring and control. The I/O wait time threshold refers to the system's peak I/O wait time during its production workload. For a given threshold, you can specify a tolerance level that is the amount of I/O overhead allowed by CTE-LDT for rekeying data. By specifying the I/O wait time, and the tolerance level, QoS continuously monitors your system's average I/O wait time during CTE-LDT operations. It applies the tolerance factor to the average I/O wait time to adjust CTE-LDT I/O operations. This assures that the system's average I/O wait time remains within the desired range and does not exceed the threshold.

The desired range is the specified average I/O wait time (milliseconds) plus or minus the specified tolerance. **Tolerance** provides the range in which the average I/O wait time, which includes CTE-LDT I/O operations, is maintained.

For example, you may specify a desired I/O wait time during rekey. QoS maintains the desired I/O load for rekey according to the specified I/O wait time. If the total I/O wait time increases beyond the desired I/O wait time, QoS reduces the rekey I/O load by some percentage until the desired I/O wait time is achieved or the rekey I/O load reaches down to a preset N number of rekey operations.

QoS Scheduling During Backup/Restore

QoS scheduling plays an important role when backing up/restoring data without the *Apply Key* rule applied to the backup/restore process. During backup/restore, you **must** pause CTE-LDT operations before taking backups. QoS scheduling allows the administrator to enter the schedule for QoS aligned with the backup schedule, and pause the CTE-LDT processes for the duration of the backup. The schedule specifies which days of the week, and what times of day, CTE-LDT is permitted to run. CTE-LDT cannot run at any time that is not permitted by the QoS schedule. QoS suspends CTE-LDT operations at all times outside of the schedule.

When setting a QoS schedule, consider your system and application peak demand periods during the day and week. Also consider your schedule for data backups. Schedule CTE-LDT to pause when you need all available system resources for other tasks, such as meeting peak user demand or performing data backups.

Note

On Windows, if your backup applications are using VSS, then you do not need to pause CTE-LDT on Windows.

How to Set QoS

To set QoS for a host to enforce a threshold on CTE-LDT based on CPU percentage:

1. Click **Hosts > Hosts > *hostname* > GuardPoint**.

2. Set the **Schedule** parameter:

Choose one of the options from the drop-down list. By default, the list contains WEEKNIGHTS (rekey performed between 12 AM and 7:00 AM), WEEKENDS, or ANY_TIME. The default setting is ANY_TIME. By limiting CTE-LDT to periods of low application usage, you minimize the potential for resource contention between applications and CTE-LDT.

You can add to the choices in the Schedule drop-down by creating custom schedules. See ["Creating a Custom QoS Schedule" on the next page](#).

3. Enter the Rekey IO Rate threshold or percentage of CPU resources to allocate to CTE-LDT in the **Set % of available CPU usage for rekey** field:

Choose a Rekey IO Rate threshold or the percentage of total CPU resources that CTE-LDT processes can use. CTE-LDT applies a tolerance of +/- 2% on CPU threshold settings up to 7%. For threshold over 7%, CTE-LDT applies a tolerance of +/- 4%.

If CPU% is set to 0, QoS stops monitoring CPU usage and CTE-LDT operations run at maximum rekey rate within the available system resources. Setting CPU percentage to 0 does not affect CTE-LDT schedules, so CTE-LDT operations are suspended and resumed per QoS schedule.

If you do not enter CPU threshold percentage, CTE-LDT applies CPU threshold of 5% capped by default.

If CPU% is set to a very high value, such as 25%, the rekey process competes with other applications to use as many CPU cycles as it can. As a best practice, start with a setting of 10%, and increase or decrease it slowly by 5% until it reaches a reasonable level that does not adversely affect the performance of user applications. The higher the percentage, the more quickly CTE-LDT completes its processing. However, this speed causes increased competition for resources, which can significantly degrade the performance of other applications using this host.

CAUTION

Do not set CPU% to a very high value, or to 100%, in an attempt to force faster data transformation. This can potentially exhaust other system resources.

4. Set the **Cap CPU Allocation** for rekey.

Check this box to specify that the CPU allowance must never exceed the percentage set in CPU%. If Cap CPU Allocation is not checked, and additional CPU resources are available on the host, CTE-LDT consumes part of the available resources for rekey above the CPU threshold. Exceeding the threshold may impact your production workload as your production CPU resource consumption fluctuates over time.

For example, if CPU% is set to 10%, but Cap CPU Allocation is not set, the rekey process continues consuming available CPU cycles after reaching 10% CPU utilization, at which point the rekey process starts contending with applications for CPU cycles.

Note: If you choose Rekey IO Rate threshold to control the CTE-LDT processing rate, you do not need to also set the CPU threshold for CTE-LDT.

Creating a Custom QoS Schedule

CTE-LDT provides three predefined QoS schedules: ANY_TIME, WEEKENDS, and WEEKNIGHTS. You can define additional custom schedules that can be assigned to any host on the GuardPoints tab.

1. In the DSM, choose **Hosts > QoS Schedules**.
2. Click **Add**.
3. Enter a unique name for the new schedule.
This name displays in the **Schedule** dropdown list when you set QoS parameters.
4. Click **Add**.
5. Choose the start day/time and the end day/time for CTE-LDT operations.
6. Click **OK**.

QoS Best Practices

This section gives tips and examples to help you set QoS parameters for the best results.

General Best Practices for QoS

- Use Rekey I/O Rate threshold to limit CTE-LDT impact, if any, to your production workloads. Rekey I/O Rate approach is a simpler method for a DSM Administrator or system administrator to enforce a limit on the volume of data that CTE-LDT should rekey per second. You can choose a threshold, in units of MBs per second, which is a small percentage of peak IOPS from your production workload.
- You will see the effects of QoS settings only if the number and/or types of files in the GuardPoints stress the rekey or scan processes. On hosts with a relatively small number of files, the rekey or scan process may complete quickly without hitting a threshold and causing throttling to occur.
- Use QoS CPU parameters as an alternate method for controlling the effect CTE-LDT has on application performance.

Set limits on CTE-LDT CPU usage whenever runtime monitoring shows that user applications are affected by CTE-LDT. Start by setting the CPU parameter to 10%, then increase or decrease in 5% intervals, as needed, to tune the CPU allocation. When an acceptable level is reached, and CTE-LDT is not noticeably affecting user applications, leave the QoS CPU parameters at a constant setting.

- Use monitoring tools.

Monitor host CPU utilization with tools like `vmstat`, `top`, and `iotop` on Linux and `perfmon` on Windows.

You can also monitor and obtain statistics with the `voradmin ldt stats` command.

For more information about `voradmin ldt stats`, see ["Obtaining CTE-LDT Statistics at the Command Line" on page 83](#).

- Select CPU resource allocation for CTE-LDT from 1% to the available limit minus 5%.

If the monitoring tools indicate system CPU usage, without CTE-LDT, it is at N%, available CPU resource is M%, where $M = 100 - N$. Select a percentage within 1 - (M - 5) to allocate to CTE-LDT CPU usage. However, remember that QoS tolerates 2% - 4% leeway in the actual CPU usage, so adjust your selection by 2 - 4%.

- Do not set CPU resources to 0% or 100% in an attempt to minimize or stop CTE-LDT

A CPU% value of 0 or 100 is reserved for disabling the QoS CPU monitoring function. This does not stop CTE-LDT or minimize its resource usage; rather the opposite. It enables CTE-LDT to run with its maximum rekey rate. Note that when CPU % is not set, and it shows 100% setting on the DSM, CTE-LDT hosts enforce a 5% CPU threshold by default. We recommend that you change the 100% setting to 5% capped on the hosts installed with VTE versions lower than v6.1.

- Cap the CPU allocation.

QoS provides a **CAP CPU Allocation** parameter. Set this parameter to **True**. This ensures that CTE-LDT resource usage never exceeds the allocated percentage.

- Apply **await** threshold very carefully to try controlling CTE-LDT I/O load.

Example: Setting QoS before starting CTE-LDT

You can be proactive and set up QoS parameters before enabling GuardPoints that are protected with CTE-LDT policies. This ensures QoS starts monitoring and controlling CTE-LDT resource usage from the start. The following graph shows an example where 10% of the CPU is assigned to CTE-LDT. QoS makes sure that CTE-LDT is restricted to use only 10% of the CPU. There is a tolerance level of +/- 4%, so actual CTE-LDT usage can range between 5% and 15% of CPU. In the following example, applications use 75% of the CPU resources. As the graph shows, when CTE-LDT starts, application CPU utilization drops for a moment, because CTE-LDT exceeds the CPU threshold. QoS immediately reduces CTE-LDT's CPU usage to 12%, which is within tolerance levels for a 10% setting, and the application CPU share returns to normal.

Figure 4-2: QoS makes visible improvement immediately when CTE-LDT starts

The graph above was obtained on a Linux system running sysbench.

- To find the amount of CPU resources currently in use by applications, type:

```
# top -n 1 -b | grep sysbench | awk 'BEGIN {cpu=0} {cpu += $9} END {print cpu}'
```
- To find the amount of CPU currently in use by the CTE-LDT-protected host, type:

```
# top | grep Cpu
```
- To find the amount of CPU currently in use by CTE-LDT, type:

```
# voradmin ldt stats | grep CPU
```

Example: Monitoring and controlling resource usage during CTE-LDT

Suppose that CTE-LDT has started with CPU set to 25%, and users realize their applications are affected. For example, there might be a higher than expected level of CTE-LDT I/O operations. To return application performance to normal, reduce the CPU allocation for CTE-LDT.

1. Set the **CPU parameter** to a lower value, such as 10%.
2. Select the **Cap CPU Allocation** option.
3. Set the I/O wait parameter.

QoS restricts CTE-LDT CPU usage to 10%. The application user should monitor their application. If the application's performance is still affected, reduce the CPU parameter further, such as to 5%. Repeat this procedure until application performance returns to a satisfactory level.

The following graph shows an example where QoS is not enabled to monitor and control CTE-LDT CPU usage from the start. When CTE-LDT starts, application CPU usage drops from 65% to 20%. By setting the QoS CPU parameter to 10%, application usage is greatly improved.

Figure 4-3: CPU usage allocation before and after QoS CPU parameter is set

Example: How QoS CPU settings affect I/O bandwidth

Controlling CPU utilization indirectly controls I/O bandwidth. When CTE-LDT is consuming less CPU resources, it is usually performing fewer operations of all kinds, including input and output.

The following graph shows how an application's I/O throughput is affected by CTE-LDT, and how QoS can reduce this effect through monitoring and controlling the CTE-LDT CPU resource usage.

This graph is from the same system described in ["Example: Monitoring and controlling resource usage during CTE-LDT" on the previous page](#). No QoS parameters are set at first. When CTE-LDT starts, application I/O drops from more than 600 MB per second to below 30 MB per second. By setting the QoS CPU parameter to 10%, the CTE-LDT I/O operations drop to below the application's ability to perform so application I/O operations is greatly improved.

Figure 4-4: I/O operations before and after QoS CPU limit is set

To obtain the data for this graph:

- Use `iostat` and benchmarking tools on an RHEL system to obtain application I/O throughput.
- Use `voradmin ldt stats` to obtain the CTE-LDT I/O throughput and rekey rate.

Determine and Set the I/O wait time

Monitor the average I/O wait time using `iostat` on Linux, or `perfmon` on Windows, during the production workload. Thales recommends monitoring the average I/O wait time during the peak levels of the workload.

1. Run the `iostat` command and specify the number and duration of intervals to determine `iowait` time.

```
# iostat -txm 10 2
```

Note: For Windows, use `perfmon` to obtain: `\PhysicalDisk(_total)\Avg. Disk sec/Transfer`

- Get the total I/O wait time from the sampled data. It is the sum of the await field of disks.

Note: Do not include await values from volumes and device mappers.

Figure 4-5: Example of iostat data

```
Monday 04 September 2017 03:13:39 PDT
avg-cpu:  %user   %nice %system %iowait  %steal   %idle
           0.18    0.00    2.52   42.03    0.00   55.27
```

sdh	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00
sdf	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00
dm-0	0.00	0.00	0.11	2.17	0.00	0.01	0.19	0.02	7.49	0.28	0.00
dm-1	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00	1.91	1.14	0.00
dm-2	0.00	0.00	0.15	4.97	0.01	0.02	10.73	0.05	8.80	0.04	0.02

For the above example:

Total I/O wait = .61+ 88.9 + 169.15 = 258.66

- Obtain multiple samples at 10 second intervals. Estimate the `iowait` time when it stabilizes.

In the following chart, the I/O wait time is nearly 200ms when in a stable state.

- Estimate the `iowait` threshold by running CTE-LDT and watching the degradation in I/O wait time. Set the `iowait` threshold and/or tolerance parameters in units of milliseconds using `voradmin` command, type:

```
# voradmin ldt iow iowait [tolerance]
```

For example, to set the `iowait` to 350 milliseconds and the tolerance to 10 milliseconds, you would enter:

```
# voradmin ldt iow 350 10
```

In the following graph, observe that once CTE-LDT starts, the total I/O wait time jumps to 600 ms and oscillates between 400 to 500 ms. Without CTE-LDT, I/O wait time was 200 ms. If the application I/O wait time suffers because of CTE-LDT, reduce the CTE-LDT I/O usage by setting `iowait` threshold to a suitable level between 200 to 500 ms. In this example, we have chosen 350 ms as the desired/suitable level of total I/O while CTE-LDT and application workloads are running concurrently.

From the following graph, observe that QoS tried to control I/O wait time and now it oscillates near about 350 ms.

The following table explains what is monitored and controlled by QoS when CPU or I/O resource thresholds are set.

Resource Threshold Set	Monitored and Controlled by QoS
CPU (value must be greater than 0.)	CPU utilization to adjust CTE-LDT operations to maintain the set CPU threshold
I/O wait (value must be greater than 0.)	I/O average wait time to adjust CTE-LDT operations to maintain the set I/O wait threshold
CPU and I/O wait	CPU and I/O, both resources are controlled by their threshold limits
CPU and I/O wait set to 0	No resource is controlled or monitored

Select and Set Rekey I/O Rate

You can choose to set the Rekey I/O Rate to control I/O operations from CTE-LDT to minimize CTE-LDT impact to your production workload. It's assumed that you already know the maximum IOPS on your host system during your production workload. With this information, you can choose a threshold for Rekey I/O Rate and enforce the selected threshold during CipherTrust Transparent Encryption - Live Data Transformation. The work flow is as follows:

1. Set **Rekey I/O Rate** threshold using `voradmin` or in the DSM Management Console.
2. QoS retrieves the threshold and starts monitoring and controlling CTE-LDT according to the specified threshold and the tolerance factor corresponding to the threshold.
3. The selected threshold will be in effect within 2 to 4 minutes after entering the threshold.

When Rekey I/O Rate and CPU or IOWAIT thresholds are set, QoS will monitor and control the CTE-LDT processing rate based on the Rekey I/O Rate threshold. The CPU and/or IOWAIT thresholds will be ignored.

Set Rekey I/O Rate Threshold

1. Set **Rekey I/O Rate** threshold by using `voradmin`:

```
# voradmin ldt ior 10
```

You can also set the Rekey I/O Rate for one or more managed hosts on the QoS settings area of the **GuardPoint** tab under host configuration in the DSM (DSM version 6.2.0 or later). For more information about using the DSM method, see ["How to Set QoS" on page 33](#).

In the `voradmin` example above, QoS enforces the threshold of 10MB/sec with the tolerance of +/- 3MB/second. Effectively, CTE-LDT attempts to rekey the amount of data in the range of 7MBs/second to 13MB/second.

On Linux and Windows, you can use `voradmin ldt ior` to report the current threshold setting without specifying a value for threshold:

```
# voradmin ldt ior
QoS Rekey I/O rate threshold: 10 MB/sec
QoS Rekey I/O tolerance: 3 MB/sec
```

2. Be sure the threshold you enter is appropriate for your production workload. To verify this:

- a. Observe the Rekey I/O Rate for a few minutes using `voradmin`.

On Linux, you can do this using:

```
# voradmin ldt stats
Host level statistics:
File stats: rekeyed=202390, passed=0, created=0, removed=0
Data stats: rekeyed=6.2GB, truncated=0.0MB
QoS: IOR threshold=10MB/sec, tolerance=3MB/sec
current_rekey_rate=2MB/sec, current_iow=0ms
load_factor=50, delay_factor=0, delay_scan=0
```

On Windows, you can do this using:

```
voradmin ldt monitor
Host Stats:
Total number of Guard Points    = 1
Rekey Status                    = Rekey done (Finished rekey on 1 out of 1 GP's)
Total files to be transformed   = 0
Total files transformed         = 0
Total files in progress         = 0
Total transformation threads    = 0

Current rekey rate              = 0 KB/s
Rekey IO rate threshold         = 1000 MB/s
Rekey IO rate tolerance         = 4 MB/s
```

- b. Set an appropriate threshold. Do not set the threshold value too high, as QoS might not be able to achieve it because of other resource bottlenecks.

3. Check the QoS controlling rekey rate.

QoS will monitor and control CTE-LDT utilization using the specified threshold. The following figure shows an example of how QoS monitors and controls CTE-LDT utilization. In this example, the threshold is 30 MB/sec. Throughput of CTE-LDT was nearly 130 MB/sec. QoS brings it down to within the range of 30 MB/second.

4. Disable QoS.

QoS will not monitor and control resources when all the thresholds, CPU, Rekey I/O rate, and IOWAIT are set to 0. When Rekey I/O Rate and IOWAIT are not explicitly set, it is considered to be set to 90 MB/second.

QoS continues to apply its schedules for suspending CTE-LDT operations at certain days and times regardless of what values are set for CPU, Rekey I/O Rate, and IOWAIT thresholds.

Summary of QoS Resources

The following table summarizes the available thresholds and the actions of QoS module to enforce the set thresholds:

Scenario	QoS Action
Only Rekey I/O Rate threshold is set	Monitor and control the CTE-LDT processing rate based on Rekey I/O Rate
Rekey I/O Rate and CPU threshold are set	Monitor and control the CTE-LDT processing rate based on Rekey I/O Rate. CPU threshold is ignored.
Rekey I/O Rate, CPU, and IOWAIT thresholds are set	Monitor and control the CTE-LDT processing rate based on Rekey I/O Rate. CPU and IOWAIT thresholds are ignored.

Create an CTE-LDT GuardPoint

After you have installed the license and registered the CTE-LDT host (see [Chapter 3: "Setting Up CTE-LDT" on page 20](#)), you can create an CTE-LDT GuardPoint on the host. When you create the CTE-LDT GuardPoint, you select a Live Data Transformation policy and apply that policy with its transformation keys to that GuardPoint. CTE automatically gets the Quality of Service settings from the **GuardPoint** tab of the Host entry in the DSM.

This section describes two scenarios:

- ["Create an CTE-LDT GuardPoint for an Unguarded Directory" below](#)
- ["Converting a Non-CTE-LDT GuardPoint to an CTE-LDT GuardPoint" on the facing page](#)

Create an CTE-LDT GuardPoint for an Unguarded Directory

To create an CTE-LDT GuardPoint on what was previously an unprotected/unguarded directory:

1. Create an Live Data Transformation policy that transforms data from clear text to a versioned key. In the policy, set Current Key to `clear_key` and Transformation Key to the versioned key. See ["Creating CTE-LDT Policies" on page 29](#).
2. Set, or modify, the Quality of Service (QoS) parameters to account for CTE-LDT on all GuardPoints. See ["Quality of Service" on page 30](#).
3. Click **Guard**.
4. The Guard File System window displays. Set the following values:
 - a. Select an CTE-LDT Policy.
 - b. Select **Directory (Auto Guard or Manual Guard)**.
 - c. Enter or browse for the directory to protect.
 - d. Do **not** check Automount. CTE-LDT is not supported on automounted file systems.
 - e. Check **Transform Sparse Regions** if you want those regions allocated with disk blocks.

A *sparse region* is a region within the file size that has not yet been written to. Therefore, it is not allocated with disk blocks. Any attempt to read a sparse region reads stream of zeros as data. A file may have one or more sparse regions, or an entire file may be sparse.

By selecting Transform Sparse Regions, CTE-LDT transforms a file without checking or skipping sparse regions, if they exist. Consequently, as CTE-LDT operations transform and fill sparse regions with encrypted stream of zeros, sparse regions are allocated with disk blocks. This increases the number of disk blocks utilized in the file system.

By not selecting Transform Sparse Regions, CTE-LDT detects and skips transforming sparse regions. Therefore, it does not change the number of blocks utilized in the file system.

5. Click **OK**.

The **GuardPoint** tab displays again. CipherTrust Transparent Encryption - Live Data Transformation starts immediately after you enable the GuardPoint on the host.
6. Wait a moment and check the status of the GuardPoint in the Rekey Status column of the GuardPoint tab.
7. In the Status column, click the status icon (the green circle) to get status details about this GuardPoint.

The GuardPoint Status window displays. For an explanation of all the items in the GuardPoint Status dialog, see ["Obtaining Statistics in the DSM with GuardPoint Status" on page 81](#).

Note: When you first apply a GuardPoint, the key version shown in GuardPoint Status is 0. This indicates the first version of the key.

8. Wait for CTE-LDT to complete the rekey process for the GuardPoint. When the Rekey Status column shows 100%, the GuardPoint has been rekeyed and the GuardPoint status changes to rekeyed. For information about the values in the Rekey Status column, see ["Checking the Rekey Status" on page 44](#).

Converting a Non-CTE-LDT GuardPoint to an CTE-LDT GuardPoint

If you have an earlier version of CipherTrust Transparent Encryption installed, you most likely have set up GuardPoints. These legacy GuardPoints are protected with policies that do not make use of CipherTrust Transparent Encryption - Live Data Transformation. This means that you must stop all users from accessing the files in these GuardPoints while the policy performs encryption.

After installing CTE 6.0.x or higher, and setting up CTE-LDT on the hosts, you can change legacy GuardPoints to CTE-LDT GuardPoints. CTE-LDT GuardPoints provide the advantage of allowing users to access all files in the GuardPoints while encryption is occurring. There is no downtime for the user except for the time needed to apply the GuardPoint.

1. Write a new CTE-LDT policy that transforms data from the non-CTE-LDT/non-versioned key used in the existing GuardPoint, to an CTE-LDT versioned key. See ["Creating CTE-LDT Policies" on page 29](#).

The following example shows an CTE-LDT production policy that transforms data encrypted by a non-versioned key (AES256) to data encrypted with a versioned key (LDT).

Add Policy - LDT_Policy

Policy Type: Live Data Transformation
Name: LDT_Policy
Description: Transform legacy GuardPoint to LDT
Learn Mode: ☐
Clone this policy as:

Security Rules

Select All View: 20 Total: 2

Select	Order	Resource	User	Process	Action	Effect	When	Browsing
☐	1				key_all	Permit, Apply Key		No
☐	2				all_ops	Permit, Apply Key		Yes

Page 1 of 1

Key Selection Rules

Select All View: 23 Total: 1

Select	Order	Resource	Current Key	Transformation Key
☐	1		AES256	LDT

Page 1 of 1

2. Make sure there is no application activity within the GuardPoint.

CAUTION

This step is critical. Do not skip it. Make sure there is no application activity within the GuardPoint.

3. Click **Unguard** to unguard the GuardPoint.
4. Guard the directory again using the new CTE-LDT policy. Use the steps in ["Create an CTE-LDT GuardPoint for an Unguarded Directory" on the previous page](#), but choose the policy that starts from the non-versioned/non-LDT key rather than a policy that starts from `clear_key`.

Rotating Encryption Keys (Rekey)

This following sections describe procedures related to encrypting an existing GuardPoint with a new key (also called rekeying).

Manual Key Rotation

If you need to rekey your GuardPoint prior to the expiration of the current key version, you can manually start a rekey process.

On Windows, you cannot rotate a key until all current data transformations that use the same key have completed, whether those transformations are an initial data transformation or a rekey. On Linux, you can rotate the key at any time. For details, see ["Rotating Encryption Keys While a Rekey is in Progress \(Relaunch\)" on page 47](#).

1. To manually generate a new version of a key, open the DSM Management Console and choose **Keys > Agent Keys > Keys**.
2. Click the name of the key you want to rotate.
Note the hex value shown next to **Key Hash** before and after you rotate the key. The hash value represents the current key version associated with the key. After rotating the key, CTE-LDT generates a new version of the key, and the hash value changes.
3. Click **Rotate**.
4. After clicking Rotate, a Rotate Key pop-up displays. Select the *Rotation Reason* and click **Rotate**. This initiates the rekey process on all GuardPoints using the key.
5. Check the status of the GuardPoint in the Rekey Status column of the GuardPoint tab. For example, just after clicking Rotate, the status might be "Rekeying 4%".
Once CTE-LDT transforms the data, you are finished.

Checking the Rekey Status

During a rekey, you can check the progress in the UI on the GuardPoint status page on the DSM. GuardPoint status is not relayed to the DSM in real time. A delay of several minutes before the DSM displays events on the host is likely. When the number of GuardPoints on the managed host is high, for example 100+, the delay in relaying GuardPoint status is due to delays in scheduling and the execution of CTE-LDT operations on the managed host for GuardPoints.

When the host and DSM are configured for one-way communication, the delay is longer because CTE-LDT statistics are sent to the DSM once per hour, or each time a GuardPoint enable or disable status changes.

To check when the DSM last received a status update from the host, look at the Last Status Update time stamp in the GuardPoint status dialog. For information about how to display this dialog, see ["Obtaining Statistics in the DSM with GuardPoint Status" on page 81](#). For the most up-to-date statistics, inspect the host itself. To find out whether your host is configured for one-way communication, open the DSM Management Console, choose **Hosts > Hosts**, click the name of the host, and look for the FS Agent One Way Communication check box.

To see the progress of a rekey and the estimated completion time:

1. Open the DSM Management Console.
2. Choose **Hosts > Hosts**.
3. Click the name of the host you want to check.
4. Click the **GuardPoint** tab.
5. The Rekey Status column shows the current status. The status is one of the following:

Rekey Status	Description
Error (Windows only)	Runtime error occurred. Check for CTE-LDT-ALERT messages. Typically occurs when Low disk space occurs or a volume got dismounted.
Exited (Windows only)	Exited an operation like renaming folder. CTE-LDT will be restarted in the next ~20 secs or as soon as the operation completes. On restart, it will go into scan phase if file/folder deleted/renamed.
Incomplete (Windows only)	CTE-LDT did not finish. The administrator must intervene to remove the obstacle so the rekey can finish. You can run the <code>voradmin ldt skip</code> command to obtain more information.
In-Progress	CTE-LDT is transforming each file one by one.
Not Started	CTE-LDT has not started. It will go into this state when a GuardPoint is added or a key is rotated or changed.
Paused	CTE-LDT is paused on the GuardPoint, because of the QoS schedule or a direct request from administrator.
Queued	When a key rotation is in progress and another rotation is initiated.
Rekeyed	GuardPoint has been transformed to the latest key version.
Rekeying	GuardPoint transformation is in process of transforming the data with the latest key.
Scanning	Linux: CTE-LDT started, it is scanning the GuardPoint and counting bytes, files to transform in the GP before starting transformation. Required for statistics and estimation. Windows: CTE-LDT is analyzing files in the GuardPoint before initial transformation, before a rekey, or following an interrupted rekey. The scan is required for statistics and estimation. CTE-LDT can scan multiple times on completing a traversal of the guarded directory. The scanning status does not include a percent complete estimate.
Starting	GuardPoint transformation is ready to begin, but has not yet begun.
Suspended	When CTE-LDT is suspended by user or due to QoS schedule.
Unknown	GuardPoint is not active on the host, so status could not be determined.

Obtaining Information About Keys Applied to Files

Key Report Option

In the following command, you can use the `report` option of the `voradmin` command to obtain information about all of the keys in use on the GuardPoint. The report lists all keys used in the GuardPoint. For each key, it gives the key name and key version number. It lists each unique key name and version combination only once, no matter how many files use the key.

The following example shows three keys used in the GuardPoint `/oxf-fs1/gp1`:

```
# voradmin ldt key report /oxf-fs1/gp1
LDT_KEY1,1
LDT_KEY2,2
LDT_KEY3,5
```

For an overview of `voradmin ldt`, see ["CTE-LDT Command-Line Administration: voradmin command" on page 73](#).

Key Map Option

In the `voradmin ldt key [report|map] <key_name> <guard_path>` command, you can use the `map` option to obtain information about which files in a GuardPoint were transformed with a specific key, where:

- `<key_name>` is the name of the key.
- `<guard_path>` is the path of the GuardPoint where the key was used.

For example, to view information about the key `LDT_KEY2` in the GuardPoint `/oxf-fs1/gp1`, you would enter:

```
# voradmin ldt key map LDT_KEY2 /oxf-fs1/gp1
/oxf-fs1/gp1/file12345.dat10
/oxf-fs1/gp1/file12345.dat10
/oxf-fs1/gp1/file12345.dat10
/oxf-fs1/gp1/file12345.dat10
/oxf-fs1/gp1/file12345.dat10
```

Keys without a version number are used by files in an exclusion key rule or files that have yet to undergo initial key rotation. Use `voradmin ldt key map` in conjunction with `voradmin ldt attr get` to determine if a file using a key without a version number is part of an exclusion key rule or awaiting initial key rotation.

Showing GuardPoints During Rekey (Linux)

Use the following command to display a list of known CTE-LDT metadata stores and any associated GuardPoints currently undergoing transformation.

```
# voradmin ldt list all
MDS_1: type=file, nguards=0, name=/disk2/::vorm:mds::
      Guard Table: version 1 nentries 0
MDS_2: type=file, nguards=0, name=/disk3/::vorm:mds::
      Guard Table: version 1 nentries 0
MDS_3: type=file, nguards=0, name=/disk4/::vorm:mds::
      Guard Table: version 1 nentries 0
```

For an overview of `voradmin ldt` commands, see ["CTE-LDT Command-Line Administration: voradmin command" on page 73](#).

Suspending and Resuming Rekey and/or Scan Phase

The QoS schedule specifies certain time windows when CTE-LDT operations must be stopped temporarily. However, you can also suspend or resume CTE-LDT at the host level at any time.

To suspend CTE-LDT through the DSM Management Console:

1. Go to **Hosts > Hosts**.
2. Click the name of the host where you want to suspend or resume rekey.
3. Click the **GuardPoint** tab.
4. Click **Suspend/Resume Rekey** to suspend/resume CTE-LDT operations on the host.

Considerations

- Disabling, or unguarding, an CTE-LDT GuardPoint where a rekey is in progress automatically suspends the CTE-LDT rekey operation.
- You can also use the `voradmin suspend/resume` command in Windows Powershell to suspend and resume the rekey. However, if you use the `voradmin ldt suspend` command to pause the rekey process, the CTE-LDT suspended state is not retained when the system reboots. If you want to retain the state after reboot, suspend the rekey from the DSM.
- On Linux, you can pause CTE-LDT during the scan phase of CTE-LDT. When paused during scan, CTE-LDT suspends operations that traverse through the namespace of GuardPoints in the scan phase of transformation. Suspending CTE-LDT during scan stops file lookup operations of CTE-LDT. This eliminates performance impact to I/O intensive production workloads, such as file serving type workloads, that access large number of files.

Automatic Suspend and Resume of CTE-LDT Operations Due to Insufficient Disk Space (Linux)

CTE-LDT requires adequate storage space headroom to perform CTE-LDT operations such as rekeying on GuardPoints. On Linux, if available storage space drops below the threshold required for CTE-LDT operations to continue, the CTE-LDT operations are automatically suspended. Once additional storage space is available in the file system, CTE-LDT operations automatically resume.

As available space approaches the threshold for automatic suspension, CTE-LDT sends an alert to the DSM to notify you that you should free up more storage space before CTE-LDT operations are suspended. The alert on the DSM is:

```
Low space on guard point [GuardPoint], increase free space or CTE-LDT will be suspended.
```

Behavior of Automatic Suspend and Resume of CTE-LDT Operations on ext4 File Systems

By default, ext4 file systems reserve a portion of the storage space for use only by privileged processes to prevent running out of storage space in file systems. In this situation, non-privileged processes are automatically blocked from writing to the file system until the free disk space level reaches the minimum threshold. As CTE-LDT operates in privileged mode, CTE-LDT operations continue without blockage even if the free disk space threshold is low. Because of this ext4 feature, CTE-LDT operations on ext4 file systems may not be suspended due to low available storage space, even when the `df` command reports storage is 100% allocated.

Rotating Encryption Keys While a Rekey is in Progress (Relaunch)

On Linux, if a key is rotated (either manually or automatically when a key version expires) while CTE-LDT is in progress on a GuardPoint, the key rotation is processed and queued, and the GuardPoint is marked for relaunch. Relaunch indicates the need to restart CTE-LDT after the current transformation completes. If the GuardPoint has been rekeyed and is flagged for relaunch, CTE-LDT launches as soon as the GuardPoint is enabled.

Files already undergoing transformation at the time of the new key rotation complete rekey to the key version already in progress. Files that start transformation after the new key rotation request are rekeyed to the new key version. Once the current CTE-LDT of the GuardPoint is complete, CTE-LDT automatically relaunches to transform any files that are not rekeyed to the latest key version.

For example:

```
# voradmin ldt attr get /oxf-fs1/gp1
LDT stats: version=2, rekey_status=rekeying,relaunch
           Number of times rekeyed:      1 time
           Rekey start time:              2020/03/18 16:54:00
```

```
Last rekey completion time:          2020/03/18 16:53:38
Estimated rekey completion time:    0 days 0 hours 6 minutes
Policy key version:                 344
Data stats:
    total=9.8GB, rekeyed=0.0MB
    truncated=0.0MB, sparse=0.0MB
File stats:
    total=1000, rekeyed=0, failed=0
    passed=0, skipped=0, created=0, removed=0, excluded=0
```

Note

Relaunch is supported on Linux only. It is not supported on Windows.

File System Operations

The following sections describe the file system operations that may require attention from the DSM Administrator.

Renaming Files and Folders

On both Linux and Windows hosts, you can rename files during initial transformation or rekey operations.

- On Linux, you cannot rename folders (directories) in a GuardPoint during a rekey operation. Any attempt to rename a directory is rejected with the error EAGAIN (try again) while CTE-LDT is in progress including the period during which transformation is suspended.
- On Windows with VTE version 6.1.0 or later, CTE-LDT stops if it is transforming the contents of a folder and a user attempts to rename/move that folder.

You can change the stopping behavior of CTE-LDT using the configuration parameter `oxf_stop_on_rename`.

Using the Registry Editor, or the Windows command line, add a registry entry in `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\services\Vmmgmt\Parameters` for `oxf_stop_on_rename`.

Registry Name	Values	Comments
<code>oxf_stop_on_rename</code>	0 - Disabled	CTE-LDT does not stop if there is contention.
	1 - Enabled	CTE-LDT stops if there is contention. Default: Enabled

For the target folder in rename operation, CTE-LDT is never stopped.

Deleting a File

When a file is removed before it is rekeyed, the file is not included in the total number of files transformed on the GuardPoint **Status** page. Any discrepancy between total number of files to transform and those transformed is due to the removal of files from GuardPoints during CTE-LDT.

The `voradmin` command provides more detailed file level statistics related to rekey operations on the host. You can run `voradmin` to get file level statistics:

```
# voradmin ldt stats <guard_path>
```

File Handling (Windows Only)

It is critical that you understand how the CTE-LDT process handles read-only, binary (executable), NTFS encrypted and NTFS compressed files.

The CTE-LDT process is subjected to all of the File System policies and attributes set on the files. In some cases, this prevents CTE-LDT from encrypting a file. If users or applications are accessing files while CTE-LDT is in progress, CTE-LDT cannot change the attributes of the files and encrypt the file. It is critical that you understand how CTE-LDT handles various types of files:

- **NTFS Encryption and Compression**

If NTFS encryption and compression is enabled on a file or folder, the CTE-LDT process cannot encrypt these files. To maintain the data coherency, CTE-LDT skips the encryption of these files. These files display as “passthrough” files in the CTE-LDT statistics.

- **Read-Only Files**

When CTE-LDT encounters read-only files, it rekeys the file by resetting the read-only attribute and then setting the attributes back again when the rekey completes. If a file is open, CTE-LDT skips this file.

1. If the file is not opened, CTE-LDT changes the attributes of the file and stores the original attributes in the file metadata.
2. CTE-LDT starts Rekey on this file.
3. If a user requests to open a file for writing while rekey is in progress, access is denied. User can only open files for reading.
4. CTE-LDT restores the attributes once rekey is done.

- **Executable Files**

If an executable is running, or files are exclusively locked by the application, the CTE-LDT process cannot encrypt those files as it is unable to acquire the required locks on the files. CTE-LDT skips these files and changes to the INCOMPLETE state.

Enabling GuardPoints in Read-Only mounted file systems (Linux)

Access to a GuardPoint enabled in a read-only mounted file system is restricted to read operations. You cannot modify data in such file systems, therefore, you cannot perform CTE-LDT operations on GuardPoints in read-only file systems. For this reason, CTE-LDT automatically suspends operations when GuardPoints are enabled on read-only file systems. CTE-LDT ignores all attempts to resume CTE-LDT operations until the underlying file system is remounted with read/write access.

WARNING

You must disable a GuardPoint before changing the read/write mount options of the underlying file system. After changing the mount options, you can re-enable the GuardPoint. CTE-LDT operations adapt to the read/write options of the underlying file system when you enable the GuardPoint. Changing the mount options while a GuardPoint is enabled is unsupported and may result in unexpected errors.

Copying Files Into a GuardPoint

If you copy a file into a GuardPoint without an Apply Key rule, make sure that the file was previously copied from the same GuardPoint, or a GuardPoint protected with the same policy/versioned key. A copy operation, without an Apply Key rule, is the same as a backup or restore of a file from/to an CTE-LDT protected GuardPoint.

CTE enforces key rules of an CTE-LDT policy while a GuardPoint is enabled. CTE cannot enforce the key rules while a GuardPoint is disabled. Modifying or adding data/files inside a disabled GuardPoint is not only unsupported, but it also results in unrecoverable data corruption.

WARNING

Do not add new files or modify existing files inside CTE-LDT protected GuardPoints while the GuardPoint is not enabled. This results in unrecoverable data corruption and/or files that cannot be accessed when the GuardPoint is enabled.

Behavior of Hard Links Inside and Outside of GuardPoints (Windows)

When using hard links on Windows, all the hard links to a file must be within the boundary of a GuardPoint and must use the same key. The following scenarios provide additional details:

- If hard links to the same file are inside a GuardPoint and outside a GuardPoint, the effect on the file depends on what process accesses which hard link first. If the hard link within the GuardPoint is opened first, the file is transformed. If the hard link outside the GuardPoint is opened first, the file won't be transformed.
- If hard links to the same file exist in different GuardPoints with different keys, the file will be corrupted.
- If hard links to the same file exist in the same GuardPoint but with different keys, such as if folder-based rules are used, there will be a conflict in the key.

Excluding Files or Directories from Rekey

You can exclude files or directories from the initial transformation and subsequent rekeys with exclusion key rules. For example, you can exclude a subset of non-secret files from a larger set of files that are encrypted with an Live Data Transformation policy.

You set up exclusion key rules on a DSM version 6.3.0 and higher. For details, see the *DSM Administration Guide*.

Examples of Exclusion Key Rules

This section describes some examples of how to use an exclusion key rule.

Encrypt Files With Exclusion Property a Non-Versioned Key

The following exclusion key rule applies the non-versioned key, `Key_TextFiles`, to any *new* files that are created with a `*.txt` extension.

Note

Existing `*.txt` files in the GuardPoint during the initial CTE-LDT data transformation process are assumed to be already encrypted with the same key that you specify in the exclusion key rule. These existing files are *not* transformed during the initial encryption or during any subsequent rekeys. The key you specify in the exclusion key rule is applied to new `*.txt` files only.

In the Policy, do the following:

1. Add a Key Rule.
2. In the **Resource** field, select a resource set that specifies `*.txt` in the **File** field.
3. Select the **Exclusion Rule** check box. The DSM changes to show only a single **Key** field.
4. In the **Key** field, select the key `Key_TextFiles`.

5. Add any other key rules or exclusion key rules to the policy that you want. You must add at least one non-exclusion key rule that specifies the current encryption key and the versioned encryption key that you want to use with this Live Data Transformation policy.

For example, you could add another exclusion key rule that specifies all **.doc** files should be encrypted with the key `Key_DocFiles`, or one that specifies all **.zip** files should be left unencrypted by specifying the key `clear_key`.

Exempt Excluded Files from Encryption (Set to `clear_key`)

The following exclusion key rule sets all files in the resource set `/oxf-fs1/gp1/Clear_Files_Folder` (Linux) or `\oxf-fs1\gp1\Clear_Files_Folder` (Windows) to `clear_key` (in other words, not encrypted). Files in other directories that match other key rules in the same policy may be encrypted. This could allow unrestricted access to the files in `/oxf-fs1/gp1/Clear_Files_Folder` (Linux) or `\oxf-fs1\gp1\Clear_Files_Folder` (Windows) while access may be restricted to files in parallel directories.

- Linux Exclusion Key Rule: The Resource Set **Directory** field should contain `/oxf-fs1/gp1/Clear_Files_Folder`, and the **Key** should be `clear_key`.
- Windows Exclusion Key Rule: The Resource Set **Directory** field should contain `\oxf-fs1\gp1\Clear_Files_Folder`, and the **Key** should be `clear_key`.

Requirements for Exclusion Key Rules

Keep in mind the following requirements when configuring exclusion key rules:

- Before adding an exclusion key rule to an existing policy, you must disable all GuardPoints protected with the policy. Log on to the DSM to disable the GuardPoint.
- You cannot choose a versioned key for the key in an exclusion key rule. Only non-versioned keys or `clear_key` (no encryption) are valid for exclusion key rules.
- Policies with exclusion key rules:
 - Can be added to Live Data Transformation policies created in the DSM 6.3 or higher.
 - Can be applied to GuardPoints on protected hosts running VTE version 6.2 or higher.Do *not* add an exclusion key rule to an existing Live Data Transformation policy if that policy is being used to protect hosts running VTE version 6.1.x or earlier.
- All exclusion key rules must be *above* all CTE-LDT transformation key rules in the **Key Selection Rules** area in the policy.

Usage Notes and Limitations for Configuring Exclusion Key Rules

Keep in mind the information in the following sections when configuring an exclusion key rule.

Adding an Exclusion Key Rule to an Existing Policy with Versioned Keys (Linux)

When adding an exclusion key rule to an existing policy, the exclusion rule only applies to newly created files. Existing files that match the exclusion key rule remain encrypted with the same versioned key(s) specified in the non-exclusion key rule in the policy and will be rekeyed to the key in the exclusion key rule when the versioned key(s) rotates.

To force an existing file that matches an exclusion key rule to be transformed to the key in the exclusion key rule (non-versioned in this example), use one of the following methods:

- Rotate the versioned key specified in the policy to initiate rekey operations on the GuardPoint.
- Copy the existing file within the GuardPoint. The new file will be associated with the resource set in the exclusion key rule and will be encrypted with the non-versioned key. You can then delete the original file.

To perform a similar conversion on Windows, see ["Changing a Folder or Files from Versioned to Non-Versioned Key \(Windows\)" on the facing page](#).

Adding an Exclusion Key Rule That is Part of an Active GuardPoint (Linux)

To edit and/or add an exclusion key rule to an CTE-LDT policy, all GuardPoints using the policy must first be disabled before the new key rule can be added. See “Add Key Selection Rules” in the “Policies” chapter of the *DSM Administration Guide*.

Changing an Exclusion Key Rule That is Part of an Active GuardPoint (Windows)

Changes that you make to an exclusion key rule that is part of an existing policy in an active GuardPoint do not take effect until the GuardPoint that the exclusion key rule is part of is disabled and enabled again.

Conflicting Keys as the Result of Rename Operations

Do not attempt to move or rename a file encrypted with a versioned key to a name associated with an exclusion key rule with `clear_key`. If you attempt such a move or rename, the original file is unaffected but following error is output on Linux systems and a log entry is created on the DSM:

```
<command name>: setting attribute 'user::secfs:xattr:' for 'user::secfs:xattr:': Invalid argument
<command name>: failed to close '<filename>': Invalid argument
```

No error is displayed on Windows systems. The target moved or renamed file is corrupted and should be deleted. The target file is also flagged with the `xattr_error` flag on Linux and `Rekey Status Excluded` on Windows. This flag prevents subsequent read/write access to the file. You can check the CTE-LDT attributes for the presence of this flag. See ["About the Exclusion Attribute for Files Matching an Exclusion Key Rule" on page 54](#).

Also, a log entry is sent to the DSM on Linux systems when this occurs. For example, if you moved the versioned file `/gp/foo.txt` into the GuardPoint `/gp/subdir/foo.txt` with an exclusion key rule that excludes matching files with the `clear_key`, the following log message would be created on the DSM:

```
[CGA] [WARN ] [29261] [CGS3268W] LDT-ALERT: encrypted data detected in filename [foo.txt] inode [35720037] in guard point [/gp] under clear exclusion key rule
```

Overlapping Exclusion Key Rules

Multiple exclusion key rules in the same policy may overlap each other. For example on Linux, if the non-versioned key `Key_A` is associated with resource `/oxf-fs1/gp1/Folder_Enc_With_KEY_A` and the non-versioned key `Key_B` is associated with resource `*.txt`, placement of the file `/oxf-fs1/gp/Folder_Enc_With_KEY_A/foo.txt` overlaps the two key rules. In such a case, the first rule in the policy is enforced on `/oxf-fs1/gp/Folder_Enc_With_KEY_A/foo.txt` when the file is created and in subsequent file access.

On Windows, if the non-versioned key `Key_A` is associated with resource `c:\oxf-fs1\gp1\Folder_Enc_With_KEY_A` and the non-versioned key `Key_B` is associated with resource `*.txt`, then they would overlap on the file `c:\oxf-fs1\gp\Folder_Enc_With_KEY_A\foo.txt`. In such a case, the first rule in the policy is enforced on `c:\oxf-fs1\gp\Folder_Enc_With_KEY_A\foo.txt` when the file is created and in subsequent file access.

Caution About Applications That Create Temporary Files (Windows)

Some applications on Windows create a temporary file version of the original file when you open and modify a file. This behavior can affect how you implement exclusion key rules.

If you have an exclusion key rule that uses a file extension to exclude files that may be opened and modified by such an application, exclude the temporary file name extension also. If you don't exclude the temporary file, the temporary file may be encrypted by another policy that matches the temporary file extension. Then the original file, which is copied from the temporary file, will be unreadable. Also keep in mind that other applications that may create temporary files with the same file extension and consider what policies should affect those temporary files.

This situation can happen with Microsoft Office files such as the `.docx` files used by Microsoft Word. When you open and modify a `.docx` file, Word creates a `.tmp` file version of that file. So for Microsoft Word you should add `*.tmp` to the exclusion key rule resource set if you add `*.docx`.

Rename Operations Crossing Key Rules (Linux)

On Linux, when a rename operation crosses key rules, the rename operation copies the source file to a new file using the new name and removes the original file. If the source file is flagged for exclusion key rule property, the target new file is disassociated with the exclusion key rule if the new name no longer matches the resource set associated with exclusion key rule. For more information, see ["About the Exclusion Attribute for Files Matching an Exclusion Key Rule" on the next page](#).

Using Linked Files with Exclusion Key Rules (Linux)

On Linux, do not create multiple hard links to the same target file such that the pathname of each hard link is associated with a resource set of an exclusion key and the key rules have different keys. Accessing the file through the pathname of each hard link results in a different key to be applied to the file resulting in data corruption in the target file due to application of multiple keys to the same data.

If you must create hard links, be sure the pathnames of hard links and the target file are within the same resource set.

Changing a Folder or Files from Versioned to Non-Versioned Key (Windows)

Exclusion key rules provide a way to convert a subset of guarded files or the contents of a folder from being encrypted by a versioned key to being encrypted by a non-versioned key. After this conversion, the excluded files or directory contents will be encrypted at the last version of the versioned key but the encryption keys for those items will not rotate to a new version when the keys for other non-excluded files are rotated. In other words, the excluded files or folder contents will be encrypted by a non-versioned key.

Follow these steps to change selected files or folder contents to a non-versioned key:

1. In the DSM, clone the versioned key that is used in the policy that you plan to edit. Cloning a key creates a non-versioned copy of the existing version of the versioned key.
2. In the DSM, disable the GuardPoint. Disabling the GuardPoint is required before modifying a policy applied in that GuardPoint.
3. Configure one or more resource sets to match the files that you want to exclude. For example, the resource set `star-dot-text` could contain `*.txt` and the resource set `sales-folder` could contain `\sales\*`.

4. Add one or more exclusion key rules to convert matching files to a non-versioned key. In the following example, files matching *.txt and files in the sales folder (as defined in resource sets) will be converted from the current version of the versioned key AES256_versioned to AES256_clone, assuming AES256_clone is a clone of AES256_versioned.

Order	Resource	Current Key	Transformation Key	Exclusion Rule
1	star-dot-txt	AES256_clone	AES256_clone	Y
2	sales-folder	AES256_clone	AES256_clone	Y
3		clear_key	AES256_versioned	N

Exclusion key rules must be ordered before other rules.

5. On the command line, run the following command to remove the CTE-LDT metadata from the files that you want to convert from versioned key to non-versioned key encryption:

```
voradmin ldt attr delete <path_to_files>
```

To recursively delete the CTE-LDT metadata from all files matching a pattern in all subfolders, use the following form, including * as a wildcard where needed:

```
voradmin ldt attr delete <path_to_files> -filter <filename>.<extension>
```

Note: Be careful when deleting the CTE-LDT metadata from files. If you delete the metadata from a file that does not match an exclusion key rule policy, the file will be unreadable after the next rekey.

Given the example exclusion key rule described in step 4, you would need to run this command on all files with the extension .txt (first example below) and on the files in \sales (second example below).

```
voradmin ldt attr delete c:\gp1 -filter *.txt  
voradmin ldt attr delete c:\gp1\sales
```

For more information about using voradmin on CTE-LDT metadata, run voradmin ldt attr /? on the command line.

6. In the DSM, re-enable the GuardPoint that includes the new exclusion key rule.
7. In the DSM, rotate the key for the policy that includes the new exclusion key rule.

Using the example exclusion key rule in step 4, after completing this procedure, files matching *.txt and files in the sales folder will have the exclusion attribute set and will be excluded from rekeying (see ["About the Exclusion Attribute for Files Matching an Exclusion Key Rule" below](#)). Files not matching the exclusion key rule will be rekeyed to the next version of the AES256_versioned key.

To perform a similar conversion on Linux, see ["Adding an Exclusion Key Rule to an Existing Policy with Versioned Keys \(Linux\)" on page 51](#).

About the Exclusion Attribute for Files Matching an Exclusion Key Rule

Files matching an exclusion key rule have the status rekey_excluded in the CTE-LDT attribute. For more information about CTE-LDT attributes, see ["CTE-LDT Metadata in Extended Attributes" on page 59](#). To check for the exclusion attribute on a file, see ["Determining if a File is Included in an Exclusion Key Rule" on the facing page](#).

The Exclusion Attribute is Persistent

Exclusion from rekey is a persistent property. A file excluded from rekey is not rekeyed regardless of changes that may seem to disassociate the file from the exclusion key rule. For example, if you rename a file to a new name within the same GuardPoint that no longer matches the exclusion key rule that the original name matched, the file with the new name retains the encryption type (non-versioned key or clear_key) of the exclusion key rule. To remove the exclusion attribute from a file you must copy the file rather than move or rename it (see ["Removing the Exclusion Attribute From a File" on the facing page](#)).

Determining if a File is Included in an Exclusion Key Rule

Use the `voradmin ldt attr get <path to file>` command to check whether a file is associated with an exclusion key rule.

- On Linux, an excluded file will include the status `rekey_excluded` in the `voradmin` output. For example:

```
# voradmin ldt attr get /oxf-fs1/gp1/foo.txt
CTE-LDT attributes: rekeyed_size=0, rekey_status=rekey_excluded
```

- On Windows, an excluded file will include the attribute `Rekey Status Excluded` in the `voradmin` output. For example:

```
C:\> voradmin ldt attr get c:\gp1\foo.txt
CTE-LDT attributes:
Rekey Status Excluded
Initial Rekeyed Size 9 Bytes
Data Transformed 0 Bytes
```

Key:

```
Current Key Name/Version (Clear_Key)
New Key Name/Version (Clear_Key)
```

Removing the Exclusion Attribute From a File

To disassociate a file from an exclusion key rule, you must copy the file to a new file not associated with the resource set of the same or another exclusion key rule as the source file. You can then remove the original file. The new file is created under the default key rule of whatever policy applies to the new file. Moving or renaming a file does not disassociate a file from an exclusion key rule (see ["The Exclusion Attribute is Persistent" on the previous page](#)).

For example, assume the following exclusion key rule where `Key_TextFiles` is a non-versioned key:

Exclusion Key Rule: Resource set = *.txt, Key = `Key_TextFiles`

If you copy the file `test1.txt` to `test1.foo`, `test1.foo` is created with whatever key is specified in the policy that matches the new file. The key for the new file could be a non-versioned key, versioned key, `clear_key`, or, no key at all if the new file is outside of a GuardPoint. The original file `test1.txt` remains unchanged and encrypted with the `Key_TextFiles` non-versioned key because the file remains in the exclusion key rule.

Rename and Restore Operations (Linux)

The effect of rename or backup/restore operations involving files associated or not associated with exclusion key rules is mixed and somewhat confusing. In some cases, the operations to restore or rename cause conflicts between the key associated with the source file and the key associated with the target file. For example, the result of a rename operation involving a source file not associated with an exclusion key rule and target file name associated with a resource set of an exclusion key rule is different from the result of the same operation when target file name is associated with the resource set of an exclusion key rule with `clear_key`.

Note

Be sure to review the effect of the operations below and avoid administrative operations that cross associations of files across multiple resource sets with conflicting key rules.

Backup/Restore

The table below illustrates the status and the key effect of restore operations involving mixed keys associated with source files from backup image and existing target files inside GuardPoint.

Key Applied to File in Backup	Key Applied to existing file in GuardPoint	Key Effect of Restore Operation on Existing file
Versioned	Versioned	Versioned
Versioned	Exclusion key	xattr_error (failed)
Versioned	Exclusion clear key	xattr_error (failed)
Exclusion key	Versioned	Exclusion key
Exclusion key	Exclusion key	Exclusion key
Exclusion key	Exclusion clear key	xattr_error (failed)
Exclusion clear key	Versioned	Exclusion clear key
Exclusion clear key	Exclusion key	xattr_error (failed)
Exclusion clear key	Exclusion clear key	Exclusion clear key

The table below illustrates the status and the key effect of restore operations involving mixed keys associated with source files from backup image and new target files not present inside GuardPoint.

Key Applied to File in Backup	Key Applied to existing file in GuardPoint	Key Effect of Restore Operation on Existing file
Versioned	Versioned	Versioned
Versioned	Exclusion key	xattr_error (failed)
Versioned	Exclusion clear key	xattr_error (failed)
Exclusion key	Versioned	Exclusion key
Exclusion key	Exclusion key	Exclusion key
Exclusion key	Exclusion clear key	xattr_error (failed)
Exclusion clear key	Versioned	Exclusion clear key
Exclusion clear key	Exclusion key	xattr_error (failed)
Exclusion clear key	Exclusion clear key	Exclusion clear key

Rename Operation

The table below illustrates the status and the key effect of rename operations for different combinations of versioned, exclusion key, and exclusion clear key.

Key Applied to File in Backup	Key Applied to existing file in GuardPoint	Key Effect of Restore Operation on Existing file
Versioned	Versioned	Versioned

Key Applied to File in Backup	Key Applied to existing file in GuardPoint	Key Effect of Restore Operation on Existing file
Versioned	Exclusion key	Exclusion key
Versioned	Exclusion clear key	xattr_error (failed)
Exclusion key	Versioned	Exclusion key
Exclusion key	Exclusion key	Exclusion key
Exclusion key	Exclusion clear key	Exclusion key
Exclusion clear key	Versioned	Exclusion clear key
Exclusion clear key	Exclusion key	Exclusion clear key
Exclusion clear key	Exclusion clear key	Exclusion clear key

Listing All Files Included in an Exclusion Key Rule (Linux)

Determining the files that match an exclusion key rule involves two steps. You list all the keys in a GuardPoint, choose the key that you're interested in, and then run a command to list the files that match that key. This process works for both standard key rules and exclusion key rules.

1. Decide on the GuardPoint that you want to check for excluded files. For example, for the GuardPoint `/oxf-fs1/gp1`, type the following on the command line:

```
# voradmin ldt key report /oxf-fs1/gp1
LDT_KEY1,1
LDT_KEY2,2
LDT_KEY3,5
NON_VERSIONED_KEY
```

The number after the comma is the key version number. See ["Key Report Option" on page 45](#) for more information about the `voradmin` key report.

2. From the key report output, choose the key rule for which you want to list matching files. For example, to see the files associated with the `NON_VERSIONED_KEY` in the previous step, you would type:

```
# voradmin ldt key map NON_VERSIONED_KEY /oxf-fs1/gp1
/oxf-fs1/gp1/file1.dat10
/oxf-fs1/gp1/file2.dat10
/oxf-fs1/gp1/file3.dat10
/oxf-fs1/gp1/file4.dat10
/oxf-fs1/gp1/file5.dat10
```

See ["Key Map Option" on page 46](#) for more information about the `voradmin` key map report.

Listing All Files Included in an Exclusion Key Rule (Windows)

Determining the files that match an exclusion key rule involves two steps. You list all the keys in a GuardPoint, choose the key that you're interested in, and then run a command to list the files that match that key. This process works for both standard key rules and exclusion key rules.

1. Decide on the GuardPoint that you want to check for excluded files. For example, for the GuardPoint `c:\gp1`, type the following on the command line:

```
C:\> voradmin ldt key report c:\gp1
Keys used for GP, c:\gp1 :
clear_key,0
CS1-CTE-LDT-AES256,11
```

The number after the comma is the key version number. The `clear_key` key is not versioned, so the version number is 0.

2. From the key report output, choose the key rule for which you want to list matching files. For example, to show the files associated with the `clear_key` listed above, you would type:

```
C:\> voradmin ldt key map c:\gp1 clear_key,0
Files rekey with key (clear_key,0)-
c:\gp1\file1.txt
c:\gp1\file2.txt
c:\gp1\file3.txt
c:\gp1\file4.txt
c:\gp1\file5.txt
```

Using CTE-LDT with SAP HANA Fibre Channel Systems (Linux Only)

You must add additional CTE commands to the HANA administrator entry. To do so, edit the `/etc/sudoers` with a text editor and add entries for `/usr/bin/voradmin` and `/usr/bin/vmsec`. For example:

```
# hanadm ALL=NOPASSWD:
/usr/bin/secfsd,/usr/bin/voradmin,/usr/bin/vmsec,/sbin/multipath,/sbin/multipathd,/etc/init.d/m
ultipathd,/usr/bin/sq_
persist,/bin/mount,/bin/umount,/bin/kill,/usr/bin/lsof,/sbin/vgchange,/sbin/vgscan
```

If you are using an ext3 file system, you must mount it with extended attributes. To do so, edit the storage section of the `global.ini` file using a text editor and add the following lines:

```
partition_*_data__mountOptions = -o user_xattr
partition_*_log__mountOptions = -o user_xattr
```

Note

See the *CTE Agent for Linux Advanced Configuration and Integration Guide* or the *CTE Agent for Windows Advanced Configuration and Integration Guide* for more information about SAP HANA.

Chapter 5: CTE-LDT Administration

This chapter contains the following sections:

CTE-LDT Metadata in Extended Attributes	59
DFSR and Replication (Windows)	63
Multi-Node Configuration and Operation	64
Backing Up and Restoring CTE-LDT GuardPoints	64
CTE-LDT Command-Line Administration: voradmin command	73
Upgrading or Downgrading Agent Software On an CTE-LDT Host	74
Moving a CTE-LDT GuardPoint from One CTE-LDT Policy to Another	75
Removing CTE-LDT and Security Encryption	76
Uninstalling the Agent while CTE-LDT is Rekeying GuardPoints	80

CTE-LDT Metadata in Extended Attributes

An *extended attribute* is a name/value pair permanently associated with a file or directory stored in a file system. CipherTrust Transparent Encryption (CTE) creates and maintains its own user extended attributes on CTE-LDT GuardPoint directories and files. The extended attributes are used to store metadata related to each file or directory that is protected using an CTE-LDT policy.

On Linux, CTE-LDT sets extended attributes on GuardPoint directories. The CTE-LDT attribute of an CTE-LDT GuardPoint stores the following metadata:

- Current key version.
- Rekey status.
- Rekey start and end times.
- Estimated completion time.
- Total amount of data transformed.
- Total number of files transformed.
- Current key signature and applied key signature.

On both Linux and Windows, CTE-LDT sets extended attributes on files. The CTE-LDT attribute of a file stores the following metadata:

- Name of the current key.
- Name of the versioned key.
Also referred to in the DSM Management Console and product documentation as the new key or the transformation key.
- Version number of the versioned key.
- CTE-LDT rekey status of the file.

In most cases, the current and new key names are the same. The exception is during initial transformation from a legacy policy to an CTE-LDT policy, when the file has been encrypted with the current key and is being transformed to the current version of the transformation key.

Note

Before you set up a GuardPoint for CTE-LDT, ensure that there is sufficient disk space available in your file system for CTE-LDT metadata. The amount of disk space you need depends on the number of files in your GuardPoint. For more information about the disk space requirement, see ["Planning for CTE-LDT Attribute Storage" on page 62](#).

The state of a file changes during CTE-LDT operations. The extended attributes are continually updated to reflect the current file status, which falls into one of the following categories:

- Rekeyed to the current version of the key.
- Rekeyed to the previous version of the key, or the initial key state (before the first CTE-LDT rekey has been performed).
- Partially rekeyed, where some regions of the file are rekeyed to the new key version and other regions are still keyed to the previous key version or the initial key.

Listing Extended Attributes

You can list extended attributes by using native operating system commands, or system calls. As part of GuardPoint administration, CTE can modify or delete extended attributes.

In Linux, CTE-LDT attributes are set on GuardPoint directories and regular files in GuardPoint directories protected with CTE-LDT policies. The CTE extended attribute name is `::secfs:xattr:.`

The following example uses the native Linux operating system command `attr` to display the CTE-LDT attribute for the GuardPoint `/oxf-fs1/gp1` and the file `/oxf-fs1/gp1/File_1.txt`.

Example 1:

```
# attr -l /oxf-fs1/gp1/File_1.txt
Attribute "::secfs:xattr:" has a 1044 byte value for /oxf-fs1/gp1/File_1.txt
Attribute "selinux" has a 37 byte value for /oxf-fs1/gp1/File_1.txt
```

Example 2:

```
# attr -l /oxf-fs1/gp1
Attribute "::secfs:xattr:" has a 1044 byte value for /oxf-fs1/gp1
Attribute "selinux" has a 37 byte value for /oxf-fs1/gp1
```

Example 3:

In the following example, the file `/oxf-fs1/gp1/File_1.txt` has the same name for current and new keys at the same key version. In the following example, if the versioned key `LDT_KEY` is at version 755, the file is rekeyed to the latest key version under the CTE-LDT policy.

```
# voradmin ldt attr get /oxf-fs1/gp1/File_1.txt
CTE-LDT attributes: rekeyed_size=4096, rekey_status=none
Key:    name=LDT_KEY, version=755
```

Example 4: (Linux)

The following is example of an CTE-LDT attribute on a GuardPoint directory on Linux:

```
# voradmin ldt attr get /oxf-fs1/gp1
LDT stats: version=1, rekey_status=rekeying
  Number of times rekeyed:      3 times
  Rekey start time:             2018/08/04 16:24:45
  Last rekey completion time:   2018/07/04 16:24:04
  Estimated rekey completion time: N/A
  Policy key version:           2043
```

```
Data stats:
    total=3.3GB, rekeyed=1.5GB, truncated=0.0MB
File stats:
    total=4307, rekeyed=1181,
    passed=2, skipped=0, created=0, removed=0
```

Example 5: (Windows)

The attribute for the GuardPoint `c:\GP 1` contains the status (rekeyed) and statistics specific to the GuardPoint and CTE-LDT. Following is sample output of `voradmin` command on Windows for statistics on a file:

```
C:\> voradmin ldt attr get c:\GP\Test.txt
LDT attributes:
    Rekey Status          Rekeyed
    Initial Rekeyed Size  10 Bytes
Key:
    Key Name/Version      (LDT_KEY, 28)
```

The attribute for GuardPoint `C:\GP` contains the status (rekeyed) and statistics specific to the GuardPoint and CTE-LDT:

```
C:\> voradmin ldt attr get c:\gp\
LDT Stats
-----
    Rekey Status          LDT_ST_REKEYED
    Last rekey completion time    10/2/2017 4:26:50
    Rekey Start time            10/2/2017 4:26:17
    Estimated rekey completion time    000:00:00

File Stats:
    Total      444
    Rekeyed    444
    Skipped    0
    Errored    0
    Passed     0
    Removed    0

Data Stats:
    Total      11 GB (12649143417 Bytes)
    Rekeyed    11 GB (12649143417 Bytes)
    Truncated  0 Bytes
```

MDS File (Linux)

In addition to CTE-LDT attributes, the CTE-LDT process on Linux requires persistent storage for additional metadata related to encrypting, or rekeying, files in GuardPoints. CTE-LDT allocates the storage space as soon as the CTE-LDT process starts on a GuardPoint. It maintains this storage space during the entire transformation process, until the GuardPoint is completely transformed.

Storage for this metadata is allocated and managed in a special file, called the MDS (metadata store) file. The MDS file resides inside a GuardPoint directory so each GuardPoint has its own MDS file.

The MDS file is a CTE protected file with the name `::vorm:mds::`. For example:

```
# ls -l /oxf-fs1/gp1/::vorm:mds::
-rwxr-xr-x. 1 root  root 31754474496 Dec  8 09:09 /oxf-fs1/::vorm:mds::
# du -B 1024 /oxf-fs1/gp1/::vorm:mds::
25056    /oxf-fs1/::vorm:mds::
```

As shown above, the MDS file is sparse. In the example, the file size is approximately 30GB, however the file is allocated with approximately 25MB of disk storage. CTE-LDT automatically creates the MDS file the first time the CTE-LDT process starts on any GuardPoint in the file system namespace. It populates the MDS file with all of the metadata for the GuardPoint at the beginning of the CTE-LDT process. Disk space allocated to the MDS file is freed and the MDS file in the GuardPoint directory is removed when the CTE-LDT process completes on the GuardPoint.

WARNING

The MDS file is protected. You cannot remove it unless the administrator runs the `voradmin` command to manually remove the MDS file once it is no longer needed. See ["Deleting CTE-LDT Metadata \(Linux\)" on page 79](#) for more information.

CTE-LDT automatically allocates and deallocates disk space for the MDS file as part of the CTE-LDT process. Deallocation of disk space for a GuardPoint does not change the MDS file size, although it frees the disk blocks. MDS files are sparse and very large in size. With no GuardPoint undergoing CTE-LDT, the minimum allocation of an MDS file is approximately 25MB.

Planning for CTE-LDT Attribute Storage

Before a GuardPoint is enabled for CTE-LDT, make sure that there is sufficient free disk space in the file system to which the GuardPoint belongs. Free space is required for CTE-LDT attributes (CTE extended attributes) and (in Linux) metadata in the MDS file. CTE-LDT attributes are created during initial encryption and are never freed until the GuardPoint is permanently unguarded and removed from the protection of an CTE-LDT policy. In contrast, disk space for metadata in the MDS file is temporary, kept only during the live transformation process.

When planning how much free disk space to reserve for CTE-LDT on a GuardPoint, consider the following:

- Number of files in the GuardPoint
- (Linux) Average length of absolute pathnames of files in the GuardPoint

The CTE-LDT process pre-allocates disk space for the Linux MDS file based on a minimum of 200K files with an average pathname of 1024 bytes per GuardPoint. The minimum space amounts to 325MB of disk space for the MDS file for each GuardPoint, even if file count is very low. (In Windows, CTE-LDT reserves the space when the file is rekeyed.)

Using `voradmin` To Estimate Disk Space Required for CTE-LDT (Linux)

In Linux, you can use the `voradmin ldt space` command to estimate the amount of disk space required for CTE-LDT attributes and the MDS file. The result is rounded to the nearest MB. The syntax of the command is:

```
# voradmin ldt space <guard path>
```

The following example shows how to estimate the required disk space to perform CipherTrust Transparent Encryption - Live Data Transformation on 1501 files in the GuardPoint `/oxf-fs1/gp1`. Estimate the disk space before protecting `/oxf-fs1/gp1` using an CTE-LDT policy. For example:

```
# voradmin ldt space /oxf-fs1/gp1
/oxf-fs1/gp1: found 1501 files without CTE-LDT extended attributes
CTE-LDT disk space requirements: total 169MB (CTE-LDT attributes=6MB, MDS=163MB)
```

The `voradmin` command reports that 1501 files in `/oxf-fs1/gp1` without CTE-LDT attributes. These files are new to CTE-LDT. 6MB of space is required for the CTE-LDT extended attributes and 163MB for metadata in the MDS file.

The following example shows the output of the same command after encryption completes. This estimates the additional disk space needed for the next CTE-LDT rekey operation. For example:

```
# voradmin ldt space /oxf-fs1/gp1
/oxf-fs1/gp1: found 0 files without CTE-LDT extended attributes
CTE-LDT disk space requirements: total 163MB (CTE-LDT attributes=0MB, MDS=163MB)
```

The voradmin command still reports on the same 1501 files, but because encryption has occurred using CTE-LDT, the files all have their CTE-LDT attributes. No additional space is required for CTE-LDT extended attributes on the next run. However, since the MDS file is transient and deletes after it finishes encrypting the GuardPoint, it requires additional space for the next key rotation.

Note

Windows estimates space using the following equations:

- Permanent Space = Number of Files * 4K
- Temporary Space = 128K * (Number of CPU * 2)

Displaying Metadata

Use the following command to see CTE-LDT file attributes or GuardPoint attributes:

```
# voradmin ldt attr get [<file name path> | <guard path>]
```

For an overview of voradmin ldt, see ["CTE-LDT Command-Line Administration: voradmin command" on page 73](#).

Verifying Metadata (Windows only)

Use the following command to verify if the metadata is corrupt:

```
# voradmin ldt attr verify [<file name path> | <guard path>]
```

For an overview of voradmin ldt, see ["CTE-LDT Command-Line Administration: voradmin command" on page 73](#).

DFSR and Replication (Windows)

The Distributed File System Replication (DFSR) service is a multi-master replication engine used to maintain synchronized folders on multiple servers. Replicating data to multiple servers increases data availability and provides users in remote sites with fast, reliable access to files.

If you are creating GuardPoints in a DFSR environment, you must first add the DFSR private folder guard path to the exclusion list in the Windows Registry. CTE-LDT should not attempt data transformation on this read-only directory.

1. Using the Registry Editor, or the Windows command line, add a registry entry in: `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\services\Vmmgmt\Parameters` named "LDTEExclusionGPList" of type REG_MULTI_SZ.
2. Add the `DfsrPrivate` directory path to the `LDTEExclusionGPList`.
For example, if the DFSR private directory path is `D:\data\DfsrPrivate`, add this string in `LDTEExclusionGPList`.
3. Reboot the system to make the change take effect.

Note

CTE-LDT does not perform a rekey on the DFSR private directory. Its rekey status is always "N/A".

If an application, or user, is performing a rename or a delete folder operation inside a GuardPoint with an CTE-LDT policy, this may restart the rekey process. Files which are already rekeyed will not be rekeyed again.

- If a rename or a delete operation is already performed on rekeyed files/folder, then the rekey process does not restart.
- If a rename or delete operation is performed in a folder where a rekey is in progress, CTE-LDT needs to stop the rekey process and restart the rekey again.

Multi-Node Configuration and Operation

This section describes what to expect at runtime when CTE-LDT operates in a multi-node cluster environment.

CTE-LDT Behavior on Failover

In a multi-node cluster, CTE-LDT runs in active-passive mode. A GuardPoint is only enabled on the active node, and CTE-LDT only runs on the active node. On the DSM Management Console, you can only view statistics for the active host.

If the active host fails over, and the standby host takes control, CTE-LDT also fails over to the second host. On the DSM Management Console, CTE-LDT statistics now appear on the other host.

Veritas Cluster Server

In an HA environment with Veritas Cluster Server, manual failover of service to a stand-by host may require manual intervention. If any GuardPoint is in the scan phase at the time of the manual failover, the failover process fails with the error "UNABLE to OFFLINE". The reason for the failure may be the scan state of a GuardPoint that cannot be suspended. CTE-LDT suspends CTE-LDT operations during the rekey state of transformation. Because CTE-LDT scan operations cannot be suspended, the Veritas Cluster Server fails to suspend CTE-LDT on GuardPoints in the scan phase of CTE-LDT operation. This state of CTE-LDT operation prevents Veritas Cluster Server to manually offline the service for fail-over.

Backing Up and Restoring CTE-LDT GuardPoints

This section describes procedures and considerations related to backing up and restoring data in CTE-LDT GuardPoints.

In addition to the files in a GuardPoint, CTE-LDT stores metadata in extended file attributes. These CTE-LDT attributes contain information that is required for decrypting the files and for the proper operation of CTE-LDT. Therefore, it is critical that your backup application also backs up the extended attributes of the files along with file data.

Clear Text Backup and Restore

A policy that applies a Security Rule with the Apply Key effect on backup/restore operations does not require any special rules for data access by backup applications. Under such a policy, backup applications always read clear data and store clear data in backup media. The backup application is not required to back up the CTE-LDT extended attributes, and a QoS schedule is not required to suspend CTE-LDT during backups.

Encrypted Backup and Restore

When a policy does not enforce a Security Rule with the Apply Key effect on backup/restore operations, the policy does not decrypt data on I/O operations from that backup application. Under such a policy, the backup application stores encrypted data and the CTE-LDT extended attributes of the file on the backup media.

In Linux, CTE-LDT operations must be suspended during backup. Suspending CTE-LDT completes the ongoing rekey operations on regions of files before starting the backup. During live transformation, CTE-LDT first preserves those regions of a file to be rekeyed in the MDS file. Then it updates some of the metadata in order to update the status of the data preserved in the MDS file in preparation for the rekey. Then it starts rekeying and updating those regions in the underlying file.

Suspending CTE-LDT waits for ongoing rekey operations to complete, and saves the metadata in the CTE-LDT extended attribute section of the MDS file. Suspending CTE-LDT ensures that the rekey status stored in the CTE-LDT extended attribute accurately reflects the rekey status of the data in the entire file during backup.

Note

This requirement does not apply to CTE-LDT for Windows.

The following table summarizes the state of the data in files in backup media:

CTE-LDT State of File	Security Policy	Backup Metadata or Alternate Data Streams Along with File data	Effect
Not rekeyed	Permit	Yes	Data in backup may be in clear format or encrypted with older key version.
Rekey in progress	Permit	Yes	File in backup storage is partially rekeyed. Some parts are in clear format or encrypted with older key version, and other parts are encrypted with current key version.
Rekey complete	Permit	Yes	File in backup storage is in the encrypted format with new key version.

CTE-LDT Policy for Encrypted Backup and Restore

Suppose you have an CTE-LDT policy allowing a backup user, or a backup process, to perform an encrypted backup. The backup user, or the backup process, reads encrypted data from files and stores the same encrypted data in backup media.

For example, suppose you wanted to back up GuardPoint `/oxf-fs1/gp1` protected by `My_LDT_Policy_1`. The key version before the key rotation is 8. The following steps occur:

1. Key version 8 expires and is rotated to version 9.
2. Rotating the encryption key triggers CTE-LDT to start running on the data under the GuardPoint.
3. The QoS schedule suspends CTE-LDT because a backup process is running.
4. The backup process begins, runs and later ends.
5. The QoS schedule resumes CTE-LDT.
6. CTE-LDT on the GuardPoint completes.

Note

Although the backup/restore scenarios and examples described in the rest of this section are specific to CTE-LDT on Linux platform, the concepts also apply to CTE-LDT on the Windows platform.

Consider the state of the three files in the GuardPoint during the CTE-LDT process, right after CTE-LDT is suspended in preparation for the backup. You can obtain the state of each file through the `voradmin ldt attr get` command, which examines the CTE-LDT state of each file captured in the CTE-LDT extended attributes of those files. (For an overview of `voradmin CTE-LDT`, see ["CTE-LDT Command-Line Administration: voradmin command" on page 73](#)).

- **File_1.dat** is rekeyed/encrypted to completion. The applied and new key versions are at version 9 of the key.

```
# voradmin ldt attr get /oxf-fs1/gp1/data_files/file_1.dat
LDT attributes: rekeyed_size=1440743424, rekey_status=none
Key:      name=LDT_AES256_KEY, version=9
```

- **File_2.dat** is partially rekeyed/encrypted. The applied key version is at version 8 and the transformation key is at version 9.

```
# voradmin ldt attr get /oxf-fs1/gp1/data_files/file_2.dat
LDT attributes: rekeyed_size=1440743424, rekey_status=rekeying,state_saved
Current Key:      name=LDT_AES256_KEY, version=8
New Key:          name=LDT_AES256_KEY, version=9
```

- **File_3.dat** has not been rekeyed/encrypted. The applied key and transformation key are both at version 8, which is the version before the current key rotation.

```
# voradmin ldt attr get /oxf-fs1/gp1/data_files/file_3.dat
LDT attributes: rekeyed_size=1440743424, rekey_status=none
Key:      name=LDT_AES256_KEY, version=8
```

While CTE-LDT is suspended on the GuardPoint, the backup process starts and archives these three files, including extended attributes, in the backup media.

```
# my_backup --preserve=xattr /oxf-fs1/gp1/data_files/file_1.dat \
    /backup-media/oxf-fs1/gp1/data_files/file_1.dat
# my_backup --preserve=xattr /oxf-fs1/gp1/data_files/file_2.dat \
    /backup-media/oxf-fs1/gp1/data_files/file_2.dat
# my_backup --preserve=xattr /oxf-fs1/gp1/data_files/file_3.dat \
    /backup-media/oxf-fs1/gp1/data_files/file_3.dat
```

Notes

- On Linux platforms, you must perform backups on a GuardPoint during periods when CTE-LDT is not actively transforming data in the GuardPoint. You must schedule backups in conjunction with CTE-LDT schedules or during periods when CTE-LDT is paused. Make sure to coordinate with the backup administrator and schedule accordingly.
- If the preferred method of backup is to create device level snapshots of the file system on the managed host or in the storage array subsystem, you must ensure that the schedule for creating snapshots pauses CTE-LDT before a snapshot is created.

Backup/Restore of Metadata Store File (MDS) in GuardPoints Undergoing Rekey

Backing up an entire GuardPoint using commands such as `cp`, `tar`, or `rsync`, or even commercial backup products that sweep the file system namespace for backing up files is supported. This method of backup performed while live transformation is in progress over GuardPoint poses some challenges when files in GuardPoint are backed up in encrypted format. The challenge with this method of backup is existence of the CTE-LDT Metadata Store file (MDS) in GuardPoint during backup or restore process and strict protection enforced on MDS files preventing deletion or modification to MDS files. Second, your backup utility must backup and restore extended attributes of files, and because CTE-LDT extended attributes are also protected similar to MDS files, your backup must be enabled to restore extended attribute of files. To overcome both restrictions, your policy on GuardPoint must include a security rule without Apply Key Effect to enable your backup utility to replace MDS file and CTE-LDT extended attribute of files as

part of backup/restore operations. Additionally, your backup utility must be signed with a signature set from the DSM for added security, and be executed with the option to preserve extended attribute options available with the standard Linux utilities.

The following table lists the supported backup utilities, required options to preserve extended attributes, and supported versions of the utilities.

Command	Required options	Supported version
cp	--preserve=all	OS default
tar	--xattrs	OS default
rsync	-vapIXWP --inplace	OS default
netbackup	overwrite existing files	v7.6.1 and v7.7.3

You can also backup and restore GuardPoint data, including the MDS file, if the requirements listed above on the backup utility are satisfied. GuardPoints associated with an MDS file located outside of GuardPoint namespace cannot be backed up or restore using this method of backup.

Note

You must suspend CTE-LDT on GuardPoint before performing backup or restore.

You can check your GuardPoint to determine if you can use this method of backup. If the directory of your GuardPoint is a mount point, MDS files reside inside your GuardPoint and this method of backup can be used for backing up or restoring your GuardPoint. However, GuardPoint directories below file system mount points must be checked and verified to use this method of backup. To verify, you can run the `voradmin` command to determine the MDS file associated your GuardPoint.

For example:

```
# voradmin ldt list all
MDS_1:  type=file, nguards=1, name=/oxf-fs1/gp1/:vorm:mds::

Guard Table: version 1 nentries 1
Guard 0: type=GP, state=REKEYING SUSPENDED (vadm), flags=GP LOCKED, gp=/oxf-fs1/gp1
File List: count 4308
```

The report on `/oxf-fs1/gp1` GuardPoint indicates association of the MDS file `/oxf-fs1/gp1/:vorm:mds::` with the GuardPoint. As the MDS file resides inside the GuardPoint directory, you can use this method of backup to backup and restore this GuardPoint.

Before restoring the GuardPoint, you must suspend CTE-LDT operations on the GuardPoint if live transformation is in progress. Failure to do so will fail to restore the MDS file in the backup image. Failure to restore MDS file affects partially rekeyed files restored to the GuardPoint. In such a situation the restored data is invalid, and you must remove all the files restored to the GuardPoint and repeat the restore operation after suspending CTE-LDT.

Restoring a GuardPoint from a Backup

To properly restore GuardPoint along with the MDS file, the following steps must be done in order:

1. Verify if live transformation is in progress on the GuardPoint and suspend the CTE-LDT operations. (Skip this step if no live transformation is occurring.)
2. With the same tool that was used for backup, restore to the GuardPoint.

3. Once restore is complete, GuardPoint needs to be disabled and enabled again. Run the `voradmin` command as shown below to determine how the GuardPoint was suspended at the time of backup. For manual GuardPoint, run the `secfsd` command as shown below. For auto-guards, disable and enable GuardPoints on DSM.

```
# secfsd -unguard <GuardPoint>
# secfsd -guard <GuardPoint>
```

4. Since GuardPoint was in suspended state during the time of backup, it will be restored in suspended state. You must resume CTE-LDT to complete CTE-LDT on the restored GuardPoint. You must resume CTE-LDT on the DSM if CTE-LDT was suspended on the DSM at the time of backup, otherwise you will resume CTE-LDT using `voradmin` command.

Run the `voradmin` command below to determine if CTE-LDT must be resumed on DSM or through `voradmin`. If the tag string next to SUSPENDED state of GuardPoint is `vadm`, run `voradmin` command to resume CTE-LDT, otherwise the tag value is `qos` and CTE-LDT must be resumed on DSM. In the example below, GuardPoint `/oxf-fs1/gp1` was suspended using `voradmin`, and it must be resumed after restore using `voradmin` command.

```
# voradmin ldt list all
MDS_1:  type=file, nguards=1, name=/oxf-fs1/gp1::vorm:mds::
        Guard Table: version 1 nentries 1
        Guard 0: type=GP, state=REKEYING SUSPENDED (vadm), flags=GP LOCKED, gp=/oxf-fs1/gp1
        File List: count 4308
# voradmin ldt resume /oxf-fs1/gp1
```

5. Wait for CTE-LDT completion on GuardPoint.
6. We strongly recommend that you disable and re-enable the GuardPoint once more.

The restore is now complete and files in your GuardPoint can be accessed.

The CTE Agent sends the following alert message to DSM if the restore operation is rejected:

```
LDT-ALERT: Restore of LDT protected file <GuardPoint> not allowed by policy
```

Potential Warnings During Restore Operation

When using `cp` for backup/restore, the `cp` command may report a failed attempt to preserve permissions on the Metadata Store File (MDS) during a restore. If you encounter the below message, continue to proceed with the restore steps since this will not affect the MDS file or dataset that is being restored.

```
cp: preserving permissions for '/oxf-fs1/gp1::vorm:mds::': Permission denied
```

When using `rsync` for backup/restore, the `rsync` command may report a failed attempt to set extended attribute when restoring the MDS file on system with selinux configured in enforced mode. If user encounters the below message, continue to proceed with the restore steps since this will not affect the MDS file or dataset that is being restored.

```
rsync: copy_xattrs: lsetxattr("/oxf-fs1/gp1::vorm:mds::","security.selinux") failed:
Permission denied (13)
rsync: rsync_xal_set: lsetxattr("/oxf-fs1/gp1::vorm:mds::","security.selinux") failed:
Permission denied (13)
```

Restore an Encrypted Backup

This section illustrates restoration of the three files from the backup media to the same GuardPoint, `/oxf-fs1/gp1`. The files are restored to a different directory under the GuardPoint.

Restore a File Fully Rekeyed to the Latest Key Version

Recall that `file_1.dat` was archived in the backup media when it was fully rekeyed to version 9 of the key. As the current version of the key is also 9, `file_1.dat` is restored from backup without any changes. After restoring the file, the state of the restored file and its applied and current key versions remain unchanged, as compared to the original file

that was backed up.

```
# my_backup --preserve=xattr /backup-media/oxf-fs1/gp1/data_files \ /file_1.dat /oxf-  
fs1/gp1/restored_files/file_1.dat  
  
# voradmin ldt attr get /oxf-fs1/gp1/restored_files/file_1.dat  
LDT attributes: rekeyed_size=1440743424, rekey_status=none  
Key:      name=LDT_AES256_KEY, version=9  
  
# voradmin ldt attr get /oxf-fs1/gp1/data_files/file_1.dat  
LDT attributes: rekeyed_size=1440743424, rekey_status=none  
Key:      name=LDT_AES256_KEY, version=9
```

Restore a Partially Rekeyed/encrypted File

Recall that *file_2.dat*, archived in the backup media, was partially rekeyed between versions 8 and 9. As the current version of the key was 9 at the time of backup, *file_2.dat* is restored to the GuardPoint with the same version of the key from the time of backup. The file is flagged for *lazy rekey*, meaning that a background rekey operation is scheduled to transform the file to the latest key version the next time an application tries to access the file.

At the completion of restoration, the file is fully transformed to the key version (v9). The key version is also the latest one in the policy. Although the file is flagged for lazy rekey (LAZY_RK), the file does not need to be transformed to the latest key version because it's already there. Had the file been partially rekeyed from version 7 to version 8 of the key at the time of backup, the restored file would have completed rekeying to version 8 at the end of the restoration. Therefore, the LAZY_RK flag would initiate a background transformation to update the key version to the latest key version when the file is accessed.

If this file is not accessed by any application, the file remains unchanged in the GuardPoint. It is not transformed to the latest key version. To trigger a rekey, either re-push the CTE-LDT policy from the DSM, or access the file with an application, such as a file explorer.

```
# my_backup --preserve=xattr /backup-media/oxf-fs1/gp1/data_files/\ file_1.dat /oxf-  
fs1/gp1/restored_files/file_2.dat  
  
# voradmin ldt attr get /oxf-fs1/gp1/restored_files/file_2.dat  
LDT attributes: rekeyed_size=1440743424, rekey_status=lazy_rekey  
Key:      name=LDT_AES256_KEY, version=9  
  
# voradmin ldt attr get /oxf-fs1/gp1/restored_files/file_2.dat  
LDT attributes: rekeyed_size=1440743424, rekey_status=none  
Key:      name=LDT_AES256_KEY, version=9
```

Restore a File Not Rekeyed/encrypted with an Older Key Version

Recall *file_3.dat* was archived in the backup media when it was keyed to version 8 of the key, one version below the latest version at the time of backup. At completion of the restoration, *file_3.dat* is restored from backup to the same version, version 8, that it was keyed to when it was backed up.

However, the file is flagged for lazy rekey. After restoring the file, it is keyed to version 8 and flagged for lazy rekey (LAZY_RK). The file is rekeyed to the latest key version, version 9, as soon as an application accesses the file. If this file is not accessed by any application, the file remains unchanged in the GuardPoint.

```
# my_backup --preserve=xattr /backup-media/oxf-fs1/gp1/data_files \ /file_3.dat /oxf-  
fs1/gp1/restored_files/file_3.dat  
  
# voradmin ldt attr get /oxf-fs1/gp1/restored_files/file_3.dat  
LDT attributes: rekeyed_size=1440743424, rekey_status=lazy_rekey  
Key:      name=LDT_AES256_KEY, version=8
```

```
# sum /oxf-fs1/gp1/restored_files/file_3.dat
39994 1406976

# voradmin ldt attr get /oxf-fs1/gp1/restored_files/file_3.dat
LDT attributes: rekeyed_size=1440743424, rekey_status=none
Key:      name=LDT_AES256_KEY, version=9
```

Restoring Non-CTE-LDT Backup Data to an CTE-LDT GuardPoint

This section describes how to restore data encrypted with a non-versioned key to an CTE-LDT GuardPoint.

If the backup was performed with the Apply Key effect, the backup files are in clear text. Simply restore the clear text files to the CTE-LDT GuardPoint with the Apply Key effect. All files will be encrypted with the versioned key.

If the backup of the non-CTE-LDT GuardPoint was performed without the Apply Key effect, the backup is encrypted, and you must do the following:

Note

The following example is for a manual guarding. The steps may differ slightly if your GuardPoint is configured for auto guard.

1. Create a temporary directory for restoring the files, type:

```
# mkdir -p /oxf-fs1/tmp_restore
```

2. Restore the encrypted backup files into the temporary directory, type:

```
# cp -pr /backup-media/oxf-fs1/gp1/data_files/* /oxf-fs1/tmp_restore
```

3. Create a Standard Policy with the Apply Key effect for all operations, using the same key as the policy applied on the GuardPoint at the time of backup.

4. Create and enable a new GuardPoint for the temporary directory using the Standard Policy just created.

```
# secfsd -guard /oxf-fs1/tmp_restore
```

5. Ensure that the temporary GuardPoint and CTE-LDT GuardPoint are both enabled.

```
# secfsd -status guard
```

GuardPoint	Policy	Type	ConfigState	Status	Reason
-----	-----	----	-----	-----	-----
/oxf-fs1/gp1	LDT_AES256	manual	guarded	guarded	N/A
/oxf-fs1/tmp_restore	AES256	manual	guarded	guarded	N/A

6. Move the restored files from the temporary folder to the GuardPoint enabled with the CTE-LDT policy. The CTE agent encrypts the files in the CTE-LDT GuardPoint using the current key version in effect for the CTE-LDT policy.

```
# mv /oxf-fs1/tmp_restore/* /oxf-fs1/gp1
```

7. Disable the temporary GuardPoint and remove the temporary restore directory.

```
# secfsd -unguard /oxf-fs1/tmp_restore
# rm -fr /oxf-fs1/tmp_restore
```

8. Delete the temporary GuardPoint on the DSM.

Using fsfreeze (Linux only)

If you use the `fsfreeze` command to quiesce access to the file system before creating a snapshot, refer to the `fsfreeze` section in CTE Admin Guide in the Linux Utilities chapter on how to run the `fsfreeze` command to quiesce access to both the file system and the GuardPoint(s).

WARNING

Do not use CTE-LDT schedules and do not pause CTE-LDT to align backup schedules with CTE-LDT. Instead, use the `fsfreeze` command.

- Running `fsfreeze -f` on the GuardPoint directory pauses CTE-LDT operations in-progress and freezes access to both the GuardPoint and the underlying file system.
- Running `freeze -u` reverses `freeze -f`, allowing access to underlying file system and resuming CTE-LDT operations.

CTE-LDT Backups Using a File System or Storage-Level Snapshot Tool

You can make a file system snapshot using a Logical Volume Manager service or mirroring/splitting storage level LUNs of a file system inside the storage subsystem. CTE-LDT does not have requirements for where and how you create a file system snapshot. However, it is required that you **suspend CTE-LDT processes before you take the file system snapshot**. Suspending CTE-LDT ensures data and metadata consistency between files and CTE-LDT extended attributes.

You may choose to suspend CTE-LDT manually on the managed host using `voradmin ldt suspend` command or `fsfreeze -f`, or suspend CTE-LDT on the DSM.

Note

Be aware that suspending CTE-LDT on the DSM suspends CTE-LDT on the entire host.

After creating a file system snapshot, you can resume CTE-LDT processes on the GuardPoint using `voradmin ldt resume`, or `fsfreeze -u`, or resuming CTE-LDT on the DSM. Do not mix the use of `fsfreeze` and `voradmin ldt suspend` to pause and resume CTE-LDT. CTE suspends or resumes CTE-LDT processes during live transformation when freezing or unfreezing GuardPoint access using `fsfreeze -f` or `-u` option. See the *CTE Agent for Linux Advanced Configuration and Integration Guide* on the use of the `fsfreeze` command on a GuardPoint.

Note

You can make sure CTE-LDT is suspended at backup time by setting the QoS schedule.

You can mount a file system snapshot for data recovery. Configuration for GuardPoints must be duplicated over the mount point of the snapshot file system. Make sure to use the same CTE-LDT policy. Enabling GuardPoints over or under the snapshot mount point provides access to the protected files for recovery. You can choose to manually resume key rotation on the GuardPoints of the snapshot file system, although this is not necessary.

Following is an example of the `fsfreeze` command used to freeze access to the file system `/oxf-fs1` in order to create a snapshot of the file system device. This examples illustrates three GuardPoints enabled inside the file system namespace, `/oxf-fs1/gp-1`, `/oxf-fs1/gp-2`, and `/oxf-fs1/gp-3`. Executing the command `fsfreeze -f` targets any of the GuardPoints in the `/oxf-fs1` mount point and suspends CTE-LDT processes on all of the GuardPoints. Then it freezes access to the file system.

```
# fsfreeze -f /oxf-fs1/gp-1
# voradmin ldt list all
MDS_1:  type=file, nguards=1, name=/oxf-fs1/gp-3::vorm:mds::
        Guard Table: version 1 nentries 1
        Guard 0: type=GP, state=REKEYING SUSPENDED (vadm), flags=GP LOCKED,
fs1/gp-3
                File List: count 4308

MDS_2:  type=file, nguards=1, name=/oxf-fs1/gp-2::vorm:mds::
        Guard Table: version 1 nentries 1
        Guard 0: type=GP, state=REKEYING DIRTY, flags=GP LOCKED, gp=/oxf-fs1/gp-2
                File List: count 4308
```

```
MDS_3:  type=file, nguards=1, name=/oxf-fs1/gp-1/::vorm:mds::  
        Guard Table: version 1 nentries 1  
        Guard 0: type=GP, state=REKEYING SUSPENDED (vadm), flags=GP LOCKED, gp=/oxf-fs1/gp-1  
        File List: count 4308
```

After the file system snapshot is created, executing the `fsfreeze -u` command on any of the GuardPoints in the file system namespace unfreezes access to the file system and resumes CTE-LDT processes on all of the GuardPoints.

```
# fsfreeze -u /oxf-fs1/gp-1  
# voradmin ldt list all  
MDS_1:  type=file, nguards=1, name=/oxf-fs1/gp-3/::vorm:mds::  
        Guard Table: version 1 nentries 1  
        Guard 0: type=GP, state=REKEYING DIRTY, flags=GP LOCKED, gp=/oxf-fs1/gp-3  
        File List: count 4308  
  
MDS_2:  type=file, nguards=1, name=/oxf-fs1/gp-2/::vorm:mds::  
        Guard Table: version 1 nentries 1  
        Guard 0: type=GP, state=REKEYING DIRTY, flags=GP LOCKED, gp=/oxf-fs1/gp-2  
        File List: count 4308  
  
MDS_3:  type=file, nguards=1, name=/oxf-fs1/gp-1/::vorm:mds::  
        Guard Table: version 1 nentries 1  
        Guard 0: type=GP, state=REKEYING DIRTY, flags=GP LOCKED, gp=/oxf-fs1/gp-1  
        File List: count 4308
```

Windows Backup and Snapshots

On Windows, most backup applications use Volume Snapshot Service (VSS) for the backup. Using VSS is required for backing up files in CTE-LDT GuardPoints. VSS service provides a consistent view of the data to backup and restore applications by taking a snapshot of the volume. Windows Backup uses the snapshot volume, while other applications can continue using the original volume for normal I/O operations. VSS snapshot volume uses a “Copy on write” mechanism to provide a consistent view of the data. Some of the high-level steps of the Windows backup process are:

1. Backup application takes a snapshot of the volume using the VSS service.
2. Backup application mounts this VSS volume to read the data to be backed up.
3. The CTE Agent uses the same policy as that of the original volume to protect these snapshots.
4. The CTE Agent applies the policy and rules to all the I/O requests coming from the backup and restore applications.

Restoring ESXi VM Snapshots of a Protected Host

Some organizations may use ESXi virtual machines for protected hosts and create VM snapshots to back up sensitive data. If you are restoring an older ESXi VM snapshot of a protected host, that contains an previous encryption key, follow these steps:

1. Restore the VM to update to the latest version of the encryption key.
2. In the DSM Management Console, choose **Hosts > Hosts**, then click the name of the VM host.
3. Click the **GuardPoint** tab.
4. Click **Re-Push Policies**.

CTE-LDT Backup and Restore Troubleshooting

Restored files to a GuardPoint protected with conflicting key rules

When restoring an encrypted file from backup media to an CTE-LDT protected GuardPoint without the Apply Key effect, and the file in the backup media does not have an CTE-LDT extended attribute, the file restored to the GuardPoint is set with an CTE-LDT extended attribute that specifies the current key version of the key in the policy associated with the data in the restored file. As the key and key version in the policy do not match the key that was applied to the data at the time of backup, the file restored to the CTE-LDT protected GuardPoint is unreadable.

When restoring an encrypted file from backup media to an CTE-LDT protected GuardPoint without Apply Key effect, and the key specified in the CTE-LDT extended attribute of the file in backup media conflicts with the key rules of the policy on the GuardPoint, the restore operation fails and flags the restored file in error. You can only remove the file, or truncate it, to clear the error status on the file. Access to such files, except remove or truncate, fail with an EINVAL error.

CTE-LDT Command-Line Administration: voradmin command

Use the `voradmin` utility to gather statistics and administer CTE-LDT on a host. It has slightly different syntax and command capabilities depending on whether the host is running Linux or Windows.

Note

Refer to the `voradmin` man page for `voradmin` usage in Linux.

To use `voradmin`:

1. Log in to the host running the CTE Agent with CTE-LDT enabled.
2. At the command line, type `voradmin`.
3. Follow the usage outputs onscreen to find the available commands and their syntax. The general syntax is:

```
# voradmin ldt <command> [args]
```

Command	Description
<code>voradmin ldt attr get delete <guard path> <object path></code>	Get or delete attributes for a GuardPoint or Object path.
<code>voradmin ldt key <report map <key> > <guard path></code>	Creates a report, or map, containing statistics after each key rotation on a GuardPoint.
<code>voradmin ldt list all</code>	(Linux only) List all MDS files and GuardPoints undergoing CTE-LDT processing.
<code>voradmin ldt monitor [interval]</code>	(Windows only) Monitor CTE-LDT progress. If an interval is specified (in units of seconds), it continually updates the monitoring output at the specified interval.
<code>voradmin ldt rekey report <guard path> [output file]</code>	Generate a rekey report manually for a Guardpath.
<code>voradmin ldt resume <guard path> all</code>	Resume guarding the GuardPoint directory.
<code>voradmin ldt space <guard path></code>	Estimates disk space needed for metadata and mds store information.

Command	Description
<code>voradmin ldt stats [<guard path>] [<interval>]</code>	Obtains transformation CTE-LDT statistics such as: • Current rekey status • Start time • Estimated completion time • Percentage completed • Total data • Amount of data transformed • Total files • Number of files transformed • Number of files skipped • Number of files remaining for rekey

Upgrading or Downgrading Agent Software On an CTE-LDT Host

Consider the following when upgrading or downgrading software on protected hosts.

Upgrading

If a host contains an agent software version lower than 6.0, and you upgrade to version 6.0 or later, the CTE-LDT feature does not automatically enable on all upgraded hosts. You must:

1. Upgrade the DSM.
2. Install the CTE-LDT license.
3. Restart the 6.x agent, or reboot the host on which the CTE Agent is installed.
4. Select the CTE-LDT option to enable it, once the CTE-LDT option displays in the host's menu.

After upgrading the DSM, the keys and policies on the DSM remain unchanged. They are standard keys and policies not usable with CTE-LDT. To use CTE-LDT, create versioned keys and policies set to type: CipherTrust Transparent Encryption - Live Data Transformation.

On the DSM, select the Live Data Transformation option on the **Edit > Host** page to enable CTE-LDT on target host.

After upgrading a protected host to 6.x from an earlier version, existing policies, keys, and GuardPoints on the managed host remain unchanged and enforced.

Note

In v6.1, you can automatically register CTE-LDT with the DSM installation.

For more information, see [Chapter 3: "Setting Up CTE-LDT" on page 20](#).

Note

If you are using CTE-LDT with the Hadoop Distributed File System (HDFS), see the HDFS chapter in the *CTE Agent Installation and Configuration Guide* for more information.

Downgrading

To roll back from 6.0 (or greater) to a version before 6.0, it is not sufficient to uninstall the 6.0 software and reinstall the earlier version. You must migrate GuardPoints protected with CTE-LDT encryption policies to a non-CTE-LDT policy first, reverse the CTE-LDT host's registration with the DSM, then re register the host after installing the earlier software version. See ["Removing CTE-LDT and Security Encryption" on page 76](#).

Moving a CTE-LDT GuardPoint from One CTE-LDT Policy to Another

To change the CTE-LDT policy that an CTE-LDT GuardPoint uses, complete the following steps to ensure that the GuardPoint is migrated properly from one CTE-LDT policy to another CTE-LDT policy.

Scenario

The GuardPoint is currently attached to LDT-Policy-1, which rekeys from `clear_key` to `LDT-Key-1`. The objective is to migrate the data in the GuardPoint to another versioned key, `LDT-Key-2`. Migration to `LDT-Key-2` requires detaching the GuardPoint from `LDT-Policy-1`, and then attaching it to `LDT-Policy-2`, assuming `LDT-Key-2` is the versioned key specified in `LDT-Policy-2`. This is a two step migration:

1. Migrate a GuardPoint out of the CTE-LDT policy to protection under a standard policy.
The step requires cloning `LDT-Key-1` to a non-versioned key, and migrating the GuardPoint out of the CTE-LDT policy. Because the cloned key and the the current version of `LDT-Key-1` have the same key material, the data in the GuardPoint directory remains encrypted to the same key after migration of the GuardPoint out of CTE-LDT.
2. Migrate a GuardPoint protected under a standard policy to protection with an CTE-LDT policy.

Note that you may set the transformation key to `clear_key` instead of `LDT-Key-2` in the second policy (`LDT-Policy-2`). The effect of `clear_key` is transformation of the data in the GuardPoint directory to clear text. Although the transformation key in CTE-LDT policies must be a versioned key, `clear_key` is an exception. It allows CTE-LDT GuardPoints to be transformed to clear using the CTE-LDT process.

To properly move the GuardPoint from `LDT-Policy-1` to `LDT-Policy-2`:

Note

Ensure that no active processes or users are accessing files in the GuardPoint, or its subdirectories, until all steps have been completed.

1. Follow the instructions for, ["Converting a GuardPoint from an CTE-LDT policy to a non-CTE-LDT policy" on the next page](#).
2. Assuming the current version of the `LDT-Key-1` is version 5, then clone version 5 of the key to `Cloned-LDT-Key-1v5`.
 - a. In the DSM Management Console, select **Keys > Agent Keys > Keys**.
 - b. Click the name of the versioned key that you want to clone.
 - c. Click **Clone** to clone the key.
3. Follow the instructions for ["Using voradmin To Estimate Disk Space Required for CTE-LDT \(Linux\)" on page 62](#).
4. Follow instructions for ["Converting a GuardPoint from an CTE-LDT policy to a non-CTE-LDT policy" on the next page](#) using the cloned key (`Cloned-LDT-Key-1v5`) as the Initial Key and `LDT-Key-2` as the key for the new CTE-LDT policy. The files are now rekeyed from `Cloned-LDT-Key-1v5` to `LDT-Key-2`.

Removing CTE-LDT and Security Encryption

If you want to stop using CTE-LDT on a GuardPoint or on a whole host, follow the instructions in the following sections.

Migrating a GuardPoint Out of CTE-LDT

Migrating a GuardPoint from CTE-LDT removes the security encryption. It also provides a DSM Administrator with the flexibility to relax the compliance requirement, when strict compliance for frequent key rotation on specific data is no longer mandatory. The following sections describe how to migrate a GuardPoint from CTE-LDT to a non-CTE-LDT policy, or to remove encryption protection from it.

Converting a GuardPoint from an CTE-LDT policy to a non-CTE-LDT policy

If you want to do more than just change the policy on a GuardPoint from an CTE-LDT policy to a non-CTE-LDT policy, see ["Deleting CTE-LDT Metadata \(Linux\)" on page 79](#) or ["Deleting CTE-LDT Metadata \(Windows\)" on page 80](#).

1. Clone the versioned key associated with the CTE-LDT GuardPoint to a non-versioned key.

The clone function creates a new key with the same cryptographic encryption material as the current version of the cloned versioned key.

This allows CTE-LDT to use the cloned key in a non-CTE-LDT policy to convert the GuardPoint from an CTE-LDT to a non-CTE-LDT managed policy.

- a. In the DSM Management Console, select **Keys > Agent Keys > Keys**.
- b. Click the name of the versioned key that you want to clone.
- c. On the **General** tab, click **Clone** to clone the current version of the key.

By default, the DSM creates a name for the cloned key that combines the name of the key and the current version number. You can specify a different name if desired. For example, if you are cloning version 5 of a key named `LDT-Key-1`, the name of the cloned key would default to `LDT-Key-1__5`.

2. Click **Hosts > host_name > GuardPoint** tab.
3. Select the GuardPoint and then click **Disable**.
4. After CTE-LDT disables the GuardPoint, click **Unguard** to delete the GuardPoint.
5. (Linux only) Ensure that the GuardPoint is removed on the managed host:

```
# secfsd -status guard
No GuardPoints configured
```

6. CTE-LDT creates extended attributes for every file under the GuardPoint as well as the GuardPoint directory. Now that the CTE-LDT policy does not manage the GuardPoint, you must remove the extended attributes for every file in the GuardPoint, type:

```
# voradmin ldt attr delete /<GuardPoint>
```
7. The command may take some time depending on the number of files in the GuardPoint.

Note: For all of the file system mount points that contain an CTE-LDT protected GuardPoint, you must clean up the metadata first. See ["Deleting CTE-LDT Metadata \(Linux\)" on page 79](#).

8. Create a non-CTE-LDT policy using the cloned key you created earlier in this procedure.
 - a. Click **Policies > Manage Policies > Manage Policies**.
 - b. Click **Add**.
 - c. In Policy Type, choose **Standard**.
 - d. In Key Selection Rules, click **Add**.
 - e. In Key, choose the cloned key1.
 - f. Click **Select Key**.
 - g. Finish creating the policy as usual for a non-CTE-LDT policy.
9. Apply the non-CTE-LDT policy to the GuardPoint.

CAUTION

Make sure that you have removed all of the CTE-LDT metadata from the GuardPoint before applying the non-CTE-LDT policy.

- a. Click **Hosts > host_name > GuardPoint** tab.
- b. Click **Guard**.
- c. In the *Guard File System* window, select the Policy that you just created.
- d. Select *Type: Directory (Auto Guard) or (Manual Guard)*, and enter or browse to the directory to protect.

Remove Protection from a GuardPoint

When compliance may no longer require protecting data in a GuardPoint, you may choose to unprotect/decrypt it. Before removing protection from your GuardPoint, you must decrypt the data in your GuardPoint by setting it to clear. You have two options to decrypt your data:

- While a GuardPoint is protected and enabled under an CTE-LDT policy, you can use copy or backup/restore commands to save files in your GuardPoint to a location outside of your GuardPoint.
- Use the `dataxform` command to transform your GuardPoint to clear in an offline transformation process.

Copying Files to Decrypt Them

If you choose to copy your files, you must create a directory outside of the GuardPoint and then copy the files into the GuardPoint directory. After finishing copying, complete the following steps:

1. Click **Hosts > host_name > GuardPoint** tab.
2. Select the GuardPoint and then click **Disable**.
3. After CTE-LDT disables the GuardPoint, click **Unguard** to delete the GuardPoint.
4. (Linux only) Ensure that the GuardPoint is removed on the managed host:

```
# secfsd -status guard
No GuardPoints configured
```

This completes removal of the GuardPoint under an CTE-LDT policy. You can now remove the original files and data within the GuardPoint namespace.

Using Dataxform Command to Transform the Files

If you choose to use the dataxform command to transform data in your GuardPoint to clear, use the `voradmin` command to verify that earlier versions of the versioned key are not in use on your GuardPoint. Complete the following steps to clear all metadata in your GuardPoint. Then, transform your GuardPoint to clear.

1. Clone the key.
 - a. In the DSM Management Console, select **Keys > Agent Keys > Keys**.
 - b. Click the name of the versioned key that you want to clone.
 - c. Click **Clone** to clone the key.

By default, the DSM uses the name of the versioned key, and the current version number of the versioned key, for naming the cloned key. You can choose a different name, if desired.

2. Create an offline dataxform policy to transform your GuardPoint from the cloned key created in step 1 to `clear_key`. See the *DSM Administration Guide* for more information.

3. In the DSM Management Console, click **Hosts > Hosts > Hostname**.

4. Click the **GuardPoint** tab.

5. Click **Disable** to disable the GuardPoint.

6. After CTE-LDT disables the GuardPoint, click **Unguard** to delete the GuardPoint.

Before you apply the offline data transformation policy to your GuardPoint, you must clean up the CTE-LDT metadata from your GuardPoint. CTE-LDT creates extended attributes for every file under the GuardPoint, as well as the GuardPoint directory. Now that the CTE-LDT policy does not manage the GuardPoint, you can remove the extended attributes for every file in the GuardPoint.

7. Remove the extended attributes of files in a GuardPoint, type:

```
# voradmin ldt attr delete <GuardPoint>
```

The command may take some time depending on the number of files in the GuardPoint. After metadata deletion is complete, you can apply the offline transformation policy on the GuardPoint.

8. On the DSM, guard and enable the GuardPoint with the offline dataxform policy you created earlier.

9. After enabling your GuardPoint, run the dataxform command on the managed host to transform the GuardPoint to a `clear_key`, type:

```
# dataxform --rekey --gp /<GuardPoint>/ --preserve_modified_time --preserve_access_time --cleanup_on_success
```

10. After completion of dataxform, unguard the GuardPoint.

- a. Click the **Hosts > Hostname > GuardPoint** tab.
- b. Select the GuardPoint and click **Disable**.
- c. After CTE-LDT disables the GuardPoint, click **Unguard** to delete the GuardPoint.

11. Remove the GuardPoint from the dataxform policy on the DSM.

- a. Click **Policies > PolicyName**.
- b. Select the **GuardPoint**.
- c. Click **Delete**.
- d. Click **Apply**.

Deleting CTE-LDT Metadata (Linux)

To remove the metadata associated with the GuardPoint, you must run the `voradmin` command on the managed host to remove the CTE-LDT metadata associated with the GuardPoint.

WARNING

Before you attempt to remove an MDS file, make sure that no CTE-LDT-protected GuardPoints remain configured under the file system mount point.

In the following example:

- `/oxf-fs1` is the mount point
- `/oxf-fs1/gp1` is the CTE-LDT-protected GuardPoint

To delete the metadata associated with the GuardPoint:

1. Ensure that the GuardPoint is not enabled on the host. Run the command below and verify that the GuardPoint pathname does not appear in the output of the `secfsd` command, type:

```
# secfsd -status guard
```

2. Run the `voradmin` command to remove CTE-LDT attributes on the GuardPoint, type:

```
# voradmin ldt attr delete <GuardPoint path>
```

For example:

```
# voradmin ldt attr delete /oxf-fs1/gp1
LDT metadata has been removed from all files in GuardPoint /oxf-fs1/gp1
```

If the last transformation on your GuardPoint completed when the VTE Agent was running version 6.0.2, you may have to remove the MDS file that is located in the mount point directory of the file system in which GuardPoint resides. Before you remove the MDS file, make sure that the MDS file is not in use with other GuardPoints under the same file system mount point. For example, if you removed the metadata for GuardPoint `/oxf-fs1/gp-1` where `/oxf-fs1` is the mount point of the mounted file system, make sure that `/oxf-fs1` does not appear in the output of the `secfsd -status guard` command, and then proceed:

1. Remove the MDS file from the mount points or GuardPoints. As of the CTE 6.1 release, CTE-LDT always creates and manages the MDS file inside the GuardPoint directory. Earlier versions created and managed the MDS file inside mount point directory while sharing the MDS file with all the GuardPoints under the mount point. Type:

```
# voradmin ldt rmstore <mount_point>
```

For example:

```
# voradmin ldt rmstore /oxf-fs1
Enter YES if /oxf-fs1 does not include any GuardPoints associated with an CTE-LDT policy -
>YES
MDS file /oxf-fs1/::vorm:mds:: has been removed.
```

2. Verify that the metadata store has been removed from the secfs mount points, type:

```
# ls -altr <file_system_mount_point>
```

For example:

```
# ls -altr /oxf-fs1
```

You should not see `/oxf-fs1/::vorm:mds::` listed.

Deleting CTE-LDT Metadata (Windows)

Use the following command to delete the CTE extended attribute for a file or a GuardPoint. This is useful when removing a GuardPoint from under an CTE-LDT policy (see ["Migrating a GuardPoint Out of CTE-LDT" on page 76](#)).

```
# voradmin ldt attr delete [<file name path> | <guard path>]
```

For an overview of `voradmin ldt`, see ["CTE-LDT Command-Line Administration: voradmin command" on page 73](#).

Removing CTE-LDT from a Host

Once you have registered a host and enabled CTE-LDT, you cannot disable the CTE-LDT feature by unchecking the CTE-LDT box. You must unregister the host from the DSM, then register it again without CTE-LDT. When you remove the CTE-LDT feature from a host entirely, the host's CTE-LDT license becomes available for use on another host.

1. Stop all applications from accessing data in CTE-LDT GuardPoints on the host.
2. Migrate data in every CTE-LDT GuardPoint using the steps described in the section ["Remove Protection from a GuardPoint" on page 77](#).

WARNING

Potential data loss. Ensure that you have decrypted the data and, optionally, copied it out of the GuardPoint. Once the CTE Agent software is removed, access to data is no longer controlled by CTE. If the data was encrypted, it remains encrypted, and there is no way to read it.

3. Remove the GuardPoints on the host from the DSM.
 - a. Remove the CTE-LDT metadata from those GuardPoints.
 - b. Remove the MDS files associated with those GuardPoints, if necessary. See ["Deleting CTE-LDT Metadata \(Linux\)" on the previous page](#) for more information.
4. Remove the host from the DSM. For details, see the *CTE Agent for Linux Advanced Configuration and Integration Guide* or the *CTE Agent for Windows Advanced Configuration and Integration Guide*.
5. Re-install the agent on the host.
6. Register the host with the DSM. This time, do not select the CipherTrust Transparent Encryption - Live Data Transformation option. See ["Enabling CTE-LDT on a Protected Host" on page 25](#).

Uninstalling the Agent while CTE-LDT is Rekeying GuardPoints

You cannot uninstall the CTE Agent if CTE-LDT is rekeying any GuardPoints on that host.

If you want to uninstall the CTE Agent from a host that contains CTE-LDT GuardPoints, you must first unencrypt the files on each CTE-LDT GuardPoint using the steps noted in the previous sections.

Chapter 6: Troubleshooting CTE-LDT

Monitoring and Statistics	81
Protecting CTE-LDT GuardPoints against Failure in Underlying Filesystems (Linux)	84
Alerts Playbook	85
Error Messages	90
Warning and Info Messages	92
Upgrading CTE Agent	93
Recommendations and Considerations	93

The CTE-LDT administrator needs to monitor and respond to runtime statistics and alerts.

Monitoring and Statistics

This section describes how to find the runtime status of CTE-LDT and how to get statistics about its operation.

Note

When you check GuardPoint status on the DSM, be aware that the status is not relayed in real time. There can be a delay of several minutes before the DSM becomes aware of events on the host. When you configure the host and v for one-way communication, the delay is longer, up to an hour, because CTE-LDT sends statistics to the DSM only once per hour.

To find out when the DSM last received a status update from the host, check the Last Status Update timestamp in the GuardPoint Status dialog (for information about how to display this dialog, see ["Obtaining Statistics in the DSM with GuardPoint Status" below](#)). For the most up-to-date statistics, inspect the host. Run the `voradmin` command on the managed hosts to retrieve status and statistics pertaining to GuardPoints.

To find out whether your host is configured for one-way communication, open the DSM Management Console, choose **Hosts > Hosts**, click the name of the host, and look for the FS Agent One Way Communication checkbox.

Obtaining Statistics in the DSM with GuardPoint Status

During and after data transformation, you can view statistics about any GuardPoint on any host in your system. Either use the DSM Management Console, as described in this section, or use the `voradmin` command, as described in ["Obtaining CTE-LDT Statistics at the Command Line" on page 83](#).

To display the GuardPoint status in the DSM Management Console:

1. In the DSM Management Console, choose **Hosts > Hosts**.
2. Click the name of the host you want to inspect.
3. Click the **GuardPoint** tab.
4. In the Status column, click the icon.

The GuardPoint Status window opens. The window displays the following values:

GuardPoint Status Field	Description
Reason	If the key rotation was initiated manually on an CTE-LDT host, the requester selected a reason such as "normal maintenance" or "key compromised."

GuardPoint Status Field	Description
GuardPoint Status	Status of the GuardPoint.
GuardPoint State	State of the GuardPoint.
Usage	Displays the reference count for the GuardPoint.
Guarded on	Date when the policy went into effect on this GuardPoint.
Policy Name	Name of the policy.
Policy Version	The current policy version. If you make any changes to a policy after creating it, the policy version number increases by 1. The first version is number 0.
Last Status Update	Time stamp that displays when the DSM last received status information from the agent on the protected host. There can be a delay between status updates from agent to DSM. If it is imperative that you see the most recent data, go to the agent and use the voradmin command to inspect it. For an overview of voradmin CTE-LDT, see "CTE-LDT Command-Line Administration: voradmin command" on page 73 .
Policy Aggregate Key Version	Indicates the version of the key used to transform data.
Transformation Status	A one-word summary of the current (or most recent) CipherTrust Transparent Encryption - Live Data Transformation. The same value is shown in the Rekey Status column on the host's GuardPoint tab. For details about each status code, see "Checking the Rekey Status" on page 44 .
Last Transformation Completion Time	Timestamp from the last time that transformation completed successfully.
Last Transformation Start Time	Timestamp showing the last time transformation was started. If this time is later than the Last Transformation Completion Time, the transformation did not complete normally. The Transformation Status should reflect this, such as with Incomplete.
Estimated Rekey Completion Time	If transformation is underway, this field displays the rekey duration.
Total Number of Files Deleted	Number of files in the GuardPoint that were deleted by users while data transformation was underway.
Total Files to Be Transformed	Number of files found during the initial scan of the GuardPoint. For more information, see "CTE-LDT Runtime Flow" on page 14 .
Total Bytes to Be Transformed	Size of all of the files found during the initial scan of the GuardPoint.
Total Bytes Transformed	Number of bytes in the GuardPoint that were successfully transformed in the most recent CTE-LDT operation. If this does not match Total Bytes to Be Transformed, look for Total Files Skipped or Total Files Errored.
Total Files Transformed	Number of files in the GuardPoint that were successfully transformed in the most recent CTE-LDT operation. If this does not match Total Files to Be Transformed, look for Total Files Skipped or Total Files Errored.

GuardPoint Status Field	Description
Total Files Skipped	Total number of files that CTE-LDT did not transform in this pass. The files were intended for transformation, but were not transformed for some reason. For example, (on Windows) the file is read-only, or it is an executable file that is currently running. On a Windows host, transformation continues on the next available file in the GuardPoint, and CTE-LDT maintains a list of the files that it skipped.
Total Files Errored	Total number of files that triggered alerts. See "Alerts Playbook" on page 85 .

Obtaining CTE-LDT Statistics at the Command Line

You can obtain CTE-LDT statistics from the command line using the following command:

```
# voradmin ldt stats <guard path> [interval]
```

This command displays transformation statistics for a GuardPoint, or for all GuardPoints, if none are specified. If you specify an interval (in units of seconds), the command continually updates the statistics on the given interval. If no GuardPoint is specified, the command returns the aggregate statistics at the host level, including specific statistics related to QoS. If a GuardPoint is specified, statistics include:

- Current rekey status
- Rekey Start time
- Last rekey completion time
- Estimated Rekey completion time
- Data Statistics including the amount of data transformed
- File statistics including:
 - Number of files transformed
 - Number of files skipped
 - Number of files remaining for rekey

Obtaining a Rekey Report

CTE-LDT generates a report automatically after completion of a key rotation. The report lists the files in the GuardPoint and the key and version of the key applied to each file. This kind of report may be a common compliance requirement.

The administrator can also request a rekey report during rekey, if the need to see the partial transformation results so far.

About the rekey report

On Linux hosts, CTE-LDT writes rekey reports to a local file on the agent host in `/var/log/vormetric/`. The file name begins with `ldtaudit-log-`. It is followed by the file system directory name, GuardPoint directory name, and a timestamp. For example, for a GuardPoint at `/oxf-fs2/gp2` with rekey completed on November 19, 2016, just after 2:00 p.m. (hour 14), the rekey report file name would be `ldtaudit-log-_oxf-fs2_gp2-2016111914917`.

The report includes:

- Total number of files in the GuardPoint
- Number of files transformed
- Rekey start and end times
- List of all files transformed
- Applied key and key version for each file (for example, files in different resource sets might have used different keys)

Manually generating a rekey report

To generate a rekey report manually, use the following command:

```
# voradmin ldt rekey report <GuardPoint> [<logfile>]
```

In `<GuardPoint>`, type the GuardPoint path. In `<logfile>`, you can optionally direct the output to a file. If no logfile is specified, the report displays on `stdout`.

Monitoring Ongoing CTE-LDT Operations at the Command Line (Windows only)

Use the following syntax to monitor CTE-LDT progress. If an interval is specified (in units of seconds), it continually updates the monitoring output at the specified interval.

```
C:\> voradmin ldt monitor [interval]
```

For an overview of `voradmin ldt`, see ["CTE-LDT Command-Line Administration: voradmin command" on page 73](#).

Protecting CTE-LDT GuardPoints against Failure in Underlying Filesystems (Linux)

CTE-LDT Recovery Challenges

The main challenge with CTE-LDT recovery is a failure to access files or specific blocks in files inside a GuardPoint. Before CTE-LDT runs the recovery process on a GuardPoint, the underlying file system was recovered before file system was mounted. File system recovery may create orphan files in the `lost+found` directory inside the mount point. If an orphan file belongs to the GuardPoint, CTE-LDT cannot recover the file as the file is no longer in the same directory as it was prior to the crash while it was undergoing rekey.

CTE-LDT Recovery Enhancement

CTE-LDT has been improved for handling inconsistencies in the underlying file system during execution of CTE-LDT recovery. When enabling a GuardPoint after a system crash, CTE-LDT performs consistency checks on the files undergoing rekey at the time of crash before enabling GuardPoint. If the CTE-LDT recovery process is unable to recover any of the affected files, the GuardPoint will not be enabled and CTE-LDT will send the following alert to the DSM:

```
[CGS3266E] LDT-ALERT: Cannot enable guard point [GuardPoint] due to inconsistencies in  
underlying file system encountered during LDT recovery.
```

You can check the status of a GuardPoint and the reason for failing to enable a GuardPoint using the `secfsd -status guard` command. For example, the GuardPoint `/mnt/gp` failed to guard because Guard point needs LDT recovery as reported in the `Reason` column for the following example GuardPoint.

GuardPoint	Policy	Type	ConfigState	Status	Reason
/mnt/gp	LDT220	manual	guarded	not guarded	Guard point needs LDT recovery

Details on the specific issues encountered, including any files that could not be recovered, are reported to a log file in the `/var/log/vormetric` directory. The log file name is in the format:

```
ldt_recovery_log:<guardpoint_name>:<timestamp>.txt
```

The log file name starts with `ldt_recovery_log`, followed by the GuardPoint pathname and the date and time of the recovery attempt. The GuardPoint pathname and date and time are separated with “:”. For example:

```
/var/log/vormetric/ldt_recovery_log:_mnt_gp:2018-12-08-14:6:12.txt
```

Refer to the issues listed in the log file, and resolve those issues before enabling the GuardPoint again. A GuardPoint cannot be enabled in subsequent guard attempts until those issues are resolved. Each attempt generates a new log file. Check the CTE-LDT log file for missing files whose inode numbers match inode numbers of orphan files in `lost+found`. If there is a match, restore the file from `lost+found` to the pathname specified in the CTE-LDT recovery log file. Be sure to run the `mv` command to restore the file to the original location, do not run the `cp` command. After resolving all or some of the reported issues, you must run the command `voradmin ldt recover <GuardPoint>` to repeat the recovery process.

```
voradmin ldt recover <GuardPoint>
```

Running this command resolves the problems that can be corrected and clears the failed recovery status on the GuardPoint, allowing the GuardPoint to enable automatically within 30 seconds. If the GuardPoint does not enable, you can enable it using `secfsd -guard` command, if manual guard, or enable it on the DSM, if auto-guard. Note that if you are unable to resolve all of the reported issues, you accept the loss of some data or files, as reported in the latest recovery log file for the GuardPoint, when you run the command `voradmin ldt recover <GuardPoint>`.

Recovery Alerts

CTE-LDT sends two alerts to DSM if CTE-LDT fails to resolve the issues encountered during recovery.

The alert below is an error report sent to the DSM whenever CTE-LDT encounters failure during recovery prior to enabling GuardPoint. This alert also reports the GuardPoint specified in the message is not enabled:

```
[CGS3266E] LDT-ALERT: Cannot enable guard point [GuardPoint] due to inconsistencies in underlying file system encountered during LDT recovery.
```

The alert below is a warning report sent to the DSM only if `voradmin ldt recover` encounters errors and continues anyway. This alert reports the GuardPoint specified in the message has been enabled with some files in error status.

```
[CGS3267W] LDT-ALERT: LDT manual recovery on guard point [GuardPoint] completed with [#] errors.
```

The full message body does not currently appear in the logs on the DSM. At this time, the DSM shows the message ID without the message body.

Alerts Playbook

This section lists the CTE-LDT alerts and describes what to do in each case. CTE-LDT generates alerts when issues arise that require attention from the DSM Administrator. Without prompt attention, alerts can delay the rekey process or cause the process to remain incomplete.

Failure to Suspend or Resume CTE-LDT Operation

- **LDT-ALERT: Failed to suspend rekey on GuardPoint [GuardPoint]**

Solution: An I/O error is the most common cause of failure when updating the persistent state of a GuardPoint. For I/O errors, you must fix the problem at the host OS or storage level.

The appropriate corrective action depends on when this problem occurs and the reason for the suspension. If the suspend request was at the host level as part of a QoS schedule, or it was initiated by a user on the DSM, the failure occurred at the host level rather than the specified GuardPoint.

Otherwise, the source is probably the initiation of a suspension on a specific GuardPoint before backup. If the backup operation is in progress when this alert message occurs, you must fix the cause of the suspension failure and then restart the backup. If the backup has already completed when the alert message occurs, the backup image on the GuardPoint may have inconsistent data and CTE-LDT metadata. Discard this backup image and do a fresh backup.

If you cannot find and fix the host OS or storage issue, contact Thales Support for troubleshooting and recovery.

- **LDT-ALERT: Failed to resume rekey on GuardPoint [GuardPoint]**

- **LDT-ALERT: Failed to resume rekey on all GuardPoints**

Solution: An I/O error is the most common cause of failure when updating persistent state of a GuardPoint. For I/O errors, you must fix the problem at the host OS or storage level.

The appropriate corrective action depends on when this problem occurs and the source of the problem. If the resume request was at the host level as part of a QoS schedule, or the resume request was initiated by a user on the DSM, the failure occurred at the host level rather than the specified GuardPoint.

Otherwise, the source is probably initiation of a resume operation on a specific GuardPoint after a backup is completed.

If you cannot find and fix the host OS or storage issue, contact Thales Support for troubleshooting and recovery.

Insufficient Resources

The following alerts trigger when there are not enough resources for CTE-LDT operations.

- **LDT-ALERT: Aborting rekey of file [FileName] due to insufficient disk space**

The key rotation process was stopped on a GuardPoint because there was not enough available disk space.

Solution: Resize or free up space in the file system where the PathName resides. Key rotation automatically starts again when sufficient free space becomes available.

- **LDT-ALERT: Failed to launch transformation on [GuardPoint]**

CTE-LDT failed to launch the data transformation process on the specified GuardPoint.

Solution: The most common causes of this failure are:

- Low amount of system resources, such as free disk space.
- Check the system logs for insufficient free space in underlying file systems. You can free up space by removing older files or resizing your underlying file system. You may resize the file system on-line or off-line.

For other issues, contact Customer Support.

- **LDT-ALERT: QoS failed to start**

The Quality of Service subsystem failed to launch QoS services due to lack of system resources.

Solution: A low amount of available memory is the most common cause of this failure.

Contact Customer Support.

- **LDT-ALERT: Skipped key rotation on GuardPoint [GuardPoint] due to insufficient disk space**

- **LDT-ALERT: MDS file [PathName] exceeded disk space quota on gp [GuardPoint]**

There was not enough storage space in one or more file systems containing GuardPoints undergoing rekey.

Solution: Check the file systems where your GuardPoints reside to see how much space it is using. Add more storage space as needed. After the condition is corrected and disk space is available, CTE-LDT operations resume automatically.

- **LDT-ALERT: Low space on guard point [GuardPoint], increase free space or LDT will be suspended.**

Available storage space in the file system containing the GuardPoint is nearing the threshold below which CTE-LDT rekeying cannot continue. If available space does drop below that threshold, rekeying will be automatically suspended.

Solution: Check the file system where your GuardPoint resides to see how much space is available. Make more free space available if necessary. After the condition is corrected and storage space is available, rekeying resumes automatically.

Failed to Update CTE-LDT Attribute

The following alerts trigger when CTE-LDT extended attributes are not properly updated.

- **LDT-ALERT: Failed to update LDT attribute on GuardPoint [GuardPoint]. Error: [ErrorNumber]**

Solution: I/O error is the most common cause of failure when updating CTE-LDT extended attributes. For I/O errors, fix the problems at the host OS or storage level. In Linux, if you experience an I/O error, identify the file that had the error, and restore it from backup. See ["Backing Up and Restoring CTE-LDT GuardPoints" on page 64](#).

In Windows, you can recover a file that has corrupt metadata as follows:

- If the file is fully encrypted, remove the metadata. Type:

```
# voradmin ldt attr delete <file name path>
```

Then apply the same policy that was used to encrypt the data.

- If the file was only partially rekeyed, restore the file from a backup.

If you cannot find and fix the underlying host OS or storage issue that is causing corrupt metadata, contact Customer Support for troubleshooting and recovery.

- **LDT-ALERT: Failed to update LDT attribute**

CTE-LDT failed to create or update an CTE-LDT extended attribute of a file in a GuardPoint.

Solution: An I/O error is the most common cause of failure when updating an CTE-LDT extended attribute. For I/O errors, fix the problem at the host OS or storage level.

If you cannot find and fix the host OS or storage issue, contact Customer Support for troubleshooting and recovery.

Rekey Stopped

The following alert is specific to Windows and is triggered when rekey is stopped before it completes normally.

LDT-ALERT: Suspending rekey of binary file [PathName] during its execution

CTE-LDT operations encountered an executable file that is running.

CTE-LDT cannot rekey a running executable file until the execution of the binary file stops.

Solution (Windows)

1. Obtain the name of the executable file from the alert message.
2. Stop execution of the binary file.

Incomplete Key Rotation

- **LDT-ALERT: Failed to rotate key on GuardPoint [GuardPoint]. Another rekey operation is already in progress** (Windows only)
- **LDT-ALERT: Key rotation failed on GuardPoint [GuardPoint]**

CTE-LDT failed to complete the key rotation process on the specified GuardPoint. On Windows, this may occur if a key rotation process is already in progress on the GuardPoint. This pre-existing rekey operation could be active, or it could be in a suspended state, either because of the QoS schedule or a manual pause initiated by the administrator. See ["Suspending and Resuming Rekey and/or Scan Phase" on page 46](#).

Solution

1. On Linux, you can run the following command to see whether key rotation is in progress on the GuardPoint.

```
# voradmin ldt list all
```
2. On Linux or Windows, check the rekey status of GuardPoints in the DSM Management Console.
3. If key rotation is already in progress on a Windows GuardPoint, wait for the key rotation to complete.
4. On the **GuardPoint** tab on the DSM, select **Re-push Policies** to manually re-push the policies to the host to initiate key rotation on GuardPoints ready for key rotation.

Contact Customer Support if this error occurs on Linux or if the cause of key rotation failure on Windows is not a key rotation in progress.

Skipped Key Rotation

The following alerts trigger when CTE-LDT skips key rotation.

- **LDT-ALERT: Skipped key rotation on GuardPoint [GuardPoint]. It is on a read-only file system**
Key rotation is skipped on a specified GuardPoint because the mount point where the GuardPoint resides does not permit write operations.

Solution:

1. Remount the file system where the GuardPoint resides, and change the mount option to read/write.
 2. On the GuardPoint page on the DSM, press **Re-push Policies** to manually re-push the policies to the host to initiate key rotation on GuardPoints ready for key rotation.
- **LDT-ALERT: Failed to rotate key on GuardPoint [GuardPoint] during pre-commit**
 - **LDT-ALERT: Failed to rotate key on GuardPoint [GuardPoint] during commit**
 - **LDT-ALERT: Skipped key rotation on GuardPoint [GuardPoint]. Error: [ErrorNumber]**

- **LDT-ALERT: Failed to update LDT attribute on GuardPoint [GuardPoint]. Error: [ErrorNumber]**

CTE-LDT failed to start a key rotation process on a GuardPoint during a guard operation or when processing a key rotation notification from the DSM. For [ErrorNumber], a Linux error number is substituted, such as `errorcode 17`.

Solution: The host returns error code 17 during CTE-LDT key rotation if it cannot perform the key rotation because there is already a rekey in progress. This pre-existing rekey operation could be active, or it could be in a suspended state, either because of the QoS schedule or a manual pause initiated by the administrator. See ["Suspending and Resuming Rekey and/or Scan Phase" on page 46](#).

An I/O error is the most common cause of failure when updating the persistent state of a GuardPoint. For I/O errors, fix the problem at the host OS or storage level.

If you cannot find and fix the host OS or storage issue, contact Customer Support for troubleshooting and recovery.

Failed to Update CTE-LDT Metadata During Scan Phase

CTE-LDT triggers the following alerts when CTE-LDT cannot properly update metadata during the scan phase. (See ["CTE-LDT Runtime Flow" on page 14](#) for information about the scan phase.)

- **LDT-ALERT: Scan error on [GuardPoint] removing MDS guard for relaunching dataxform**

CTE-LDT failed to update metadata when restarting a scan on the specified GuardPoint.

Solution: An I/O error is the most common cause of failure when updating CTE-LDT metadata. For I/O errors, fix the problem at the host OS or storage level and then restart operations.

If you cannot find and fix the underlying host OS or storage issue that is causing the error, contact Thales Support for troubleshooting and recovery.

- **LDT-ALERT: Online Dataxform failed during post scan stage on [GuardPoint]**

CTE-LDT failed to update metadata when transitioning from scan to rekey phase on the specified GuardPoint.

Solution: An I/O error is the most common cause of failure when updating CTE-LDT metadata. For I/O errors, the problem must be fixed at the host OS or storage level and the operation restarted.

If you cannot find and fix the underlying host OS or storage issue that is causing the error, contact Customer Support for troubleshooting and recovery.

File system inconsistencies after system crash

CTE-LDT sends two alerts to the DSM if CTE-LDT fails to resolve the issues encountered during recovery.

The alert below is an error report sent to the DSM whenever CTE-LDT encounters failure during recovery prior to enabling GuardPoint. This alert also reports the GuardPoint specified in the message is not enabled:

- **LDT-ALERT: Cannot enable guard point [GuardPoint] due to inconsistencies in underlying file system encountered during LDT recovery**

The alert below is a warning report sent to the DSM only if `voradmin ldt recover` encounters errors and continues anyway. This alert reports the GuardPoint specified in the message has been enabled with some files in error status.

- **LDT-ALERT: LDT manual recovery on guard point [GuardPoint] completed with [#] errors.**

Solution: See ["Protecting CTE-LDT GuardPoints against Failure in Underlying Filesystems \(Linux\)" on page 84](#).

Error Messages

This section describes runtime error messages. For information about other types of runtime messages, see ["Alerts Playbook" on page 85](#) and ["Warning and Info Messages" on page 92](#).

Failed to Transform File During Rekey

CTE-LDT could not complete transformation on a file.

Related Messages:

- **LDT: Rekey failed for file [PathName] on GuardPoint [GuardPoint]**
- **LDT: Extended attribute of inode [InodeNumber] is corrupted under GuardPoint [GuardPoint]**

Solution: An I/O error is the most common cause of failure when updating CTE-LDT metadata. For I/O errors, fix the problem at the host OS or storage level, and then restore the file from a backup.

If you cannot find and fix the underlying host OS or storage issue that is causing the error, contact Customer Support for troubleshooting and recovery.

Failure to Suspend CTE-LDT

A request to stop CTE-LDT processing did not succeed. The suspend request was at the host level as part of a QoS schedule, or the suspend request was initiated by a user on the DSM.

Related Messages:

- **LDT: Failed to suspend rekey on all GuardPoints**
- **LDT operations could not be suspended on the host**

Solution: An I/O error is the most common cause of failure when updating the persistent state of a GuardPoint. For I/O errors, fix the problem at the host OS or storage level.

If a backup operation is in progress when this message occurs, you must fix the cause of the suspend failure and then restart the backup. If the backup has already completed when the alert message occurs, the backup image on the GuardPoint may have inconsistent data and CTE-LDT metadata. Discard this backup image and do a fresh backup.

If you cannot find and fix the host OS or storage issue, contact Customer Support for troubleshooting and recovery.

Failure to Start or Stop Transformation

The following general messages are recorded when there are errors attempting to start or stop CTE-LDT:

- **LDT: Failed to abort key rotation on GuardPoint [GuardPoint]**
- **LDT: Failed to start**
- **LDT: Failed to stop**
- **LDT: Failed to exit**

Solution: Examine system logs for additional information as to the cause. If you cannot find and fix the underlying host OS or storage issue that is causing the error, contact Customer Support for troubleshooting and recovery.

Failure to Restart Transformation

The following message is recorded when an attempt to restart transformation after a system reboot fails because the file system is mounted as read-only. Transformation on the specified GuardPoint cannot continue until the file system is mounted with write permission.

- **LDT: Skipped LDT recovery on read-only file system [GuardPoint]**

Solution: Re-mount the file system with write permissions.

Temporary Failure to Start Transformation on a File

The following messages are recorded when there are communication issues or lack of resources on the host. Once the condition is corrected, transformation of the file continues automatically:

- **LDT: Insufficient memory condition encountered during LDT on GuardPoint [GuardPoint]**
- **LDT: Encryption key for file [PathName] unavailable for LDT, possibly due to loss of communication to DSM**
- **LDT: Aborting rekey of file [PathName] due to lack of free memory. Try closing other application to resolve the issue**

Solution: Resolve the communication issues or increase the available resources, then verify that CTE-LDT has resumed processing.

Transient Condition while enabling GuardPoint

The following messages are recorded when a request is made to guard an CTE-LDT GuardPoint when GuardPoint initialization is already in progress. During the GuardPoint initialization, the system initializes MDS file associated with the GuardPoint in preparation for CTE-LDT. Initialization of the MDS file can take a few minutes. During this time, if the system retries the guard operation, one of the following messages displays.

Related Messages:

- **Not re-guarding path [path] (Reason: GuardPoint initialization already in progress)**
- **Not re-guarding path [path] from container [container] (Reason: GuardPoint initialization already in progress)**

Solution: Wait for the current GuardPoint initialization to complete and then resubmit the new GuardPoint initialization request if desired.

Failed to transform passthrough files for AD database files (Windows Only)

CTE-LDT skipped the transformation of passthrough files for all AD database files. The problem occurs when the AD database remains in the default folder location.

Related Messages:

- **Skipping transformation of passthrough file [filename]. The file resides in the boot directory. CTE cannot encrypt boot directory files.**
- **Skipping transformation of passthrough file [filename]. CTE cannot encrypt these files. They are already encrypted using NTFS encryption or compressed.**
- **Skipping transformation of passthrough file [filename]. File is not in a GuardPoint directory.**

Solution: To fix this issue, move the AD database to any folder other than `c:\windows` or `c:\program files`.

Warning and Info Messages

This section describes runtime error messages. For information about other types of runtime messages, see ["Alerts Playbook" on page 85](#) and ["Error Messages" on page 90](#).

Stopping Transformation of a File on Volume Dismount (Windows only)

The following warning message is recorded when transformation of a file is stopped because the containing volume is dismounted.

- **LDT: Volume dismounted. Aborting transformation at file [PathName]**

Issues with Policy or System Configuration

The following warning messages are recorded when CTE cannot perform CTE-LDT on the GuardPoint, because there are errors in the policy associated with the GuardPoint, or the file system containing the GuardPoint is not supported by CTE-LDT. Files in the GuardPoint can still be accessed, but no CTE-LDT encryption occurs.

- **LDT: The GuardPoint [GuardPoint] does not have a valid transformation policy, there is no new key rule**
- **LDT: The GuardPoint [GuardPoint] does not have a valid transformation policy, there is no key_op rule**
- **LDT: The GuardPoint [GuardPoint] does not support online rekey, only file operations from the offline data transform process will be allowed**

Failure to Enable GuardPoint During Cleanup

CTE-LDT records the following informational message when a user attempts to enable a newly added GuardPoint. This message displays if the GuardPoint directory was previously guarded with an CTE-LDT policy and the CTE-LDT metadata cleanup is in progress when user is guarding under the new policy.

- **LDT: Cannot enable GuardPoint [GuardPoint] during LDT clean-up process**
Solution: Retry the operation once the cleanup completes.

General CTE-LDT Operations

The following informational messages are recorded during various CTE-LDT operations. No action is required.

- **LDT: Successfully suspended rekey on GuardPoint [GuardPoint]**
- **LDT: Successfully suspended rekey on all GuardPoints**
- **LDT: Successfully resumed rekey on GuardPoint [GuardPoint]**
- **LDT: Successfully resumed rekey on all GuardPoints**
- **LDT: Rekey operation completed on GuardPoint [GuardPoint]**

Missing CTE-LDT extended attribute

The following warning message reports that the file with the specified inode number in the specified GuardPoint directory does not have an CTE-LDT extended attribute, therefore, access to the file is denied.

- **LDT: Extended attribute of inode [InodeNumber] is missing under GuardPoint [GuardPoint]**
Solution: CTE-LDT cannot determine the encryption key associated with the data in the file, therefore, you can only remove the file.

Locking Contention

The following messages are recorded during the rekey process on a file. When user access to the file is very high, it causes a high degree of locking contention between the rekey process and user access. The second message reports when the contention is no longer in effect and the rekey process has resumed accessing file to rekey.

- **LDT: Exclusive access for rekey delayed on inode [InodeNumber]**
- **LDT: Exclusive access for rekey granted after delay on inode [InodeNumber]**

Initiation and completion of CTE-LDT metadata cleanup

The following messages are recorded at the beginning and completion of CTE-LDT metadata cleanup through voradmin command.

- **LDT: Metadata will start getting removed from all files in GuardPoint [GuardPoint]**
- **LDT: Metadata has been removed from all files in GuardPoint [GuardPoint]**

Upgrading CTE Agent

On Windows, you cannot upgrade the CTE agent if there is an CTE-LDT GuardPoint with an active rekey in progress, that is at the mount point. On Linux, CTE-LDT is forced-suspended when upgrading CTE.

Reboot is required when upgrading earlier versions of CTE Agent to 6.0.1, if CTE-LDT is in-progress on a GuardPoint. Perform following steps to upgrade to version 7.0.0:

1. From the DSM Management Console, click **Host > Hosts > hostName > GuardPoint** tab.
2. Click **Suspend Rekey**.
3. Click **Refresh** and ensure that the GuardPoint(s) being rekeyed now show a status of Suspended.
4. Reboot the host.
5. Run the 7.0.0 CTE Agent install program and upgrade the agent.
Wait for the upgrade to complete.
6. From the DSM Management Console, click **Host > Hosts > hostName > GuardPoint** tab.
7. Click **Resume Rekey**.
8. Click **Refresh** and ensure that the GuardPoints being rekeyed now show a status of Rekeying.

Recommendations and Considerations

The following information provides guidance for a better user experience.

All Platform Recommendations and Considerations

Binary Re-signing

Any executable that is part of either a Signature set or a Host setting, and that resides in a GuardPoint that uses an CTE-LDT policy, will use different signatures for an CTE-LDT key rotation. The result is that the Host Settings binaries will no longer be authenticated, or that the Signature Set policy rules will no longer trigger for those binaries.

To prevent these issues, the Security Administrator must manually re-sign each affected binary after each key rotation.

Alternatively, CTE can generate unencrypted signatures of binaries inside GuardPoints to avoid these problems. For details, see the *DSM Administration Guide*.

Check for available disk space for CTE-LDT metadata

Before launching CTE-LDT on a GuardPoint:

1. Check the available free disk space in the file system where your GuardPoint resides.
2. Type the following command to check the disk space requirement of CTE-LDT on a target GuardPoint:

```
# voradmin ldt space /oxf-fs1/gp1
/oxf-fs1/gp1: found 1501 files without LDT extended attributes
LDT disk space requirements: total 169MB (LDT attributes=6MB, MDS=163MB)
```

In this example, the output shows that CTE-LDT requires 169MB of available disk space to launch and execute CTE-LDT on /oxf-fs1/gp1.

Note

Make sure that the free space in your file system exceeds the disk space requirement for CTE-LDT.

CTE-LDT Requirements for Backup

CTE offers the option to backup encrypted data from files through a security rule, which skips the Apply Key function when reading encrypted files by backup applications or processes. Such files can also be restored from backup streams, to the same or a different GuardPoint, without Apply Key. If you choose to restore to another GuardPoint, the target GuardPoint must be protected with the same key and security rules as the source GuardPoint.

If you backup encrypted data from files inside GuardPoints with CTE-LDT policies, CTE-LDT imposes a hard requirement on the backup application, or process, to backup or restore CTE-LDT metadata. The CTE-LDT metadata is stored as an extended attribute on Linux and as alternate data streams on files on Windows platforms. If the backup process cannot backup the metadata, then CTE-LDT protected GuardPoints must be backed up in clear key.

Customers are required to verify their backup application, or process, to ensure extended attributes (on Linux) or alternate data streams (on Windows) are backed up and restored through their backup/restore processes.

Note

Make sure that you suspend CTE-LDT operations before you start the backup process, and resume them after the backup process completes.

Learn Mode

Learn Mode provides a temporary method for disabling the blocking behavior of regular CTE or CTE-LDT policies. While useful for quality assurance, troubleshooting, and mitigating deployment risk, Learn Mode is not intended to be enabled permanently for a policy in production. This prevents the policy Deny rules from functioning as designed in the policy rule set.

Ensure that the policy is properly configured for use in Learn Mode. Any Security Rule that contains a Deny effect must have Apply Key applied as well. This is to prevent data from being written in mixed states, resulting in the loss of access or data corruption.

Note

Apply Key will have no effect when combined with a Deny rule unless the policy is in Learn Mode.

Quality of Service (QoS)

By default, the QoS component of CTE-LDT does not monitor live transformation operations unless you enable QoS on your host by entering QoS parameters on the DSM. To avoid overhead of CTE-LDT on your production system, you must select QoS parameters suitable to your production environment. For information on tuning QoS, see ["Quality of Service" on page 30](#). It is critical that you understand the impact of CTE-LDT on your system and how to manage this impact using QoS.

Upgrade to CTE 7.0.0

Since the the first release of the CTE-LDT feature, Thales has made several improvements in the areas of error handling, interoperability with applications, and Quality of Service (QoS). Thales strongly recommends that new deployments use version 7.0.0 (or later) of CTE. Thales further recommends that customers who have already deployed the CTE-LDT feature upgrade to version 7.0.0.

Windows Recommendations and Considerations

File Handling

The CTE-LDT process is subjected to all of the File System policies and attributes set on the files. In some cases, this prevents CTE-LDT from encrypting a file. If users or applications are accessing files while CTE-LDT is in progress, CTE-LDT cannot change the attributes of the files and encrypt the file. It is critical that you understand how CTE-LDT handles various types of files:

- **NTFS Encryption and Compression**

If NTFS encryption or compression is enabled on a file or folder, the CTE-LDT process cannot encrypt these files. To maintain the data coherency, CTE-LDT skips the encryption of the these files. These files display as "passthrough" files in the CTE-LDT statistics.

- **Read-Only Files**

As the CTE-LDT process performs a read-encrypt-write operation on a file, it cannot encrypt read-only files. The CTE-LDT process skips these files and changes to the INCOMPLETE state.

- **Executable Files**

If a executable is running or files are exclusively locked by the application, the CTE-LDT process cannot encrypt those files as it is unable to acquire the required locks on the files. CTE-LDT skips these files and changes to the INCOMPLETE state.

File Modification

The CTE-LDT process performs a read-encrypt-write operation on the files that need to be encrypted, (also known as rekeying). Previously, file modification and access dates were changed when CTE-LDT was processing. In order to maintain compatibility for applications, we addressed this issue by saving a copy of the original access and modification times, and restoring them after the encryption completed. Preserved timestamps are updated during the rekey process, if an application/user accesses the files during rekey.

Note

Thales strongly recommends that you upgrade to the newly released v6.1.0 so that the access time and modification time is restored correctly.

CTE-LDT Limitations

- CTE-LDT on CIFS is not supported.
- CTE-LDT on a ReFS file system runs slowly because of limited support from the Extended Attributes on the ReFS file system.

Note

Customers running older versions of ReFS.sys on Windows Server 2012 R2 should be aware of the memory growth issue encountered by the Thales engineering team. This issue seems to occur only when CTE-LDT is running on a large number of files. As the system memory consumption by REFS file system increases, it can eventually make the system unresponsive. This issue does not occur with the recent versions of ReFS file system drivers available on Windows Server 2016. After consulting with Microsoft, they suggest that all customers migrate to Windows Server 2016 if they are using ReFS file.

Logical Sector Size

CTE-LDT Windows transformation is supported if the **logical sector size** is more than 512 Bytes. (A logical sector size of 4K is supported.) To find the logical sector size of the file system, type:

```
> fsutil fsinfo ntfsInfo <volume pathname>
```

For example:

```
> fsutil fsinfo ntfsInfo C:
NTFS Volume Serial Number :      0x5092568a92567506
NTFS Version      :              3.1
LFS Version      :              2.0
Number Sectors :      0x000000001c004eeb
Total Clusters :      0x00000000038009dd
Free Clusters :      0x00000000008bb274
Total Reserved :      0x0000000000001864
Bytes Per Sector :      512
.
.
.
```

Upgrade Notes

CAUTION

Do not upgrade the Windows agent without valid DSM connectivity.

During the upgrade, InstallShield cleans up the agent configuration on the host. If the agent does not have DSM connectivity, then it cannot pull the configuration from the DSM after it reboots. As the configuration is cleaned up, the Windows agent removes all of the GuardPoints from the host.

VSS Volumes

If a Shadow Copy volume is present on a volume before CTE-LDT starts, and this volume is accessed by the application or user, then CTE reads the CTE-LDT metadata from the shadow copy volume snapshot and incorrectly uses this metadata for the original file. Because the metadata on the snapshot is old, this may lead to double encryption of the files inside the GuardPoint.

Thales highly recommends that, if you are running a version of VTE earlier than 6.0.3.68, you must delete all of the old VSS volumes where CTE-LDT GuardPoints exist in order to avoid this issue.

CTE-LDT Limitations on Linux

- CTE-LDT on NFS share is not supported.
- CTE-LDT support is limited to `ext3`, `ext4`, `XFS`, and `VxFS` file systems when `user_xattr` mount option is enabled.

CTE OS Support Life Cycle

Version: v1.0.0 (latest)

30 January 2026

Contents

- CTE OS Lifecycle Taxonomy 3

CTE OS Lifecycle Taxonomy

- CTE OS Support Guidelines
- CipherTrust Transparent Encryption Support
- CipherTrust Transparent Encryption UserSpace Support
- CipherTrust Transparent Encryption for Kubernetes Support
- Extended Support Considerations

CipherTrust Transparent Encryption Support

CipherTrust Transparent Encryption is an agent that runs in the kernel of an operating system. Due to the nature of the product, CipherTrust Transparent Encryption has many updates per year. On average, there are two to three feature releases per year. These releases contain major and/or minor new features or enhancements, support for new third-party databases or applications, and support for new major or minor versions of operating systems. During the rest of the year, Thales may release an update to CipherTrust Transparent Encryption on an almost weekly basis, in order to roll in new operating system kernel patch support and hot fixes. Following are the details of the CipherTrust Transparent Encryption product lifecycle, as well as the OS support guidelines.

CipherTrust Transparent Encryption Release Types

The following table describes the CipherTrust Transparent Encryption release types:

CipherTrust Transparent Encryption Release	Major	Service Pack	Cumulative Patch	Hot Fix or New Kernel Support Build
Numbering	1.0.0	1.1.0	1.1.1	1.1.0.x
Cadence	3+ Years	6 Months	As needed	As needed
Contents	Major change in functionality	New features, fixes, major or minor OS support	New minor features, fixes, minor OS support	Hot fix or minor OS support, kernel updates if new CipherTrust Transparent Encryption build is needed

CipherTrust Transparent Encryption Support Phase Definitions

The following table contains the CipherTrust Transparent Encryption support phase definitions:

Support Phase	Definition	Timeframe
Active	Period during which Thales	From GA to the start of Continued

Support Phase	Definition	Timeframe
	customer support assists customers with issues. A maintenance agreement makes the customer eligible for patches, and service packs.	Support
Continued Support	Customer support can be engaged mainly for troubleshooting and workarounds. Thales engineering will fix bugs and provide validation for new OS kernels and new minor OS releases on an as-need basis. However, no additional investment will be made by development and engineering departments.	Begins with the release of the next Service Pack; Ends after 6 months.
Extended Support	Support provided on an as-needed basis. An extended maintenance agreement must be in place. Thales will provide bug fixes only. Thales will not add support for new operating systems or kernels.	Support time frame begins after Continued Support ends, and lasts for 6 months.

CipherTrust Transparent Encryption Life Cycle

Following is a diagram of the CipherTrust Transparent Encryption Life cycle. The version numbers are an example. They are not valid version numbers. The actual release time lines for these versions of CipherTrust Transparent Encryption may be different. In general, there will be two “live” CipherTrust Transparent Encryption versions at a time: one CipherTrust Transparent Encryption version that is in active phase, and one that is in the Continued Support phase. In some cases, a third CipherTrust Transparent Encryption version will also be in the extended support phase. This is to allow customers more time to move to the newer versions.

CTE Lifecycle

LTHF = Linux Taxonomy Hot Fix

Linux Taxonomy refers to the qualification of new Linux kernel releases with CTE.

When a cumulative patch is released for a CipherTrust Transparent Encryption version that will be considered as the **active** CipherTrust Transparent Encryption version, the current active service pack version, and the previous service pack release, continue to be supported for the continued support period. For instance, for the two active CipherTrust Transparent Encryption versions 7.0.0 and 7.1.0, if a cumulative patch for 7.1.1 is released, CipherTrust Transparent Encryption 7.1.1 and CipherTrust Transparent Encryption 7.1.0 would be the supported versions for hot fixes.

CipherTrust Transparent Encryption UserSpace Support

Overview

CipherTrust Transparent Encryption Userspace, (formerly SafeNet ProtectFile FUSE), is a file-system level transparent encryption solution that leverages the cryptographic and key management features of the platform to protect unstructured data. CipherTrust Transparent Encryption Userspace is based on Linux FUSE and hence, is not required to be updated when there is a Linux kernel update from the OS vendor. Following are the details of the CipherTrust Transparent Encryption Userspace product lifecycle.

CipherTrust Transparent Encryption Userspace Release Types

CTE Release	Major	Service Pack	Cumulative Patch
Numbering	1.0.0	1.1.0	1.1.1
Cadence	3+ Years	6 Months	As needed
Contents	Major change in functionality	New features, fixes, major or minor OS support	New minor features, fixes, minor OS support

CipherTrust Transparent Encryption Userspace Definitions

Support Phase	Definition	Timeframe
Active	Period during which Thales customer support will assist customers with issues. A	From GA to the start of Continued Support.

Support Phase	Definition	Timeframe
	maintenance agreement will make the customer eligible for patches, and service packs.	
Continued Support	Customer support can be engaged mainly for troubleshooting and workarounds. Thales engineering will provide bugs and security fixes on an as-needed basis. No additional investment will be made by development and engineering departments.	Begins with the release of the next Service Pack; Ends after 6 months.
Extended Support	Support provided on an as-needed basis. An extended maintenance agreement must be in place. Thales will provide bug fixes only.	Only applies to the last Service pack before a Major release. Support timeframe begins after Continued Support ends and lasts 6 months.

Extended Support Considerations

Support changes for Red Hat Enterprise Linux v7 with CipherTrust Transparent Encryption 7.8.0

In May, 2022, Red Hat released a new major version of its Enterprise Linux operating system: v9. Thales was able to begin supporting Red Hat Enterprise Linux (RHEL) 9 immediately with CipherTrust Transparent Encryption version 7.2.0 as a participant in the Early Adopter Program (EAP). This means that Thales is phasing out support for RHEL v7. Thales tries to maintain the operating system support policy of providing support with CipherTrust Transparent Encryption for the two latest major versions of an operating system as outlined in this guide. Accordingly, Thales has shifted to a One-Off manual qualification process on a need-only basis for RHEL 7.9 kernels. Thales understand that this is a highly adopted and widely used operating system, so Thales is willing to extend CipherTrust Transparent Encryption support for a grace period to allow customers to move their RHEL 7 systems to a newer version before removing support.

According to Red Hat support portal, End of “Maintenance Support 2 (Product Retirement)” from Red Hat for RHEL 7 will be June 30, 2024. Thales would like to align, as best as possible, to this date.

Thales will review the need for supporting RHEL 7 during the Extended Lifecycle Support (ELS) which ends, June 30, 2026, and it will only be available to customers with additional extended support contracts for CipherTrust Transparent Encryption agents.

Thales will provide priority bug fixes on an as-needed basis and technical support for customers with paid support contracts. Thales will not add any new features, enhancements, performance improvements, update third party databases or provide application interoperability support on the CipherTrust Transparent Encryption agents for RHEL 7.

Support changes for Red Hat Enterprise Linux v8 with CipherTrust Transparent Encryption 7.9.0

In May, 2025, Red Hat released a new major version of its Enterprise Linux operating system: v10. Thales was able to begin supporting Red Hat Enterprise Linux (RHEL) 10 kernels immediately with CipherTrust Transparent Encryption version 7.8.0 as a participant in the Early Adopter Program (EAP). This means that Thales is phasing

out support for RHEL v8. Thales tries to maintain the operating system support policy of providing support with CipherTrust Transparent Encryption for the two latest major versions of an operating system as outlined in this guide. Accordingly, Thales has shifted to a One-Off manual qualification process on a need-only basis for RHEL 8.10 kernels. Thales understands that this is a highly adopted and widely used operating system, so Thales is willing to extend CipherTrust Transparent Encryption support for a grace period to allow customers to move their RHEL 8 systems to a newer version before removing support.

CTE 7.9.0, would be the last release supporting RHEL 8.10 formally and CTE 8.0.0 would stop supporting RHEL 8.

According to Red Hat support portal, End of “Maintenance Support (Standard)” from Red Hat for RHEL 8 will be May 31, 2029. Thales would continue to support new kernels as they become available for RHEL 8.10 with CTE 7.9.0 latest patch release.

Thales will provide priority bug fixes on an as-needed basis and technical support for customers with valid support contracts. Thales will not add any new features, enhancements, performance improvements, or update third party application interoperability support on the CipherTrust Transparent Encryption 7.9.0 agents for RHEL 8.

With reference to CTE-UserSpace, considering it is not dependent on Linux kernel, we'll continue to maintain support for RHEL 8 in future CTE-UserSpace releases until End of “Maintenance Support (Standard)” from Red Hat for RHEL 8.

CipherTrust Transparent Encryption for Kubernetes Support

CTE for Kubernetes is an implementation of the CipherTrust Transparent Encryption with native support for Kubernetes through the implementation of a CSI (Container Storage Interface) driver. Unlike traditional CTE, product installation and GuardPoint management is done through Kubernetes. This means that as the cluster scales up with more nodes, CTE for Kubernetes scales with it. CTE for Kubernetes is designed to protect Kubernetes Persistent Storage Claims that are backed by storage with filesystem semantics.

Thales qualifies only [Active Kubernetes releases](#) when releasing a CTE-K8s feature release.

CTE for Kubernetes release types

CTE Release	Major	Service Pack	Cumulative Patch
Numbering	1.0.0	1.1.0	1.1.1
Cadence	3+ Years	4+ Months	As needed
Contents	Major change in functionality	New features, fixes	New minor features, fixes

Support Phase Definitions

Support Phase	Definition	Timeframe
Active	Period during which Thales customer support will assist customers with issues. A maintenance agreement will make the customer eligible for patches, and service packs.	From GA to the start of Continued Support
Continued Support	Customer support can be engaged mainly for troubleshooting and work-arounds. Thales engineering will provide bugs and security fixes on an as-needed basis. No additional investment will be made by development and engineering departments.	Begins with the release of the next Service Pack; Ends after six months.
Extended Support	Support provided on an as-needed basis. An extended maintenance agreement must be in place. Thales will provide bug fixes only.	Only applies to the last Service pack before a Major release. Support timeframe begins after Continued Support ends and lasts six months

CTE OS Support Guidelines

CipherTrust Transparent Encryption supports the latest **TWO** major versions of an OS, for example RedHat Enterprise Linux 7 & 8, at any given time. CipherTrust Transparent Encryption also supports the latest minor version (or Service Pack) of a major OS. Two examples are RedHat Enterprise Linux (RHEL) 7.9 and RHEL 8.4. Thales will qualify new kernel patches on the most recent minor or service pack version of an OS only. This mainly applies to Linux operating systems where kernel compatibility is critical. CipherTrust Transparent Encryption is generally compatible with new kernel patches for any OS, but Linux creates patches more frequently and there is a higher probability for incompatibility.

CipherTrust Transparent Encryption Compatibility Portal

The [CipherTrust Transparent Encryption compatibility portal](#) online compatibility portal lists all of the supported operating system kernels.

In addition, go to [CTE Packages Repository](#) to download a JSON file of all of the CTE supported kernels. Upload this file to your Key Manager to monitor agent compatibility. Request credentials to the packages repository from the [Thales Support team](#).

OS Kernel Validation Process

Operating system vendors (especially Linux) release new kernel patches very frequently. Thales will automatically pick up these kernel patches, and test them with the latest version of CipherTrust Transparent Encryption. In the majority of cases, CipherTrust Transparent Encryption will not need an update to support a new kernel patch. Once validation is completed, Thales will announce kernel support with the current CipherTrust Transparent Encryption version, or release a new build. Keep in mind that Thales will test kernel patches from the latest service pack (or minor version) of the two most recent major OS versions. The compatibility matrices will be updated (including the JSON file version) with the new kernel support, and if a new build is required, it will be posted for download from the Thales repositories.

Extended Update or Long-Term Support Kernels

Thales does not regularly validate kernel patches from OS versions that have entered Extended Update (EUS) or long-term support phases. This is in keeping with the policy of supporting the latest two major, and the latest minor version, of an OS. However, OS vendors are required to patch vulnerabilities in their software even if the OS has gone into an extended support or long-term support phase of the lifecycle. They are frequently releasing new kernel patches to their customers on these extended support branches. For this reason, Thales will validate EUS kernels for RHEL and LTSS kernels for SUSE, on a case-by-case basis using a “one-off” (or manual) validation process.

The following tables contain information on the validation processes for the OS distributions:

RedHat Enterprise Linux Support

RHEL Release	Thales Release	Time frame for support (by vendor, from GA date)	Example	Comment
Major	Next major or service pack CTE release	60 Business Days	RHEL 8	Major OS releases typically include significant kernel enhancements, new features and file systems.
Minor/Service Pack	Next major, service pack, or cumulative patch CTE release	20 Business Days	RHEL 8.4	OS Service pack or update releases do not include significant new features but on occasion break kernel binary compatibility.
Critical kernel security patch	Next CTE release, any type	4 Business Days		In exceptional cases, when more than 4 days are required, Thales will inform customers of the planned release date.
One-off EUS Kernel	Next CTE release, any type	30 Business Days		Must have Product Management

RHEL Release	Thales Release	Time frame for support (by vendor, from GA date)	Example	Comment
				approval; contact Thales support to request a one-off validation.

SUSE Linux Enterprise Server Support

Note

Thales does not generally support long-term service pack support kernels, (LTSS).

SUSE Linux Release	Thales Release	Time frame for support (by vendor, from GA date)	Example	Comment
Major	Next major or service pack CTE release	Up to 90 business days	SLES 15	Major OS releases typically include significant kernel enhancements, new features and file systems.
Minor/Service Pack	Next major, service pack, or cumulative patch CTE release	Up to 60 business days	SLES 15 SP1	OS Service pack or update releases do not include significant new features but on occasion break kernel binary compatibility.
Critical kernel security patch	Next CTE release, any type	Up to 4 business days		In exceptional cases, when more than 20 days are required, Thales will inform customers of the planned release date.
One-off LTSS kernel	Next CTE release, any type	Up to 30 business days		Must have Product Management approval; contact Thales support to request a one-off validation.

Ubuntu Server Linux Support

Thales Ubuntu support includes an exception. Thales will support two kernel series on the latest two major versions: e.g., the GA kernel and the HWE (hardware enablement) kernel series.

Ubuntu Linux security patches often break compatibility, and require a new build of CTE. Thales will release a new build according to the SLA noted below. The “one-off” kernel validation process does not apply to Ubuntu.

Ubuntu Linux Release	Thales Release	Time frame for support (by vendor, from GA date)	Example	Comment
Major	Next major or service pack CTE release	Up to 90 business days	Ubuntu 20.04	Major OS releases typically include significant kernel enhancements, new features and file systems.
Minor/Service Pack	Next major, service pack, or cumulative patch CTE release	Up to 60 business days	Ubuntu 20.04.1	OS Service pack do not include significant new features but on occasion break kernel binary compatibility.
Critical kernel security patch	Next CTE release, any type	Up to 15 business days		

Windows Support

Thales supports both Windows Server and Windows Client versions. Check the [CipherTrust Transparent Encryption compatibility portal](#) for the list of supported operating systems.

Windows Release	Thales Release	Time frame for support (from the time of GA by vendor)	Example	Comment
Major/Long-term servicing channel	Next major or service pack CTE release	Up to 90 business days	Windows 2019	Windows long-term servicing channel releases typically include significant enhancements, new features and file systems.
Semi-annual channel releases	Next major, service pack, or cumulative patch CTE release	Up to 60 business days		Semi-annual channel releases do not include significant new features, but on occasion break kernel compatibility.
Security,	N/A	N/A		Windows patches

Windows Release	Thales Release	Time frame for support (from the time of GA by vendor)	Example	Comment
Cumulative Patches				rarely break compatibility. No CTE update required.

Note

CipherTrust Transparent Encryption Windows will drop support for Operating systems when end of support is announced by Microsoft for an Operating system.

AIX

AIX Release	Thales Release	Time frame for support (from the time of GA by vendor)	Example	Comment
Major	Next major or service pack CTE release	Up to 180 business days	AIX 8.1	Major releases typically include significant kernel enhancements, new features and file systems.
Technology Level	Next major, service pack, or cumulative patch CTE release	Up to 90 business days	AIX 7.2 TL1	Technology Level releases do not include significant new features but on occasion break kernel binary compatibility.
Kernel & Security patches or service pack for Technology Level	Next major, service pack, or cumulative patch CTE release	Up to 30 business days	AIX 7.2 TL1 SP5	Kernel patches or TL SP typically do not break compatibility. When they do, Thales will release a new CTE patch.

All information herein is either public information or is the property of and owned solely by Thales DIS France S.A. and/or its subsidiaries or affiliates who shall have and keep the sole right to file patent applications or any other kind of intellectual property protection in connection with such information.

Nothing herein shall be construed as implying or granting to you any rights, by license, grant or otherwise, under any intellectual and/or industrial property rights of or concerning any of Thales DIS France S.A. and any of its subsidiaries and affiliates (collectively referred to herein after as "Thales") information.

This document can be used for informational, non-commercial, internal and personal use only provided that:

- The copyright notice below, the confidentiality and proprietary legend and this full warning notice appear in all copies.
- This document shall not be posted on any network computer or broadcast in any media and no modification of any part of this document shall be made.

Use for any other purpose is expressly prohibited and may result in severe civil and criminal liabilities.

The information contained in this document is provided "AS IS" without any warranty of any kind. Unless otherwise expressly agreed in writing, Thales makes no warranty as to the value or accuracy of information contained herein.

The document could include technical inaccuracies or typographical errors. Changes are periodically added to the information herein. Furthermore, Thales reserves the right to make any change or improvement in the specifications data, information, and the like described herein, at any time.

Thales hereby disclaims all warranties and conditions with regard to the information contained herein, including all implied warranties of merchantability, fitness for a particular purpose, title and non-infringement. In no event shall Thales be liable, whether in contract, tort or otherwise, for any indirect, special or consequential damages or any damages whatsoever including but not limited to damages resulting from loss of use, data, profits, revenues, or customers, arising out of or in connection with the use or performance of information contained in this document.

Thales does not and shall not warrant that this product will be resistant to all possible attacks and shall not incur, and disclaims, any liability in this respect. Even if each product is compliant with current security standards in force on the date of their design, security mechanisms' resistance necessarily evolves according to the state of the art in security and notably under the emergence of new attacks. Under no circumstances, shall Thales be held liable for any third party actions and in particular in case of any successful attack against systems or equipment incorporating Thales products. Thales disclaims any liability with respect to security for direct, indirect, incidental or consequential damages that result from any use of its products. It is further stressed that independent testing and verification by the person using the product is particularly encouraged, especially in any application in which defective, incorrect or insecure functioning could result in damage to persons or property, denial of service or loss of privacy.

Policy [{0}]: old and new key resources do not match [key rule {1}]

Short Form

Mismatched key resource

Parameters

Label	CEF Label	Type	Usage
pol	cs1	Text	Policy name
ruleNo	vds_ruleNo	Numeric	Index into policy rule set

Description

None

Message ID : CGA2655E

Severity

Error

Message ID : CGA2654E

Long Form

Failed to import key [{0}]

Short Form

Key import failed

Parameters

Label	CEF Label	Type	Usage
key	cs3	Text	Name of key or key pair

Description

None

Message ID : CGA2656E

Severity

Error

Long Form

Failed to find encryption key [%lld]

Message ID : CGA2655E

Short Form

Encryption key not found

Parameters

No parameters are provided for this message type

Description

None

Message ID : CGA2657E

Severity

Error

Long Form

Failed to validate policy on [{0}], rekey in progress

Short Form

Policy failure, rekey in progress

Message ID : CGA2656E

Parameters

Label	CEF Label	Type	Usage
filePath	filePath	Text	Full path to file

Description

None

Message ID : CGA2658E

Severity

Error

Long Form

Failed to validate policy on [{0}]

Short Form

Policy validation failure

Parameters

Label	CEF Label	Type	Usage
filePath	filePath	Text	Full path to file

Message ID : CGA2657E

Description

None

Message ID : CGA2659E

Severity

Error

Long Form

Unsupported key type in policy on [{0}]

Short Form

Unsupported key type in policy

Parameters

Label	CEF Label	Type	Usage
filePath	filePath	Text	Full path to file

Description

None

Message ID : CGA2658E

Message ID : CGA2662E

Severity

Error

Long Form

Failed to validate key [{0}]

Short Form

Key validation failed

Parameters

Label	CEF Label	Type	Usage
key	cs3	Text	Name of key or key pair

Description

None

Message ID : CGA3003E

Message ID : CGA2662E

Severity

Error

Long Form

EVENT: {0}

Short Form

Event

Parameters

Label	CEF Label	Type	Usage
showStr	reason	Text	Code specifying reason for allowing access, if any

Description

None

Message ID : CGA3004E

Severity

Error

Message ID : CGA3003E

Long Form

An invalid host password was entered

Short Form

Invalid host password

Parameters

No parameters are provided for this message type

Description

None

Message ID : CGA3007E

Severity

Error

Long Form

NOTUSED

Message ID : CGA3004E

Short Form

No short form is provided for this message type

Description

None

Message ID : CGA3008E

Severity

Error

Long Form

Pid [{0}] has not been initialized properly in [{1}]

Short Form

Bad caller

Parameters

Label	CEF Label	Type	Usage
pid	dvcpid	Numeric	Numeric process ID

Message ID : CGA3007E

Label	CEF Label	Type	Usage
func	vds_func	Text	A function name

Description

Internal error; try start/stop of agent or reinstallation of agent.

Message ID : CGA3009E

Severity

Error

Long Form

NOTUSED

Short Form

No short form is provided for this message type

Description

An internal error occurred. Please contact Thales Support.

Message ID : CGA3010E

Severity

Error

Long Form

Failed to write to file [{0}] in [{1}]

Short Form

Write fail

Parameters

Label	CEF Label	Type	Usage
filePath	filePath	Text	Full path to file
func	vds_func	Text	A function name

Description

None

Message ID : CGA3011E

Severity

Error

Long Form

Failed to read file [{0}] in [{1}]

Short Form

Read fail

Parameters

Label	CEF Label	Type	Usage
filePath	filePath	Text	Full path to file
func	vds_func	Text	A function name

Description

None

Message ID : CGA3012E

Severity

Error

Long Form

NOTUSED

Short Form

No short form is provided for this message type

Message ID : CGA3013E

Message ID : CGA3015E

Severity

Error

Long Form

Bad version [{0}] in configuration

Short Form

Bad config version

Parameters

Label	CEF Label	Type	Usage
verno	vds_verno	Numeric	A version number

Description

None

Message ID : CGA3016E

Severity

Error

Long Form

NOTUSED

Short Form

No short form is provided for this message type

Description

None

Message ID : CGA3017E

Severity

Error

Long Form

Failed to apply new security configuration

Message ID : CGA3016E

Short Form

Security config update failed

Parameters

No parameters are provided for this message type

Description

None

Message ID : CGA3018E

Severity

Error

Long Form

Challenge/Response: An invalid challenge/response was entered

Short Form

Invalid challenge/response

Message ID : CGA3017E

Parameters

No parameters are provided for this message type

Description

None

Message ID : CGA3021E

Severity

Error

Long Form

Challenge/Response: Error processing challenge/response

Short Form

Challenge/Response encryption error

Parameters

No parameters are provided for this message type

Message ID : CGA3018E

Description

None

Message ID : CGA3022E

Severity

Error

Long Form

Key Protection: Key integrity check failed in [{0}]

Short Form

Key integrity check failed

Parameters

Label	CEF Label	Type	Usage
func	vds_func	Text	A function name

Description

None

Message ID : CGA3021E

Message ID : CGA3023E

Severity

Error

Long Form

Short Form

No short form is provided for this message type

Description

None

Message ID : CGA3024E

Severity

Error

Long Form

Key Protection: Extract rkey: Hardware signature has changed

Message ID : CGA3023E

Short Form

Hardware signature changed

Parameters

No parameters are provided for this message type

Description

None

Message ID : CGA3059E

Severity

Error

Long Form

[AUDIT] Process[{0}] Pid[{1}] Uid[{2}] Operation[{3}] File[{4}] Failure[{5}] Effect[PERMIT]

Short Form

Sysfile modified error

Parameters

Label	CEF Label	Type	Usage
command	command	Text	Task struct comm field
pid	dvcpid	Numeric	Numeric process ID
uid	suid	Numeric	User id
op_name	op_name	Text	Operation name
filePath	filePath	Text	Full path to file
ecode	cn1	Numeric	An error code

Description

None

Message ID : CGA3060E

Severity

Error

Long Form

[ALARM] Process[{0}] Pid[{1}] Uid[{2}] Operation[{3}] File[{4}] Effect[DENIED]

Message ID : CGA3059E

Short Form

Sysfile protected

Parameters

Label	CEF Label	Type	Usage
command	command	Text	Task struct comm field
pid	dvcpid	Numeric	Numeric process ID
uid	suid	Numeric	User id
op_name	op_name	Text	Operation name
filePath	filePath	Text	Full path to file

Description

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGA3133E

Severity

Error

Long Form

Not guarding path [{0}] from container [{1}] (Reason: Does not exist)

Short Form

BadCntnrGrdPath NotExist

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Message ID : CGA3132E

Label	CEF Label	Type	Usage
dockerid	dockerid	Text	Docker image or container id

Description

None

Message ID : CGA3134E

Severity

Error

Long Form

Not guarding path [{0}] (Reason: Does not exist)

Short Form

BadGrdPath NotExist

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Message ID : CGA3133E

Description

None

Message ID : CGA3135E

Severity

Error

Long Form

Not unguarding path [{0}] from container [{1}] (Reason: Does not exist)

Short Form

BadCntnrUngrdPath NotExist

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory
dockerid	dockerid	Text	Docker image or container id

Message ID : CGA3134E

Description

None

Message ID : CGA3136E

Severity

Error

Long Form

Not unguarding path [{0}] (Reason: Does not exist)

Short Form

BadUngrdPath NotExist

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGA3135E

Message ID : CGA3137E

Severity

Error

Long Form

Not guarding path [{0}] from container [{1}] (Reason: Already mounted)

Short Form

BadCntnrGrdPath AlreadyMounted

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory
dockerid	dockerid	Text	Docker image or container id

Description

None

Message ID : CGA3138E

Severity

Error

Long Form

Not guarding path [{0}] (Reason: Already mounted)

Short Form

BadGrdPath AlreadyMounted

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGA3139E

Severity

Error

Long Form

Not guarding path [{0}] from container [{1}] (Reason: Max guard point limit reached)

Short Form

BadCntnrGrd MaxGrds

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory
dockerid	dockerid	Text	Docker image or container id

Description

None

Message ID : CGA3140E

Message ID : CGA3139E

Severity

Error

Long Form

Not guarding path [{0}] (Reason: Max guard point limit reached)

Short Form

BadGrd MaxGrds

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGA3141E

Severity

Error

Message ID : CGA3140E

Long Form

Not guarding path [{0}] from container [{1}] (Reason: Resource not available)

Short Form

BadCntnrGrd ResrcUnavail

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory
dockerid	dockerid	Text	Docker image or container id

Description

None

Message ID : CGA3142E

Severity

Error

Message ID : CGA3141E

Long Form

Not guarding path [{0}] (Reason: Resource not available)

Short Form

BadGrd ResrcUnavail

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGA3143E

Severity

Error

Long Form

Not guarding path [{0}] from container [{1}] (Reason: Operation timed out, retrying)

Message ID : CGA3142E

Short Form

BadCntnrGrd TimedOut

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory
dockerid	dockerid	Text	Docker image or container id

Description

None

Message ID : CGA3144E

Severity

Error

Long Form

Not guarding path [{0}] (Reason: Operation timed out, retrying)

Message ID : CGA3143E

Short Form

BadGrd TimedOut

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGA3145E

Severity

Error

Long Form

Not unguarding path [{0}] from container [{1}] (Reason: Operation timed out, retrying)

Short Form

BadCntnrUngrd TimedOut

Message ID : CGA3144E

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory
dockerid	dockerid	Text	Docker image or container id

Description

None

Message ID : CGA3146E

Severity

Error

Long Form

Not unguarding path [{0}] (Reason: Operation timed out, retrying)

Short Form

BadUngrd TimedOut

Message ID : CGA3145E

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGA3147E

Severity

Error

Long Form

Not guarding path [{0}] from container [{1}] (Reason: Invalid guard point)

Short Form

BadCntnrGrdPath InvalGrdPath

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Message ID : CGA3146E

Label	CEF Label	Type	Usage
dockerid	dockerid	Text	Docker image or container id

Description

None

Message ID : CGA3148E

Severity

Error

Long Form

Not guarding path [{0}] (Reason: Invalid guard point)

Short Form

BadGrdPath InvalGrdPath

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Message ID : CGA3147E

Description

None

Message ID : CGA3149E

Severity

Error

Long Form

Not guarding path [{0}] from container [{1}] (Reason: Invalid, AUTOFS but type is not automount)

Short Form

BadCntnrGrdPath AUTOFSNoAuto

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory
dockerid	dockerid	Text	Docker image or container id

Message ID : CGA3148E

Description

None

Message ID : CGA3150E

Severity

Error

Long Form

Not guarding path [{0}] (Reason: Invalid, AUTOFS but type is not automount)

Short Form

BadGrdPath AUTOFSNoAuto

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGA3149E

Message ID : CGA3151E

Severity

Error

Long Form

Not guarding path [{0}] from container [{1}] (Reason: Partially guarded)

Short Form

BadCntnrGrd PartialGrd

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory
dockerid	dockerid	Text	Docker image or container id

Description

None

Message ID : CGA3152E

Severity

Error

Long Form

Not guarding path [{0}] (Reason: Partially guarded)

Short Form

BadGrd PartialGrd

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGA3153E

Severity

Error

Long Form

Not guarding path [{0}] from container [{1}] (Reason: Logical drive or path compressed)

Short Form

BadCntnrGrd IsCompressed

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory
dockerid	dockerid	Text	Docker image or container id

Description

None

Message ID : CGA3154E

Message ID : CGA3153E

Severity

Error

Long Form

BadGrd IsCompressed

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGA3155E

Severity

Error

Message ID : CGA3154E

Long Form

Not guarding path [{0}] from container [{1}] (Reason: Logical drive or path encrypted)

Short Form

BadCntnrGrd IsEncrypt

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory
dockerid	dockerid	Text	Docker image or container id

Description

None

Message ID : CGA3156E

Severity

Error

Message ID : CGA3155E

Long Form

Not guarding path [{0}] (Reason: Logical drive or path encrypted)

Short Form

BadGrd IsEncrypt

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGA3157E

Severity

Error

Long Form

Not guarding path [{0}] from container [{1}] (Reason: System Error/Module not present)

Message ID : CGA3156E

Short Form

BadCntnrGrd SysError

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory
dockerid	dockerid	Text	Docker image or container id

Description

None

Message ID : CGA3158E

Severity

Error

Long Form

Not guarding path [{0}] (Reason: System Error/Module not present)

Message ID : CGA3157E

Short Form

BadGrd SysError

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGA3159E

Severity

Error

Long Form

Not unguarding path [{0}] from container [{1}] (Reason: System Error/Module not present)

Short Form

BadCntnrUngrd SysError

Message ID : CGA3158E

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory
dockerid	dockerid	Text	Docker image or container id

Description

None

Message ID : CGA3160E

Severity

Error

Long Form

Not unguarding path [{0}] (Reason: System Error/Module not present)

Short Form

BadUngrd SysError

Message ID : CGA3159E

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGA3161E

Severity

Error

Long Form

Not guarding path [{0}] from container [{1}] (Reason: Protected file system is stale)

Short Form

BadCntnrGrdPath StaleFS

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Message ID : CGA3160E

Label	CEF Label	Type	Usage
dockerid	dockerid	Text	Docker image or container id

Description

None

Message ID : CGA3162E

Severity

Error

Long Form

Not guarding path [{0}] (Reason: Protected file system is stale)

Short Form

BadGrdPath StaleFS

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Message ID : CGA3161E

Description

None

Message ID : CGA3163E

Severity

Error

Long Form

Not guarding path [{0}] from container [{1}] (Reason: Unsupported filesystem type)

Short Form

BadCntnrGrdPath FSNotSupp

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory
dockerid	dockerid	Text	Docker image or container id

Message ID : CGA3162E

Description

None

Message ID : CGA3164E

Severity

Error

Long Form

Not guarding path [{0}] (Reason: Unsupported filesystem type)

Short Form

BadGrdPath FSNotSupp

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGA3163E

Message ID : CGA3165E

Severity

Error

Long Form

Not guarding path [{0}] from container [{1}] (Reason: Guard point has metadata, only Live Data Transform policy allowed)

Short Form

BadCntnrGrd BadPol

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory
dockerid	dockerid	Text	Docker image or container id

Description

None

Message ID : CGA3166E

Severity

Error

Long Form

Not guarding path [{0}] (Reason: Guard point has metadata, only Live Data Transform policy allowed)

BadGrd BadPol

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGA3167E

Severity

Error

Long Form

Not guarding path [{0}] from container [{1}] (Reason: Filesystem type is not supported with Live Data Transform policy)

Short Form

BadCntnrGrd BadFS

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory
dockerid	dockerid	Text	Docker image or container id

Description

None

Message ID : CGA3168E

Message ID : CGA3167E

Severity

Error

Long Form

Not guarding path [{0}] (Reason: Filesystem type is not supported with Live Data Transform policy)

Short Form

BadGrd BadFS

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGA3169E

Severity

Error

Message ID : CGA3168E

Long Form

Not guarding path [{0}] from container [{1}] (Reason: File system not mounted with Extended attribute support)

Short Form

BadCntnrGrd XattrDisabled

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory
dockerid	dockerid	Text	Docker image or container id

Description

None

Message ID : CGA3170E

Severity

Error

Message ID : CGA3169E

Long Form

Not guarding path [{0}] (Reason: File system not mounted with Extended attribute support)

Short Form

BadGrd XattrDisabled

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGA3171E

Severity

Error

Long Form

Not guarding path [{0}] from container [{1}] (Reason: Nested mount path not allowed for LDT)

Message ID : CGA3170E

Short Form

BadCntnrGrd NestMount

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory
dockerid	dockerid	Text	Docker image or container id

Description

None

Message ID : CGA3172E

Severity

Error

Long Form

Not guarding path [{0}] (Reason: Nested mount path not allowed for LDT)

Message ID : CGA3171E

Short Form

BadGrd NestMount

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGA3173E

Severity

Error

Long Form

Not unguarding path [{0}] from container [{1}] (Reason: LDT metadata removal in progress)

Short Form

BadCntnrGrd LDTMetadata

Message ID : CGA3172E

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory
dockerid	dockerid	Text	Docker image or container id

Description

None

Message ID : CGA3174E

Severity

Error

Long Form

Not unguarding path [{0}] (Reason: LDT metadata removal in progress)

Short Form

BadGrd LDTMetadata

Message ID : CGA3173E

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGA3175E

Severity

Error

Long Form

Not guarding path [{0}] from container [{1}] (Reason: Inactive)

Short Form

BadCntnrGrd Inactive

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Message ID : CGA3174E

Label	CEF Label	Type	Usage
dockerid	dockerid	Text	Docker image or container id

Description

None

Message ID : CGA3176E

Severity

Long Form

Not guarding path [{0}] (Reason: Inactive)

Short Form

BadGrd Inactive

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Message ID : CGA3175E

Description

None

Message ID : CGA3177E

Severity

Error

Long Form

Not unguarding path [{0}] from container [{1}] (Reason: Inactive)

Short Form

BadCntnrUngrd Inactive

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory
dockerid	dockerid	Text	Docker image or container id

Message ID : CGA3176E

Description

None

Message ID : CGA3178E

Severity

Error

Long Form

Not unguarding path [{0}] (Reason: Inactive)

Short Form

BadUngrd Inactive

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGA3177E

Message ID : CGA3179E

Severity

Error

Long Form

Not guarding path [{0}] from container [{1}] (Reason: Unknown)

Short Form

BadCntnrGrd BadFlag

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory
dockerid	dockerid	Text	Docker image or container id

Description

None

Message ID : CGA3180E

Severity

Error

Long Form

Not guarding path [{0}] (Reason: Unknown)

Short Form

BadGrd BadFlag

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGA3181E

Severity

Error

Long Form

Not unguarding path [{0}] from container [{1}] (Reason: Unknown)

Short Form

BadCntnrUngrd BadFlag

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory
dockerid	dockerid	Text	Docker image or container id

Description

None

Message ID : CGA3182E

Message ID : CGA3181E

Severity

Error

Long Form

Not unguarding path [{0}] (Reason: Unknown)

Short Form

BadUngrd BadFlag

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGA3184E

Severity

Error

Message ID : CGA3182E

Long Form

Failed to guard path [{0}] (Reason: [{1}] file system not supported)

Short Form

FS NotSupp

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGA3185E

Severity

Error

Long Form

Not guarding path [{0}] (Reason: Can't guard root)

Message ID : CGA3184E

Short Form

GrdPath IsRoot

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGA3187E

Severity

Error

Long Form

An encryption policy was applied to a folder containing NTFS compressed files, [{0}]. NTFS compressed files are not encrypted

Short Form

Folder IsCompressed

Message ID : CGA3185E

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGA3188E

Severity

Error

Long Form

An encryption policy was applied to a folder containing NTFS encrypted files, [{0}]. NTFS encrypted files are not encrypted

Short Form

Folder IsCrypt

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Message ID : CGA3187E

Description

None

Message ID : CGA3189E

Severity

Error

Long Form

Guard path [{0}]: Guard point has metadata, only Live Data Transform policy allowed

Short Form

Bad GrdPath Pol

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGA3188E

Message ID : CGA3190E

Severity

Error

Long Form

Guard path [{0}]: Wrong fs type for this guard point

Short Form

Bad GrdPath FS

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGA3191E

Severity

Error

Long Form

Guard path [{0}]: Extended attribute not enabled for guard point

Short Form

GrdPath XattrDisabled

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGA3192E

Severity

Error

Message ID : CGA3191E

Long Form

Guard path [{0}]: Nested mount not allowed for Live Data Transform

Short Form

GrdPath NestMount

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGA3206E

Severity

Error

Long Form

LDT: failed to encrypt data

Message ID : CGA3192E

Short Form

LDT Crypt Fail

Parameters

No parameters are provided for this message type

Description

None

Message ID : CGA3212E

Severity

Error

Long Form

LDT-ALERT: Error in scanning guardpoint [{0}].

Short Form

LDT-ALERT: Error in scanning guardpoint

Message ID : CGA3206E

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGA3218E

Severity

Error

Long Form

LDT: Skipping transformation of file [{0}], due to pre-check error.

Short Form

LDT: Skipping transformation of file, due to pre-check error

Parameters

Label	CEF Label	Type	Usage
filePath	filePath	Text	Full path to file

Message ID : CGA3212E

Description

None

Message ID : CGA3220E

Severity

Error

Long Form

LDT: Error recovering ranges from previous transformation for file [{0}].

Short Form

LDT: Error recovering ranges from previous transformation for file

Parameters

Label	CEF Label	Type	Usage
filePath	filePath	Text	Full path to file

Description

None

Message ID : CGA3218E

Message ID : CGA3222E

Severity

Error

Long Form

[AUDIT] Process[{0}] Pid[{1}] Uid[{2}] Operation[{3}] File[{4}] ContainerID[{5}] Failure[{6}] Effect[PERMIT]

Short Form

Sysfile modified error

Parameters

Label	CEF Label	Type	Usage
command	command	Text	Task struct comm field
pid	dvcpid	Numeric	Numeric process ID
uid	suid	Numeric	User id
op_name	op_name	Text	Operation name
filePath	filePath	Text	Full path to file
cid	cid	Text	Container ID
ecode	cn1	Numeric	An error code

Description

None

Message ID : CGA3223E

Severity

Error

Long Form

[ALARM] Process[{0}] Pid[{1}] Uid[{2}] Operation[{3}] File[{4}] ContainerID[{5}] Effect[DENIED]

Short Form

Sysfile protected

Parameters

Label	CEF Label	Type	Usage
command	command	Text	Task struct comm field
pid	dvcpid	Numeric	Numeric process ID
uid	suid	Numeric	User id
op_name	op_name	Text	Operation name

Message ID : CGA3222E

Label	CEF Label	Type	Usage
filePath	filePath	Text	Full path to file
cid	cid	Text	Container ID

Description

None

Message ID : CGA3227E

Severity

Error

Long Form

LDT: Error while rekeying guardpoint [{0}]

Short Form

LDT: Error while rekeying guardpoint

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Message ID : CGA3223E

Description

None

Message ID : CGA3228E

Severity

Error

Long Form

Ptrace denied on authenticator [{0}] pid [{1}]

Short Form

Ptrace authenticator denied

Parameters

Label	CEF Label	Type	Usage
filePath	filePath	Text	Full path to file
pid	dvcpid	Numeric	Numeric process ID

Message ID : CGA3227E

Description

None

Message ID : CGA3229E

Severity

Error

Long Form

Ptrace denied on protected process [{0}] pid [{1}]

Short Form

Ptrace protected denied

Parameters

Label	CEF Label	Type	Usage
filePath	filePath	Text	Full path to file
pid	dvcpid	Numeric	Numeric process ID

Message ID : CGA3228E

Description

None

Message ID : CGA3230E

Severity

Error

Long Form

LDT: Terminating rekey ON [{0}] due to data corruption

Short Form

LDT: terminated, corruption

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGA3229E

Message ID : CGA3232E

Severity

Error

Long Form

LDT: Data transformation is aborted on file [{0}]. Error : {1}

Short Form

LDT: Data transformation is aborted on file

Parameters

Label	CEF Label	Type	Usage
filePath	filePath	Text	Full path to file
ecode	cn1	Numeric	An error code

Description

None

Message ID : CGA3233E

Severity

Error

Long Form

LDT: Data transformation is aborted on file [{0}]. Error : {1}. Reason : {2}

Short Form

LDT: Data transformation is aborted on file

Parameters

Label	CEF Label	Type	Usage
filePath	filePath	Text	Full path to file
ecode	cn1	Numeric	An error code
showStr	reason	Text	Code specifying reason for allowing access, if any

Description

None

Message ID : CGA3235E

Severity

Error

Long Form

Key Protection: Failed to generate derived key in function [{0}]

Short Form

Generate derived key failed

Parameters

Label	CEF Label	Type	Usage
func	vds_func	Text	A function name

Description

None

Message ID : CGA3236E

Severity

Error

Long Form

Key Protection: Encryption error in function [{0}]

Short Form

Encryption error

Parameters

Label	CEF Label	Type	Usage
func	vds_func	Text	A function name

Description

None

Message ID : CGA3237E

Severity

Error

Message ID : CGA3236E

Long Form

Key Protection: Invalid access file in [{0}] at [{1}]

Short Form

Invalid access file

Parameters

Label	CEF Label	Type	Usage
func	vds_func	Text	A function name

Description

None

Message ID : CGA3238E

Severity

Error

Long Form

Not re-guarding path [{0}] from container [{1}] (Reason: Guard point initialization already in progress)

Message ID : CGA3237E

Short Form

BadCntnrGrd InProgress

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory
dockerid	dockerid	Text	Docker image or container id

Description

None

Message ID : CGA3239E

Severity

Error

Long Form

Not re-guarding path [{0}] (Reason: Guard point initialization already in progress)

Message ID : CGA3238E

Short Form

BadGrd InProgress

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGA3252E

Severity

Error

Long Form

LDT-ALERT: Cannot enable guard point [{0}], LDT initialization failed with error [{1}]

Short Form

LDT: enable failure

Message ID : CGA3239E

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory
ecode	cn1	Numeric	An error code

Description

None

Message ID : CGA3256E

Severity

Error

Long Form

LDT-ALERT: Error initializing resources, LDT will not be operational.

Short Form

LDT init fail

Message ID : CGA3252E

Parameters

No parameters are provided for this message type

Description

None

Message ID : CGA3272E

Severity

Error

Long Form

{0} does not have UUID

Short Form

UUID does not exist

Parameters

Label	CEF Label	Type	Usage
filePath	filePath	Text	Full path to file

Message ID : CGA3256E

Description

None

Message ID : CGA3274E

Severity

Error

Long Form

Failed to write classification {0} to {1}

Short Form

Failed to write

Parameters

Label	CEF Label	Type	Usage
tag	tag	Text	Tag
filePath	filePath	Text	Full path to file

Message ID : CGA3272E

Description

None

Message ID : CGA3275E

Severity

Error

Long Form

Data classification transaction {0} failed for operation {1} with {2} : {3}

Short Form

Classification transaction failed

Parameters

Label	CEF Label	Type	Usage
filePath	filePath	Text	Full path to file
filePath	filePath	Text	Full path to file

Message ID : CGA3274E

Description

None

Message ID : CGA3278E

Severity

Error

Long Form

Key Conflict for File [{0}]: key information in LDT metadata does not match with the key specified under policy

Short Form

Mismatch policy

Parameters

Label	CEF Label	Type	Usage
filePath	filePath	Text	Full path to file

Description

None

Message ID : CGA3275E

Message ID : CGA3279E

Severity

Error

Long Form

ESG/IDT-ALERT: IO error on header for ESG/IDT-Capable device [{0}]

Short Form

header IO error

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGA3280E

Severity

Error

Long Form

ESG/IDT-ALERT: Data transformation failure on ESG/IDT-Capable device [{0}]

Short Form

IDT fail

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGA3282E

Severity

Error

Message ID : CGA3280E

Long Form

ESG/IDT-ALERT: Failed to update new device size on ESG/IDT-Capable device [{0}]

Short Form

resize fail

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGA3284E

Severity

Error

Long Form

LDT: Failed to flag GuardPoint [{0}] for deferred key rotation, error [{1}]

Message ID : CGA3282E

Short Form

Defer rotate fail

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory
ecode	cn1	Numeric	An error code

Description

None

Message ID : CGA3289E

Severity

Error

Long Form

Failed to have permission to remediate {0}

Message ID : CGA3284E

Short Form

Failed to have permission to remediate

Parameters

Label	CEF Label	Type	Usage
filePath	filePath	Text	Full path to file

Description

None

Message ID : CGA3292E

Severity

Error

Long Form

Failed to prepare remediation for {0}

Short Form

Failed to prepare remediation

Message ID : CGA3289E

Parameters

Label	CEF Label	Type	Usage
filePath	filePath	Text	Full path to file

Description

None

Message ID : CGA3295E

Severity

Error

Long Form

Failed to remediate {0} offline

Short Form

Failed to remediate offline

Parameters

Label	CEF Label	Type	Usage
filePath	filePath	Text	Full path to file

Message ID : CGA3292E

Description

None

Message ID : CGA3298E

Severity

Error

Long Form

Failed to commit remediation for {0}

Short Form

Failed to commit remediation

Parameters

Label	CEF Label	Type	Usage
filePath	filePath	Text	Full path to file

Description

None

Message ID : CGA3295E

Message ID : CGA3301E

Severity

Error

Long Form

Failed to remediate {0} online

Short Form

Failed to remediate online

Parameters

Label	CEF Label	Type	Usage
filePath	filePath	Text	Full path to file

Description

None

Message ID : CGA3304E

Severity

Error

Long Form

ESG-ALERT: Process [{0}] disallowed on ESG device [{1}]

Short Form

Disallow ESG

Parameters

Label	CEF Label	Type	Usage
sproc	sproc	Text	Source process
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGA3306E

Message ID : CGA3304E

Severity

Error

Long Form

LDT: Skipping transformation of file [{0}], Unable to retrieve the File Information MD.

Short Form

LDT: Skipped invalid INF

Parameters

Label	CEF Label	Type	Usage
filePath	filePath	Text	Full path to file

Description

None

Message ID : CGA3307E

Severity

Error

Message ID : CGA3306E

Long Form

LDT: Skipping transformation of file [{0}], As failed to validate LDT file MetaData. Please contact support for more information.

Short Form

LDT: Skipped invalid metadata

Parameters

Label	CEF Label	Type	Usage
filePath	filePath	Text	Full path to file

Description

None

Message ID : CGA3308E

Severity

Error

Long Form

LDT: Skipping transformation of file [{0}], Key in the policy doesn't match with the key in the MD. Please contact support for more information.

Message ID : CGA3307E

Short Form

LDT: Skipped key mismatch

Parameters

Label	CEF Label	Type	Usage
filePath	filePath	Text	Full path to file

Description

None

Message ID : CGA3309E

Severity

Error

Long Form

LDT: Skipping transformation of file [{0}],file is being restored or exclusively accessed by the application. Please retrigger the rekey again after application finishes the processing on the file.

Short Form

LDT: Skipped restore

Message ID : CGA3308E

Parameters

Label	CEF Label	Type	Usage
filePath	filePath	Text	Full path to file

Description

None

Message ID : CGA3310E

Severity

Error

Long Form

LDT: Skipping transformation of file [{0}],As failed to remove the read-only attribute of the file. Please retrigger the rekey again after checking the file permissions.

Short Form

LDT: Skipped read only

Parameters

Label	CEF Label	Type	Usage

Message ID : CGA3309E

Label	CEF Label	Type	Usage
filePath	filePath	Text	Full path to file

Description

None

Message ID : CGA3356E

Severity

Error

Long Form

Not guarding path [{0}] (Reason: Can't guard directory inside a system folder)

Short Form

IgnrGrd InsideRoot

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Message ID : CGA3310E

Description

None

Message ID : CGA3361E

Severity

Error

Long Form

[ALARM] User[{0},uid={1},gid={2}] Process[{3}] Action[{4}] Res[{5}{6}] Effect[MFA {7}]

Short Form

MFA denied

Parameters

Label	CEF Label	Type	Usage
user	suser	Text	User name
uid	suid	Numeric	User id
gid	vds_gid	Numeric	Group id
command	command	Text	Task struct comm field

Message ID : CGA3356E

Label	CEF Label	Type	Usage
op_name	op_name	Text	Operation name
gp	fileId	Text	GuardPoint base directory
filePath	filePath	Text	Full path to file
showStr	reason	Text	Code specifying reason for allowing access, if any

filePath	filePath	Text	Full path to file

Message ID : CGA3294I

Description

None

Message ID : CGA3297I

Severity

Information

Long Form

Committed remediation for {0}

Short Form

Committed remediation

Parameters

Label	CEF Label	Type	Usage
filePath	filePath	Text	Full path to file

Description

None

Message ID : CGA3296I

Message ID : CGA3299I

Severity

Information

Long Form

Remediating {0} from {1} to {2} online

Short Form

Remediating online

Parameters

Label	CEF Label	Type	Usage
filePath	filePath	Text	Full path to file
key	cs3	Text	Name of key or key pair
key	cs3	Text	Name of key or key pair

Description

None

Message ID : CGA3300I

Severity

Information

Long Form

Remediated {0} from {1} to {2} online

Short Form

Remediated online

Parameters

Label	CEF Label	Type	Usage
filePath	filePath	Text	Full path to file
key	cs3	Text	Name of key or key pair
key	cs3	Text	Name of key or key pair

Description

None

Message ID : CGA3305I

Severity

Information

Long Form

ESG-INFO: Process [{0}] allowed on ESG device [{1}]

Short Form

Allow ESG

Parameters

Label	CEF Label	Type	Usage
sproc	sproc	Text	Source process
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGA3343I

Severity

Information

Long Form

Remediation is being done on other cte client for {0}

Short Form

Remediation on nfs

Parameters

Label	CEF Label	Type	Usage
filePath	filePath	Text	Full path to file

Description

None

Status [{1}]

Short Form

LDT-ALERT: LDT recovery failure

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory
count	vds_count	Numeric	A generic count value

Description

None

Message ID : CGS3304E

Severity

Error

Message ID : CGS3266E

Long Form

IDT-TD-ALERT: Node {0} did not respond to pcl command

Short Form

IDT-TD-ALERT: Remote node did not respond to pcl

Parameters

Label	CEF Label	Type	Usage
shost	shost	Text	Source host name

Description

None

Message ID : CGS3305E

Severity

Error

Long Form

IDT-TD-ALERT: Node {0} failed to perform voradmin task

Message ID : CGS3304E

Short Form

IDT-TD-ALERT: voradmin failed on remote node

Parameters

Label	CEF Label	Type	Usage
shost	shost	Text	Source host name

Description

None

Message ID : CGS3306E

Severity

Error

Long Form

IDT-TD-ALERT: Failed to find clique for disk {0}

Short Form

IDT-TD-ALERT: Failed to find clique

Message ID : CGS3305E

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGS3307E

Severity

Error

Long Form

IDT-TD-ALERT: Failed to distribute IDT-Capable metadata file to remote nodes

Short Form

IDT-TD-ALERT: Failed to distribute IDT-Capable metadata

Parameters

No parameters are provided for this message type

Message ID : CGS3306E

Description

None

Message ID : CGS3308E

Severity

Error

Long Form

IDT-TD-ALERT: Failed to move or rename IDT-Capable metadata file on remote nodes

Short Form

IDT-TD-ALERT: Failed to move or rename IDT-Capable metadata

Parameters

No parameters are provided for this message type

Description

None

Message ID : CGS3307E

Message ID : CGS3309E

Severity

Error

Long Form

IDT-TD-ALERT: Failed to get GuardPoint status on remote nodes

Short Form

IDT-TD-ALERT: Failed to get GuardPoint status

Parameters

No parameters are provided for this message type

Description

None

Message ID : CGS3311E

Severity

Error

Long Form

IDT-TD-ALERT: Failed to complete rekey on remote nodes

Short Form

IDT-TD-ALERT: Failed to complete rekey

Parameters

No parameters are provided for this message type

Description

None

Message ID : CGS3312E

Severity

Error

Long Form

LDT-NFS-ALERT: Host waiting to take over NFS GuardPoint {0} for LDT

Short Form

Waiting to take over

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGS3313E

Severity

Error

Long Form

LDT-ALERT: Cannot enable GuardPoint due to wrong policy applied to [{0}]

Short Form

Incorrect policy

Message ID : CGS3312E

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGS3314E

Severity

Error

Long Form

LDT: Cannot enable [{0}] due to stale policy

Short Form

LDT: stale policy

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Message ID : CGS3313E

Description

None

Message ID : CGS3315E

Severity

Error

Long Form

LDT-NFS-ALERT: Cannot enable GuardPoint [{0}] on a read-only file system

Short Form

LDT-NFS: Guarding ROFS

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGS3314E

Message ID : CGS3316E

Severity

Error

Long Form

LDT-ALERT: Failed to process directory rename for {0}, error {1}

Short Form

LDT: dir rename failed

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory
ecode	cn1	Numeric	An error code

Description

None

Message ID : CGS3317E

Severity

Error

Long Form

LDT-ALERT: Failed to rekey {0} file(s) in directory {1}

Short Form

LDT: dir rekey errors

Parameters

Label	CEF Label	Type	Usage
count	vds_count	Numeric	A generic count value
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGS3319E

Severity

Error

Long Form

LDT-NFS-ALERT: Failed to start or stop rekey on GuardPoint [{0}] over NAS, error [{1}]

Short Form

LDT-NFS-ALERT: start or stop failed

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory
ecode	cn1	Numeric	An error code

Description

None

Message ID : CGS3327E

Severity

Error

Long Form

LDT-ALERT: Election of this host for LDT Group Primary role has failed for GuardPoint [{0}]

Short Form

LDT-NFS-ALERT: primary election failed

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGS3328E

Severity

Error

Long Form

LDT-NFS-ALERT: File operation recovery failed on new primary host after primary election, GuardPoint [{0}] objID [%llu] error [{1}] source [{2}]

Short Form

LDT-NFS-ALERT: fop recovery failed

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory
node	vds_node	Numeric	A node identifier
ecode	cn1	Numeric	An error code
count	vds_count	Numeric	A generic count value

Description

None

Message ID : CGS3329E

Severity

Error

Long Form

LDT-NFS-ALERT: LDT recovery failed on new primary host after primary election, GuardPoint [{0}] objID [%llu] error [{1}]

Short Form

LDT-NFS-ALERT: LDT recovery failed

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory
node	vds_node	Numeric	A node identifier
ecode	cn1	Numeric	An error code

Description

None

Message ID : CGS3331E

Severity

Error

Long Form

LDT-NFS-ALERT: File operation failed on secondary host, GuardPoint [{0}] objID [%llu] error [{1}] source [{2}]

Short Form

LDT-NFS-ALERT: fop failed on secondary

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory
node	vds_node	Numeric	A node identifier
ecode	cn1	Numeric	An error code
count	vds_count	Numeric	A generic count value

Description

None

Message ID : CGS3335E

Severity

Error

Long Form

LDT-ALERT: Failed to check rekey status on file {0}, error {1}

Short Form

LDT: monitor failed

Parameters

Label	CEF Label	Type	Usage
filePath	filePath	Text	Full path to file
ecode	cn1	Numeric	An error code

Description

None

Message ID : CGS3336E

Severity

Error

Long Form

LDT-ALERT: Failed to enable/apply GuardPoint [{0}]

Short Form

Guard failed

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGS3337E

Severity

Error

Long Form

LDT-ALERT: Failed to disable/delete GuardPoint [{0}]

Short Form

Unguard failed

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGS3338E

Severity

Error

Message ID : CGS3337E

Long Form

LDT-ALERT: Failed to join GuardPoint group [{0}]

Short Form

LGS join failed

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGS3339E

Severity

Error

Long Form

LDT-ALERT: Failed to leave GuardPoint group [{0}]

Message ID : CGS3338E

Short Form

LGS leave failed

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGS3340E

Severity

Error

Long Form

LDT-ALERT: Failed to enumerate GuardPoint [{0}], please verify the provided CIFS credentials. CIFS credentials may be expired or may not have permission to access.

Short Form

Invalid creds

Message ID : CGS3339E

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGS3341E

Severity

Error

Long Form

LDT-ALERT: Failed to authenticate a user.

Short Form

CIFS Login error

Parameters

No parameters are provided for this message type

Message ID : CGS3340E

Description

None

Message ID : CGS3342E

Severity

Error

Long Form

LDT-NFS-ALERT: Error processing LDTC message for GuardPoint [{0}], error [{1}], source [{2}]

Short Form

LDT-NFS-ALERT: bad msg

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory
ecode	cn1	Numeric	An error code
count	vds_count	Numeric	A generic count value

Message ID : CGS3341E

Description

None

Message ID : CGS3344E

Severity

Error

Long Form

LDT-NFS-ALERT: Not guarding path [{0}] (Reason: LDT version installed on host is incompatible with version on primary host)

Short Form

LDT-NFS-ALERT: msg ver mismatch

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGS3342E

Message ID : CGS3349E

Severity

Error

Long Form

LDT-NFS-ALERT: Demotion of Primary host of GuardPoint [{0}] failed, error [{1}]

Short Form

LDT-NFS-ALERT: Primary host demotion failed

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory
ecode	cn1	Numeric	An error code

Description

None

Message ID : CGS3354E

Severity

Error

Long Form

LDT-NFS-ALERT: Manual recovery of DEMOTED GuardPoint failed, GuardPoint [{0}] objID [%llu] error [{1}]

Short Form

LDT-NFS-ALERT: Primary DEMOTION recovery failed

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory
node	vds_node	Numeric	A node identifier
ecode	cn1	Numeric	An error code

Description

None

Message ID : CGS3358E

Severity

Error

Long Form

LDT-NFS-ALERT: DEMOTED GuardPoint [{0}] being recovered while the old demoted primary host is still alive, objID [%llu]

Short Form

LDT-NFS-ALERT: Primary DEMOTION admin recovery, old primary still alive

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory
node	vds_node	Numeric	A node identifier

Description

None

Message ID : CGS3360E

Severity

Error

Long Form

LDT-RAW: Write operation to relocation zone on [/dev/secvm{0}] blocked

Short Form

LDT-RAW: write blocked

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGS3362E

Severity

Error

Long Form

RWP-RW-ALERT: Potential Ransomware activity[{0}] detected in process ID [{1}], Process name: [{2}]. Num original files written to disk: [{3}]. Sensitivity: [{4}] Mode: [{5}] Reboot or remount on separate VM to access clear files on disk. Prev Code Path: [0x{6}] Latest Code Path: [0x{7}]. Last file checked is [{8}], AlgoSuspect:1 proc flags: [{9}]

Short Form

RWP: Ransomware detected

Parameters

Label	CEF Label	Type	Usage
rwtype	rwtype	Text	string type of RW proocess flags
pid	dvcpid	Numeric	Numeric process ID
pname	pname	Text	Process name
nfiles	vds_nfiles	Numeric	The total number of files in an operation
rwsensvty	rwsensvty	Numeric	Numeric value of RWP sensitivity
rwmode	rwmode	Text	string mode of RW : alert/block
rwcodepath	rwcodepath	Numeric	hex code for tracing RW detection
rwcodepath	rwcodepath	Numeric	hex code for tracing RW detection

Label	CEF Label	Type	Usage
filePath	filePath	Text	Full path to file
rwflags	rwflags	Numeric	bitmap for RW

Description

None

Message ID : CGS3364E

Severity

Error

Long Form

LDT-ALERT: Couldn't elect the primary during failover for [{0}], check DPS config.

Short Form

LDT-ALERT: Couldn't elect primary during failover, please check DPS config

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Message ID : CGS3362E

Description

None

Message ID : CGS3365E

Severity

Error

Long Form

LDT-ALERT: No primary exists to join GuardPoint group [{0}]

Short Form

LGS join failed no primary

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGS3364E

Message ID : CGS3370E

Severity

Error

Long Form

LDT-NFS-ALERT: Rekey started on LDT GuardPoint Group [{0}] containing different CTE versions

Short Form

LDT-NFS-ALERT: mixed mode rekey

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : CGS3371E

Severity

Error

Long Form

LDT-NFS-ALERT: GuardPoint Group Service recovery failed for [{0}] error [{1}]

Short Form

LDT-NFS-ALERT: Group Service recovery failed

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory
ecode	cn1	Numeric	An error code

Description

None

Logger CGS: Information

Short Form

LDT-NFS-ALERT: key rotation mixed mode

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Logger COM: Errors

Message ID : COM4547E

Severity

Error

Long Form

Internal error: Invalid configuration type given to communications subsystem. Contact support.

Short Form

No short form is provided for this message type

Description

None

Message ID : COM4631E

Severity

Error

Long Form

OPENSSL ERROR: {0}

Short Form

OpenSSL error

Parameters

Label	CEF Label	Type	Usage
showStr	reason	Text	Code specifying reason for allowing access, if any

Description

None

Message ID : COM4638E

Severity

Error

Long Form

We have detected a change in the system hardware. Communication to the Key Manager has been disabled. This condition can be fixed by re-registering this agent with the Key Manager.

Message ID : COM4631E

Short Form

Hardware Change

Parameters

No parameters are provided for this message type

Description

None

Message ID : COM4644E

Severity

Error

Long Form

An invalid REST object has been received - {0}

Short Form

Bad REST object

Message ID : COM4638E

Parameters

Label	CEF Label	Type	Usage
detail	vds_detail	Text	Fault detail

Description

None

Logger COM: Fatal errors

Message ID : COM4503F

Severity

Fatal error

Long Form

Communications module initialization failure. Contact support.

Short Form

Comms init fail

Parameters

No parameters are provided for this message type

Description

None

Message ID : COM4506F

Severity

Fatal error

Long Form

Failed to set up logger "{0}". Contact support.

Short Form

Logger setup error

Parameters

Label	CEF Label	Type	Usage
showStr	reason	Text	Code specifying reason for allowing access, if any

Description

None

Message ID : COM4511F

Severity

Fatal error

Message ID : COM4506F

Long Form

The communication request to the Key Manager was garbled or otherwise incorrect: error {0}. Contact support.

Short Form

Bad policy request

Parameters

Label	CEF Label	Type	Usage
ecode	cn1	Numeric	An error code

Description

None

Message ID : COM4512F

Severity

Fatal error

Long Form

Policy response garbled: unable to find attribute "{0}".

Message ID : COM4511F

Short Form

Resp attr missing

Parameters

Label	CEF Label	Type	Usage
showStr	reason	Text	Code specifying reason for allowing access, if any

Description

None

Message ID : COM4513F

Severity

Fatal error

Long Form

Unable to configure secure communication channel. Contact support.

Short Form

No short form is provided for this message type

Message ID : COM4512F

Description

None

Message ID : COM4514F

Severity

Fatal error

Long Form

The communication request to the Key Manager was garbled or otherwise incorrect: error {0}. Contact support.

Short Form

Server init req error

Parameters

Label	CEF Label	Type	Usage
ecode	cn1	Numeric	An error code

Description

None

Message ID : COM4513F

Message ID : COM4515F

Severity

Fatal error

Long Form

There was a communication failure with the Key Manager. The server returned a fault: {0}{1}; "{2}"; Subcode: "{3}"; Reason: "{4}"; Detail: "{5}".

Short Form

No short form is provided for this message type

Description

None

Message ID : COM4521F

Severity

Fatal error

Long Form

Internal version not supported, version required: {0}.

Short Form

Bad SDK version

Parameters

Label	CEF Label	Type	Usage
version	vds_version	Text	Software version string

Description

None

Message ID : COM4523F

Severity

Fatal error

Long Form

Unable to establish a connection to a Key Manager for the purpose of policy evaluation. Verify that the configuration file has the correct URL(s) to the server.

Message ID : COM4521F

Short Form

Policy info missing

Parameters

No parameters are provided for this message type

Description

None

Message ID : COM4527F

Severity

Fatal error

Long Form

The Agent could not obtain configuration information. The Agent failed to initialize. Verify connectivity to the Key Manager and retry the operation.

Short Form

Agent config missing

Message ID : COM4523F

Parameters

No parameters are provided for this message type

Description

None

Message ID : COM4529F

Severity

Fatal error

Long Form

Unable to establish an initial connection to any Key Manager. Verify that the configuration file has the correct URL(s) to the server.

Short Form

No config from server

Parameters

No parameters are provided for this message type

Message ID : COM4527F

Description

None

Message ID : COM4531F

Severity

Fatal error

Long Form

Unable to configure secure communication channel. Contact support.

Short Form

SSL setup fail

Parameters

No parameters are provided for this message type

Description

None

Message ID : COM4529F

Message ID : COM4533F

Severity

Fatal error

Long Form

{0} from file does not match that from backup. File: "{1}". Backup: "{2}".

Short Form

Backup opaque data mismatch

Parameters

No parameters are provided for this message type

Description

None

Message ID : COM4534F

Severity

Fatal error

Message ID : COM4533F

Long Form

File type mismatch: {0} must be a directory.

Short Form

Not a dir

Parameters

Label	CEF Label	Type	Usage
filePath	filePath	Text	Full path to file

Description

None

Message ID : COM4538F

Severity

Fatal error

Long Form

The Key Manager URL ({0}) must start with "https:".

Message ID : COM4534F

Short Form

Invalid URL

Parameters

Label	CEF Label	Type	Usage
url	request	Text	A uniform resource location

Description

None

Message ID : COM4542F

Severity

Fatal error

Long Form

The agent could not allocate enough memory. Contact support.

Short Form

Out of memory

Message ID : COM4538F

Parameters

No parameters are provided for this message type

Description

None

Message ID : COM4548F

Severity

Fatal error

Long Form

Policy request garbled: unable to find attribute "{0}".

Short Form

Req attr missing

Parameters

Label	CEF Label	Type	Usage
showStr	reason	Text	Code specifying reason for allowing access, if any

Message ID : COM4542F

Description

None

Message ID : COM4551F

Severity

Fatal error

Long Form

The Agent failed to initialize, reporting "{0}". Verify the logging configuration on the Key Manager and retry the operation. If the problem persists, contact support.

Short Form

Agent init error

Parameters

Label	CEF Label	Type	Usage
showStr	reason	Text	Code specifying reason for allowing access, if any

Description

None

Message ID : COM4548F

Message ID : COM4552F

Severity

Fatal error

Long Form

Communication with the Key Manager was established, but an invalid response (error {0}) was received. The requested operation cannot continue. Contact support.

Short Form

Bad policy response

Parameters

Label	CEF Label	Type	Usage
ecode	cn1	Numeric	An error code

Description

None

Message ID : COM4554F

Severity

Fatal error

Long Form

Communication with the Key Manager was established, but an invalid response (error {0}) was received. The requested operation cannot continue. Contact support.

Short Form

Comms response error

Parameters

Label	CEF Label	Type	Usage
ecode	cn1	Numeric	An error code

Description

None

Message ID : COM4558F

Severity

Fatal error

Message ID : COM4554F

Long Form

Key Manager communications failure. URL: {0}. Check the URL in the agent.conf file. Verify that the server url is correct and retry the operation.

Short Form

Bad config from server

Parameters

Label	CEF Label	Type	Usage
url	request	Text	A uniform resource location

Description

None

Message ID : COM4562F

Severity

Fatal error

Long Form

The communication request to the Key Manager was garbled or otherwise incorrect: error {0}. Contact support.

Message ID : COM4558F

Short Form

Comms init error

Parameters

Label	CEF Label	Type	Usage
ecode	cn1	Numeric	An error code

Description

None

Message ID : COM4563F

Severity

Fatal error

Long Form

Key Manager connection failure. Check the URL in the agent.conf file. Verify that the server url is correct and retry the operation.

Short Form

No short form is provided for this message type

Message ID : COM4562F

Description

None

Message ID : COM4567F

Severity

Fatal error

Long Form

Communication with the Key Manager was established, but an invalid response (error {0}) was received. The requested operation cannot continue. Contact support.

Short Form

SDK response error

Parameters

Label	CEF Label	Type	Usage
ecode	cn1	Numeric	An error code

Description

None

Message ID : COM4563F

Message ID : COM4569F

Severity

Fatal error

Long Form

The Key Manager URL is too long. It is {0} characters, while the maximum size is {1} characters. The URL is {2}.

Short Form

URL too long

Parameters

Label	CEF Label	Type	Usage
slen	in	Numeric	Input byte count or length
dlen	out	Numeric	Output byte count or length
url	request	Text	A uniform resource location

Description

None

Message ID : COM4571F

Severity

Fatal error

Long Form

File access failure: Unable to open {0}: {1}.

Short Form

Open error

Parameters

Label	CEF Label	Type	Usage
filePath	filePath	Text	Full path to file
showStr	reason	Text	Code specifying reason for allowing access, if any

Description

None

Message ID : COM4577F

Severity

Fatal error

Long Form

Error adding host {0} information to server.

Short Form

No short form is provided for this message type

Description

None

Message ID : COM4578F

Severity

Fatal error

Long Form

Request from {0} to add host is invalid.

Message ID : COM4577F

Description

None

Message ID : COM4579F

Severity

Fatal error

Long Form

Response to add host request from {0} is invalid: {1}.

Short Form

No short form is provided for this message type

Description

None

Message ID : COM4578F

Message ID : COM4583F

Severity

Fatal error

Long Form

Error initializing agent.

Short Form

Agent init fail

Parameters

No parameters are provided for this message type

Description

The agent is unable to reach the key manager. You may see any of the following error messages: COM4583F, COM4633W, VMD3770F, VMD3885I or VMD3886I. You may experience any of the following:

1. Connection to the key manager is down.
2. The VMD Host has been deleted from the key manager.
3. The host does not have "Communication Enabled" in the key manager UI.
4. The VMD's host may be deleted from the key manager. Run the register_host utility to re-register the VMD with the key manager.

Message ID : COM4584F

Severity

Fatal error

Long Form

Initialize Agent request invalid, {0} ({1}).

Short Form

Invalid config

Parameters

Label	CEF Label	Type	Usage
ecode	cn1	Numeric	An error code
showStr	reason	Text	Code specifying reason for allowing access, if any

Description

None

Message ID : COM4586F

Severity

Fatal error

Long Form

Error evaluating policy.

Short Form

Policy eval fail

Parameters

No parameters are provided for this message type

Description

None

Message ID : COM4587F

Severity

Fatal error

Message ID : COM4586F

Long Form

Error evaluating policy request, {0}.

Short Form

Policy eval error

Parameters

Label	CEF Label	Type	Usage
ecode	cn1	Numeric	An error code

Description

None

Message ID : COM4588F

Severity

Fatal error

Long Form

Error evaluating policy response, {0}.

Message ID : COM4587F

Short Form

Policy response error

Parameters

Label	CEF Label	Type	Usage
ecode	cn1	Numeric	An error code

Description

None

Message ID : COM4592F

Severity

Fatal error

Long Form

Error running VMSDK server, {0} (port: {1}).

Short Form

VMSDK server error

Message ID : COM4588F

Parameters

Label	CEF Label	Type	Usage
ecode	cn1	Numeric	An error code
port	spt	Numeric	A socket port number

Description

None

Message ID : COM4599F

Severity

Fatal error

Long Form

An error was encountered when trying to listen to requests from the server. The listening interface is "{0}" and the port is {1}.
Error: {2}.

Short Form

No short form is provided for this message type

Message ID : COM4592F

Description

None

Message ID : COM4600F

Severity

Fatal error

Long Form

There was a communication failure with the Key Manager ({0}). The server returned a fault: {1}{2}; "{3}"; Subcode: "{4}"; Reason: "{5}"; Detail: "{6}".

Short Form

SOAP client error

Parameters

Label	CEF Label	Type	Usage
url	request	Text	A uniform resource location
showStr	reason	Text	Code specifying reason for allowing access, if any
ecode	cn1	Numeric	An error code
context	vds_context	Text	Fault context

Message ID : COM4599F

Label	CEF Label	Type	Usage
subcode	vds_subcode	Text	Fault subcode
showStr	reason	Text	Code specifying reason for allowing access, if any
detail	vds_detail	Text	Fault detail

Description

None

Message ID : COM4603F

Severity

Fatal error

Long Form

Unable to parse the URL {0}. This attribute is located in the config file at {1}. Please fix the URL or re-install this product.

Short Form

Bad URL

Parameters

Label	CEF Label	Type	Usage

Message ID : COM4600F

Label	CEF Label	Type	Usage
url	request	Text	A uniform resource location
filePath	filePath	Text	Full path to file

Description

None

Message ID : COM4604F

Fatal error

Long Form

Internal error: unable to set attribute {0}.

Short Form

Cannot set attr

Parameters

Label	CEF Label	Type	Usage
showStr	reason	Text	Code specifying reason for allowing access, if any

Message ID : COM4603F

Description

None

Message ID : COM4628F

Severity

Fatal error

Long Form

Unable to connect to a Key Manager. URL: {0}. Please verify that the agent host is registered with a Key Manager.

Short Form

Server connect fail

Parameters

Label	CEF Label	Type	Usage
url	request	Text	A uniform resource location

Description

None

Message ID : COM4604F

Message ID : COM4629F

Severity

Fatal error

Long Form

The server at {0} attempted to contact this machine, but it was denied access due to an invalid certificate.

Short Form

Bad cert from server

Parameters

Label	CEF Label	Type	Usage
url	request	Text	A uniform resource location

Description

None

Message ID : COM4630F

Severity

Fatal error

Long Form

A machine identifying itself as {0} tried to contact the VMD, but there was an error: {1}{2}; "{3}"; Subcode: "{4}"; Reason: "{5}"; Detail: "{6}".

Short Form

SOAP server error

Parameters

Label	CEF Label	Type	Usage
url	request	Text	A uniform resource location
showStr	reason	Text	Code specifying reason for allowing access, if any
ecode	cn1	Numeric	An error code
context	vds_context	Text	Fault context
subcode	vds_subcode	Text	Fault subcode
showStr	reason	Text	Code specifying reason for allowing access, if any
detail	vds_detail	Text	Fault detail

Description

None

Message ID : COM4637F

Severity

Fatal error

Long Form

Failed to bind to port {0}. Please ensure that this port is not in use by another program.

Short Form

SDK bind error

Parameters

Label	CEF Label	Type	Usage
port	spt	Numeric	A socket port number

Description

None

Message ID : COM4630F

Logger COM: Information

Message ID : COM4601I

Severity

Message ID : COM4602I

Severity

Information

Long Form

Failed Agent init with Key Manager ({0}).

Short Form

Comms init fail

Parameters

Label	CEF Label	Type	Usage
url	request	Text	A uniform resource location

Description

None

Message ID : COM4626I

Severity

Information

Long Form

The agent failed to initialize with the Key Manager. This may indicate that the connection to the server is down, the agent's host has been deleted from the Key Manager, or "Communication Enabled" for the host has not been enabled in the Key Manager UI.

Short Form

No short form is provided for this message type

Description

None

Message ID : COM4627I

Severity

Information

Long Form

The agent's host may no longer be registered with a Key Manager. The agent's host may have been deleted from the Key Manager. You may want to run the register_host utility to re-register the agent with a Key Manager.

Message ID : COM4626I

Short Form

Agent not registered

Parameters

No parameters are provided for this message type

Description

None

Logger COM: Warnings

Message ID : COM4596W

Severity

Warning

Long Form

{0} Logging discarded due to backlog of {1} MB

Short Form

Backlog high

Parameters

Label	CEF Label	Type	Usage
logger	cs4	Text	Name of originating logger
count	vds_count	Numeric	A generic count value

Description

None

Message ID : COM4597W

Severity

Warning

Long Form

{0} Logging resumed due to reduced backlog

Short Form

Backlog OK

Parameters

Label	CEF Label	Type	Usage
logger	cs4	Text	Name of originating logger

Description

None

Message ID : COM4605W

Severity

Warning

Long Form

Logging destination changed from {0} to {1}

Short Form

Upload dest change

Parameters

Label	CEF Label	Type	Usage
shost	shost	Text	Source host name
url	request	Text	A uniform resource location

Description

None

Message ID : COM4632W

Message ID : COM4605W

Severity

Warning

Long Form

There was a communication failure with the Key Manager. The server returned a fault: {0}{1}; "{2}"; Subcode: "{3}"; Reason: "{4}"; Detail: "{5}".

Short Form

No short form is provided for this message type

Description

None

Message ID : COM4633W

Severity

Warning

Long Form

There was a communication failure with the Key Manager ({0}). The server returned a fault: {1}{2}; "{3}"; Subcode: "{4}"; Reason: "{5}"; Detail: "{6}".

Message ID : COM4632W

Short Form

SOAP client error

Parameters

Label	CEF Label	Type	Usage
url	request	Text	A uniform resource location
showStr	reason	Text	Code specifying reason for allowing access, if any
ecode	cn1	Numeric	An error code
context	vds_context	Text	Fault context
subcode	vds_subcode	Text	Fault subcode
showStr	reason	Text	Code specifying reason for allowing access, if any
detail	vds_detail	Text	Fault detail

Description

The agent is unable to reach the key manager. You may see any of the following error messages: COM4583F, COM4633W, VMD3770F, VMD3885I or VMD3886I. You may experience any of the following:

1. Connection to the key manager is down.
2. The VMD Host has been deleted from the key manager.
3. The host does not have "Communication Enabled" in the key manager UI.
4. The VMD's host may be deleted from the key manager. Run the register_host utility to re-register the VMD with the key manager.

Message ID : COM4634W

Severity

Warning

Long Form

The server at {0} attempted to contact this machine, but it was denied access due to an invalid certificate.

Short Form

Bad cert from server

Parameters

Label	CEF Label	Type	Usage
url	request	Text	A uniform resource location

Description

An attempt to contact the agent was rejected. This may be due to attempting to register an agent with a new key manager after that agent was registered with a different key manager. A COM4635W log message may give more details.

Message ID : COM4635W

Severity

Warning

Long Form

A machine identifying itself as {0} tried to contact the VMD, but there was an error: {1}{2}; "{3}"; Subcode: "{4}"; Reason: "{5}"; Detail: "{6}".

Short Form

SOAP server error

Parameters

Label	CEF Label	Type	Usage
url	request	Text	A uniform resource location
showStr	reason	Text	Code specifying reason for allowing access, if any
ecode	cn1	Numeric	An error code
context	vds_context	Text	Fault context
subcode	vds_subcode	Text	Fault subcode
showStr	reason	Text	Code specifying reason for allowing access, if any
detail	vds_detail	Text	Fault detail

Description

The key manager tried to contact the agent but did not succeed. The "reason" field tells you why the certificate was rejected, and the "detail" field tells you what action was attempted at the time.

None

Message ID : DXF4108E

Severity

Error

Long Form

The file {0} was in error for an unknown reason

Short Form

Prev xform file in error

Parameters

Label	CEF Label	Type	Usage
filePath	filePath	Text	Full path to file

Description

None

Message ID : DXF4107E

Message ID : DXF4109E

Severity

Error

Long Form

Error "{0}" opening lock file in {1}

Short Form

Lock file error

Parameters

Label	CEF Label	Type	Usage
showStr	reason	Text	Code specifying reason for allowing access, if any
filePath	filePath	Text	Full path to file

Description

None

Message ID : DXF4111E

Severity

Error

Long Form

Process {0}: error "{1}" opening lock file at {2}. This may be due to an already running data transform instance

Short Form

Lock file open error

Parameters

Label	CEF Label	Type	Usage
ecode	cn1	Numeric	An error code
showStr	reason	Text	Code specifying reason for allowing access, if any
filePath	filePath	Text	Full path to file

Description

None

Message ID : DXF4112E

Severity

Error

Long Form

Error "{0}" creating lock file in {1}

Short Form

Lock file create fail

Parameters

Label	CEF Label	Type	Usage
showStr	reason	Text	Code specifying reason for allowing access, if any
filePath	filePath	Text	Full path to file

Description

None

Message ID : DXF4113E

Severity

Error

Long Form

Cannot create the data transform recovery/status file {0}, {1}

Short Form

Status file create error

Parameters

Label	CEF Label	Type	Usage
filePath	filePath	Text	Full path to file
showStr	reason	Text	Code specifying reason for allowing access, if any

Description

None

Message ID : DXF4114E

Severity

Error

Long Form

Error "{0}" getting file info for {1}

Short Form

Stat fail

Parameters

Label	CEF Label	Type	Usage
showStr	reason	Text	Code specifying reason for allowing access, if any
filePath	filePath	Text	Full path to file

Description

None

Message ID : DXF4115E

Severity

Error

Long Form

Error "{0}" getting file attributes for {1}

Short Form

Attr fail

Parameters

Label	CEF Label	Type	Usage
showStr	reason	Text	Code specifying reason for allowing access, if any
filePath	filePath	Text	Full path to file

Description

None

Message ID : DXF4116E

Severity

Error

Long Form

Error "{0}" setting file attributes for {1}

Short Form

Parameters

Label	CEF Label	Type	Usage
ecode	cn1	Numeric	An error code
filePath	filePath	Text	Full path to file

Description

None

Message ID : DXF4325E

Severity

Error

Message ID : DXF4315E

Long Form

Cannot perform data transform for {0}, does not exist

Short Form

Does not exist

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : DXF4326E

Severity

Error

Long Form

Cannot perform data transform for {0}, access denied

Message ID : DXF4325E

Short Form

Access denied

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : DXF4328E

Severity

Error

Long Form

Secfs component gave unexpected status {0}

Short Form

Unexpected Secfs error

Message ID : DXF4326E

Parameters

Label	CEF Label	Type	Usage
ecode	cn1	Numeric	An error code

Description

None

Message ID : DXF4330E

Severity

Error

Long Form

No file name provided to hold recovery file list

Short Form

Logger DXF: Warnings

Message ID : DXF3210W

Severity

Warning

Long Form

If Shadow Copy was used on your system, you must back up your data before attempting to run dataxform. Once DataXform has been completed, you may restart Shadow Copy. Note, however, that all Shadow Copy backups made prior to running dataxform will be unusable and should be discarded. Attempting to restore your cleartext Shadow Copy backups made prior to running dataxform into your encrypted data will result in data corruption.

Short Form

Shadow copy

Parameters

Short Form

Domain bind error

Parameters

Label	CEF Label	Type	Usage
domain	dntdom	Text	A domain name (policy, network, users, etc)

Message ID : VMD3843E

Label	CEF Label	Type	Usage
ecode	cn1	Numeric	An error code

Description

None

Message ID : VMD3845E

Severity

Error

Long Form

Failed to query the domain {0} by {1}. Error {2}: {3}.

Short Form

NIS query error

Parameters

Label	CEF Label	Type	Usage
domain	dntdom	Text	A domain name (policy, network, users, etc)
effect	vds_effect	Text	Policy effect

Message ID : VMD3844E

Label	CEF Label	Type	Usage
ecode	cn1	Numeric	An error code
showStr	reason	Text	Code specifying reason for allowing access, if any

Description

None

Message ID : VMD3846E

Severity

Error

Long Form

Failed to query the group {0} in the domain {1} by {2}. Error {3}: {4}.

Short Form

NIS group query error

Parameters

Label	CEF Label	Type	Usage
group	vds_group	Text	Group name

Message ID : VMD3845E

Label	CEF Label	Type	Usage
domain	dntdom	Text	A domain name (policy, network, users, etc)
effect	vds_effect	Text	Policy effect
ecode	cn1	Numeric	An error code
showStr	reason	Text	Code specifying reason for allowing access, if any

Description

None

Message ID : VMD3848E

Severity

Error

Long Form

Domain browsing failed.

Short Form

Domain browse fail

Message ID : VMD3846E

Parameters

No parameters are provided for this message type

Description

None

Message ID : VMD3849E

Severity

Error

Long Form

Error getting common name: {0}

Short Form

Cannot determine common name

Parameters

Label	CEF Label	Type	Usage
showStr	reason	Text	Code specifying reason for allowing access, if any

Message ID : VMD3848E

Description

None

Message ID : VMD3855E

Severity

Error

Long Form

Failed to send {0} signatures for the signature request {1} to the Key Manager

Short Form

Send sigs error

Parameters

Label	CEF Label	Type	Usage
nsig	vds_nsig	Numeric	The number of signatures generated
showStr	reason	Text	Code specifying reason for allowing access, if any

Message ID : VMD3849E

Description

None

Message ID : VMD3858E

Severity

Error

Long Form

The Secfs component was unable to implement the new security configuration

Short Form

New config to Secfs fail

Parameters

No parameters are provided for this message type

Description

An error occurred while attempting to apply a policy push from a key manager.

Message ID : VMD3855E

Message ID : VMD3864E

Severity

Error

Long Form

Unable to parse LDAP URL {0} - error "{1}"

Short Form

Bad LDAP url

Parameters

Label	CEF Label	Type	Usage
url	request	Text	A uniform resource location
showStr	reason	Text	Code specifying reason for allowing access, if any

Description

None

Message ID : VMD3865E

Severity

Error

Long Form

Unable to query LDAP server {0} - error "{1}"

Short Form

Bad LADP server

Parameters

Label	CEF Label	Type	Usage
url	request	Text	A uniform resource location
showStr	reason	Text	Code specifying reason for allowing access, if any

Description

None

Message ID : VMD3866E

Severity

Error

Long Form

Invalid LDAP posixAccount data returned

Short Form

Invalid LDAP account

Parameters

Error

Message ID : VMD3866E

Long Form

Invalid LDAP posixGroup data returned

Short Form

Invalid LDAP group

Parameters

No parameters are provided for this message type

Description

None

Message ID : VMD3872E

Severity

Error

Long Form

Internal error: bad arguments to secfs component

Message ID : VMD3867E

Short Form

Bad args to Secfs

Parameters

No parameters are provided for this message type

Description

An internal error occurred. Please contact Thales Support

Message ID : VMD3873E

Severity

Error

Long Form

Internal error: the secfs component does not believe it's talking to the correct VMD

Short Form

Secfs rejecting VMD

Message ID : VMD3872E

Parameters

No parameters are provided for this message type

Description

None

Message ID : VMD3874E

Severity

Error

Long Form

The secfs component is unable to read its private key

Short Form

Secfs priv key fail

Parameters

No parameters are provided for this message type

Message ID : VMD3873E

Description

None

Message ID : VMD3875E

Severity

Error

Long Form

The secfs component unable to obtain its PWD

Short Form

Secfs passwd fail

Parameters

No parameters are provided for this message type

Description

None

Message ID : VMD3874E

Message ID : VMD3876E

Severity

Error

Long Form

The secfs component contains an invalid PWD

Short Form

Secfs passwd bad

Parameters

No parameters are provided for this message type

Description

None

Message ID : VMD3877E

Severity

Error

Long Form

The secfs component was unable to extract the key-encrypting-key

Short Form

Secfs key extract fail

Parameters

No parameters are provided for this message type

Description

None

Message ID : VMD3878E

Severity

Error

Long Form

The secfs component failed to pass internal sanity checks around the key-encrypting-key

Message ID : VMD3877E

Short Form

Secfs key sanity fail

Parameters

No parameters are provided for this message type

Description

None

Message ID : VMD3879E

Severity

Error

Long Form

The secfs component was able to perform all of the crypto operations around the policy push, but was unable to actually apply the new policy configuration

Short Form

Secfs policy apply fail

Message ID : VMD3878E

Parameters

No parameters are provided for this message type

Description

None

Message ID : VMD3888E

Severity

Error

Long Form

Unable to replicate coherent guardpoint info - {0}

Short Form

Unable to replicate coherent GuardPoint info -

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Message ID : VMD3879E

Description

None

Message ID : VMD3890E

Severity

Error

Long Form

Unable to commit configuration to GPFS cluster

Short Form

Unable to commit configuration to GPFS cluster

Parameters

No parameters are provided for this message type

Description

None

Message ID : VMD3888E

Message ID : VMD3891E

Severity

Error

Long Form

Non-clustered GP {0} not allowed on clustered filesystem

Short Form

Non-clustered GP not allowed on clustered filesystem

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : VMD3892E

Severity

Error

Long Form

Clustered GP {0} not allowed on non-clustered filesystem

Short Form

Clustered GP not allowed on non-clustered filesystem

Parameters

Label	CEF Label	Type	Usage
gp	fileId	Text	GuardPoint base directory

Description

None

Message ID : VMD3901E

Severity

Error

Message ID : VMD3892E

Long Form

Docker host browsing failed.

Short Form

Docker host browse fail

Parameters

No parameters are provided for this message type

Description

None

Message ID : VMD3903E

Severity

Error

Long Form

Docker host browsing for image {0} failed.

Message ID : VMD3901E

Short Form

Docker host browse fail

Parameters

Label	Type	Usage
dockerid	Text	Docker image or container id

Description

None

Message ID : VMD3905E

Severity

Error

Long Form

Docker image {0} file browsing for {1} failed.

Short Form

Docker image file browse fail

Message ID : VMD3903E

Parameters

Label	CEF Label	Type	Usage
dockerid	dockerid	Text	Docker image or container id
filePath	filePath	Text	Full path to file

Description

None

Message ID : VMD3907E

Severity

Error

Long Form

Docker container {0} file browsing for {1} succeeded.

Short Form

Docker container file browse fail

Message ID : VMD3905E

Parameters

Label	CEF Label	Type	Usage
dockerid	dockerid	Text	Docker image or container id
filePath	filePath	Text	Full path to file

Description

None

Message ID : VMD3909E

Severity

Error

Long Form

User browsing for image {0} with {1} failed.

Short Form

Docker image user browse fail

Message ID : VMD3907E

Parameters

Label	CEF Label	Type	Usage
dockerid	dockerid	Text	Docker image or container id
domain	dntdom	Text	A domain name (policy, network, users, etc)

Description

None

Message ID : VMD3911E

Severity

Error

Long Form

User browsing for container {0} with {1} failed.

Short Form

Docker container user browse fail

Message ID : VMD3909E

Parameters

Label	CEF Label	Type	Usage
dockerid	dockerid	Text	Docker image or container id
domain	dntdom	Text	A domain name (policy, network, users, etc)

Description

None

Message ID : VMD3913E

Severity

Error

Long Form

Domain browsing for image {0} failed.

Short Form

Docker image domain browse fail

Message ID : VMD3911E

Parameters

Label	Type	Usage
dockerid	Text	Docker image or container id

Description

None

Message ID : VMD3915E

Severity

Error

Long Form

Domain browsing for container {0} failed.

Short Form

Docker container domain browse fail

Parameters

Label	Type	Usage
dockerid	Text	Docker image or container id

Message ID : VMD3913E

Description

None

Message ID : VMD3916E

Severity

Error

Long Form

The current docker version "{0} {1}" is not supported.

Short Form

No short form is provided for this message type

Description

None

Message ID : VMD3917E

vm_write_file: fopen failed for {0} mode {1} errno {2}

Short Form

File open error

Parameters

Label	CEF Label	Type	Usage
filePath	filePath	Text	Full path to file
mode	vds_mode	Text	File open mode
ecode	cn1	Numeric	An error code

Description

None

Message ID : VMD4612E

Severity

Error

Long Form

vm_write_file: fwrite() failed error {0}

Short Form

Write error

Parameters

Label	CEF Label	Type	Usage
ecode	cn1	Numeric	An error code

Description

None

Message ID : VMD4617E

Severity

Error

Long Form

The previous message {0} was repeated {1} times

Short Form

Repeat message

Parameters

Label	CEF Label	Type	Usage
msgid	vds_msgid	Text	A unique log message identifier
count	vds_count	Numeric	A generic count value

Description

None

Logger VMD: Fatal errors

Message ID : VMD3767F

Severity

Fatal error

Long Form

No attribute {0} was found in the configuration file located at {1}. Please supply this attribute or re-install the product and try again.

Short Form

Attribute missing

Parameters

Label	CEF Label	Type	Usage
showStr	reason	Text	Code specifying reason for allowing access, if any
filePath	filePath	Text	Full path to file

Description

None

Message ID : VMD3768F

Severity

Fatal error

Long Form

Unable to parse the URL {0}. This attribute is located in the config file at {1}. Please fix the URL or re-install this product.

Short Form

Bad URL in config file

Parameters

Label	CEF Label	Type	Usage
url	request	Text	A uniform resource location
filePath	filePath	Text	Full path to file

Description

None

Message ID : VMD3769F

Severity

Fatal error

Long Form

Internal error: unable to set attribute {0}.

Short Form

Bad attribute

Parameters

Label	CEF Label	Type	Usage
showStr	reason	Text	Code specifying reason for allowing access, if any

Description

None

Message ID : VMD3770F

Severity

Fatal error

Long Form

The VMD failed to establish a communication channel to the Key Manager.

Short Form

Cannot contact server

Parameters

No parameters are provided for this message type

Description

The agent is unable to reach the key manager. You may see any of the following error messages: COM4583F, COM4633W, VMD3770F, VMD3885I or VMD3886I. You may experience any of the following:

1. Connection to the key manager is down.
2. The VMD Host has been deleted from the key manager.
3. The host does not have "Communication Enabled" in the key manager UI.
4. The VMD's host may be deleted from the key manager. Run the register_host utility to re-register the VMD with the key manager.

Message ID : VMD3771F

Severity

Fatal error

Long Form

Logging setup failure. Error code {0}; "{1}"

Short Form

Log setup error

Parameters

Label	CEF Label	Type	Usage
ecode	cn1	Numeric	An error code
showStr	reason	Text	Code specifying reason for allowing access, if any

Description

None

Message ID : VMD3772F

Severity

Fatal error

Long Form

Logging setup failure: VMD logger information not found in Key Manager response.

Short Form

Missing logger info

Parameters

No parameters are provided for this message type

Description

None

Message ID : VMD3797F

Severity

Fatal error

Message ID : VMD3772F

Long Form

The VMD is unable to listen for requests from the Key Manager. Shutting down.

Short Form

Cannot list for server req.

Parameters

No parameters are provided for this message type

Description

None

Message ID : VMD3894F

Severity

Fatal error

Long Form

The server does not support required oneway communications.

Message ID : VMD3797F

Message ID : VMD4618W

Severity

Warning

Long Form

The previous message {0} was repeated {1} times

Short Form

Repeat message

Parameters

Label	CEF Label	Type	Usage
msgid	vds_msgid	Text	A unique log message identifier
count	vds_count	Numeric	A generic count value

Message ID : VMD3933W

Description

None

Message ID : VMD4621W

Severity

Warning

Long Form

The space available for log files in {0} is dangerously low ({1} MB)

Short Form

Log space low

Parameters

Label	CEF Label	Type	Usage
filePath	filePath	Text	Full path to file
count	vds_count	Numeric	A generic count value

Message ID : VMD4618W

Description

The directory used to process log files is low on space. The "filePath" field gives the path and directory. The "count" field gives the remaining space (in MB).

When space is low audit trails may become compromised, and error conditions may be unreported. This should be resolved immediately.

Message ID : VMD4622W

Severity

Warning

Long Form

Raising drop log message level to {0} because space consumed is now greater than {1}% and less than or equal to {2}%.

Short Form

Raise drop space level

Parameters

Label	CEF Label	Type	Usage
showStr	reason	Text	Code specifying reason for allowing access, if any
count	vds_count	Numeric	A generic count value

Label	CEF Label	Type	Usage
count	vds_count	Numeric	A generic count value

Description

The space that holds log files uploaded to the key manager is increasing. Logging levels are automatically modified to accommodate the load. The "reason" field details the change being imposed, and the two "count" fields depict the lower and upper "percentage full" values that caused this condition. The following strings may occur on the "reason" field:

Reason	Meaning
Drop None	No adjustments currently in force
Speed Up	The agent will try to upload logs to the key manager in larger batches
Drop Info	No INFO level logs will be uploaded
Drop Warn	No WARN level logs will be uploaded
Drop Error	No ERROR level logs will be uploaded

Message ID : VMD4623W

Severity

Warning

Message ID : VMD4622W

1100

Long Form

Raising drop log message level to {0} because number of files is now greater than {1}% and less than or equal to {2}%.

Short Form

Raise drop file level

Parameters

Label	CEF Label	Type	Usage
showStr	reason	Text	Code specifying reason for allowing access, if any
count	vds_count	Numeric	A generic count value
count	vds_count	Numeric	A generic count value

Description

Files pending upload to the key manager are increasing, so the agent has temporarily adjusted the logging parameters to handle the situation. The "reason" field details the change imposed, and the two "count" fields indicate the lower and upper percentages of the maximum permitted number of files. See VMD4622W for usage of the "reason" field.

Message ID : VMD4624W

Severity

Warning

Message ID : VMD4623W

1101

Long Form

Lowering drop log message level to {0} because space consumed is now greater than {1}% and less than or equal to {2}%.

Short Form

Lower drop space level

Parameters

Label	CEF Label	Type	Usage
showStr	reason	Text	Code specifying reason for allowing access, if any
count	vds_count	Numeric	A generic count value
count	vds_count	Numeric	A generic count value

Description

The space used to hold log files for uploading to the key manager is decreasing, so the agent has temporarily adjusted the logging parameters to handle the situation. See VMD4622W for details about the fields used.

Message ID : VMD4625W

Severity

Warning

Message ID : VMD4624W

Long Form

Lowering drop log message level to {0} because number of files is now greater than {1}% and less than or equal to {2}%.

No parameters are provided for this message type

Description

None

Message ID : XFM4590E

1113

Logger XFM: Fatal errors

Message ID : XFM4508F

Severity

Fatal error

Long Form

Unable to find chunk headers; possible data corruption.

Short Form

Missing chunk hdr

Parameters

No parameters are provided for this message type

Description

None

Message ID : XFM4509F

Severity

Fatal error

Long Form

Decompression/decryption failure: output buffer size ({0} bytes) is too small.

Short Form

Decomp/decrypt buffer too small

Parameters

Label	CEF Label	Type	Usage
dlen	out	Numeric	Output byte count or length

Description

None

Message ID : XFM4518F

Severity

Fatal error

Message ID : XFM4509F

Long Form

Invalid encryption key size received from Key Manager. The operation will fail.

Short Form

Invalid encr. key size

Parameters

No parameters are provided for this message type

Description

None

Message ID : XFM4519F

Severity

Fatal error

Long Form

The agent could not allocate enough memory. Contact support.

Message ID : XFM4518F

1116

Short Form

Out of memory

Parameters

No parameters are provided for this message type

Description

None

Message ID : XFM4525F

Severity

Fatal error

Long Form

Decryption fatal error: {0}. The restore operation will fail.

Short Form

Decryption error

Message ID : XFM4519F

1117

Parameters

Label	CEF Label	Type	Usage
ecode	cn1	Numeric	An error code

Description

None

Message ID : XFM4532F

Severity

Fatal error

Long Form

Decryption information mismatch; possible data corruption.

Short Form

Decryption info mismatch

Parameters

No parameters are provided for this message type

Message ID : XFM4525F

Description

None

Message ID : XFM4536F

Severity

Fatal error

Long Form

Compression module returned fatal error: {0}. The operation will fail.

Short Form

Compression error

Parameters

Label	CEF Label	Type	Usage
ecode	cn1	Numeric	An error code

Description

None

Message ID : XFM4532F

Message ID : XFM4539F

Severity

Fatal error

Long Form

Unable to set up encryption subsystem. The operation will fail.

Short Form

Encryption setup fail

Parameters

No parameters are provided for this message type

Description

None

Message ID : XFM4540F

Severity

Fatal error

Message ID : XFM4539F

Long Form

Decompression information mismatch; possible data corruption.

Short Form

Decompression info mismatch

Parameters

No parameters are provided for this message type

Description

None

Message ID : XFM4541F

Severity

Fatal error

Long Form

Data read problem: corrupted buffer header. Data corruption has possibly occurred. The restore operation will fail.

Message ID : XFM4540F

Short Form

Corrupt buffer header

Parameters

No parameters are provided for this message type

Description

None

Message ID : XFM4544F

Severity

Fatal error

Long Form

Unable to set up compression subsystem. The operation will fail.

Short Form

Compression setup fail

Message ID : XFM4541F

Parameters

No parameters are provided for this message type

Description

None

Message ID : XFM4546F

Severity

Fatal error

Long Form

Compression module initialization failure. The backup operation will fail.

Short Form

Compression init fail

Parameters

No parameters are provided for this message type

Message ID : XFM4544F

Description

None

Message ID : XFM4561F

Severity

Fatal error

Long Form

Decompression fatal error: {0}. The restore operation will fail.

Short Form

Decompression error

Parameters

Label	CEF Label	Type	Usage
ecode	cn1	Numeric	An error code

Description

None

Message ID : XFM4546F

Message ID : XFM4565F

Severity

Fatal error

Long Form

Input data length does not match buffer length: {0} != {1}. Data corruption has possible occurred. The restore operation will fail.

Short Form

Data lenght mismatch

Parameters

Label	CEF Label	Type	Usage
slen	in	Numeric	Input byte count or length
dlen	out	Numeric	Output byte count or length

Description

None

Logger XFM: Information

Message ID : XFM4507I

Severity

Information

Long Form

Using no encryption.

Short Form

Using no encryption

Parameters

No parameters are provided for this message type

Description

None

Message ID : XFM4517I

Severity

Information

Long Form

Shutting down compression/decompression subsystem.

Short Form

Comp/decomp shutdown

Parameters

No parameters are provided for this message type

Description

None

Message ID : XFM4522I

Severity

Information

Message ID : XFM4517I

Long Form

Data transformation code now using single-threaded algorithm.

Short Form

Single-thread transform

Parameters

No parameters are provided for this message type

Description

None

Message ID : XFM4526I

Severity

Information

Long Form

Using no compression.

Message ID : XFM4522I

Short Form

Using no compression

Parameters

No parameters are provided for this message type

Description

None

Message ID : XFM4549I

Severity

Information

Long Form

Using compression.

Short Form

Using compression

Message ID : XFM4526I

Parameters

No parameters are provided for this message type

Description

None

Message ID : XFM4557I

Severity

Information

Long Form

Using {0} encryption algorithm.

Short Form

Using enc algorithm

Parameters

Label	CEF Label	Type	Usage
key	cs3	Text	Name of key or key pair

Message ID : XFM4549I

Description

None

Message ID : XFM4559I

Severity

Information

Long Form

Shutting down encryption/decryption subsystem.

Short Form

Encrypt/decrypt shutdown

Parameters

No parameters are provided for this message type

Description

None

Message ID : XFM4557I

Logger XFM: Warnings

Message ID : XFM4550W

Severity

Warning

Long Form

Compression initialization failure: failed to initialize algorithm {0} upon startup.

Short Form

Compression init fail

Parameters

No parameters are provided for this message type

Description

None

CipherTrust Transparent Encryption

ADMINISTRATOR GUIDE

Document Information

Product Version	2.0.0
Release Date	11 September 2020

Thales and the Thales logo are trademarks and service marks of Thales and/or its subsidiaries and affiliates and are registered in certain countries. All other trademarks and service marks, whether registered or not in specific countries, are the properties of their respective owners.

Disclaimer

All information herein is either public information or is the property of and owned solely by Thales and/or its subsidiaries who shall have and keep the sole right to file patent applications or any other kind of intellectual property protection in connection with such information.

Nothing herein shall be construed as implying or granting to you any rights, by license, grant or otherwise, under any intellectual and/or industrial property rights of or concerning any of Thales DIS France S.A. and any of its subsidiaries and affiliates (collectively referred to herein after as “Thales”) information.

This document can be used for informational, non-commercial, internal, and personal use only provided that:

- > The copyright notice, the confidentiality and proprietary legend and this full warning notice appear in all copies.
- > This document shall not be posted on any publicly accessible network computer or broadcast in any media, and no modification of any part of this document shall be made.

Use for any other purpose is expressly prohibited and may result in severe civil and criminal liabilities.

The information contained in this document is provided “AS IS” without any warranty of any kind. Unless otherwise expressly agreed in writing, Thales makes no warranty as to the value or accuracy of information contained herein.

The document could include technical inaccuracies or typographical errors. Changes are periodically added to the information herein. Furthermore, Thales reserves the right to make any change or improvement in the specifications data, information, and the like described herein, at any time.

Thales hereby disclaims all warranties and conditions with regard to the information contained herein, including all implied warranties of merchantability, fitness for a particular purpose, title and non-infringement. In no event shall Thales be liable, whether in contract, tort or otherwise, for any indirect, special or consequential damages or any damages whatsoever including but not limited to damages resulting from loss of use, data, profits, revenues, or customers, arising out of or in connection with the use or performance of information contained in this document.

Thales does not and shall not warrant that this product will be resistant to all possible attacks and shall not incur, and disclaims, any liability in this respect. Even if each product is compliant with current security standards in force on the date of their design, security mechanisms' resistance necessarily evolves according to the state of the art in security and notably under the emergence of new attacks. Under no circumstances,

shall Thales be held liable for any third party actions and in particular in case of any successful attack against systems or equipment incorporating Thales products. Thales disclaims any liability with respect to security for direct, indirect, incidental or consequential damages that result from any use of its products. It is further stressed that independent testing and verification by the person using the product is particularly encouraged, especially in any application in which defective, incorrect or insecure functioning could result in damage to persons or property, denial of service, or loss of privacy.

PREFACE: About this Document

This introductory section identifies the audience, explains the importance of the release notes, provides a brief summary of the user guide's contents, explains how to best use the written material, and discusses the documentation conventions used. It contains the following sections:

- > "Release Notes" below
- > "Audience" below
- > "What's in This Guide" below
- > "Organization" on page 1
- > "Document Conventions" on page 1
- > "Related Documents" on page 13
- > "Support Contacts" on page 14

Release Notes

The release notes provide important information about this release that is not included in other customer documentation. It is strongly recommended that you read the release notes to fully understand the capabilities, limitations, and known issues for this release. You can view or download the latest version of the release notes for this release at the following location:

<https://supportportal.thalesgroup.com>

Audience

This document is intended for CipherTrust Transparent Encryption (CTE) administrators responsible for deploying security policies on client machines.

All products manufactured and distributed by Thales Group are designed to be installed, operated, and maintained by personnel who have the knowledge, training, and qualifications required to safely perform the tasks assigned to them. The information, processes, and procedures contained in this document are intended for use by trained and qualified personnel only.

It is assumed that the users of this document are proficient with data security concepts.

What's in This Guide

This guide describes the CipherTrust Manager interfaces to use CTE. The document explains the CTE concepts such as clients and client groups, signature sets, security rules, and GuardPoints. Next, the document describes how to manage clients and client groups, signature sets, security policies on the CipherTrust Manager. Finally, the document describes how to manage GuardPoints.

- > It is assumed, for this document, that you have already configured the CipherTrust Manager appliance. Refer to the CipherTrust Manager product documentation for instructions.
- > The next step is to activate and install the CTE license. Refer to ["Licensing" on page 21](#) for details.
- > After the license is installed, you can configure CTE Agents. Refer to the CTE Agent Quick Start Guide specific to your platform for details. Installation of the CTE Agents is required for protecting directories and files stored on clients.

NOTE This document, may at times, abbreviate:

- > "CipherTrust Transparent Encryption" to "CTE"
- > "CipherTrust Manager" to "CM"

Organization

The CipherTrust Transparent Encryption Administrator Guide contains the following chapters:

1. ["Interfaces" on page 15](#)
Provides an overview of the CipherTrust Manager interfaces—Command Line Interface (CLI), REST Application Programming Interface (REST API), and Graphical User Interface (GUI).
2. ["Licensing" on page 21](#)
Describes the CTE licensing models.
3. ["Concepts" on page 24](#)
Describes CTE concepts such as clients, client groups, GuardPoints, policies, and security rules.
4. ["Introduction to Data Transformation" on page 33](#)
Provides an overview of the data transformation process.
5. ["Managing Profiles" on page 42](#)
Describes how to configure client log criteria and client Syslog settings.
6. ["Managing Clients and Client Groups" on page 55](#)
Describes how to add, register, and manage clients and client groups on the CipherTrust Manager appliance.
7. ["Managing Signature Sets" on page 86](#)
Describes how to create signature sets and how to sign and re-sign files in a signature set. The chapter also describes how to stop file signing and how to delete signatures and signature sets on the CipherTrust Manager appliance.
8. ["Managing Policies" on page 101](#)
Describes rules and effects of security policies, and provides instructions to create, configure, import, and export security policies on the CipherTrust Manager appliance.
9. ["Managing GuardPoints" on page 135](#)

Describes how to create, view, and delete GuardPoints on the CipherTrust Manager appliance. The chapter provides information on automatic and manual GuardPoints and provides steps to configure Windows network drives.

10. "Operations" on page 158

Describes the operations that the CTE Server Administrator performs on the CipherTrust Manager. These operations include registering CTE clients with the CipherTrust Manager, using external CA certificates, reregistering the clients, and protecting file system on a CTE client.

11. "Common Scenarios" on page 164

Describes the common encryption scenarios in which the paths can be encrypted using the CTE solution.

12. "Troubleshooting" on page 172

Describes how to handle the issues that you might face when using CTE with the CipherTrust Manager.

Document Conventions

This section describes the conventions used in this document.

Command Syntax and Typeface Conventions

This document uses the following conventions for command syntax descriptions, and to highlight elements of the user interface.

Format	Convention
bold	The bold attribute is used to indicate the following: > Command-line commands and options that you enter verbatim (Type dir /p.) > Button names (Click Save As.) > Check box and radio button names (Select the Print Duplex check box.) > Dialog box titles (On the Protect Document dialog box, click Yes.) > Field names (User Name: Enter the name of the user.) > Menu names (On the File menu, click Save.) (Click Menu > Go To > Folders.) > User input (In the Date box, type April 1.)
<i>italics</i>	In type, the italic attribute is used for emphasis or to indicate a related document. (See the <i>Installation Guide</i> for more information.)
<variable>	In command descriptions, angle brackets represent variables. You must substitute a value for command line arguments that are enclosed in angle brackets.
[optional] [<optional>]	Represent optional keywords or <variables> in a command line description. Optionally enter the keyword or <variable> that is enclosed in square brackets, if it is necessary or desirable to complete the task.

Format	Convention
<code>{a b c}</code> <code><a> <c></code>	Represent required alternate keywords or <variables> in a command line description. You must choose one command line argument enclosed within the braces. Choices are separated by vertical (OR) bars.
<code>[a b c]</code> <code><a> <c></code>	Represent optional alternate keywords or variables in a command line description. Choose one command line argument enclosed within the braces, if desired. Choices are separated by vertical (OR) bars.

Notifications and Alerts

Notifications and alerts are used to highlight important information or alert you to the potential for data loss or personal injury.

Tips

Tips are used to highlight information that helps to complete a task more efficiently.

TIP This is some information that will allow you to complete your task more efficiently.

Notes

Notes are used to highlight important or helpful information.

NOTE Take note. Contains important or helpful information.

Cautions

Cautions are used to alert you to important information that may help prevent unexpected results or data loss.

CAUTION! Exercise caution. Contains important information that may help prevent unexpected results or data loss.

Warnings

Warnings are used to alert you to the potential for catastrophic data loss or personal injury.

****WARNING**** Be extremely careful and obey all safety and security measures. In this situation you might do something that could result in catastrophic data loss or personal injury.

Related Documents

The following documents contain related or additional information:

- > CTE Release Notes
- > CTE Agent for Linux Quick Start Guide

- > CTE Agent for Windows Quick Start Guide
- > CTE Agent for AIX Advanced Configuration and Integration Guide
- > CTE Agent for Linux Advanced Configuration and Integration Guide

- > CTE-Live Data Transformation with CipherTrust Manager

Support Contacts

If you encounter a problem while installing, registering, or operating this product, please refer to the documentation before contacting support. If you cannot resolve the issue, contact your supplier or [Thales Customer Support](#).

Thales Customer Support operates 24 hours a day, 7 days a week. Your level of access to this service is governed by the support plan arrangements made between Thales and your organization. Please consult this support plan for further information about your entitlements, including the hours when telephone support is available to you.

Customer Support Portal

The Customer Support Portal, at <https://supportportal.thalesgroup.com>, is where you can find solutions for most common problems. The Customer Support Portal is a comprehensive, fully searchable database of support resources, including software and firmware downloads, release notes listing known problems and workarounds, a knowledge base, FAQs, product documentation, technical notes, and more. You can also use the portal to create and manage support cases.

NOTE You require an account to access the Customer Support Portal. To create a new account, go to the portal and click on the **REGISTER** link.

Telephone

The support portal also lists telephone numbers for voice contact ([Contact Us](#)).

Email Support

You can also contact technical support by email at technical.support.DIS@thalesgroup.com.

CHAPTER 1: Interfaces

This chapter provides an overview of the CipherTrust Manager interfaces

CLI

The CipherTrust Manager includes a CLI tool, named **ksctl**, that can be downloaded and run locally to control a remote CipherTrust Manager appliance. **ksctl** exclusively uses the REST API to communicate with the CipherTrust Manager, so anything that you can do with the tool, you can also do directly with the REST API. Conversely, **ksctl** exposes most of the functionality of the REST API. It can perform management functions, such as managing registration tokens and clients.

NOTE **ksctl** is designed to be run from a remote system, not on the CipherTrust Manager itself.

To use the CLI:

1. Open the **CipherTrust Manager** URL in a browser.
2. Click the **API & CLI Documentation** link. The API playground is displayed.
3. At the top left, click **CLI Guide**. The CLI documentation is displayed.
4. At the top right, click the **CLI** download button. This downloads the **ksctl_images.zip** file.
5. Unzip the **ksctl_images.zip** file. The extracted files contain platform specific files. For example, the file for Windows is **ksctl-win-amd64**, and for Linux, the file is **ksctl-linux-amd64**.
6. Set up the **ksctl-<os>** file for your system. Refer to the CipherTrust Manager CLI documentation for details.
7. Run **ksctl cte** to run CipherTrust Transparent Encryption specific commands.

Refer to the *CipherTrust Manager* documentation for details. For details on commands related to CipherTrust Transparent Encryption, refer to the online documentation of `ksctl cte`.

REST API

Use the REST interface from the *API playground* or through any REST client such as curl. The REST interface acquires an authorization token internally and uses it for making API calls.

Acquiring an Authorization Token

To acquire a token:

1. Open the **CipherTrust Manager** URL in a browser.

2. Click the **API & CLI Documentation** link. The API playground is displayed.
3. At the top right, click **Authenticate**.
4. Enter **username** and **password**.
5. Click **POST**.

NOTE This acquires an API token and prefills it in the playground examples. The token expires in 300 seconds (5 minutes). When it expires, use this tool again to acquire a new token.

On successful token generation, the remaining token expiry time in seconds is displayed. Two new buttons, **Clear Credentials** and **Re Authenticate**, are also displayed at the top right.

Using the Token

The authorization token acquired above is used in examples in the API playground. The token expires in 5 minutes; if expired, generate a new token, as described in ["Acquiring an Authorization Token" on the previous page](#).

Making an API Call

To make an API call, find the API in the left pane and click it. In the right pane, specify the required parameters, and click an appropriate button (for example, **POST**, **GET**, **DELETE**, or **Curl**). For example, to create a CTE policy on CipherTrust Manager:

1. In the left pane of the API playground, click **CTE/Policies**.
2. Under **cte/policies**, click **Create**. The **Create** section of the API playground is displayed in the right pane.
3. In the **body** field, specify required parameters with their values, as shown below.

```
{
  "name": "TestPolicy",
  "policy_type": "Standard",
  "never_deny": false,
  "security_rules": [
    {
      "effect": "permit",
      "action": "all_ops",
      "partial_match": false,
      "resource_set_id": "TestResourceSet",
      "exclude_resource_set": true
    }
  ]
}
```

Expand **schema** under the **body** field for names and types of fields. Hover your mouse over each field to view its description. The parameter names and casing in the **body** field must match with those shown in the schema. Also, ensure that parameters and their values are specified in double quotes.

4. Click **POST**.

Alternatively, to get an equivalent `curl` command, click the **Curl** button. The `curl` equivalent will be shown in the text field below. Use the `curl` tool to run the command to make the REST API call.

Similarly, all API calls can be made by referring to the schema shown in the playground.

GUI

Use the CipherTrust Manager's GUI (also called the Management Console) to perform management functions such as managing profiles, policies, clients and client groups, and GuardPoints. These functions can also be performed using the CLI tool or the REST API.

To use the GUI:

1. Open the **CipherTrust Manager** URL in a browser.
2. Enter **Username** and **Password**.
3. Click **Log In**. By default, the Applications page is displayed.
4. Click **CTE** to open the application.

The Clients page of the CTE GUI is displayed, as shown below.

The main components of a CTE GUI are:

- > "Header" below
- > "Left Pane" on the next page
- > "Page" on the next page
- > "Notifications" on page 20

Header

Element	Description
	App switcher. Click to view and switch to another application such as Keys & Access Management and Admin Settings .
CTE	Application name. For CTE, CTE is displayed.

Element	Description
API	Link to the API playground.
	Link to the CipherTrust Manager product documentation.
	Logged in user. Click to switch domains, view and update user settings (Email address and password), and log out.

Left Pane

Contains links to manage CTE resources - clients, policies, and profiles.

Element	Description
Clients	Click to manage clients and client groups. Clients > Clients is the option selected by default. Refer to "Managing Clients and Client Groups" on page 55 for details.
Policies	Click to manage policies and policy elements—resource sets, user sets, process sets, and signature sets. Refer to "Managing Policies" on page 101 for details.
Profiles	Click to manage profiles. Refer to "Managing Profiles" on page 42 for details.

Page

A page is the main working area that provides options to manage CTE resources. Depending on the selected option in the left pane, the page shows different types of information. These options are described in this document, where appropriate.

At any time, a page can either be in the list view or in the edit view. A sample screenshot of the list view of the Clients page is shown below. Most pages follow the similar pattern except that they show different content based on the resource being managed.

The sample page shown above can be divided into the following elements:

Element	Description
Title	Shows the page name.
Status bar	Shows the total number of clients added to the CipherTrust Manager, the number of clients with errors, warnings, healthy state. The status bar also shows the number of unregistered and expunged clients on the CipherTrust Manager. The status bar also acts as a filter. Click a health status to see the list of clients with that status.
Search box ()	Filters clients based on their partial or full names. Search is case-insensitive.
List	Shows the clients based on the selected health status. By default, all the clients added to the CipherTrust Manager are displayed.
Delete icon ()	Deletes the selected clients. A message is prompted to confirm the action.
Check box (☐)	Provides an option to select a client for deletion or modification. Multiple clients can be selected to perform the delete operation on them. Use the check box provided just under the Search box to select all clients visible on the page.
Expand icon ()	Shows mini detail view of a client in the clients list.

Element	Description
Custom View icon (⚙)	Hides/shows optional columns. For example, click this icon on the Clients page shows:  Select or clear the desired column and click OK.
Overflow icon (⋮)	Shows additional options. Depending on the current state of a client, the options can vary.
Pagination	Helps configure the number of records to display. By default, 10 records per page are displayed. 

Notifications

CTE prompts toast notifications at the top right corner of the main page area. These notifications are shown when operations such as creation or deletion of an entity is performed.

Green success toast notifications are displayed for successful operations.

Red error notifications are displayed for failed operations.

CHAPTER 2: Licensing

CTE base and LDT add-on licenses are offered through the following licensing models:

- > ["Trialware" below](#)
- > ["Time-limited Rental" below](#)
- > ["Perpetual Licensing Model" below](#)
- > ["Add-on Licenses" on the next page](#)
- > ["Installing CTE Licenses" on the next page](#)

Trialware

Provides the fully-functional CTE solution for 90 days with pre-installed trial license. After the trial period expires, CTE configurations on the CipherTrust Manager become read-only. Only decryption of GuardPoints is allowed; LDT-enabled registration is not allowed.

This is the default license shipped with the CipherTrust Manager.

Time-limited Rental

Provides the fully-functional CTE solution for a prepaid charge for a specific period of time, for a specific number of clients.

This license comes with a grace period of 90 days. After the license period expires, the grace period starts. During the grace period, CTE continues working normally. However, after the grace period is over, CTE configurations on the CipherTrust Manager become read-only. Only decryption of GuardPoints is allowed; LDT-enabled registration is not allowed.

The CipherTrust Manager GUI starts showing a notification about the remaining license time. The license renewal can be ordered before the license expires.

NOTE The number of clients that can be registered with the CipherTrust Manager is limited by the number of licenses purchased.

For example, if a 1-year license is purchased for 1000 clients, then only 1000 clients can be registered with the CipherTrust Manager.

Perpetual Licensing Model

Provides the fully-functional CTE solution for a prepaid charge with no time limit, for a specific number of clients.

NOTE The number of clients that can be registered with the CipherTrust Manager is limited by the number of licenses purchased.

For example, if a perpetual license is purchased for 1000 clients, then only 1000 clients can be registered with the CipherTrust Manager.

A CipherTrust Manager appliance administrator can install the CTE license.

Add-on Licenses

CTE offers the Live Data Transformation (LDT) feature as an add-on license. To use the LDT feature, you need a CTE base license activated on the CipherTrust Manager.

Installing CTE Licenses

Installing a CTE license requires a license string for the CipherTrust Manager with which the clients will be registered. This string is generated when a license is activated on the Sentinel EMS License Portal.

To install a CTE license:

1. Log on to the **CipherTrust Manager** GUI as administrator.
2. Click **Admin Settings** to open the application.
3. Click **Licensing**, if needed. A list of licenses is displayed on the right.
4. Click the **Lock codes** tab.
5. Click to expand **Connector Lock Code**.
6. Copy the **Connector Lock Code**. Every CipherTrust Manager appliance has a unique connector lock code. This lock code is needed to activate a CTE license for the CipherTrust Manager.

NOTE In a CipherTrust Manager cluster, the connector lock code is applicable to all nodes of the cluster to enforce connector licenses across the cluster nodes. When a CTE license is activated for one CipherTrust Manager appliance, the license is replicated on all the nodes of the cluster.

7. Activate the CTE license.

When you purchase a CipherTrust Manager and connectors, you receive an email after the Purchase Order (PO) is processed. Accompanying this email is a PDF attachment that contains the Entitlement ID (EID). This ID is needed to activate your license.

To activate the CTE license:

- a. Log on to the [License Portal](#). Use your EID when logging on for the first time.
- b. Register your account, if not already done. After registration, you can find the details about your EID and your available licenses.
- c. On the **Entitlements** tab, select the CTE license.
- d. Click **Activate**.

- e. In the **Quantity** field, specify the number of licenses to activate.
- f. In the **License Lock Code** field, paste the **Connector Lock Code** copied earlier.
- g. Click **Activate**.

NOTE

- > Based on the requirements, a CTE license is activated and a license string is generated.
- > The license string generated for one CipherTrust Manager cannot be used on any other CipherTrust Manager.

- h. Copy the **License String**. This license string is needed to install the CTE license on the CipherTrust Manager.
- 8. Return to the CipherTrust Manager GUI.
 - 9. Click the **Features** tab.
 - 10. Click **Add License**. The Add License dialog box is displayed.
 - 11. Paste the copied **License String** to the **License String** field.
 - 12. Click **Add**. The license is now installed.

The license is displayed in the installed licenses table with the feature name **CTE - TransparentEncryption**.

After the base CTE license is installed, an LDT add-on license can be activated and installed. The installed LDT license is displayed with the feature name **CTE - LiveDataTransformation**.

NOTE When a client is unregistered (unenrolled), the number of Used Clients on the Licensing page remains the same. To update the clients usage, the unregistered client must be deleted from the CipherTrust Manager. After the client is deleted, the license is released and can be used to register another client.

CHAPTER 3: Concepts

This chapter describes the following concepts:

- > ["Clients" below](#)
- > ["Client Groups" below](#)
- > ["GuardPoints" on the next page](#)
- > ["Policies" on the next page](#)
- > ["Security Rules" on page 26](#)
- > ["Resource Sets" on page 29](#)
- > ["User Sets" on page 29](#)
- > ["Signature Sets" on page 29](#)
- > ["Process Sets" on page 30](#)
- > ["Key Rules" on page 30](#)
- > ["Data Transformation Rules" on page 30](#)
- > ["Profiles" on page 31](#)
- > ["Learn Mode" on page 31](#)
- > ["User Roles" on page 31](#)

Clients

A client is a computer system where the data needs to be protected. A compatible CTE Agent software is installed on the client. The CTE Agent can protect data on the client or devices connected to it. A client can be associated with multiple GuardPoints for encryption of various paths (refer to ["Managing GuardPoints" on page 135](#) for details).

Client Groups

A client group is used to group one or more clients to simplify configuration and administration. GuardPoints created on a client group are applied to all members of the group. Additionally, you can apply client group configuration settings to all clients in a client group. A client can be a member of multiple client groups.

If you have created a group of one type of clients, then you should only add similar clients to the group. Same configuration settings can only be applied to clients of the type with which the client group is created. If a different type of client is added, configuration settings cannot be applied to that client.

Refer to ["Managing GuardPoints" on page 135](#) for details on creating GuardPoints on client groups.

GuardPoints

A GuardPoint specifies the list of folders that contains paths to be protected. Access to files and encryption of files under the GuardPoint is controlled by security policies.

Refer to ["Managing GuardPoints" on page 135](#) for details.

Policies

A policy is a collection of rules that govern data access and encryption. Think of a policy as an if-then statement. Policy rules are processed sequentially. If the criteria of rule one are not met, the policy enforcement engine moves on to the second rule and so on.

Policies specify:

- > **Actors:** Users, groups, and processes that are permitted/denied access to protected data.
- > **Actions:** What actions authorized actors are allowed to perform. For example create/delete, read/write, decrypt, modify permissions, and so on.
- > **Files acted upon:** Policy rules may apply to entire directories and mount points, or only to files named in a specific way (for example, .docx files may be encrypted and restricted to read only access by designated users, while other files may be stored clear and read and written by anyone).

Additionally, each CTE policy specifies one or more encryption keys used to encrypt blocks of file data when applications write them, and decrypt them when they are read.

CTE encryption is transparent to applications. This means that the CTE Agent encrypts blocks of data as they are written, and decrypts data when they are read by authorized users and applications. This architecture separates administration of files from access to the data in them. Backup programs, for example, may be authorized to read files, but not view the data in them. Therefore, data can be backed up and taken offsite while remaining encrypted so that security is not breached.

A policy comprises ["Security Rules" on the next page](#), ["Key Rules" on page 30](#), and ["Data Transformation Rules" on page 30](#).

CTE supports the following policy types:

- > **Standard:** Access to data is blocked during initial encryption or rekeying of data.
- > **Live Data Transformation (LDT):** Encryption and rekeying of data takes place in the background, without disrupting user or application access to that data.
- > **Cloud Object Storage (COS):** Applicable to GuardPoints in Amazon S3 buckets. Access to data is blocked during initial encryption or rekeying of data.

The following diagram shows the main components of a policy:

Refer to ["Managing Policies" on page 101](#) for details.

Security Rules

A security rule defines:

- > Who can access the data (User or Group)
- > What they can do with the data (Action)
- > What applications or executables have access to the data (Process)
- > Where the data is located (Resource)
- > How the data can be accessed (Effect)
- > Whether it can be enforced on the subdirectories of the GuardPoint (Browsing)

Security Rule Criteria

Security rules consist of five criteria. They specify the attributes of an access attempt, and effects, which define whether that access is permitted or denied, and whether encryption/decryption is required. The following table lists policy rule criteria.

Criteria	Description
Resource	Specifies which files and/or directories in a GuardPoint are to be protected. For example, <code>/secure_dir/financials</code> .
User	Specifies a which users or groups of users can access the files.
Process	Specifies executables that can operate on the files.
Action	Specifies the allowed file action. Action could be read, write, remove, rename, and make directory. Refer to "Actions" on the next page for the complete list of supported actions.

Criteria	Description
Effect	Describes the type of access granted or denied according to the rule. Refer to "Security Rule Effects" on the next page for the list of supported effects.

Actions

Action specifies the type of access (read, write, copy, and move etc.) being made on the protected files. The following table lists all basic and advanced actions:

Basic Actions

Action	Description
read	read operations
write	write operations
all_ops	all operations
key_op	key operations

Advanced Actions

Action	Description
f_rd	read file
f_wr	write file
f_wr_app	write file appending
f_cre	create file
f_ren	rename file
f_link	link file
f_rm	remove file
f_rd_att	read file attribute
f_chg_att	change file attribute
f_rd_sec	read file security
f_chg_sec	change file security

Action	Description
d_rd	read directory
d_ren	rename directory
d_rd_att	read directory attribute
d_chg_att	change directory attribute
d_rd_sec	read directory security
d_chg_sec	change directory security
d_mkdir	make directory
d_rmdir	remove directory

Security Rule Effects

An effect describes the type of access granted or denied according to the rule. The following table lists policy effects that can be applied to GuardPoints.

Effect	Description
Permit	Allows access attempts to the resource. For example, you can specify an effect that allows writing to a directory.
Deny	Denies access attempts to the resource. For example, you can specify an effect that denies any attempts to access a resource.
ApplyKey	Applies an encryption key to the data in a GuardPoint. When applied, the data copied to the GuardPoint is encrypted with the specified key. When the data in the GuardPoint is accessed, it is decrypted using the same key.
Audit	Creates a message log entry for each qualifying event that records who is accessing what information and when.

How Security Policy Works

Every time a user's application tries to access a GuardPoint file, the security policy tests that access attempt against the criteria of each rule. For example, suppose a user, Harry, wants to access and modify a file called `secret`, using the command `cp`. For Harry to be successful, there must be a rule that allows access to `secret` (resource), by user Harry (user), using the command `cp` (process), and includes the permission `write` (action).

- > If criteria is not specified, a value of *All* is used.
- > If *resource* is not specified, the rule applies to all resources.
- > If *user* is not specified, the rule applies to all users.

- > If *process* is not specified, the rules apply to all executables, and so on.
- > *Effect* cannot be left unspecified. It must have at least a permit (allow access) or deny (disallow access).

A policy can have multiple rules. Rules are evaluated much like firewall rules. They are evaluated in order, from first to last. Evaluation stops when a rule is found for which all the criteria are met. The effect for that rule is then enforced. Therefore, you must carefully order a policy's rules to achieve the desired result.

Resource Sets

A resource is a combination of a directory, a file, and patterns or special variables. A resource set is a named collection of directories, files, or both, that a user or process will be permitted or denied access to.

Refer to ["Creating Resource Sets" on page 104](#) for details on creating resource sets.

User Sets

A user set is a collection of users and user groups that you want to grant or deny access to GuardPoints. User sets are configured in policies. Policies can be applied to user sets, not to individual users.

Refer to ["Creating User Sets" on page 105](#) for details on creating user sets.

Signature Sets

A signature set is a collection of hashes of processes and executables that you want to grant or deny access to GuardPoints. A signature set can be configured in a policy as part of a process set to verify the integrity of a process before it is allowed access to guarded data. Policies are applied to signature sets, not to individual signatures.

A cryptographic hash is created for each file in a signature set that meets a specific criterion. It would take longer, bloat the CipherTrust Manager database, and reduce performance to sign all the files in a signature set, especially when the set comprises top-level directories. The criteria is listed below. All other files are skipped.

Executables accessing a GuardPoint can be inside or outside the GuardPoint. If they are inside:

- > On a Windows client, *all* files in a signature set that are *inside* a GuardPoint are signed. Only the *compiled* Windows executables in the signature set that are *outside* the GuardPoint are signed. Non-executables outside the GuardPoint are not signed.
- > On a UNIX client, it makes no difference whether the files are inside or outside a GuardPoint. Only the files in a signature set with one or more execute bits set (for example, `-rwxrwxrwx-`) are signed.
- > File extension has no impact. Even files like the following are skipped:
 - [On Windows] `.bat` and Visual Basic programs if they are not inside a GuardPoint
 - [On Linux] `.so` files if they do not have an execute bit set

Every instance of a file that is copied to a different location or to a different name will have the same signature. This can be a convenient way to detect duplicate files on your system.

By default, a generic error message is displayed about a non-existent source being detected. The name of the offending file or directory is not specified. However, it is specified in the Agent log on the client. Review the logs to:

- > Identify the offending file or directory.
- > Determine how many files were affected, what file "is invalid for the signature request".
- > Identify the files that were not signed. Look for files with "is invalid for the signature request".

Refer to ["Managing Signature Sets" on page 86](#) for details on the signing process.

Process Sets

A process set is a collection of processes (executables) that you want to grant or deny access to GuardPoints. Like user sets, process sets can be configured in policies. Policies can be applied to process sets, not to individual processes.

Optionally, file signing can be configured to check the authenticity and integrity of executables and applications before they are allowed to access GuardPoint data. A signature set must already exist before you can configure file signing in a policy for a process set.

Refer to ["Creating Process Sets" on page 110](#) for details on creating process sets.

Key Rules

A key rule defines the encryption key to apply to a specific resource set or the encryption key to use as the default key, if no other key rule matches. The key rule defines the sequence in which the key rules are to be executed (Order), the location of the data to be encrypted (Resource), and the encryption key to be applied to the resource set (Key).

When defining a key rule for an LDT policy, you can select a key that is applied to the resource set (Current Key Name) and the key to use to rekey that resource set (Transformation Key Name).

NOTE Keys are created and stored on a CipherTrust Manager appliance.

Data Transformation Rules

Data transformation (dataxform) rules define:

- > Resources to be protected
- > Symmetric encryption key to use for
 - Rekeying the specified resources from one encryption key to a different key or
 - Rekeying resources into a plaintext format (also referred to as clear, unencrypted, or decrypted)

Profiles

A profile contains the CipherTrust Manager logging criteria for CTE clients, Syslog server configuration, default logging level, LDT Quality of Service (QoS) settings, and other settings that can be used for several CTE clients.

A default profile, `DefaultClientProfile`, is created automatically when either of the following happens:

- > On successful registration of the *first* client if no profile is specified during registration.
- > On creation of the *first* client group. A new client group is automatically linked to `DefaultClientProfile`.

When registering a CTE client, the installer prompts to specify a profile for the client. If not specified, `DefaultClientProfile` is automatically linked to the client on successful registration. The linked profile can be modified later. It is recommended to not delete or modify `DefaultClientProfile`.

Learn Mode

Learn Mode permits a policy to be tested without actually denying access to the GuardPoint. In Learn Mode, all actions that would have been denied are instead permitted, but logged. This allows you to test policies by tracking how rules are evaluated, without enforcing the policy. Monitor the log to determine how data is being accessed, then modify the policy accordingly.

In Learn Mode:

- > If the policy contains a security rule with the effect permission `Permit` and the effect option `ApplyKey`, then a security rule with the permission `Deny` **MUST** include the option `ApplyKey`. If it does not include the option `ApplyKey`, a user with the `Deny` permission can overwrite or edit data, which can corrupt the data.
- > Effect permission `Deny` has the same effect as `Permit`, and `Deny ApplyKey` has the same effect as `Permit ApplyKey`.

This option generates an `ERROR` log each time an access attempt is made that matches any security rule in the policy. The `ERROR` log is labeled `[LEARN MODE]` and can be viewed in the CTE Agent logs or under Records on the CipherTrust Manager GUI (if the log level is configured as `ERROR`).

Learn Mode is recommended for policies that restrict by application (process). Many applications use multiple binaries that may not be known to the creator of the policy at the time of creation. So, Learn Mode should be enabled when creating policies for such applications.

CAUTION! Use Learn Mode to analyze access patterns and make informed decisions about final encryption policies. Do not keep Learn Mode running for long time.

User Roles

CTE has the following users with different responsibilities in administering and using the system.

CAUTION! It is critical that credentials of these users are kept in a secure location. If a credential is compromised, an attacker could gain access to sensitive data.

CTE Admins

Initially, there is a System Defined Group named "CTE Admins". Users within the "CTE Admins" group are CTE Administrators.

A CTE Administrator is responsible for creating and managing the following resources:

- > Clients and client groups
- > Profiles, policy elements, and policies
- > GuardPoints
- > Client registration tokens

NOTE Only the users of the "CTE Admins" group can delete CTE keys.

CTE Clients

There is a System Defined Group named "CTE Clients". CTE clients registered with the CipherTrust Manager are part of this group.

CHAPTER 4: Introduction to Data Transformation

This chapter provides an overview of the data transformation process. It covers the following information:

- > ["The Data Transformation Process" below](#)
- > ["Data Transformation Techniques" on page 35](#)
- > ["Protection Policies" on page 40](#)

The Data Transformation Process

Data transformation is the process of transforming GuardPoint data from:

- > Plaintext (clear) to encrypted with a key
- > Encrypted with a key to plaintext
- > Encrypted with one (old) key to encrypted with another (new) key

This section covers the following information:

- > ["Uses of Data Transformation" below](#)
- > ["How CTE Protects Files" below](#)
- > ["Components of the CTE Solution" on the next page](#)
- > ["Properties of Data Transformation" on the next page](#)

Uses of Data Transformation

- > **Initial Data transformation:** Encrypting GuardPoint data for the first time.
- > **Rekeying:** Changing the encryption key for GuardPoint data, also called key rotation.
- > **Reverse Transformation:** Decrypting GuardPoint data to clear text (not a common procedure).
- > **Convert:** Non-LDT GuardPoints to LDT GuardPoints.

NOTE Data transformation is complex and disruptive to data center operations. It is strongly recommended that you read and understand this section before you proceed to the initial data transformation and rekey.

How CTE Protects Files

The CTE Agent encrypts the data within a file one block at a time. It does not encrypt file metadata such as a file's name or size. This enables administrators to manage files without being able to view or modify their contents. Whether initially encrypting files, rekeying them, or decrypting them, the CTE Agent must therefore:

- > **Read** each block of file data to be transformed.
- > **Transform** the block by encrypting, decrypting, or rekeying it.
- > **Write** the transformed block, either to its original location, or to an alternate one.

Components of the CTE Solution

CTE protects data either at the file level or at the storage device level. CTE file-level protection consists of two main components:

> CipherTrust Manager

An appliance that manages a database of the file sets protected by CTE GuardPoints, the encryption keys that protect them, policies that specify access rights and encryption protections that can be applied to GuardPoints. The CipherTrust Manager is also a central point for logging events related to accessing protected files.

> CTE Agents

Software components that run on clients with file sets to be protected. A CTE Agent manages the files behind a GuardPoint by enforcing the policy associated with it, and communicates data access events to the CipherTrust Manager for logging.

A GuardPoint is usually associated with a Linux mount point or a Windows volume, but may also be associated with a directory subtree. The CTE Agent sits between applications and the file system that clients files within the GuardPoint. It intercepts every file access request, and enforces the access and encryption rules defined in the GuardPoint's policy.

Figure: CTE Operation

Properties of Data Transformation

For large file sets (hundreds of GBs or more), bulk transformation is time consuming. Managing transformation time is important, because file set content must be frozen (inaccessible to applications) throughout the transformation process. Once transformation starts, it must continue until complete. So transformation time determines the window of data unavailability. Two major components contribute to transformation time:

> Number of Blocks of File Data

Because CTE must read, transform, and rewrite each block of file data, this component can be estimated by multiplying the number of file blocks to be transformed by the average read, transformation, and write time for a block.

> Number of Files

Because the CTE Agent transforms data file by file, each file must be “looked up,” opened, and closed during transformation, using underlying file system mechanisms. This typically requires multiple disk accesses. Therefore, file sets that consist of many small files, per file overhead, can actually exceed file block transformation time.

Other factors, such as file system fragmentation, and load from concurrent applications, may also affect transformation time. Mainly, the number of blocks and number of files to be transformed are fundamental because they cannot be reduced or eliminated.

Data Transformation Techniques

Three methods to initially encrypt and rekey files are:

- > **The Copy/Restore Method:** Using the operating system file copy utility, the client administrator can copy unprotected files to a location protected by a CTE GuardPoint with a standard/production policy.
- > **The CTE Dataxform Utility Method:** Every CTE Agent includes a utility program that can encrypt or transform protected files. The dataxform utility encrypts, rekeys, or decrypts data in-place. Refer to the CTE Data Transformation Guide for details.
- > **The Live Data Transformation (LDT):** The CipherTrust Manager Security Administrators can encrypt or rekey GuardPoint data **without blocking** the user or application access to that data. Refer to the CTE-Live Data Transformation with CipherTrust Manager for details.

These methods have advantages and limitations that make them suitable in different scenarios. These are discussed in the subsequent sections.

Apart from encrypting data, you can reverse the transformation, that is, decrypt the data to plaintext. To **decrypt** protected files, copy them to an *unprotected* location.

NOTE CTE can also be configured to protect data at the disk level. For data protected in this way, only the copy transformation technique is available for encryption.

The Copy Method

Properties of the Copy Method

The copy method performs initial encryption, rekeying, and decryption by copying data from one directory, or GuardPoint, to another directory or GuardPoint.

> Initial Encryption

The client administrator encrypts a file set by copying it to a directory protected by a CTE GuardPoint with a standard policy. Encryption is transparent to the copy utility.

Figure: Initial Encryption

> Rekeying Protected Data

Encrypted files protected by a CTE GuardPoint are rekeyed by copying them to a directory protected by another GuardPoint with a different encryption key. Both decryption and re-encryption are transparent to copy utilities.

Figure: Rekeying Protected Data

> Decrypting Data by Copying

Decrypt a protected file set by copying files from their protected location to unprotected directories. The CTE Agent decrypts file blocks before delivery to the copy utility for rewriting.

Figure: Decrypt Data by Copying

CAUTION! If the governing policy does not authorize the copy utility user to access data, CTE delivers encrypted file blocks to it.

Advantages of the Copy Method

> Simplicity

After an Agent is installed and GuardPoints are activated on a client, the client's administrator can encrypt, decrypt, or rekey file sets simply by copying them from one location to another. There are no procedures to learn, and no requirements to coordinate with the CipherTrust Manager Security Administrator. Data transformation is simply another routine administrative task.

> Recoverability

If a copy-based transformation is interrupted, for example, by a power failure or a system crash, the transformation resumes at or prior to the point of interruption. This is because the source files remain available and can be recopied, overwriting files at the destination that may have been only partially re-encrypted.

Limitations of the Copy Method

> Storage Resource Consumption

Copying a file set requires that both source and destination files exist simultaneously. Storage capacity sufficient for both must be available during initial encryption. For very large protected data sets, “extra” temporary storage may be a significant expense. However, a greater concern is likely to be the impact of moving production file sets as they are transformed. File data is unprotected while in the copy utility’s buffers.

> Impact on Operating Procedures

Original and copied file sets have different path names and/or network addresses. After transformation, either both file sets must be renamed (the old path to a new name, and the new path to the old name), or applications must be adapted to process the transformed data set at the new directory. For a small data center with a few protected file sets, some combination of these options is usually practical. For data centers with hundreds of protected file sets, the administrative complexity and consequent chance of error make copying a complex option.

The Restore Method

A variation of the copy method is to make a backup of the files for transformation and restore the backup to the destination location. This works because:

- > Backing up data causes it to be read and decrypted.
- > Restoring data causes it to be written (re-encrypting it with an alternative key).
- > CTE protection is transparent to backup programs.

This technique also creates a backup of the data set. However, a disadvantage is the time required to copy data twice (once from the source location to backup, and once from backup to destination location).

These considerations suggest that copying data to transform it is more suitable for initial encryption (and final decryption), and less so for rekeying. Additionally, the simplicity of recovering an interrupted transformation makes the copy/restore method useful in situations where the probability of interruption during transformation is significant.

The Dataxform Utility Method

The CTE dataxform utility transforms data-in-place and contains two components:

- > User mode that controls the overall operation
- > Kernel mode that transforms files block-by-block

Figure: Offline Rekey

Advantages of the Dataxform Utility

Transforming data in place has two advantages:

> Minimal Storage Requirements

Because dataxform transforms files in place, where they reside, it does not require temporary file storage. However, the utility does need storage in which to create a list of files for transformation.

> Security

The period of time that the data transformed by the dataxform utility appears in memory, outside the GuardPoint and therefore, unprotected, is shorter than with copying. This is significant for rekeying (compared to copying), which holds clear file data in memory between reading and rewriting. Moreover, dataxform requires coordination between the client and CipherTrust Manager Security Administrators, so that no one individual can subvert security during transformation.

Limitations of the Dataxform Utility

Offsetting the advantages of the dataxform utility method is the complexity of recovering from an interrupted dataxform run. Because dataxform transforms files in-place, data in a file undergoing transformation at the time of a failure may be only partly transformed. There is no way to determine which blocks have been transformed and which have not. These files must be recreated after the dataxform runs from a backup copy. The client administrator must:

1. Determine (by examining dataxform logs) which files may have been incompletely transformed.
2. Delete them from the transformed file set.
3. Recreate them by selective copying from a backup.

Live Data Transformation

The CipherTrust Manager security administrators can encrypt or rekey the GuardPoint data without blocking the user or application access to that data.

After enabling GuardPoints, LDT performs initial encryption or rekeying in the background, unnoticed by users. The data stays live and available. This accelerates CTE deployments and eliminates the need to block application and user access to data during encryption or rekey operations, which can seriously inconvenience users and affect operational efficiency.

Phases of LDT runtime operation:

1. Initial data transformation starts or key expires

Live Data Transformation begins when an LDT policy is first applied to a GuardPoint, or when a current key version expires. The CipherTrust Manager pushes the new policy, or the notification of a key version change, to the clients that are protected by those policies.

2. New key version triggers a rekey on the affected GuardPoints

On each client, CTE determines which GuardPoints are using the key that has just rotated to a new version. CTE starts an LDT rekey on each of those GuardPoints. (If another rekey is already underway on that GuardPoint, the new rekey is rejected).

3. Scan for files

On each GuardPoint where CTE has started a rekey, LDT determines which files to transform. LDT takes inventory of files encrypted with earlier versions of the rotated key and makes a persistent list of the files for transformation. During this phase, the rekey status of the GuardPoint becomes starting, then scanning.

The scan phase might be interrupted, such as by a client reboot. In this case, when the client reboots and the GuardPoint is enabled again, the scan operation starts over from the beginning.

4. Rekey/Key Rotation

a. Each file, from the persistent list of files, is decrypted using the old version of the key. The old key is applied to each file and then re-encrypted using the new version of the key. Note that new files created during the LDT process do not need to be rekeyed, as they inherit the new version of the key. Multiple files and multiple regions of files are rekeyed simultaneously.

b. The LDT extended attribute of each file is updated.

c. The LDT rekey operation can be suspended and resumed manually, or through the QoS schedule.

This manages the impact LDT has on other applications and processes. During this phase, the rekey status of the GuardPoint is rekeying or suspended.

If system errors occur during rekeying, such as IO errors or crashes, LDT can manage and recover from them after the system error is fixed.

5. Finish

When all of the required files in the GuardPoint have been rekeyed, the system and storage resources used by LDT are released, except for the storage required for the extended attributes. Upon completion of rekey, the rekey status of the GuardPoint is rekeyed.

Summary

The following table summarizes the strengths and weaknesses of the two file set transformation methods.

Factor	Copy Method	The dataxform Utility Method	Live Data Transformation
Temporary storage required	Equal to size of file set.	Sufficient to hold a list of path names of files in file set.	Additional space is required to store LDT metadata only.

Factor	Copy Method	The dataxform Utility Method	Live Data Transformation
Security	File data is unprotected while in copy utility's buffers.	File data is never outside the CTE GuardPoint.	File data is never outside the CTE GuardPoint.
Initial encryption	Files can be copied directly from source directory to a CTE-protected directory.	Files must be in a protected location before transformation.	Files must be in a protected location before transformation.
Operational impact	No access to files during transformation. Path names or operating procedures must be adjusted after transformation.	No access to files during transformation. No other impact on operating procedures.	Encryption and rekeying of the data takes place in the background, without disrupting user or application access.
Recoverability	Restart copy operation at, or prior to, point of failure.	Files undergoing transformation at the point of failure must be discovered from dataxform logs and restored from backup.	Transformation process automatically restarts from the point of failure.

Protection Policies

The basic unit of CTE data protection policy application is the GuardPoint. GuardPoints are typically associated with file system mount points, but may also be associated with directory sub-trees.

NOTE Nested mount points within a directory, or mount points protected by a GuardPoint, are also protected in Linux environments.

Figure: CTE GuardPoints

All files in the directory hierarchy, below a GuardPoint, are subject to the GuardPoint's policy, which consists of rules that specify:

- > **Protected files:** Filenames or filename patterns (example: *.dat) to which the policy applies.
- > **Authorized users:** User(s) group(s), and application(s) permitted to access the protected files.
- > **Permissions:** Actions permitted to users (example: create/delete, read/write, rename, decrypt).

Policies also specify the name of an encryption algorithm and a key for encrypting protected files. For example, a policy might specify that all Excel workbooks protected by a GuardPoint be encrypted using an AES256 key called EXCEL KEY. Additionally, only users in group 128 have access to the files. All other files that are not encrypted, are freely accessible to all users.

Types of Policies

CTE Agents use two types of policies:

> Initial Data Transformation

Dataxform policies contain the elements listed above, plus a data transformation key, used by the dataxform utility to rekey file data. Transformation policies contain strict access control rules that prevent application and user access to files during transformation. CTE only uses dataxform policies for the initial transformation. Afterwards, you replace it with a production policy.

Dataxform operates on a per-GuardPoint basis. For initial encryption, the dataxform policy specifies a clear production key (meaning that the utility does not decrypt data because the data is unencrypted) and a new data transformation key to encrypt the data.

> Production/Standard

Production policies contain the elements listed above. They protect data within GuardPoint(s) during day-to-day IT operations.

For decryption, the policy specifies a clear data transformation key (that is, the utility does not re-encrypt files as it rewrites them) and the current production key.

A rekeying transformation policy specifies both a current production ("old") key and a transformation ("new") key.

CHAPTER 5: Managing Profiles

A profile contains the CipherTrust Manager logging criteria for CTE clients, Syslog server configuration, default logging level, LDT Quality of Service (QoS) settings, and other settings that can be used for several CTE clients.

A default profile, `DefaultClientProfile`, is created automatically when either of the following happens:

- > On successful registration of the *first* client if no profile is specified during registration.
- > On creation of the *first* client group. A new client group is automatically linked to `DefaultClientProfile`.

When registering a CTE client, the installer prompts to specify a profile for the client. If not specified, `DefaultClientProfile` is automatically linked to the client on successful registration. The linked profile can be modified later. It is recommended to not delete or modify `DefaultClientProfile`.

This section covers the following information:

- > ["Creating a Profile" below](#)
- > ["Setting Client Log Configuration" on the next page](#)
- > ["Setting Client Syslog Configuration" on page 48](#)
- > ["Setting Quality of Service Configuration" on page 50](#)
- > ["Concise Logging" on page 52](#)
- > ["Modifying Profiles" on page 53](#)
- > ["Deleting Profiles" on page 54](#)

Creating a Profile

To create a profile:

1. Open the **CTE** application.
2. In the left pane, click **Profiles**.
3. Click **Create Profile**.
4. Specify a unique **Name** for the profile. This is a mandatory field.
5. Provide a **Description** for the profile.
6. Click **Create**.

The newly created profile appears in the profiles list.

After you have created a profile, you can define client logging criteria, Syslog configurations, and QoS configurations. These configurations apply to the clients linked to this profile. Refer to the subsequent sections for details.

Setting Client Log Configuration

Client log configuration includes basic information such as the level of logs to capture, whether to enable the Syslog server, settings to upload logs to the CipherTrust Manager, and settings to store logs on clients.

To define client log configurations for a profile:

1. Open the **CTE** application.
2. In the left pane, click **Profiles**.
3. Under **Name**, click the desired profile. The edit view of the profile is displayed. Profile settings are divided into three categories, as shown below:

4. Click **CLIENT LOGGING CONFIGURATION** to expand it. The client log configuration settings are categorized into basic, log upload to key manager, and log to the file on the clients.

Basic Log Settings

Log Level: INFO

Duplicates: SUPPRESS

Threshold: 5

Suppress Interval (sec): 600

☐ Enable Concise Logging

☐ Syslog Enabled

☐ Log Upload to Key Manager

Upload Log Level: INFO

Connection Timeout (sec): 50

☐ Drop if Busy

Upload Timeout (sec) 1-900: 600

Max Interval (sec) 1-1000: 20

Min Interval (sec) 1-30: 10

Message Upload Range (100-1000): 1000

☐ Allow Purge

Cache Settings

Max Files: 200

Max Space (MB): 100

Basic Log Settings

5. Specify the basic settings:

Field	Description
Log Level	Level of logs to generate. It defines the detail and extent of information to be logged by the linked agents. In sequence, the options are: > DEBUG: Fine-grained informational events that are targeted towards support engineers and developers. > INFO: Informational messages that highlight the progress of the application at coarse-grained level. > WARN: Potentially harmful situations. > ERROR: Error events that might still allow the application to continue running. This is the default log level. > FATAL: Severe error events that will presumably lead the application to abort. Log levels are cumulative. The level that you select not only generates log entries for events that occur at that level, but all the levels below. For example, the WARN level also includes events that occur on the ERROR and FATAL levels.
Duplicates	Treatment for duplicate logs. The options are: > SUPPRESS: Messages follow the configured Threshold as to how many times duplicate messages are sent to the CipherTrust Manager during the given Interval. > ALLOW: All duplicate messages are captured and displayed in the log.

Field	Description
Threshold	(Used when the Duplicates field is set to <code>SUPPRESS</code> .) Maximum number of duplicate messages the CTE Agent can send to the CipherTrust Manager within the time specified by <code>Suppress Interval</code> (see below). The default value is 5 messages.
Suppress Interval (sec)	(Used when the Duplicates field is set to <code>SUPPRESS</code> .) Time in which the number of duplicate messages, specified by <code>Threshold</code> , can be uploaded to the CipherTrust Manager. When <code>Suppress Interval</code> exceeds, the count specified by <code>Threshold</code> starts again. The default interval is 600 seconds (10 minutes).
Enable Concise Logging	Whether to enable Concise Logging for the linked clients. Select to enable, clear to disable. By default, Concise Logging is disabled. When enabled, a reduced number of audit log messages are captured. Refer to "Concise Logging" on page 52 for details.
Syslog Enabled	Whether the Syslog server is enabled. Select to enable, clear to disable. When you select Syslog Enabled, make sure that client Syslog configurations are defined. Refer to "Setting Client Syslog Configuration" on page 48 for details. When the Syslog server is disabled, the logs are sent to the client messages file such as <code>/var/adm/messages</code> . On a Windows client, the messages are sent to the Event Viewer (Application events).

Log Upload Settings

6. Configure settings to upload logs to the CipherTrust Manager:

Field	Description
Log Upload to Key Manager	Whether to enable log upload to the CipherTrust Manager. Select to enable, clear to disable. When this option is selected, you can configure the settings listed below. The logs are displayed under the Client Records page of the CipherTrust Manager GUI.

Field	Description
Upload Log Level	Level of logs to upload. In sequence, the options are: > DEBUG: Fine-grained informational events that are targeted towards support engineers and developers. > INFO: Informational messages that highlight the progress of the application at coarse-grained level. > WARN: Potentially harmful situations. > ERROR: Error events that might still allow the application to continue running. This is the default log level. > FATAL: Severe error events that will presumably lead the application to abort. Log levels are cumulative. The level that you select not only generates log entries for events that occur at that level, but all the levels below. For example, the WARN level also includes events that occur on the ERROR and FATAL levels.
Connection Timeout (sec)	Interval after which the connection attempt to the key manager expires. The default value is 59 seconds.
Drop if Busy	Whether to slow log generation and drop log files during periods of extreme logging (that is, when the server is busy). Select to drop, clear to keep trying. This setting is clear by default.
Upload Timeout (sec) 1-900	Interval after which the log upload attempt expires. The default period is 600 seconds (10 minutes).
Max Interval (sec) 1-1000	Maximum interval to wait before the CTE Agent can upload messages to the CipherTrust Manager. Use this option to update the log viewer even when the Message Upload Range has not been reached. Lower the interval if there is little CTE Agent activity. The default maximum interval is 20 seconds.
Min Interval (sec) 1-30	Minimum interval to wait before the CTE Agent can upload messages to the CipherTrust Manager. Increase the interval if there is considerable CTE Agent activity, so the agents do not flood the network with log messages. The minimum interval is 10 seconds.
Message Upload Range (100-1000)	Maximum number of logs to upload at one time. When the specified number of logs is reached, they are uploaded to the CipherTrust Manager. The default number is 1000.
Cache Settings	Settings to cache logs. The options are: > Max Files: Maximum number of log files to cache. The default number is 200. > Max Space (MB): Maximum log size to cache. The default value is 100 MB.

Log to File Settings

7. Configure settings to gather logs in files on clients:

Field	Description
Log to File	Whether to write logs to files on clients. This option is selected by default. This means that, by default, the logs are written to files on clients. The logs are sent to the <code>/var/log/vormetric/vorvmd_root.log</code> file of a UNIX client, or a Windows equivalent, such as <code>\Documents and Settings\All Users or WINDOWS\Application\Data\Vormetric\DataSecurityExpert\agent\log\vorvmd.log</code>. When the Log to File option is selected, you can configure the settings listed below.
File Log Level	Level of logs to capture in the log file. In sequence, the options are: > DEBUG: Fine-grained informational events that are targeted towards support engineers and developers. > INFO: Informational messages that highlight the progress of the application at coarse-grained level. > WARN: Potentially harmful situations. > ERROR: Error events that might still allow the application to continue running. This is the default log level. > FATAL: Severe error events that will presumably lead the application to abort. Log levels are cumulative. The level that you select not only generates log entries for events that occur at that level, but all the levels below. For example, the WARN level also includes events that occur on the ERROR and FATAL levels.
Max File Size (1-1000 MB)	Maximum size of a log file. The CTE Agent starts a new, empty log file when the specified limit is exceeded. The default maximum file size is 1000 MB.
Max Old Files (1-100)	The maximum number of old log files to keep. The default number is 100.
Allow Purge	Whether to allow purging the old log files. Select to allow purge, clear to disallow. This option works in conjunction with the Max Old Files option (see above). For example, set Max Old Files to 3 and select the Allow Purge check box. After 3 log files are generated, the first log file, log1, is deleted and a new log file, log4, is created. If Allow Purge check box is clear, log files continue to accumulate in the server database and you have to remove them manually.

8. Click **Apply**.

The changes are effective immediately and apply to the clients linked with the profile.

The CTE client logs can be seen on the **Keys & Access Management > Records > Client Records** page of the CipherTrust Manager GUI. Filter the records by **Client Type** and look for the **CTE** records, as shown below.

Client	Client Type	Timestamp	Severity	Event	Details
3.34.30.9	CTE	Aug 31st 2020 - 13:04:08	ERROR	BadGridPath NotFound	<pre>{ "log": "CGA", "uid": "CGA37348", "pid": 1013, "args": [["op": "/Non-Existent-Path"]], "message": "Not guarding path [/Non-Existent-Path] (Reason: Does not exist)", "version": "3.0.0.38", "filename": "SecFS_upload_3.04.05.9.343", "hostname": "3.04.30.9", "client_id": "70c511e-29c2-4f66-8b5d-0072aee5f585" }</pre>

Refer to the "Records" section in the CipherTrust Manager Administrator Guide for details.

Setting Client Syslog Configuration

When you have Syslog servers up and running in your environment, you can redirect your client logs to them. A CipherTrust Manager administrator can configure profiles to redirect client logs to Syslog servers.

To configure Syslog settings in a profile:

1. Open the **CTE** application.
2. In the left pane, click **Profiles**.
3. Under **Name**, click the desired profile.
4. Expand **CLIENT SYSLOG CONFIGURATION**.

Show Additional Servers

5. Specify the following details:

NOTE

- > You can configure up to four servers, labeled as **Server 1**, **Server 2**, **Server 3**, and **Server 4**. By default, Server 1 and Server 2 are visible. To view Server 3 and Server 4, click **Show Additional Servers**.
- > This document describes steps to configure one server, Server 1. Extend the steps to suit your setup requirements.

Field	Description
Log Level	Level of logs to redirect. In sequence, the options are: > DEBUG: Fine-grained informational events that are targeted towards support engineers and developers. > INFO: Informational messages that highlight the progress of the application at coarse-grained level. > WARN: Potentially harmful situations. > ERROR: Error events that might still allow the application to continue running. This is the default log level. > FATAL: Severe error events that will presumably lead the application to abort. Log levels are cumulative. The level that you select not only generates log entries for events that occur at that level, but all the levels below. For example, the WARN level also includes events that occur on the ERROR and FATAL levels.
Local	Whether logs are sent to the client. If selected, the logs are saved on the client at <code>/var/log/messages</code> . By default, the option is clear.
Server 1	
Hostname or IP	Hostname or IP address of the Syslog server.
Port	Port of the Syslog server.
Message Format	Format in which the log messages are transferred to the Syslog server. The options are: > Plain Message > CEF > RFC5424 > LEEF The default log format is RFC5424. This format adheres to the Syslog Protocol RFC 5424 guidelines.

Field	Description
Protocol	Transport protocol for the Syslog connection. The options are UDP, TCP, and TLS. The default protocol is TCP. When you select TLS, the following fields appear: > CA Certificate: Click Browse to select the CA certificate. > Certificate: Click Browse to select the certificate. > Private Key: Click Browse to select the private key.

6. Click **Apply**.

The Syslog server settings are configured.

Setting Quality of Service Configuration

The QoS configuration settings apply to clients that have the LDT feature enabled on them. Administrators use these settings to maintain operational efficiencies in their systems in conjunction with LDT operations. They can specify percentage of CPU usage or a rekey rate and schedules for LDT operations. Refer to the CTE-Live Data Transformation with CipherTrust Manager for best practices about using LDT and QoS.

A CipherTrust Manager administrator can configure LDT QoS on the CipherTrust Manager.

To configure LDT QoS settings in a profile:

1. Open the **CTE** application.
2. In the left pane, click **Profiles**.
3. Under **Name**, click the desired profile.
4. Expand **QUALITY OF SERVICE CONFIGURATION**.

5. Specify the rekey option. The options are:

- **Rekey by Rate:** Select to rekey by rate (in MB/s). This is the default setting. Specify the **LDT QoS Rekey Rate**. The default value is 0.

- **Rekey by CPU:** Select to rekey by CPU usage. By default, LDT operations use all of the available CPU memory.

Optionally, you can reserve percentage of the clients' CPU for LDT rekey operations. To do so:

- Select **Cap CPU Allocation**. The **CPU Percentage** field becomes editable.
- Enter the **CPU Percentage**. The value must be greater than 0.

- Specify a QoS schedule to run LDT. Under **QoS Schedules**, select an **LDT QoS Schedule**. The options are:

Name	Time Ranges	Description
ANYTIME	Sunday 12:00 AM - Saturday 11:59 PM	LDT runs any day at any time of the week
WEEKNIGHTS	Monday 12:00 AM - Monday 07:00 AM Monday 09:00 PM - Tuesday 07:00 AM Tuesday 09:00 PM - Wednesday 07:00 AM Wednesday 09:00 PM - Thursday 07:00 AM Thursday 09:00 PM - Friday 07:00 AM Friday 09:00 PM - Friday 11:59 PM	LDT runs between midnight to 7:00 AM from Monday to Friday
WEEKENDS	Sunday 12:00 AM - Monday 07:00 AM Friday 09:00 PM - Saturday 11:59 PM	LDT runs between 9:00 PM Friday to 7:00 AM on Monday
CUSTOM	<Custom Range>	LDT runs at a custom schedule (described below)

Creating a Custom LDT Schedule

To create a custom LDT schedule:

- Select **CUSTOM** from the **LDT QoS Schedule** drop-down list. Now, the **Create New QoS Schedule** button is available.

The screenshot shows the 'QoS Schedules' configuration area. Under the 'LDT QoS Schedule' dropdown, 'CUSTOM' is selected. A blue button 'Create New QoS Schedule' is visible. Below this, there are two input fields: 'Name' and 'Time Ranges'.

- Click **Create New QoS Schedule**. The Create QoS Schedule dialog box is displayed.

The screenshot shows a 'Create QoS Schedule' dialog box. It has a title bar with a close button (X). Inside, there are four input fields arranged in a 2x2 grid. The top row contains 'Starting Day:' with a dropdown menu showing 'Monday' and 'Ending Day:' with a dropdown menu showing 'Monday'. The bottom row contains 'Starting Time:' with three input fields (1, :, 00) and a dropdown menu (A...), and 'Ending Time:' with three input fields (2, :, 00) and a dropdown menu (A...).

- i. Select the **Starting Day**. The LDT process will start on this day of the week. The default starting day is Monday.
 - ii. Specify the **Starting Time** in the HH:MM AM/PM format. Use the arrows to select time in hours (1 to 11) and minutes (00 to 59). Select **AM** or **PM** from the drop-down list. The default starting time is 1:00 AM.
 - iii. Select the **Ending Day**. The LDT process will end on this day of the week. The default ending day is Monday.
 - iv. Specify the **Ending Time** in the HH:MM AM/PM format. The default ending time is 2:00 AM.
- c. Click **Create**. The custom LDT QoS schedule is displayed on the screen. The specified Time Ranges are also displayed.

The screenshot shows the 'QoS Schedules' section. At the top, there's a label 'QoS Schedules'. Below it, on the left, is 'LDT QoS Schedule:' with a dropdown menu showing 'CUSTOM'. To the right is a blue button labeled 'Create New QoS Schedule'. Below these is a table with two columns: 'Name' and 'Time Ranges'. The table has one row with 'CUSTOM' in the 'Name' column and 'Monday 1:00 AM - Friday 5:00 AM' in the 'Time Ranges' column. There is a three-dot menu icon to the right of the table row.

7. Click **Apply**. The configuration is saved successfully.

NOTE

- > To create a new custom schedule, click **Create New QoS Schedule**.
- > To delete a custom schedule, click **Delete** corresponding to the schedule you want to delete.

Concise Logging

CTE's standard operational logging sends audit messages for every file system operation. An audit message is sent every time a file is opened, read, updated, or written. Standard logging can generate high volumes of log data. Security administrators might not need most of these logs to monitor file system activities on the protected clients.

A CipherTrust Manager administrator can enable or disable Concise Logging for a profile. After Concise Logging is enabled or disabled, CTE Agent generates a log message to record that event:

```
"[CGA] [INFO] [CGA3201I] [08/07/2020 10:57:18] Concise logging enabled"
```

```
"[CGA] [INFO] [CGA3202I] [08/07/2020 10:57:27] Concise logging disabled"
```

Advantages

Concise Logging:

- > Helps security administrators to focus on relevant audit messages and important actionable messages such as errors and warnings.
- > Can eliminate repetitive and unimportant audit messages generated by read and write activities on a file, read and write directory attributes, and other file system activities.
- > Eliminates audit messages:
 - For each block read by a user or an application. Only one audit message is sent for every read/write activity.
 - That read the attributes, basic information of file set attributes, and other event-based messages.
 - For directory open, read directory attributes, and directory close.

Considerations

Concise Logging:

- > Changes the set of messages that are sent to Security Information and Event Management (SIEM) software systems. If this results in loss of data required for customer reports, then disable Concise Logging.
- > Applies to all GuardPoints and for all users of the clients linked with a profile. There is no fine-grained control such as per GuardPoint, user, or message type.
- > Applies to the existing clients and the new clients to be linked with the profile subsequently.
- > Is supported by CTE secfs only.
- > Should not be used with Learn Mode.

Modifying Profiles

To modify a profile:

1. Open the **CTE** application.
2. In the left pane, click **Profiles**.
3. Under **Name**, click the desired profile.
Alternatively, click the overflow icon () corresponding to the desired profile and click **Edit**.
4. Expand **CLIENT LOGGING CONFIGURATION**.
 - a. Modify the settings, as appropriate. Refer to ["Setting Client Log Configuration" on page 43](#) for details.
 - b. Click **Apply**.
5. Expand **CLIENT SYSLOG CONFIGURATION**.
 - a. Modify the settings, as appropriate. Refer to ["Setting Client Syslog Configuration" on page 48](#) for details.
 - b. Click **Apply**.
6. Expand **QUALITY OF SERVICE CONFIGURATION**.
 - a. Modify the settings, as appropriate. Refer to ["Managing Profiles" on page 42](#) for details.

- b.** Click **Apply**.

The profile settings are updated.

Deleting Profiles

Single or multiple profiles can be deleted from the CipherTrust Manager GUI in one go. Before deleting a profile make sure that no clients or client groups are linked to it.

Deleting Individual Profiles

To delete a profile:

1. Open the **CTE** application.
2. In the left pane, click **Profiles**.
3. Click the overflow icon () corresponding to the desired profile.
Alternatively, select the desired profile and click the delete icon ().
4. Click **Delete**.

The selected profile is removed from the profiles list.

Deleting Multiple Profiles

To delete multiple profiles:

1. Open the **CTE** application.
2. In the left pane, click **Profiles**.
3. Select the check boxes corresponding the desired profiles.
To select all profiles visible on the page for deletion, select the top check box to the left of the Name heading.
4. Click the delete icon (). A dialog box appears prompting to confirm the action.
5. Click **Delete**.

CHAPTER 6: Managing Clients and Client Groups

A client is a computer system where the data needs to be protected. A compatible CTE Agent software is installed on the client. The CTE Agent can protect data on the client or devices connected to it. A client can be associated with multiple GuardPoints for encryption of various paths (refer to ["Managing GuardPoints" on page 135](#) for details).

The Clients page of the CipherTrust Manager GUI displays all clients protected by encryption Agents. CipherTrust Manager Administrators can manage clients on this page.

NOTE Before proceeding, make sure that:

- > A compatible CTE Agent is installed on the client.
- > The client is registered with CipherTrust Manager.

Refer to the CTE Agent Quick Start Guide specific to your platform for information on installing and configuring CTE Agents.

This chapter covers the following sections:

- > ["Registering Clients" below](#)
- > ["Searching Clients" on the next page](#)
- > ["Viewing Clients" on the next page](#)
- > ["Enabling Live Data Transformation" on page 57](#)
- > ["Setting Client Locks" on page 59](#)
- > ["Client Settings" on page 65](#)
- > ["Modifying Client Configuration" on page 71](#)
- > ["Changing Client Password" on page 72](#)
- > ["Managing Membership" on page 74](#)
- > ["Deleting Clients" on page 75](#)
- > ["Configuring Client Groups" on page 77](#)

Registering Clients

When CTE clients are registered, they are added to the CipherTrust Manager GUI. Refer to the CTE Agent Quick Start Guide specific to your platform for information on installing and configuring CTE Agents.

NOTE Before proceeding, you must change the client password using the manual password creation method. Refer to ["Changing Client Password" on page 72](#) for details.

Searching Clients

The Clients page on the CipherTrust Manager GUI shows the list of registered clients.

To search for a registered client:

1. Log on to the CipherTrust Manager GUI as administrator.
2. Open the **CTE** application. The Clients page is displayed. This page lists the clients added to this CipherTrust Manager appliance.
3. In the **Search** box, enter the client name. Search is case-insensitive. You can enter all or part of a client name. A partial client name displays every client with a name that contains the specified string.

Viewing Clients

The Clients page shows the total number of clients, clients with errors, clients with warnings, healthy clients, unregistered clients. The Status Bar contains the following tabs:

- > **<N> Total Clients:** Shows the total number of registered and unregistered clients with all types of health status.
- > **<N> Errors:** Shows the number of clients with errors.
- > **<N> Warnings:** Shows the number of clients with warnings.
- > **<N> Healthy:** Shows the number of healthy clients.
- > **<N> Unregistered:** Shows the number of unregistered clients.
- > **<N> Expunged:** Shows the number of expunged clients.

Click each tab to filter the clients. The clients list displays names of clients in the CipherTrust Manager database and details about their configuration.

To view the clients registered with a CipherTrust Manager:

1. Open the **CTE** application.
2. Click **Clients > Clients**. The clients list shows the following details:

	Status	Client Name ↑	OS Type	Kernel Version	Agent Version	Description	⚙
+	☐  Healthy	P_1	LINUX	3.10.0-957.el7.x86_64	7.0.0.34	TestHost	⋮
+	☐  Healthy	P_10	LINUX	3.10.0-957.el7.x86_64	7.0.0.34	TestHost	⋮
+	☐  Healthy	P_11	LINUX	3.10.0-957.el7.x86_64	7.0.0.34	TestHost	⋮
+	☐  Healthy	P_12	LINUX	3.10.0-957.el7.x86_64	7.0.0.34	TestHost	⋮

Column	Description
Status	Health status of the client: > Healthy > Error > Warning > Unregistered > Expunged When a registered client is uninstalled, its status on the Clients page becomes Unregistered. The status of a deleted client becomes Expunged.
Client Name	Name link of the client on CipherTrust Manager.
OS Type	OS running on the client: > AIX > Linux > Windows
Kernel Version	Version of the kernel installed on the client. For Windows clients, NA is displayed.
Agent Version	Version of the CTE Agent installed on the client.
Description	(Optional) Description to identify the client.

Enabling Live Data Transformation

The Live Data Transformation (LDT) feature enables the CipherTrust Manager Security Administrators to encrypt or rekey GuardPoint data without blocking the user or application access to that data.

In standard CTE deployments, data access is blocked during the initial encryption or rekeying of the data, and each rekey operation requires guarding your data under separate production and offline data transformation policies. With LDT, encryption and rekeying of the data takes place in the background using one policy, without disrupting user or application access.

Prerequisites

To use LDT, you must have the following:

- > CTE Agent license. The feature is called TransparentEncryption on the Licensing page.
- > CTE LDT add-on license. The feature is called LiveDataTransformation on the Licensing page.
- > CTE Agent installed on a client. Refer to the CTE Clients Guide for information about installing and registering CTE clients.

Refer to the CTE LDT Guide and the CipherTrust Manager Compatibility Matrix for information about implementing LDT and the supported platforms.

Important Notes

- > If the CipherTrust Manager fails, all keys that were automatically rotated after the last backup would be lost, making all data encrypted with those keys unusable or unrecoverable. Therefore, it is recommended that the LDT feature is used in a high availability CipherTrust Manager deployment.
- > If LDT must be used in a single CipherTrust Manager configuration, it is recommended to:
 - Set "Persistent on Client" to "Yes" for all keys that are created.
 - Set the password creation method to "Manual" for all clients.
- > If the standalone CipherTrust Manager fails or is unavailable, the data on the client can still be accessed by entering the known passphrase. The data is accessible as the encryption keys are cached on the client.

Enable LDT

Enable the LDT support for a client either during registration or after registration with the CipherTrust Manager.

- > If LDT is enabled during registration, the Live Data Transformation check box appears selected by default on the CipherTrust Manager GUI.
- > If LDT is not enabled during registration, you can enable it on the CipherTrust Manager GUI, as described below.

To enable LDT on a client after CTE installation:

1. Open the **CTE** application.
2. Click **Clients > Clients**.
3. Under **Client Name**, click the desired client.
4. In the mini detail view, select **Live Data Transformation**.

By default, LDT performs rekey operations on the LDT protected GuardPoints as soon as GuardPoints are enabled. To pause LDT rekey operations, click the Suspend Live Data Transformation icon (■). The icon changes to Resume Live Data Transformation (■).

5. Click **Apply.** LDT is now enabled on the client.

After LDT has been enabled, it cannot be disabled. To remove the feature, you must migrate existing data protected under LDT policies, unregister the client, and delete the client. Then, you can reregister the client without enabling the feature. This allows you reclaim the license for use on another client.

Refer to ["Managing GuardPoints" on page 135](#) for details on creating LDT GuardPoints. For details about how LDT works, guidelines, and best practices for using the feature, refer to the CTE-Live Data Transformation with CipherTrust Manager.

Setting Client Locks

Agent Lock and System Lock are used to protect the CTE Agent and certain system files. CTE Agent protection includes preventing:

- > Certain changes to the CTE Agent installation directory.
- > Unauthorized termination of the CTE Agent processes.

These locks can be applied to individual clients or client groups. By default, the Agent Lock and System Lock are disabled.

NOTE Uninstallation of the Agent software might fail when the Agent Lock and System Lock are enabled. It is recommended to disable the:

- > Agent Lock before uninstalling the Agent software on the client system.
- > Agent Lock before deleting the client records from the CipherTrust Manager GUI.
- > System Lock before updating, deleting, or modifying the protected system files.

This section covers the following information:

- > ["Agent Lock" on the next page](#)
- > ["System Lock" on page 61](#)
- > ["Setting Locks on Individual Clients" on page 62](#)
- > ["Setting Locks on a Client Group" on page 63](#)
- > ["Verifying Locks on Clients" on page 63](#)
- > ["Unlocking Clients Manually" on page 64](#)
- > ["Disabling Locks" on page 64](#)
- > ["Administering Locking Issues" on page 65](#)

Agent Lock

Agent Lock locks the contents of the CTE Agent directories on the client. These directories are `/<install root>/agent/secfs` and `/<install root>/agent/vmd`.

Files in these directories cannot be modified or removed when Agent Lock is enabled; however, the CipherTrust Manager can still propagate updates to the client system.

When Agent Lock is Disabled

- > CTE Agent software on the client is not protected

NOTE Do not unregister or delete the CTE Agent while locks are applied. The locks stay in effect after the Agent is unregistered, and without Agent credentials, the CipherTrust Manager can neither administer that Agent nor disable the locks. You must boot the client into single-user mode and manually modify the Agent configuration to disable the locks.

When Agent Lock is Enabled

- > Certificates are exchanged and the client is bound to the CipherTrust Manager
- > CTE Agent installation directory cannot be deleted or overwritten
- > CTE Agent services cannot be stopped
- > CTE Agent GuardPoints cannot be forcefully unmounted
- > On Linux systems:
 - All operations are permitted on the following directory:

```
/<install root>/agent/secfs/tmp
```
 - Following directories cannot be removed or renamed, and directory and file creation will fail.

```
/<install root>/agent/secfs/bin
/<install root>/agent/vmd
```
 - File creations and other operations will work for the following directory, but the directory cannot be removed or renamed.

```
/<install root>/agent/secfs/
```
- > On AIX systems:
 - Contents of the following directories cannot be changed or moved.

```
/<install root>/agent/vmd
```
 - Contents of the following files and directories can be modified, but not removed or renamed.

```
/<install root>/agent/secfs/
/<install root>/agent/secfs/tmp
```
- > On Windows systems:
 - Following folder cannot be moved and its contents cannot be modified.

```
C:\Program Files\Vormetric\DataSecurityExpert\Agent\secfs\sec
```
 - CTE Agent entries in the registry cannot be modified or deleted.

System Lock

System Lock applies an internal policy to the client to lock client system directories, such as `/var`, `/bin`, and `/etc`.

NOTE System Lock must be disabled before upgrading or installing third-party software, adding new applications, opening SSH sessions remotely, or modifying system directories.

NOTE (Windows only) Verify that the volume letter and the path for the Windows system are correct before proceeding. When the CTE Agent is installed, the volume letter defaults to "C:". The executables on the Client Settings tab may be on a different volume or in a different folder. If the volume or path information is incorrect, the CipherTrust Manager cannot sign the applications and apply Agent Lock and System Lock.

When System Lock is Disabled

- > The internal policy is disabled.
- > You can install or update system software.

When System Lock is Enabled

- > Agent Lock is automatically enabled.
- > Operating system directories on the client are protected.
- > Microsoft Update cannot be run on Windows systems to protect the client. Microsoft update and other installation-related executables are specifically blocked. Executables like `wuacult.exe` and `msiexec.exe` cannot be run.
- > The installation utility checks if System Lock is enabled on the client system. If it is, the utility aborts installation and displays a message telling you to "unlock system before running install/update program". Other third-party installation utilities do not check if System Lock is enabled and are not prevented from installing software.
- > New file or directory creation inside a protected directory is not allowed.

The following files, directories, and subdirectories are, by default, automatically protected when System Lock is enabled. Asterisks (*) indicate pattern matching.

- > On Linux systems:
 - Following files and the contents of the following directories cannot be changed or moved.
 - `/etc/pam.d`
 - `/etc/rc*`
 - `/etc/security`
 - `/usr/lib/security`
 - Contents of the following files and directories can be modified, but not removed or renamed.
 - `/etc`
 - `/etc/init.d/secfs`

- /usr
- /usr/bin/vmd
- /usr/bin/vmsec
- /usr/bin/secfsd
- /usr/bin/dataxform
- /usr/lib
- /usr/lib/*pam*
- /usr/lib/security
- /var/log/vormetric

> On AIX systems:

- Following files and the contents of the following directories cannot be changed or moved when System Lock is enabled.
 - /etc/rc.d
 - /etc/security
 - /usr/lib/security
 - /sbin/helpers/mount_secfs
- Contents of the following files and directories can be modified, but not removed or renamed when System Lock is enabled.
 - /var/log/vormetric

> On Windows systems:

- Files with the following extensions in the Windows OS installation folder (for instance: \Windows, \WinNT, and so on) cannot be moved or modified:
 - .exe
 - .dll
 - .sys
 - .cmd
 - .com

When System Lock is applied, a protected file or path cannot be renamed or deleted; however, if it is a directory, other files may be added to it. For example, /etc cannot be deleted nor renamed, though you can add files to it. A file that cannot be modified cannot be opened and edited in any way.

Setting Locks on Individual Clients

To apply locks to an individual client:

1. Make sure that no one is currently in or accessing the Agent installation directories; otherwise, the CipherTrust Manager might not lock the Agent software.
2. Open the **CTE** application.
3. Under **Client Name**, click the desired client.

- On the lock bar, click **Agent Lock**. This protects the CTE Agent files from modification and deletion.

- Click **System Lock**. This protects a set of system files from modification and deletion.

Agent Lock is automatically enabled when System Lock is enabled. You can manually enable or disable Agent Lock only when System Lock is disabled.

- Click **Apply**.
- Verify the locks. Refer to ["Verifying Locks on Clients" below](#).

Setting Locks on a Client Group

To apply locks to a client group:

- Make sure that no one is currently in or accessing the Agent installation directories; otherwise, the CipherTrust Manager might not lock the Agent software.
- Open the **CTE** application.
- Click **Clients > Client Groups**.
- Under **Client Group Name**, click the desired client group.
- On the lock bar, click **Agent Lock**. This protects the CTE Agent files from modification and deletion.

- Click **System Lock**. This protects a set of system files from modification and deletion.

Agent Lock is automatically enabled when System Lock is enabled. You can manually enable or disable Agent Lock only when System Lock is disabled.

- Click **Apply**.
- Verify the locks. Refer to ["Verifying Locks on Clients" below](#).

NOTE To disable the locks on a client group, select the client, click **Unlock**, and click **Apply**.

Verifying Locks on Clients

A client administrator can verify that the locks are applied to the Agent on the client.

To verify the locks:

1. Log on to the client system.
2. Run the `secfsd` command with the `lockstat` argument:

```
# secfsd -status lockstat
FS Agent Lock: true
System Lock: true
```

NOTE Sometimes, the CipherTrust Manager reports the CTE Agent configuration different than the actual configuration. This can be because of the delay between log uploads to the CipherTrust Manager, or because a GuardPoint is in use when the lock is applied.

In some cases, when the locks are enabled, the CipherTrust Manager cannot administer the client. In such cases, after changing authentication credentials or removing the certificate fingerprint, the client administrator must unlock the client manually.

Unlocking Clients Manually

Unlocking Linux Clients

To unlock the client manually:

1. Boot the client into single-user mode.
2. Edit the `./secfs/.sec/conf/configuration/secfs_config` file.
3. Set both `coreguard_locked` and `system_locked` to `false`.
4. Save the file.
5. Boot the system into multi-user mode.

You can now administer the client again.

Unlocking Windows Clients

To unlock the client manually:

1. Boot in safe mode.
2. Rename `C:\Windows\system32\drivers\vmgmt.sys` and `.\drivers\vmfiltr.sys` to something else.
3. Boot in regular mode.

You can now administer the client again.

Disabling Locks

To disable the locks on a client or client group, select the client or client group, click **Unlock**, and click **Apply**. The lock bar should look like the following:

Administering Locking Issues

The client administrator must inform the Security Administrator of changes to the system hierarchy.

- > **Example 1:** The client system administrator can request to have the locks temporarily disabled to do administrative functions.
- > **Example 2:** The client system administrator can remove directories and files, then, later when the lock is reapplied, the CipherTrust Manager protects non-existent data.
- > Another common administrative issue pertains to mounted GuardPoints. The client system administrator can remove or unmount an unlocked, non-automounted GuardPoint. The CipherTrust Manager GUI is not aware of this change and does not issue a warning when you reapply the lock to the now non-existent mounted GuardPoint.
- > To recover an unmounted GuardPoint:
 - a. Disable the GuardPoint for the file system on the CipherTrust Manager GUI.
 - b. Mount the file system on the client.
 - c. Enable the GuardPoint for the file system.

Client Settings

Applications such as `su`, `sshd`, and `login` authenticate users' identity by requesting user credentials (user name and password). These are signed applications that identify and authenticate before a child process is executed.

GuardPoints can have an associated policy that restricts access to the data stored in them. For a process to access the data, the user's associated identity must be authorized. This authorization can be done by adding an entry to the Settings field on the Client Settings tab. This entry specifies a program, such as mentioned above, with a keyword that indicates the type of authorization that is applied.

Client settings configured on the CipherTrust Manager are pushed to the clients periodically.

Any changes to the client settings are not automatically signed. Signatures of the newly added processes are compared against the signatures in the existing settings. If they differ, an error message is generated. Refer to ["Re-Sign Settings" on page 70](#) for steps to configure this setting. Refer to the CTE Agent Advanced Configuration and Integration Guide specific to your platform for details about this feature.

Client settings can also be configured at the client group level, see ["Inheritance of Client Group Settings" on page 82](#) for details.

Client Settings for Linux

Specify the authentication mechanisms in place for certain binaries on the client machine.

Default Settings for Linux

```
|authenticator|/usr/sbin/sshd
|authenticator|/usr/sbin/in.rlogind
|authenticator|/bin/login
|authenticator|/usr/bin/gdm-binary
|authenticator|/usr/bin/kdm
|authenticator_euid|/usr/sbin/vsftpd
```

Add, edit, or modify authentication settings as appropriate.

Specify Authentication Settings

To specify authentication settings for the client:

1. Open the **CTE** application.
2. Under **Client Name**, click the desired client.
3. Click the **Client Settings** tab. The Settings text box contains the authentication settings.

Each line has the format:

```
|behavior|/path/to/binary
```

Refer to "[Client Settings Keywords](#)" on page 68 for keywords.

4. In the **Settings** box, specify the authentication mechanism.

NOTE

- > To delete the settings, delete the content and click **Apply**.
- > To edit the settings, modify the content and click **Apply**. When editing the setting strings, follow the format `|privilege|filename`.
- > To cancel any changes, click **Cancel**.

5. Click **Apply**.

Client Settings for Windows

For applications running under `WOW64` that require some form of user authentication, create entries on the Client Settings tab. The `syswow64` paths are created by default when the CTE Agent is installed. `\Windows` is for Windows XP and Windows Itanium operating systems.

In `WOW64`, all file access to `C:\Windows\System32` is redirected to `C:\Windows\syswow64`, and is implemented using the File System. Redirected `syswow64` paths are effective only for 64-bit Windows file agents. This is the path where programs compiled for 32-bits are stored to run on a 64-bit system.

Before proceeding, verify that the volume letter and the path for the Windows system are correct. When the CTE Agent is installed, the volume letter defaults to "C :". It is possible that the executables on the Client Settings tab are on a different volume or in a different folder. If the volume or path information is incorrect, the CipherTrust Manager cannot sign the applications, and it cannot apply Agent Lock and System Lock.

Default Settings for Windows

```
|C:\WINDOWS\system32\winlogon.exe
|lock|C:\WINDOWS\system32\msiexec.exe
|lock|C:\WINDOWS\system32\wuauclt.exe
|lock|C:\WINDOWS\system32\wupdmgr.exe
|lock|C:\Program Files\Vormetric\DataSecurityExpert\Agent\Secfs\sec\bin\vminstall.exe
|exempt|C:\WINDOWS\explorer.exe
|exempt|C:\WINDOWS\regedit.exe
|exempt|C:\WINDOWS\system32\regedt32.exe
|exempt|C:\WINDOWS\system32\svchost.exe
|exempt|C:\WINDOWS\system32\services.exe
|exempt|C:\WINDOWS\system32\smss.exe
```

Add, edit, or modify authentication settings as appropriate.

Specify Authentication Settings

To specify authentication settings for the client:

1. Open the **CTE** application.
2. Click **Clients > Clients**.
3. Under **Client Name**, click the desired client.
4. Click the **Client Settings** tab. The Settings text box contains the authentication settings.

Each line has the format:

```
|behavior|/path/to/binary
```

Refer to "[Client Settings Keywords](#)" on the next page for keywords.

5. In the **Settings** box, specify the authentication mechanism.

NOTE

- > To delete the settings, delete the content and click **Apply**.
- > To edit the settings, modify the content and click **Apply**. When editing the setting strings, follow the format `|privilege|filename`.
- > To cancel any changes, click **Cancel**.

6. Click **Apply**.

Oracle Database in a Guarded NFS Mount on AIX

To locate your Oracle database in a guarded NFS mount:

1. Open the **CTE** application.
2. Under **Client Name**, click the desired client.
3. Click the **Client Settings** tab. The Settings text box contains the authentication settings. Each line has the format:

```
|behavior|/path/to/binary
```

4. In the **Settings** text box, add the following entries:

```
|vfsnumber|<path to>/oracle
```

```
|vfsnumber|<path to>/dbca
```

Example:

```
|vfsnumber|/u01/app/oracle/dbhome_1/bin/oracle
```

```
|vfsnumber|/u01/app/oracle/dbhome_1/bin/dbca
```

5. Click **Apply**.

Client Settings Keywords

The following table lists the keywords that you can enter on the Client Settings tab. These keywords override different authentication requirements:

Keyword	Description
authenticator	(UNIX only) Authenticates based upon the real user ID (<code>ruid</code>) credentials of a process. The indicates that the given binary is trusted to authenticate users. For example, the <code>sshd</code> process on UNIX is a good authenticator . It takes incoming network connections and authenticates the user that attempts to log on to the system. All child processes from this session are trusted as the original user.
authenticator_euid	(UNIX only) Authenticates based upon the effective user ID (<code>euid</code>) credentials of a process. The keyword is used to authenticate the credentials of a <code>setuid</code> process with the <code>euid</code> value rather than the <code>ruid</code> value.
vfsnumber	(AIX [all supported]/Oracle 10gR2) Use when Oracle RMAN backups fail on NFS as a result of not receiving underlying file system identifiers. Apply vfsnumber to the Oracle binaries directory.
realfsid	(AIX [All supported]) Use if the <code>cp</code> operation fails while copying files with extent attributes on guarded Veritas file systems. The failure occurs because the underlying file system identifier is not received.

Keyword	Description
lock	(Windows only) Specifies an application that cannot be executed on the client. An application defined with <code>lock</code> does not go through an internal policy check. The application is not allowed to run at all. A default set of applications is locked on Windows clients to prevent their execution and potential failure during bootup. The same effect can be achieved by configuring the resource and process security rule attributes in a policy. However, certain default applications are automatically locked on the Client Settings tab as a precautionary measure. Those applications must be included in the policy. Sometimes, problems such as installation failure or application lockup occur when installing software on a locked client. In such cases, identify the locked processes, unlock them, and retry installation. The failure goes away. For example: <pre> lock c:\winnt\system32\msiexec.exe</pre>
exempt	(Windows only) When processes or applications are started, the internal policy and regular policies are checked locally or by the CipherTrust Manager. When a policy check is performed and <code>exempt</code> is applied to the process, a six second timeout is imposed on the check. Without <code>exempt</code>, an application can wait indefinitely for a policy access check to complete, as when the CipherTrust Manager is required but is inaccessible. If the check times out because the CipherTrust Manager is unavailable for any reason, access is denied. Exempt client processes are also “exempt” from popup messages that describe the occurrence of access violations. An example of what causes such popups is an application that tries to memory map a file for which it does not have encryption permission (for instance, memory map with no view ability key on Windows). The only reasons to include <code>exempt</code> in the configuration are shorter wait periods and blocked popups.

The following table shows different results you get when using `authenticator` or `authenticator_euid` to verify user identities.

Product	Application	Client Setting	User
Oracle	oracle	authenticator_euid	"oracle"
Oracle	oracle	authenticator	*

* indicates the real `uid` of the user who starts the application. This means that if the policy is configured to check the user ID, a security rule must be generated for every possible user.

NOTE Apply the `|authenticator_euid|` keyword to the `oracle` binary on the Client Settings tab to authenticate the `oracle` user because regardless of who starts the `oracle` process, the `EUID` is always `oracle`.

Configuring Application Authentication Credentials

To configure application authentication credentials:

1. Open the **CTE** application.
2. Click **Clients > Clients**.

3. Under **Client Name**, click the desired client.
4. Click the **Client Settings** tab. The Settings box displays the default set of system applications that may require authentication entries.
5. In the **Settings** box, add, modify, or delete entries to control their access permissions. When you add more processes, you must include the entire path.

NOTE A keyword such as `|authenticator|` must be used in front of a process, otherwise, the entry is ignored by the CipherTrust Manager GUI.

6. Click **Apply**.

Client users currently logged on to the client must log off and log on again to refresh their user authentication credentials. They can verify the change by logging on to the client, accessing a GuardPoint, and checking the user information in the message logs.

Re-Sign Settings

If you add another process to the set of trusted applications on the Client Settings tab, enable the Re-sign Settings toggle. This ensures that the new process is signed and authenticated by the client.

Subsequently, when the client settings are pushed to the CTE Agent, the updated settings are re-signed. The Re-sign Settings toggle is turned off (or reset).

To ensure that new processes are signed and authenticated by the client:

1. Open the **CTE** application.
2. Click **Clients > Clients**.
3. Under **Client Name**, click the desired client.
4. Click the **Client Settings** tab.

5. In the **Settings** box, update settings as appropriate.
6. Turn on the **Re-sign Settings** toggle.

7. Click **Apply**.

Enabling the Re-sign Settings toggle forces a signature update. On subsequent push of the client settings to the CTE Agent, the updated settings are re-signed and the Re-sign Settings toggle is turned off (or reset). If you do not turn on this toggle after adding a new process, the client ignores the newly added process.

Modifying Client Configuration

To modify the client configuration:

1. Open the **CTE** application.
2. Click **Clients > Clients**.
3. Under **Client Name**, click the desired client. The mini detail view of the client is displayed.

Linux Client

Windows Client

Alternatively, click the expand icon (▸) to the left of the desired client in the clients list.

4. Modify the following, as appropriate:
 - **Live Data Transformation:** Enable or disable LDT. By default, any ongoing rekey operations on the LDT GuardPoints on the client are resumed. To disable the setting, click the Suspend Live Data Transformation icon (■). The icon changes to Resume Live Data Transformation (■).
 - **Encryption Key Protection:** Enable or disable protection of encryption keys.
 - **Cloud Object Storage:** (Non-editable, Linux only) Enabled or disabled based on the feature selection during registration. From the GUI, you can neither disable nor enable the Cloud Object Storage feature. To enable or disable it, register the client again and opt or opt out of the Cloud Object Storage feature. Refer to the CTE Agent for Linux Quick Start Guide for details.
 - **Secure Start:** (Non-editable, Windows only) Enabled or disabled based on the installed Agent capability. If the Agent supports the Secure Start feature, then this option is enabled, otherwise, the option is disabled.
 - **Unlock:** Unlock Agent Lock and System Lock.
 - **Agent Lock:** Lock the contents of the CTE Agent directories on the client.
 - **System Lock:** Apply an internal policy to the client to lock client system directories, like /var, /bin, /etc. Enabling System Lock automatically enables Agent Lock.

- **Communication Enabled:** Whether to enable the client's communication with the CipherTrust Manager. Select to enable, clear to disable communication. By default, the communication is enabled.
- **Password Creation Method:** Set the password creation method—Manual or Generate. Refer to ["Changing Client Password" below](#) for details.
- **Client Profile:** Select a profile for the client. The default profile is DefaultClientProfile. If you did not specify a profile during registration, the client is linked with default profile. To change the client profile, refer to ["Changing the Profile" below](#) for details.

5. Click **Apply**.

Changing the Profile

To change the client profile:

1. Open the **CTE** application.
2. Under **Client Name**, click the desired client.
3. Next to **Client Profile**, click the profile link (for example, DefaultClientProfile). The Select Profile dialog box shows the current client profile and Rekey Option, Rekey Rate, and Schedule of the selected profile.

Profile	
DefaultClientProfile	
Rekey Option:	RekeyRate
Rekey Rate:	0
Schedule:	ANY_TIME

4. From the **Profile** drop-down list, select the desired profile.
5. Click **OK**. The selected profile is linked successfully.

Changing Client Password

Offline Password

CTE supports the offline password feature. This feature is designed to protect the data on a laptop or similar portable system from being accessed by unauthorized users. When the CTE Agent is unreachable from the CipherTrust Manager, then you must provide the offline password to decrypt/encrypt files that are encrypted with an offline key (cached or persistent on client).

The offline password feature controls access to encryption keys that are stored locally on a client. This keeps the data secure when the CipherTrust Manager is inaccessible. To access the data, provide the offline password. Then, the CTE Agent encrypts/decrypts the guarded data according to the applied policy.

Password Types

The client password is initially set when the client is added to the CipherTrust Manager. Passwords can be set on a client-by-client or client group basis. The CipherTrust Manager supports two types of offline passwords:

- > **Manual** (Static): A password is specified manually. After a client is registered, you must change the client password using this method.
- > **Generate** (Dynamic): A password is generated automatically by CipherTrust Manager. Support for dynamic method is limited in this release. Refer to the CipherTrust Manager Release Notes for details.

Changing the Password Manually

NOTE The manual password creation method is recommended for disaster recovery scenarios.

To change the password:

1. Open the **CTE** application.
2. Click **Clients > Clients**.
3. Under **Client Name**, click the desired client.

Alternatively, click the expand icon (▸) to the left of the desired client in the clients list.

4. From the **Password Creation Method** drop-down list, select **Manual**. The **Regenerate Password** button is replaced by **Change Password**.

5. Click **Change Password**.
6. Enter the new password in the **Password** and **Confirm Password** fields. The password must match in both the fields.

NOTE The password must contain minimum eight characters including at least:

- > One capital letter
- > One number
- > One of these special characters: ! @ # \$ % ^ & * () { } []

To cancel the password change, click **Cancel Change Password**.

7. Click **Apply**.

When changing a static password or changing a client from a dynamic password to a static password, provide the new static password to the client user(s). Without the password, they cannot access encrypted data when there is no network connection between the client and CipherTrust Manager.

Changing the Password Dynamically

To change the password:

1. Open the **CTE** application.
2. Click **Clients > Clients**.
3. Under **Client Name**, click the desired client.

Alternatively, click the expand icon (▸) to the left of the desired client in the clients list.

4. From the **Password Creation Method** drop-down list, select **Generate**. This is the default method.
5. Click **Regenerate Password**.

A new generated password is downloaded to the client.

Managing Membership

View and manage the client group memberships of a client on the Membership tab. This tab provides option to remove the client from a group.

Viewing Group Membership of a Client

To view the groups of a client:

1. Open the **CTE** application.
2. Click **Clients > Clients**.
3. Under **Client Name**, click the desired client.
4. Click the **Membership** tab. This tab shows the groups the client is a member of.

Removing a Client from a Client Group

To remove a client from a group:

1. Open the **CTE** application.
2. Click **Clients > Clients**.
3. Under **Client Name**, click the desired client.
4. Click the **Membership** tab.

5. Select the group from which you want to remove the client.
6. Click the overflow icon (**...**) corresponding to the desired client.
7. Click **Remove**.

Deleting Clients

Only CipherTrust Manager administrators can delete clients. When a client is deleted from the CipherTrust Manager GUI, the client moves to the Expunged state and the CTE Agent is notified to drop client configuration. The CTE Agent installations on the client continue to run, complete with the applied policies. To completely remove a CTE Agent from the client, uninstall the Agent from the client system.

When Agent uninstallation is initiated, the client record is deleted from the CipherTrust Manager. The CipherTrust Manager pushes the configuration change to the CTE Agent running on that client. As a result, the following occur on the client:

- > CTE Agent certificates are deleted.
- > The `URL` line is removed from the `agent.conf` file.
- > The GuardPoints are removed.
- > The client is no longer recognized by the CipherTrust Manager. If the CTE Agent tries to communicate with the CipherTrust Manager, the connection is refused.

Deleting Clients with System Lock or Agent Lock

Do not unregister or delete the CTE client while locks are applied. The locks remain effective after the client is unregistered. Without client credentials, the CipherTrust Manager cannot administer that CTE Agent and cannot disable the locks. You must boot the client in single-user mode and manually modify the Agent configuration to disable the locks.

To remove everything associated with a client (including the CTE Agent):

1. Apply a rekey policy and run `dataxform` on the client to decrypt encrypted files.
2. Disable the locks on the client. Refer to ["Disabling Locks" on page 64](#).
3. Remove all the GuardPoints from the client.
4. Click **Clients > Clients**.
5. Under **Client Name**, click the overflow icon () corresponding to the desired client.
6. Click **Delete**. A dialog box appears prompting to confirm the action.
7. Click **Delete**.

The client administrator with root permissions must log on to the client system and uninstall the CTE Agent.

Deleted Client Indicators

A client is successfully deleted from the CipherTrust Manager GUI if:

- > CipherTrust Manager URL is deleted from the CTE Agent `agent.conf` file.
- > Certificates are removed from the `./agent/pem` directory.

However, if the client is deleted and its identity is changed while it is *offline*:

- > The GuardPoints are not removed
- > The certificates remain intact in the `./agent/pem` directory
- > The `agent.conf` file remains unchanged
- > But the Agent and CipherTrust Manager still cannot communicate with each other.

Logging for the CTE Agent on the CipherTrust Manager is also affected if an offline client is deleted. When the client comes online, log messages about the denied connection can be viewed only by CipherTrust Manager administrators of type System or All (when not in a domain). This is because the CipherTrust Manager:

- > No longer has the client's record.
- > Does not know which domain and the group the client belongs to.
- > Cannot send messages to the appropriate log service.

Deleting Multiple Clients

To delete multiple clients from the CipherTrust Manager GUI:

1. Open the **CTE** application.
2. Click **Clients > Clients**.
3. Select the check boxes corresponding the desired clients.
To select all clients visible on the page for deletion, select the top check box to the left of the Status heading.
4. Click the delete icon (). A dialog box appears prompting to confirm the action.
5. Click **Delete**.

Configuring Client Groups

A client group is used to group one or more clients to simplify configuration and administration. GuardPoints created on a client group are applied to all members of the group. Additionally, you can apply client group configuration settings to all clients in a client group. A client can be a member of multiple client groups.

If you have created a group of one type of clients, then you should only add similar clients to the group. Same configuration settings can only be applied to clients of the type with which the client group is created. If a different type of client is added, configuration settings cannot be applied to that client.

This section covers the following information:

- > ["Creating a Client Group" below](#)
- > ["Adding Clients to a Client Group" on the next page](#)
- > ["Displaying Client Groups" on page 79](#)
- > ["Modifying Client Groups" on page 79](#)
- > ["Changing Client Group Password" on page 81](#)
- > ["Inheritance of Client Group Settings" on page 82](#)
- > ["Configuring Client Group Settings" on page 84](#)
- > ["Deleting Client Groups" on page 84](#)

Creating a Client Group

To create a client group:

1. Open the **CTE** application.
2. Click **Clients > Client Groups**.
3. Click **Create Client Group**. The Create Client Group dialog box is displayed.
4. Enter a unique **Name** for the client group.
5. (Optional, displayed if a profile already exists) From the **Client Profile** drop-down list, select the desired client profile. The default profile is DefaultClientProfile.
6. (Optional) Provide **Description** to identify the client group. The maximum length can be 256 characters.

The screenshot shows a 'Create Client Group' dialog box with the following fields:

- Name:** A text input field containing 'testclientgroup'.
- Client Profile:** A dropdown menu with 'DefaultClientProfile' selected.
- Description:** A text input field containing 'test client group'.

7. Click **Create**. The client group is created.

The newly created client group appears in the client groups list. Now, you can add clients to the group, if needed. Refer to ["Adding Clients to a Client Group" on the next page](#) for details.

As soon as the first client group is created, DefaultClientProfile is also created, if it does not exist.

Adding Clients to a Client Group

Clients can be added a client group either manually or by specifying the group when registering clients with the CipherTrust Manager. If you specify a client group during client registration, the client automatically appears under the client group on the CipherTrust Manager GUI. Refer to the CTE Agent Clients Guide for information on the registration process.

To manually add clients to a client group:

1. Open the **CTE** application.
2. Click **Clients > Client Groups**.
3. Under **Client Group Name**, click the desired client group.
4. In the mini detail view, click **Add Client**. The **Add Client To Client Group <ClientGroupName>** dialog box is displayed with the list of available clients, if any. At least, one client must already exist.

Add Client To Client Group A1

	Status	Name	OS Type	Description
☒	Healthy	P_1	LINUX	TestHost
☐	Healthy	P_10	LINUX	TestHost
☐	Healthy	P_11	LINUX	TestHost

5. Select the desired clients.
6. Click **Add**. A dialog box is displayed asking you to confirm settings inheritance.
7. Confirm whether the selected clients should inherit settings from the client group. The options are:
 - **Inherit Client Group Settings:** This is the default and recommended option. Clients inherit the following properties of the group *except the password*:
 - Client Settings
 - Agent Lock
 - System Lock
 - Communication Enabled
 - Profile Settings
 - QoS Settings
 - GuardPoints

Refer to ["Inheritance of Client Group Settings" on page 82](#) for details.

- **Do not Inherit Client Group Settings:** Clients retain their individual settings. Selecting this option can introduce configuration conflicts. This is not the recommended option. Read the instructions carefully before selecting this option.

8. Click **OK**.

The selected clients are added to the group. They are displayed in the mini view of the client group. Also, the client group is now displayed on the Membership tab of the client. You can remove the client from the group by clicking **Remove**.

Displaying Client Groups

To view the list of client groups:

1. Open the **CTE** application.
2. Click **Clients > Client Groups**. The list of available client groups is displayed.

The client groups list shows the following details:

Column	Description
Client Group Name	Name link of the client group on CipherTrust Manager. Click the link to open client group details in edit mode. The edit mode shows additional details and configuration settings. In the edit mode, you can also view and add clients, GuardPoints, and Client Group Settings.
Description	(Optional) Description to identify the client group.

Modifying Client Groups

After you have created a client group, you can update group details and configuration settings. You can make the following changes:

- > Enable or disable Agent communication for the clients in the group
- > Lock or unlock the CTE Agent files on the clients in the group
- > Change the CTE Agent password for the clients in the group
- > Change the linked profile
- > Add new clients to the group

> Remove clients from the group

To modify a client group:

1. Open the **CTE** application.
2. Click **Clients > Client Groups**.
3. Under **Client Group Name**, click the desired client group. The mini view of the client group is displayed.

4. In the mini detail view, modify the required details:
 - **Unlock:** Unlock Agent Lock and System Lock.
 - **Agent Lock:** Lock the contents of the CTE Agent directories on the clients.
 - **System Lock:** Apply an internal policy to the clients to lock system directories like `/var`, `/bin`, and `/etc`. Enabling System Lock automatically enables Agent Lock.
 - **Communication Enabled:** Whether to enable clients' communication with the CipherTrust Manager. Select to enable, clear to disable communication.
 - **Password Creation Method:** Set the password creation method—Generate or Manual. Refer to ["Changing Client Group Password" on the next page](#) for details.
 - **Client Profile:** Select a profile for the client group. The default profile is DefaultClientProfile. To change the client profile, refer to ["Changing the Profile" below](#) for details.
5. Click **Apply**.

Additionally, you can define GuardPoints for the clients in the group. Refer to ["Managing GuardPoints" on page 135](#).

Changing the Profile

To change the profile:

1. Open the **CTE** application.
2. Under **Client Group Name**, click the desired client group.
3. Next to **Client Profile**, click the profile link (for example, DefaultClientProfile). The Select Profile dialog box shows the current client profile and Rekey Option, Rekey Rate, and Schedule of the selected profile.

4. From the **Profile** drop-down list, select the desired profile.
5. Click **OK**. The selected profile is linked successfully.

Changing Client Group Password

The CipherTrust Manager allows for client password management using client groups. For large scale deployments where the CipherTrust Manager must manage several hundreds or thousands of agents, administering passwords on a per-client basis becomes untenable and burdensome. Using a common password across all the clients in a client group mitigates the administrative burden.

This feature is also useful for offline agent recovery. If a remote agent reboots (planned or unplanned) and cannot communicate with the CipherTrust Manager in the central office, it prompts the administrator at the remote site to enter the client password. The remote site administrator typically calls the corporate help desk for the password. Using the password provided by the help desk personnel, the remote site administrator enables offline agent recovery and the resumption of services. As the password is now known to the remote site administrator and the help desk personnel, it may result in a breach of security and/or render the IT operations non-compliant with respect to guaranteeing data privacy.

To remedy the compromised situation, the security administrators should change the password—rotate the password—according to existing security practices. The client group password management feature allows changing the password on all the clients in the client group when the password is compromised.

The use cases for client group password feature can be summarized as follows:

1. Set a common password for all clients in a client group.
2. Reset the common password for all clients in a client group (if the password is provided to a remote CTE Agent administrator for offline agent recovery).

This feature is best suited for large scale deployments when many agents are under the management of a CipherTrust Manager cluster.

Changing the Password Manually

NOTE The manual password creation method is recommended for disaster recovery scenarios.

To change the password:

1. Open the **CTE** application.
2. Click **Clients > Client Groups**
3. Under **Client Group Name**, click the desired group.

Alternatively, click the expand icon (▶) to the left of the desired client group in the client groups list.

4. From the **Password Creation Method** drop-down list, select **Manual**. The **Regenerate Password** button is replaced by **Change Password**.

5. Click **Change Password**.
6. Enter the new password in the **Password** and **Confirm Password** fields. The password must match in both the fields.

NOTE The password must contain minimum eight characters including at least:

- > One capital letter
- > One number
- > One of these special characters: ! @ # \$ % ^ & * () { } []

To cancel the password change, click **Cancel Change Password**.

7. Click **Apply**.

When the new password is applied, the server pushes the password to all clients in the client group. Clients that are removed from the client group retain the password set for the group. Clients added to the group later do not receive the new password.

Changing the Password Dynamically

To change the password:

1. Open the **CTE** application.
2. Click **Clients > Client Groups**.
3. Under **Client Group Name**, click the desired group.

Alternatively, click the expand icon (▶) to the left of the desired client group in the client groups list.

4. From the **Password Creation Method** drop-down list, select **Generate**. This is the default method.
5. Click **Regenerate Password**.
6. Click **Apply**.

A new generated password is downloaded to the client.

Inheritance of Client Group Settings

Instead of specifying settings for applications running on multiple clients individually, configure them at the client group level. Those settings can be automatically applied to all clients in the group. Refer to "[Client Settings](#)" on page 65 for details on client settings.

CAUTION! Take care when defining client settings at the client group level. If a group contains clients running different operating systems (for example, Linux and Windows) that inherit client settings from the group, conflicts and issues may be observed with file and user access permissions.

- > A client that joins a client group can opt to inherit client group configuration including the client settings.
 - If the client settings are not defined at the group level, the client retains its own settings.
 - If the client settings at the group level are modified later, the updated settings apply to all group members that inherit configuration from the group.
 - Individual clients in the group have client settings overwritten by the group's client settings.

For example:

- a. `clientA` has client settings defined, joins `clientGroup1` and inherits its group configuration. `clientB` also joins `clientGroup1` but does not inherit its group configuration. `clientGroup1`, however, does not have any client settings defined. In this case, both `clientA` and `clientB` retain their own client settings.
 - b. Now, client settings of `clientGroup1` are modified. This overwrites the client settings of all clients that inherit group configuration from `clientGroup1`. So `clientA` inherits the modified group configuration but `clientB` does not, as it does not inherit client group configuration.
 - c. `clientB` is modified to inherit settings from `clientGroup1`. The next time `clientGroup1` updates its client settings, the changes apply to both `clientA` and `clientB`.
- > A client can be a member of more than one client groups. If the client inherits client group configuration from the first client group it joins, and the next groups it joins subsequently, the client inherits the client settings from the last group that it joins.

For example:

- a. `clientC` joins `clientGroup2` and inherits the client group configuration. `clientC` now has `clientGroup2` client settings.
 - b. `clientC` is added to `clientGroup1` and set to inherit client group configuration. So, `clientC` gets `clientGroup1` client settings.
- > If client settings of a client group are emptied, member clients that inherit settings from the group retain the last defined client settings.

For example:

- a. `clientGroup1` deletes its client settings. All member clients (`clientA`, `clientB`, and `clientC`) retain the last client settings defined for `clientGroup1`—blank client settings are not passed to members of the group.
 - b. `clientB` leaves `clientGroup1`. Now, `clientB` retains the client settings it last inherited from `clientGroup1`.
- > If the client settings of a member of a client group are modified, that client no longer inherits client settings from the client group.

For example, client settings on `clientB` are modified. Then, the client settings for `clientGroup1` are modified, all members except `clientB` inherit the changes made to the client settings for `clientGroup1`.

Configuring Client Group Settings

To configure client settings at group level:

1. Open the **CTE** application.
2. Click **Clients > Client Groups**.
3. Under **Client Group Name**, click the desired client group.
4. Click the **Client Group Settings** tab. Scroll down the screen, if needed.

5. In the **Settings** text box, add `|authenticator|` before the path of the binary. For example, `|authenticator|/bin/su` to allow `su` to be a trusted method of authentication. For further consideration of authentication options, refer to ["Client Settings" on page 65](#).
6. (Optional, if you add another process to the set of trusted applications) Select **Re-sign Settings** to ensure that the new process is signed and authenticated by the client. The next time the client settings are pushed to the CTE Agent, the updated client settings are re-signed and the **Re-sign Settings** check box is cleared (or reset).

If, after adding a new process, you do not select **Re-sign Settings**, the client ignores the newly added process. See ["Re-Sign Settings" on page 70](#) for more information.

7. Click **Apply**.

Deleting Client Groups

As part of CipherTrust Manager maintenance, you occasionally must remove client groups from the CipherTrust Manager.

- > When you delete a client group, only the group is removed from the CipherTrust Manager GUI. Individual clients that are members of the group remain intact.
- > If you configured a client group password, the individual clients retain the group password.

Deleting a Client Group

To remove a client group:

1. Make sure that no GuardPoints is applied on the group.
2. Open the **CTE** application.
3. Click **Clients > Client Groups**.

4. Under **Client Group Name**, click the overflow icon () corresponding to the desired group.
5. Click **Delete**. A dialog box appears prompting to confirm the action.
6. Click **Delete**.

The client group is removed from the client groups list. Also, the client group is removed from the Membership tab of the linked clients.

Deleting Multiple Client Groups

To remove single or multiple client groups:

1. Make sure that no GuardPoints are applied on the groups.
2. Open the **CTE** application.
3. Click **Clients > Client Groups**.
4. Select the check boxes corresponding to the desired groups.

To select all client groups visible on the page for deletion, select the top check box to the left of the Client Group Name heading.

5. Click the delete icon (). A dialog box appears prompting to confirm the action.
6. Click **Delete**.

The selected client groups are removed from the client groups list. Also, the client groups are removed from the Membership tab of the linked clients.

CHAPTER 7: Managing Signature Sets

File signing checks the authenticity and integrity of executables and applications before they are allowed to access GuardPoint data. When you initiate file signing on the CipherTrust Manager, the CTE Agent calculates the cryptographic signatures of the executables that are eligible to access GuardPoint data. Files are individually signed as part of a set and the set is configured in a policy that defines the processes to allow.

When an executable tries to access a GuardPoint, the secfs service checks the fingerprint, a SHA-2 (Secure Hashing Algorithm) message digest, of the executable against the fingerprint stored in the CTE database. If they match, the executable's authenticity is verified and it can be allowed to access protected data. A hostile or compromised executable, such as a Trojan application, malicious code, or rogue process, with a missing or mismatched signature, is denied access.

Once a set of files to be signed is created, the executables are signed on a selected client and a copy of each signature is stored on the CTE. This is done as a background process on the selected client. The time it takes to complete signing depends upon the number of files to be signed, the response time of the client system, and other load factors. The completion status is indicated in the Signature Sets window.

Completed signature sets are configured in a (CTE Agent) policy so that not only are the executables attempting GuardPoint access identified, but their signatures are checked to ensure that they had not been compromised.

This chapter covers the following information:

- > ["The Signing Process" on the next page](#)
- > ["Using Signature Sets in a Policy" on the next page](#)
- > ["Creating Signature Sets" on page 88](#)
- > ["Signing Files in a Signature Set" on page 90](#)
- > ["Checking Signing Completion Status" on page 92](#)
- > ["Stopping the Signing Process" on page 92](#)
- > ["Displaying Signatures of Files in a Signature Set" on page 93](#)
- > ["Detecting Duplicate Files" on page 94](#)
- > ["Deleting Signatures from Signature Sets" on page 95](#)
- > ["Deleting Source from Signature Sets" on page 96](#)
- > ["Deleting Signature Sets" on page 97](#)
- > ["Re-Signing Files in a Signature Set" on page 98](#)
- > ["Checking Agent Logs if Signing Fails" on page 99](#)

The Signing Process

The basic steps involved in the signature signing process are:

1. The CTE Server Administrator creates signature sets. Refer to ["Creating Signature Sets" on the next page](#) for details.
2. The CTE Server Administrator initiates the signature signing request. The administrator selects the signature set to be signed and the CTE client that will sign the set. Refer to ["Signing Files in a Signature Set" on page 90](#) for details.
3. The CipherTrust Manager forwards the request to the selected CTE client.
4. The CTE client signs the set and sends it to the CipherTrust Manager.
5. The CipherTrust Manager:
 - a. Updates the signatures in the set.
 - b. Updates the affected policies.
 - c. Sends the updated configuration files including the signatures to the clients that are using the affected policies.

In future, if any processes in the signature set are updated, the signature set should be signed again. The CTE Server Administrator can initiate the signature signing process again. This is referred to as the signature re-signing process.

The following diagram shows the high level signature signing process:

Using Signature Sets in a Policy

Policies can be configured to identify the executables trying to access GuardPoint data and to verify that the executables themselves are unchanged since they were signed. You must, however, anticipate the effect of encryption on file signatures.

When a file inside a GuardPoint is copied to a location outside the GuardPoint, the two files have different signatures. The file in the GuardPoint is encrypted, but the file outside the GuardPoint is not.

- > Encryption makes the two files different. The VMD process does not decrypt guarded files before checking their signatures. So, when you rekey guarded files, their signatures also change. Re-sign the files that use the signatures of those files in process sets.
- > If both files must access the GuardPoint data, add both files to the signature set and sign them. If encryption is not applied, both files have the same signature; a signature mismatch should not occur.

Creating Signature Sets

A signature set is a collection of file names and/or directory names. You can enter the full path of files and directories manually or use the browser to locate and select them. Specify a directory to sign all the files in that directory and all the subdirectories that it may contain.

Signing many files can take a while. To shorten processing time, verify that the files and directories in the signature set exist. It takes longer to process non-existent files. If they do not exist, it is recommended that you delete them as sources from the signature set. Refer to ["Deleting Source from Signature Sets" on page 96](#) for details.

To create a signature set:

1. Open the **CTE** application.
2. Click **Policies > Policy Elements**.
3. Click the **Signature Sets** tab.
4. Click **Create Signature Set**. The Create Signature Set wizard is displayed.
5. On the **General Info** screen:
 - a. Enter a unique **Name** for the set.

NOTE

- > The name must start with a character. The maximum length can be 64 characters.
- > The name can contain alphanumeric characters, underscores (_), and dashes (-).
- > The name cannot contain the following special characters:
 ? : ; | ! @ # \$ % ^ & * < = > + () { } ~ , \ / [] ' "

- b. Provide a **Description** for the set.
- c. Click **Next**. The Add Sources screen is displayed. On this screen, you can add files to be signed, as described below.

Adding Files to a Signature Set

6. Specify path of the directory or file to be signed. If a directory is specified, all files in the directory and its subdirectories are signed.
 - a. Click **Select Client**. The list of registered clients is displayed.
 - b. Select the desired client.

Status	Name	OS Type	Description
Healthy	10.164.13.209	LINUX	ABLinux
Healthy	ABWin	WINDOWS	AB Windows Client

- c. Click **Select**. The selected client appears next to Select Client.
- d. Click **Add Source**. The file system of the selected client is displayed. The file system of a client marked for deletion cannot be browsed.

The Client drop-down box shows the selected client. If needed, change the client from the list.

- e. Select the path to be signed. Select the path either typing manually or by using the browser.

To jump to a specific directory, enter the directory path in the **Start Directory** field and click **Apply**. The browser shows the subdirectories and files, as shown below.

You cannot browse above the Start Directory. Enter a start point that is higher in the directory hierarchy than all the directories and files that you want to select, or you will have to re-enter start points to locate and select the desired files. The default is the top-level, either slash (Linux) or backslash (Windows).

Alternatively, if you know the directory path, you can enter it manually in the **Path** field.

- f. Click **Add**. The selected source is displayed in the Source Directory list.

Optionally, you can add a new source by clicking **Add Source**. To remove a source, click the overflow icon () corresponding to the source and click **Remove**.

7. Click **Next**. The Confirmation screen shows general information about the set and the selected sources.
8. Verify the set details. If the details are incorrect or you want to modify them, click **Back** and update the details.
9. Click **Save**.

The newly created set appears on the Signature Sets tab. By default, the signature set has the status **UNSIGNED**.

	Name	Signing Status	Updated At: 	Description	
☐	testsigset	Unsigned	18 Aug 2020, 07:54	Test signature set	
☐	test	Unsigned	18 Aug 2020, 00:55		

It is recommended that the signature set is signed before you apply policies to processes. This ensures that a tampered with or compromised process executable is not granted permissions to access protected GuardPoints. Refer to ["Signing Files in a Signature Set" below](#) for details.

Signing Files in a Signature Set

Signing involves calculating a hash value for a file and storing the value on the CipherTrust Manager. Later, when a policy checks signatures, the signature of the process or executable accessing the GuardPoint is calculated and compared against the value in the CipherTrust Manager. If the two values match, the process or executable satisfies the Process requirement of a policy and may be granted access to the guarded data.

NOTE If the executable itself is volatile, or subject to frequent change, it may not be worthwhile to use a file signature as a criteria in a policy because you have to re-sign the executable after each change. If the volatile executables are members of a large signature set, it can take a while to re-sign the files because the signature of every file in the signature set is recalculated. If the volatile files are few, it might be quicker to add the volatile files to a different signature set and sign that set, rather than re-sign all the files in the original signature set.

To sign the files in a signature set:

1. Open the **CTE** application.
2. Click **Policies > Policy Elements**.
3. Click the **Signature Sets** tab. The list of configured signature sets is displayed.
4. Click the desired signature set.

5. Select a client to sign the signature set. A signing client is required to start the signing process.
 - a. On the **Source** tab, click **Select Client**. The list of registered clients is displayed. Select any client to sign the signature set.
 - b. Select the client.
 - c. Click **Select**. The selected client appears next to the Select Client button. The Sign icon (▶) is now enabled.

CAUTION! Do not select check boxes when signing a signature set. They are used to select source directories to be deleted from the set.

6. Click the Sign icon (▶). The signing process starts.

The signing status of the signature set becomes `InProgress`.

- > To view the percent completion of the signing process, hover over the Spinner (⌂) progress bar.
- > To stop the signing process before it completes, click the Stop Signing icon (●). Refer to ["Stopping the Signing Process" on the next page](#) for details.

The time for the signing process to complete depends on the number of files being processed. Signing occurs as a background process. So, you can use the CipherTrust Manager GUI for other administrative functions during this process.

When the signing completes, the signing status of the signature set becomes `Finished`. Refer to ["Checking Signing Completion Status" on the next page](#) for details about the signing status.

The resulting signatures are available on the Signature tab of the signature set.

Checking Signing Completion Status

To view the signing completion status of a signature set:

1. Open the **CTE** application.
2. Click **Policies > Policy Elements**.
3. Click the **Signature Sets** tab. The list of configured signature sets is displayed.

Name	Signing Status	Updated At ↓	Description
☐ testSigned	Finished	18 Aug 2020, 08:04	Test signature set
☐ test	Unsigned	18 Aug 2020, 08:55	

4. View the **Signing Status** for the signature set.

The Signing Status can be:

Status	Description
Unsigned	Signature set is unsigned. Either no files exist in the set or no attempt is made to sign them yet.
InProgress	The CipherTrust Manager is actively signing the files in the set. This can take some time depending on the system load, accessibility, and the number of files being signed at one time.
Finished	All the files in the set are signed successfully. The set is ready for use.
FinishedWithWarning	All the files in the set are processed, but one or more files in the set could not be signed. Possible causes are missing files or inadequate access permissions. Check the VMD logs for details: > On Unix, <code>vorvmd_root.log</code>. > On Windows, <code>vorvmd.log</code>. Alternatively, view the logs in Event Viewer > CipherTrust Encryption Expert. Refer to "Checking Agent Logs if Signing Fails" on page 99 for details.
Aborted	Signing was started but stopped before completion.

Stopping the Signing Process

Interrupt the signing process at any time before it completes. Click the Stop Signing (●) icon on the Source tab of the Signature Sets tab. The CipherTrust Manager does prompt you to verify your choice.

It takes a while for the signing process to stop. After the process is stopped, the Signing Status displayed on the Signature Sets tab is set to `abort`. All the files that were signed until you stopped the process remain intact and can be viewed on the Signature tab of the signature set.

Displaying Signatures of Files in a Signature Set

CipherTrust Manager provides options to display signatures of all or specific files in a signature set.

Displaying Signatures of All Files in the Signature Set

To display the signatures of all files in a signature set:

1. Open the **CTE** application.
2. Click **Policies > Policy Elements**.
3. Click the **Signature Sets** tab. The list of configured signature sets is displayed.
4. Under **Name**, click the desired signature set.
5. Click the **Signature** tab.

	Program	Signature	
☐	/usr/bin/crash	8840AA3A71BD1D2C3C0A347032E93F7A17F65553B06095409758B55E28E1CA62	...
☐	/usr/bin/vortc	56FE294800C98989D589D1983A550807DA1E06E227E63D611325F81803A9123D	...
☐	/usr/bin/voradmin	7BB14D0AAAFF0DED8FCD55D445AEAF4C2418F8B30CA3EA90844A613906E3029	...

The list of all files (programs) in the signature set with their signatures is displayed. By default, 10 records per page are displayed. Adjust the pagination to view more records.

Displaying Specific Signed Files in the Signature Set

To display specific signed files in a signature set:

1. Open the **CTE** application.
2. Click **Policies > Policy Elements**.
3. Click the **Signature Sets** tab. The list of configured signature sets is displayed.
4. Under **Name**, click the desired signature set.
5. Click the **Signature** tab. By default, all signed files in the set are displayed in alphanumeric order.
6. In the **Search** box, enter the string that matches the partial or full name of the program whose signature you are searching for.

The search is case-insensitive. All files that contain the string in their names are displayed.

Detecting Duplicate Files

Unless the content of a file is modified, its signature remains the same regardless of the file name and location. Also, the signature of all copies of a file remains the same.

So, to determine the duplicates of a file, display the files based on their signature. If you search using a signature, it is recommended to enter the complete signature.

To detect the duplicates of a file:

1. Open the **CTE** application.
2. Click **Policies > Policy Elements**.
3. Click the **Signature Sets** tab. The list of configured signature sets is displayed.
4. Under **Name**, click the signature set in which you want to detect duplicate files.
5. Click the **Signature** tab. The signatures of the files in the set are displayed.
6. Copy the signature of a file from the **Signature** column.
7. Paste the signature in the **Search** box. Remove any extra space, if inserted when pasting.
8. Notice the search result.
 - If multiple records are displayed, duplicates of the file exist.
 - If a single record is displayed, duplicates of the file do not exist.

For example, the following figure shows two files with different names and locations, but with identical content based on their signature.

Source **Signature**

7724722A749EA44B83B8ACE63C20E08DD9C4805EE34D039E1

0 selected 2 results | 2 Signatures

☐ /bin/ls	7724722A749EA44B83B8ACE63C20E08DD9C4805EE34D039E1B734A88E900D02	...

2 Signatures 10 per page

Deleting Signatures from Signature Sets

Delete either individual signatures from a set or the complete signature sets. Refer to ["Deleting Signature Sets" on page 97](#) for information on deleting complete signature sets.

Delete signatures from a signature set when you want to continue to use the signature set to authenticate processes, but you no longer want to authenticate the files that you are deleting from the set.

You can delete signatures individually or one page at a time.

Deleting Single Signatures

To delete a single signature from a signature set:

1. Open the **CTE** application.
2. Click **Policies > Policy Elements**.
3. Click the **Signature Sets** tab.
4. Click the desired signature set.
5. Click the **Signature** tab. The list of signatures in the signature set is displayed.
6. Click the overflow icon (**...**) corresponding to the desired signature.

Program	Signature	
☒ /usr/bin/crash	8829A43A71BD1D3CE3CDA847932E8F7A17F862538D99B51D9756853E2981CA82	...
☐ /usr/bin/wdtt	56FE294800C9E0805589D1983A556887D41E06E227E63D611325F31B93A9723D	...

Delete

7. Click **Delete**. A dialog box appears prompting you to confirm the action.
8. Click **Delete**.

The selected signature is removed from the list and the CipherTrust Manager database.

Deleting Multiple Signatures

To delete single or multiple signatures from a signature set:

1. Open the **CTE** application.
2. Click **Policies > Policy Elements**.
3. Click the **Signature Sets** tab.
4. Click the desired signature set.
5. Click the **Signature** tab.
6. Select the check boxes corresponding to the signatures you want to delete.

Program	Signature
☒ /usr/bin/crash	8840AA3A71BD1D2C9C0A3
☒ /usr/bin/vort	56FE204800C9B0805580D1

To select all signatures for deletion, select the top check box to the left of the Signature heading.

7. Click the delete icon (🗑️). A dialog box appears prompting you to confirm the action.
8. Click **Delete**.

The selected signatures are removed from the list and the CipherTrust Manager database.

Deleting Source from Signature Sets

Signing many files can take a while. To shorten processing time, verify that the files and directories in the signature set exist. It takes longer to process non-existent files. If they do not exist, it is recommended that you delete them as sources from the signature set.

Deleting Single Sources

To delete a single source from a signature set:

1. Open the **CTE** application.
2. Click **Policies > Policy Elements**.
3. Click the **Signature Sets** tab.
4. Click the desired signature set. The Source tab shows the list of source directories.
5. Click the overflow icon (⋮) corresponding to the desired source directory.

6. Click **Delete**. A dialog box appears prompting you to confirm the action.
7. Click **Delete**.

The selected source is removed from the list and the CipherTrust Manager database.

Deleting Multiple Sources

To delete single or multiple sources from a signature set:

1. Open the **CTE** application.
2. Click **Policies > Policy Elements**.
3. Click the **Signature Sets** tab.
4. Click the desired signature set. The Source tab shows the list of source directories.
5. Select the check boxes corresponding to the desired source directories.

To select all sources for deletion, select the top check box to the left of the Source Directory heading.

6. Click the delete icon (🗑️). A dialog box appears prompting you to confirm the action.
7. Click **Delete**.

The selected sources are removed from the list and the CipherTrust Manager database.

Deleting Signature Sets

Delete either individual signatures from a set or the complete signature sets. Refer to ["Deleting Signatures from Signature Sets" on page 95](#) for information on deleting individual signatures.

An active (in use) signature set cannot be deleted. Before deleting a signature set from the CipherTrust Manager, make sure that no policies are using it.

CipherTrust Manager provides options to delete single or multiple signature sets.

Deleting Single Signature Sets

To delete a single signature set:

1. Open the **CTE** application.
2. Click **Policies > Policy Elements**.
3. Click the **Signature Sets** tab. The list of configured signature sets is displayed.
4. Click the overflow icon (⋮) corresponding to the desired signature set.

Name	Signing Status	Updated At	Description
☐ testsigset	Finished	18 Aug 2020, 08:12	Test signature set
☐ test	Unsigned	18 Aug 2020, 08:55	

Edit
Delete

5. Click **Delete**. A dialog box appears prompting you to confirm the action.

6. Click **Delete**.

The selected signature set is removed from the list.

Deleting Multiple Signature Sets

To delete single or multiple signature sets:

1. Open the **CTE** application.
2. Click **Policies > Policy Elements**.
3. Click the **Signature Sets** tab. The list of configured signature sets is displayed.
4. Select the check boxes corresponding to the desired signature sets.

2 Selected 2 Results | 2 Signature Sets

Name	Signing Status
☒ testsigset	Finished
☒ test	Unsigned

To select all sets for deletion, select the top check box to the left of the Name column.

5. Click the delete icon (🗑️). A dialog box appears prompting you to confirm the action.

6. Click **Delete**.

The selected signature sets are removed from the list.

Re-Signing Files in a Signature Set

Signatures are computed values. Unless the files in a signature set are compromised or modified, the signature always remains the same for a given file. If the files are modified, they must be re-signed to ensure that their signatures match the signatures on the CipherTrust Manager.

To re-sign the files, you can:

- > Create and sign a new signature set with the files and directories to be signed. Use this option if the set contains only a few files and directories.
- > Create and sign a new signature set with the paths of the directories that contain the files to be signed. Use this option if the directories contain only a few files or most files in the directories need re-signing.

- > Open and re-sign the existing signature set that is originally used to sign the files. Use this option if you have the time or the signature set is small.

Computing the signature of every file in a large signature set takes a long time.

Re-signing the files in a set takes longer than signing the files the first time. It requires additional handling to update information on the CipherTrust Manager. If you plan to re-sign a large number of files (say hundreds of thousands), it can be quicker to:

1. Delete the existing signature set. Refer to ["Deleting Signature Sets" on page 97](#) for details.
2. Create the signature set again, from scratch. Refer to ["Creating Signature Sets" on page 88](#) for details.
3. Sign the files of the signature set again. Refer to ["Signing Files in a Signature Set" on page 90](#) for details.

Checking Agent Logs if Signing Fails

If signing fails, or you want more information about the signing process such as which files were skipped, check the CTE Agent logs captured on the client.

Messages are logged to:

- > (UNIX) `/var/log/vormetric/vorvmd_root.log` with Log to File enabled and to a Syslog server with Syslog enabled.
- > (Windows) `\Documents and Settings\...\agent\log\vorvmd.log` with Log to File enabled.

In the `vorvmd_root.log`/`vorvmd.log` file on the client, look for messages like:

```
[VMD] [WARN ] [3732] [VMD3824W] Failed to create the signature for
E:\apps\lib\dx1\aa_dir\dataxform_auto_config for the signature request 9, error
code 3
```

The following table lists error codes with their description:

Code	Description
0	System is okay.
1	Does not exist.
2	DO NOT USE.
3	Invalid argument.
4	Operation not supported.
5	Out of memory.
6	No space left on device.
7	Timeout reached.
8	I/O error.

Code	Description
9	Interrupted.
10	Permission denied.
11	Too many keys in key group.
12	Error in soap rpc layer.
13	Returned buffer is partially full.
14	Given target buffer is too small.
15	Unable to compress buffer.
16	Internal test failed.
17	Overflow.
18	Error setting up logging.
19	Overloaded error.
20	Server responded to a file upload with "bad request".
21	Unknown user name or bad password.
22	The directory service is not available.

CHAPTER 8: Managing Policies

The primary job of a CipherTrust Manager Security Administrator is to create policies that protect data. Policies govern access to, and encryption of, the files in GuardPoints.

This chapter covers the following information:

- > ["Overview" below](#)
- > ["Policy Rule Criteria and Effects" on the next page](#)
- > ["Creating Policy Elements" on page 103](#)
- > ["Creating Policies" on page 114](#)
- > ["Displaying Policies" on page 124](#)
- > ["Modifying Policies and Rules" on page 127](#)

Overview

A policy is a collection of rules that govern data access and encryption. Think of a policy as an if-then statement. Policy rules are processed sequentially. If the criteria of rule one are not met, the policy enforcement engine moves on to the second rule and so on.

Policies specify:

- > **Actors:** Users, groups, and processes that are permitted/denied access to protected data.
- > **Actions:** What actions authorized actors are allowed to perform. For example create/delete, read/write, decrypt, modify permissions, and so on.
- > **Files acted upon:** Policy rules may apply to entire directories and mount points, or only to files named in a specific way (for example, .docx files may be encrypted and restricted to read only access by designated users, while other files may be stored clear and read and written by anyone).

Additionally, each CTE policy specifies one or more encryption keys used to encrypt blocks of file data when applications write them, and decrypt them when they are read.

CTE encryption is transparent to applications. This means that the CTE Agent encrypts blocks of data as they are written, and decrypts data when they are read by authorized users and applications. This architecture separates administration of files from access to the data in them. Backup programs, for example, may be authorized to read files, but not view the data in them. Therefore, data can be backed up and taken offsite while remaining encrypted so that security is not breached.

The following criteria are processed by the policy enforcement engine:

Criteria	Description
Order	Security rule enforcement sequence.

Criteria	Description
Resource	Files and/or directories to which the policy will apply, plus key rules that govern those files and directories.
User	Users and user groups authorized to access the resources.
Process	Executables which will access the files.
Action	Type of user access being made (read, write, copy, move etc.). Before you can define Data Transformation Rules, you must select an Action type of Key_op.
Effect	When all the other rules match, this describes the type of access granted or denied per the rule.
Browsing	Allow browsing is enabled by default, while the Enable Communication check box is enabled on the client. This allows the server to browse the client's file system. This option can be deselected even if client communication is still enabled.

A policy comprises ["Security Rules" on page 26](#), ["Key Rules" on page 30](#), and ["Data Transformation Rules" on page 30](#).

Policy Rule Criteria and Effects

Policy Rules consist of five criteria, which specify the attributes of an access attempt, and effects, which define whether that access is permitted or denied, and whether encryption/decryption is required.

Policy Rule Criteria

Criteria	Action
Resource	Files and/or directories in a GuardPoint to be blocked. Example: <code>/secure_dir/financials</code> .
User	Users or groups of users that can access the files.
Process	Executables that can operate on the files.
Action	Allowed file action. Example: read, write, remove, rename, and make directory.

Policy Rule Effects

Effect	Action
Permit	Allows access to the data.

Effect	Action
Deny	Disallows access to the data.
Apply Key	Encrypts data written to a GuardPoint with the specified key. Decrypts data that is accessed using the same key.
Audit	Creates an entry in the Message Log that describes what is being accessed, when it is being accessed, and the security rule being applied.

Every time a user's application tries to access a GuardPoint file, the security policy tests that access attempt against the criteria of each rule. For example, suppose a user, Harry, wants to access and modify a file called `secret`, using the command `cp`. For Harry to be successful, there must be a rule that allows access to the `secret` (resource), by the user `Harry` (user), using the command `cp` (process), and includes the permission `write` (action).

A blank criteria field specifies a value of `All`. If `User` is blank, the rule applies to all users; if `Process` is blank, the rule applies to all executables, and so on. `Effect` can never be blank. It must have at least a `permit` (allow access) or `deny` (disallow access).

A policy can have multiple rules. Rules are evaluated much like firewall rules. They are evaluated in order, from first to last, and evaluation stops when a rule is found for which all the criteria are met. The effect for that rule is then enforced. So, carefully order a policy's rules to achieve the desired result.

Creating Policy Elements

Policy rule criteria consist of resource sets, user sets, signature sets, process sets, action, and effect, and are called policy elements. These elements should exist on the CipherTrust Manager before you can use them in security policies.

Although you can add policy elements when creating policies, it may be a better approach to have them created in advance. This document describes creation of policy elements separately, before creating policies.

A CipherTrust Manager administrator can create, modify, and delete resource sets, user sets, process sets, and signature sets on the CipherTrust Manager. Actions and effects are preconfigured on the CipherTrust Manager.

This section covers the following information:

- > ["Creating Resource Sets" on the next page](#)
- > ["Creating User Sets" on page 105](#)
- > ["Creating Signature Sets" on page 108](#)
- > ["Creating Process Sets" on page 110](#)

After you have created policy elements, you can use them in creating and configuring policies. Refer to ["Creating Policies" on page 114](#) for details.

Creating Resource Sets

A resource is a combination of a directory, a file, and patterns or special variables. A resource set is a named collection of directories, files, or both, that a user or process will be permitted or denied access to.

Use the Create Resource Set wizard to create resource sets.

1. Open the **CTE** application.
2. Click **Policies > Policy Elements**.
3. On the Resource Sets tab, click **Create Resource Set**. The Create Resource Set wizard is displayed.
4. On the **General Info** screen:
 - a. Enter a unique **Name** for the set.

NOTE

- > The name must start with a character. The maximum length can be 64 characters.
- > The name can contain alphanumeric characters, underscores (_), and dashes (-).
- > The name cannot contain the following special characters:

? : ; | ! @ # \$ % ^ & * < = > + () { } ~ , \ / [] ' "

- b. Provide a **Description** for the set.
 - c. Click **Next**. The Add Resources screens is displayed.
5. Specify the resource **Directory**.
The path must end with a slash. For example, a Windows path must end with a \ (backward slash). A Linux path must end with a / (forward slash).
6. Specify a **File** or enter the asterisk. The asterisk acts as a wild card character.
7. (Optional) Specify whether to include subfolders in the set. Turn on **Include Sub Folders**. By default, the subfolders are not included.

Directory: /opt/cte-test/

File: *

include Sub Folders: ☒

8. Click **Next**. The Confirmation screen is displayed.
The screen shows general information about the set and the selected sources.

Directory	File	include Sub Folders	File System Type	
/opt/cte-test/	*	Yes	Local FileSystem	...

9. Verify the resource set details.

If the details are incorrect or you want to modify them, click **Back** and update the details. To add another resource, click **Add Another Resource**, and specify the details, as described above.

10. Click **Save**. The resource set is created.

The newly created resource set appears on the Resource Sets tab.

Name	Updated At ↓	Description
☐ resourceSet	18 Aug 2020, 11:47	Resource set
☐ SG-ResourceSet	18 Aug 2020, 11:38	

Creating User Sets

A user set is a collection of users and user groups that you want to grant or deny access to GuardPoints. User sets are configured in policies. Policies can be applied to user sets, not to individual users.

Use the Create User Set wizard to create user sets. The wizard provides two options to add user sets. Specify a user set either by querying the registered client or by manually entering the members (individual members, groups, or group members). If needed, you can manually add AD users to a user set.

Creating User Sets by Browsing the Client

To create a user set:

1. Open the **CTE** application.
2. Click **Policies > Policy Elements**.
3. Click the **User Sets** tab.
4. Click **Create User Set**. The Create User Set wizard is displayed.
5. On the **General Info** screen:
 - a. Enter a unique **Name** for the set.

NOTE

- > The name must start with a character. The maximum length can be 64 characters.
- > The name can contain alphanumeric characters, underscores (_), and dashes (-).
- > The name cannot contain the following special characters:
 ? : ; | ! @ # \$ % ^ & * < = > + () { } ~ , \ / [] ' "

- b. Provide a **Description** for the set.
- c. Click **Next**. The Add Users screen is displayed.

By default, the **Browse to Add Users** tab is active. This tab allows you to browse the client for members. To add members manually, refer to ["Creating User Sets by Adding Members Manually" on page 107](#).

6. Select the **Agents** option.
7. Click **Select**. The list of registered clients is displayed.

8. Select the desired client. Members, groups, or group members of this client will be added to the set.
9. Click **Select**. The IP address or hostname of the selected client is displayed next to the Select button. The Member Choice and Max Entries to Return fields are also displayed.

Agents

Select 10.164.13.209

Member Choice
Members

Max Entries to return
300

10. From the **Member Choice** drop-down list, select members. The options are:
 - **Members**: Retrieves members (users) of the client. This is the default setting.
 - **Groups**: Retrieves user groups of the client.
 - **Group Members**: Retrieves group members of the client. When you select this option, the Select Groups field appears. This is a mandatory field. Select a group from the drop-down list. Search will retrieve members of the selected group.
11. Specify the **Max Entries to Return**. This is a mandatory field. The default number is 300.
12. Click **Submit**. The search result based on the specified criteria is displayed on the right. By default, five entries per screen are displayed. Use the on-screen pagination to view more entries.
13. Select the desired members from the list.

☐	uname	UID	gname	GID
☒	root		root	
☐	bin	1	bin	1
☐	daemon	2	daemon	2

14. Click **Next**. The Confirmation screen shows general information about the set and the selected members.

uname	UID	gname	GID	OS domain	
root		root			Remove
testuser_1	1003	testuser_1	1003		Remove

15. Verify the set details.
If the details are incorrect or you want to modify them, click **Back** and update the details.
16. Click **Save**. The user set is created.

The newly created set appears on the User Sets tab.

	Name	Updated At ↓	Description	
☐	userset	18 Aug 2020, 12:10	A test user set	...
☐	testuserset	18 Aug 2020, 12:09	Test user set	...

Creating User Sets by Adding Members Manually

This method is useful when you already know the names of users and groups that should be added to a user set. Also, use this method to add AD users and groups to the user set.

To create a user set:

1. Open the **CTE** application.
2. Click **Policies > Policy Elements**.
3. Click the **User Sets** tab.
4. Click **Create User Set**. The Create User Set wizard is displayed.
5. On the **General Info** screen:
 - a. Enter a unique **Name** for the set.

NOTE

- > The name must start with a character. The maximum length can be 64 characters.
- > The name can contain alphanumeric characters, underscores (_), and dashes (-).
- > The name cannot contain the following special characters:

? : ; | ! @ # \$ % ^ & * < = > + () { } ~ , \ / [] ' "

- b. Provide a **Description** for the set.
- c. Click **Next**. The Add Users screen is displayed.

By default, the **Browse to Add Users** tab is active. This tab allows you to browse the client for members. Refer to ["Creating User Sets by Browsing the Client" on page 105](#) for details.

6. Click the **Manually Add Users** tab.
7. Specify the following details, as appropriate:

Element	Description
uname	Login name of the user.
UID	(AIX/Linux only) ID of the user.
gname	Comma-separated list of group names.

Element	Description
GID	(AIX/Linux only) Group ID of the user. Specify only the primary group ID.
OS domain	(Windows only) Network domain of the user. Multiple domain names, separated by commas, can be entered. Specify the string <code>localhost</code> to configure a generic domain.

8. Click **Next**. The Confirmation screen shows general information about the set and the selected members.

9. Verify the set details.

If the details are incorrect or you want to modify them, click **Back** and update the details.

10. Click **Save**. The user set is created.

The newly created set appears on the User Sets tab.

Creating Signature Sets

A signature set is a collection of hashes of processes and executables that you want to grant or deny access to GuardPoints. A signature set can be configured in a policy as part of a process set to verify the integrity of a process before it is allowed access to guarded data. Policies are applied to signature sets, not to individual signatures.

To create a signature set:

1. Open the **CTE** application.
2. Click **Policies > Policy Elements**.
3. Click the **Signature Sets** tab.
4. Click **Create Signature Set**. The Create Signature Set wizard is displayed.
5. On the **General Info** screen:
 - a. Enter a unique **Name** for the set.

NOTE

- > The name must start with a character. The maximum length can be 64 characters.
- > The name can contain alphanumeric characters, underscores (`_`), and dashes (`-`).
- > The name cannot contain the following special characters:

? : ; | ! @ # \$ % ^ & * < = > + () { } ~ , \ / [] ' "

b. Provide a **Description** for the set.

c. Click **Next**. The Add Sources screen is displayed. On this screen, you can add files to be signed, as described below.

Adding Files to a Signature Set

6. Specify path of the directory or file to be signed. If a directory is specified, all files in the directory and its subdirectories are signed.
 - a. Click **Select Client**. The list of registered clients is displayed.

- b. Select the desired client.

Status	Name	OS Type	Description
 Healthy	10.164.13.209	LINUX	ABLinux
 Healthy	ABWin	WINDOWS	AB Windows Client

- c. Click **Select**. The selected client appears next to Select Client.
- d. Click **Add Source**. The file system of the selected client is displayed. The file system of a client marked for deletion cannot be browsed.

The Client drop-down box shows the selected client. If needed, change the client from the list.

- e. Select the path to be signed. Select the path either typing manually or by using the browser.

To jump to a specific directory, enter the directory path in the **Start Directory** field and click **Apply**. The browser shows the subdirectories and files, as shown below.

You cannot browse above the Start Directory. Enter a start point that is higher in the directory hierarchy than all the directories and files that you want to select, or you will have to re-enter start points to locate and select the desired files. The default is the top-level, either slash (Linux) or backslash (Windows).

Alternatively, if you know the directory path, you can enter it manually in the **Path** field.

- f. Click **Add**. The selected source is displayed in the Source Directory list.

Optionally, you can add a new source by clicking **Add Source**. To remove a source, click the overflow icon () corresponding to the source and click **Remove**.

7. Click **Next**. The Confirmation screen shows general information about the set and the selected sources.
8. Verify the set details. If the details are incorrect or you want to modify them, click **Back** and update the details.
9. Click **Save**.

The newly created set appears on the Signature Sets tab. By default, the signature set has the status **UNSIGNED**.

	Name	Signing Status	Updated At: 	Description	
☐	testsignset	Unsigned	18 Aug 2020, 07:54	Test signature set	
☐	test	Unsigned	18 Aug 2020, 00:55		

It is recommended that the signature set is signed before you apply policies to processes. This ensures that a tampered with or compromised process executable is not granted permissions to access protected GuardPoints. Refer to ["Signing Files in a Signature Set" on page 90](#) for details.

Creating Process Sets

A process set is a collection of processes (executables) that you want to grant or deny access to GuardPoints. Like user sets, process sets can be configured in policies. Policies can be applied to process sets, not to individual processes.

Optionally, file signing can be configured to check the authenticity and integrity of executables and applications before they are allowed to access GuardPoint data. A signature set must already exist before you can configure file signing in a policy for a process set.

Use the Create Process Set wizard to create process sets.

To create a process set:

1. Open the **CTE** application.
2. Click **Policies > Policy Elements**.
3. Click the **Process Sets** tab.
4. Click **Create Process Set**. The Create Process Set wizard is displayed.
5. On the **General Info** screen:
 - a. Enter a unique **Name** for the set.

NOTE

- > The name must start with a character. The maximum length can be 64 characters.
- > The name can contain alphanumeric characters, underscores (_), and dashes (-).
- > The name cannot contain the following special characters:

? : ; | ! @ # \$ % ^ & * < = > + () { } ~ , \ / [] ' "

- b. Provide a **Description** for the set.
 - c. Click **Next**. The Add Processes screen is displayed.
6. Specify the process path.
- a. Click **Browse** next to the Directory field. The list of registered clients is displayed.
 - b. Select the desired client.
 - c. Click **Next**. The Browse Path dialog box is displayed.
 - d. Browse the process.

Alternatively, specify the process name (with its path) in the **Path** field. For a Windows path, use \ (backward slashes), for a Linux path, use / (forward slashes). A directory path must end with a slash.

- e. Click **Add**.

The selected directory and process appear in the **Directory** and **File** fields. If a process is not selected, the **File** field shows an (*) asterisk. The asterisk acts as a wild card character.

Alternatively, specify the directory and process in the **Directory** and **File** fields. For a Windows path, use \ (backward slashes), for a Linux path, use / (forward slashes). A directory path must end with a slash.

7. Link the desired signature set to the process set.
 - a. Click **Select** next to the Signature field. The list of signature sets is displayed.
 - b. Select the desired signature set.
 - c. Click **Next**.

The selected signature set appears in the **Signature** field.

8. Click **Next**. The Confirmation screen shows general information about the set.

Directory	File	Signature	
/usr/bin/	*	testsigset	***

9. Verify the set details.

If the details are incorrect or you want to modify them, click **Back** and update the details. To add another process, click **Add Another Process**, and specify the details, as described above.

10. Click **Save**. The process set is created.

The newly created set appears on the Process Sets tab.

	Name	Updated At ↓	Description	
☐	testprocessset	18 Aug 2020, 12:34	Test process set	...
☐	aprocesstest	18 Aug 2020, 12:34	A process set	...

After you have created policy elements, you can use them in creating and configuring policies. Refer to ["Creating Policies" on page 114](#) for details.

Viewing Policy Elements

The Policy Elements page shows the list of configured policy elements.

To view the policy elements:

1. Open the **CTE** application.
2. Click **Policies > Policy Elements**. The Policy Elements page contains the following tabs:

Column	Description
Resource Sets	Displays the list of configured resource sets. This is the default tab.
User Sets	Displays the list of configured user sets.
Process Sets	Displays the list of configured process sets.
Signature Sets	Displays the list of configured signature sets.

3. Click the **Resource Sets** tab. This tab displays the following details:

	Name	Updated At ↓	Description	
☐	resourceSet	18 Aug 2020, 11:47	Resource set	...
☐	SG-ResourceSet	18 Aug 2020, 11:38		...

Column	Description
Name	Name of the resource set.
Updated At	Time when the set is created or updated.
Description	Optional description of the resource set.

By default, the records are displayed in descending order by Updated At. To add a new resource set, refer to ["Creating Resource Sets" on page 104](#).

To modify an existing resource set, click the desired set, modify the **Description**, and click **Apply**. The edit view also provides the **Add Resource** button to add new resources to the set.

4. Click the **User Sets** tab. This tab displays the following details:

Name	Updated At ↓	Description	
☐ userset	18 Aug 2020, 12:10	A test user set	...
☐ testuserset	18 Aug 2020, 12:09	Test user set	...

Column	Description
Name	Name of the user set.
Updated At	Time when the set is created or updated.
Description	Optional description of the user set.

By default, the records are displayed in descending order by Updated At. To add a new user set, refer to ["Creating User Sets" on page 105](#).

To modify an existing user set, click the desired set, modify the **Description**, and click **Apply**. The edit view also provides the **Browse for users** and **Manually add user** buttons to add new users to the set.

5. Click the **Process Sets** tab. This tab displays the following details:

Name	Updated At ↓	Description	
☐ testprocessset	18 Aug 2020, 12:34	Test process set	...
☐ aprocessset	18 Aug 2020, 12:34	A process set	...

Column	Description
Name	Name of the process set.
Updated At	Time when the set is created or updated.
Description	Optional description of the process set.

By default, the records are displayed in descending order by Updated At. To add a new process set, refer to ["Creating Process Sets" on page 110](#).

To modify an existing process set, click the desired set, modify the **Description**, and click **Apply**. The edit view also provides the **Add Process** button to add new processes to the set.

6. Click the **Signature Sets** tab. This tab displays the following details:

	Name	Signing Status	Updated At ↓	Description	
☐	testsigset	Unsigned	18 Aug 2020, 07:54	Test signature set	...
☐	test	Unsigned	18 Aug 2020, 00:55		...

Column	Description
Name	Name of the signature set.
Signing status	Signing status of the signature set. Refer to "Checking Signing Completion Status" on page 92 for details.
Updated At	Time when the set is created or updated.
Description	Optional description of the signature set.

By default, the records are displayed in descending order by Updated At. To add a new signature set, refer to ["Creating Signature Sets" on page 108](#).

To add a new source to an existing signature set, click the desired set, and click **Add Source** on the **Source** tab.

Creating Policies

A policy is a collection of rules that govern data access and encryption. Think of a policy as an if-then statement. Policy rules are processed sequentially. If the criteria of rule one are not met, the policy enforcement engine moves on to the second rule and so on.

Policies specify:

- > **Actors:** Users, groups, and processes that are permitted/denied access to protected data.
- > **Actions:** What actions authorized actors are allowed to perform. For example create/delete, read/write, decrypt, modify permissions, and so on.
- > **Files acted upon:** Policy rules may apply to entire directories and mount points, or only to files named in a specific way (for example, .docx files may be encrypted and restricted to read only access by designated users, while other files may be stored clear and read and written by anyone).

Additionally, each CTE policy specifies one or more encryption keys used to encrypt blocks of file data when applications write them, and decrypt them when they are read.

CTE encryption is transparent to applications. This means that the CTE Agent encrypts blocks of data as they are written, and decrypts data when they are read by authorized users and applications. This architecture separates administration of files from access to the data in them. Backup programs, for example, may be authorized to read files, but not view the data in them. Therefore, data can be backed up and taken offsite while remaining encrypted so that security is not breached.

The following diagram shows policies and how they relate to the GuardPoints, clients, and the CipherTrust Manager.

Before you can create a policy, policy elements should exist on the CipherTrust Manager. This section assumes that you have already created policy elements, as described in ["Creating Policy Elements" on page 103](#).

When creating a policy, you can specify security rules, key rules, and data transformation (dataxform) rules that apply to the policy. At least one key or security rule must be added to a policy. Use the Create Policy wizard to create a policy.

To create and configure policies:

- > ["Step 1: Specify General Information" below](#)
- > ["Step 2: Add Security Rules" on page 117](#)
- > ["Step 3: Add Key Rules" on page 119](#)
- > ["Step 4: Add Data Transformation Rules" on page 121](#)
- > ["Step 5: Confirm Details" on page 122](#)

Step 1: Specify General Information

To specify general information about policy:

1. Open the **CTE** application.
2. Click **Policies**. The Policies page shows the list of available policies.
3. Click **Create Policy**.
4. Specify a unique **Name** for the policy. For example, `basic-access-policy` or `ldt-policy`.

NOTE

- > The name must start with a character. The maximum length can be 64 characters.
- > The name can contain alphanumeric characters, underscores (_), and dashes (-).
- > The name cannot contain the following special characters:
 ? : ; | ! @ # \$ % ^ & * < = > + () { } ~ , \ / [] ' "

5. Select a **Policy Type**. The options are:

- **Standard:** Access to data is blocked during initial encryption or rekeying of data. This is the default policy type.
- **Live Data Transformation:** Encryption and rekeying of data takes place in the background, without disrupting user or application access to that data. The LDT policy is available if you have a valid LDT license.

If you select an LDT policy type, then the first security rule for the policy is created by default. This rule permits key operations on all resources for that policy, without denying user or application access to resources. This allows a rekey operation whenever the encryption key is versioned. This rule is always the first rule in an LDT policy and cannot be edited.

- Refer to ["Enabling Live Data Transformation" on page 57](#) for more information about LDT.
- An LDT policy is needed for creating LDT GuardPoints. Refer to ["Creating LDT GuardPoints on Clients" on page 140](#) for details.

- **Cloud Object Storage:** Access to data is blocked during initial encryption or rekeying of data. This policy type is needed for creating GuardPoints for cloud storages. Refer to ["Creating Cloud Object Storage GuardPoints on Clients" on page 143](#) for details.

6. (Optional) Turn on the **Learn Mode** toggle. A warning message is displayed indicating that the policy is in Learn Mode.

Refer to ["Learn Mode" on page 31](#) for details. By default, the toggle is turned off.

7. (Optional, applicable to Standard policies) Turn on the **Data Transformation** toggle. This option is used to create a [dataxform](#) policy. By default, the toggle is turned off.

NOTE The Data Transformation option is not applicable to LDT and Cloud Object Storage policies. For a dataxform policy, the Create Policy wizard shows *five* steps including the Data Transformation step, as shown below.

8. Click **Next**. The Security Rules screen is displayed.

- > For a standard dataxform policy, a security rule with the Action `key_op` and the Effect `permit, applykey` and Browsing set to Yes is added automatically. Edit or delete the rule, as appropriate. Click the overflow icon (`...`) for options.

Resource Set	User Set	Process Set	Action	Effect	Browsing	
			key_op	permit,applykey	Yes	⋮

- > For an LDT policy, the default security rule with the Action `key_op` and the Effect `permit, applykey` and Browsing set to No added automatically. The rule is *read only*.

Resource Set	User Set	Process Set	Action	Effect	Browsing	
			key_op	permit,applykey	No	

Step 2: Add Security Rules

1. Click **Create Security Rule**. The Create Security Rule dialog box is displayed. This dialog box contains the following fields:

Field	Description
Resource Set	(Applicable to Standard and LDT policies) Resource set for the rule.
User Set	User set for the rule.
Process Set	Process set for the rule.
Action	Actions for the rule. Refer to "Actions" on page 27 for the complete list of supported actions.
Effect	Effect permission and options for the rule. This is a mandatory field.
Browsing	(Applicable to Standard and LDT policies) Whether browsing of directories under the GuardPoint down to the resources in the rule is allowed.

2. (Optional, applicable to Standard and LDT policies) Select a **Resource Set**.
 - a. Click **Select** next to the Resource Set field. The list of available resource sets is displayed.
Optionally, you can add a new resource set by clicking **Create Resource Set**. Walk through the Create Resource Set wizard, as described in ["Creating Resource Sets"](#) on page 104. The newly created resource set appears in the resource sets list.
 - b. Select a resource set.
 - c. (Optional) Select **Exclude Rule** to exclude the resource set from the policy. The security rule does not apply to this resource set.
 - d. Click **Select**. The selected resource set appears in the Resource Set field.
3. (Optional) Select a **User Set**.
 - a. Click **Select** next to the User Set field. The list of available user sets is displayed.

- **ApplyKey:** Applies an encryption key to data in a GuardPoint. When applied, data copied to the GuardPoint is encrypted with the key specified on the Create Key Rule screen and data that is accessed in the GuardPoint is decrypted using the same key. It allows the access attempt to the resource. For example, you can specify an effect that allows writing to a directory.

NOTE If you select ApplyKey, you must also specify the key rules to apply for encrypting and decrypting the resources. Refer to ["Step 3: Add Key Rules" below](#) for details.

- **Audit:** Creates a message log entry for each qualifying event. It records what, when, and who is accessing the information.

d. Click **Select**. The selected effects appear in the Effect field.

7. (Optional, applicable to Standard and LDT policies) Specify whether to **Allow Browsing** the directories under the GuardPoint down to the resources in the rule.

By default, the **Allow Browsing** toggle is on. Users that match the criteria set by the security rule can access the directories between the GuardPoint and the resource. If you define a resource, then that resource should exist in the GuardPoint. The files in these directories can be listed like any file in a browser, but they cannot be modified, copied, or deleted.

To prevent users from browsing the directories under the GuardPoint, turn off the **Allow Browsing** toggle.

8. Click **Add**. The newly created security rule appears in the list of security rules.

Similarly, you can add multiple security rules to the policy by clicking **Create Security Rule**. To delete a security rule, click **Delete** next to the rule.

NOTE A security rule with the ApplyKey Effect must be supported by at least one key rule. Refer to ["Step 3: Add Key Rules" below](#).

9. Click **Next**. The Key Rules screen is displayed.

Step 3: Add Key Rules

If you added a security rule with the Effect ApplyKey on the Security Rule screen, then you must add at least one key rule.

To add a key rule:

1. Click **Create Key Rule**. The Create Key Rule dialog box is displayed.
2. (Optional, applicable to Standard and LDT policies) Select a **Resource Set**.
 - a. Click **Select** next to the Resource Set field. The list of available resource sets is displayed.
Optionally, you can add a new resource set by clicking **Create Resource Set**. The newly created resource set will appear in the resource sets list.
 - b. Select a resource set.
 - c. Click **Select**. The selected resource set appears in the Resource Set field.
3. Select a **Key Name**. This is a mandatory field. For LDT and Data Transformation policies, the field name is **Current Key Name** instead of Key Name.
 - a. Click **Select** next to the field. The list of available keys is displayed.

Optionally, you can create a new key by clicking **Create a New Key**. Optionally, specify a **Name** for the key and click **Create**. The newly created key will appear in the keys list.

Alternatively, encryption keys for CTE can be created on the **Keys** page of the **Keys & Access Management** application. Refer to ["Creating a New Key" on page 122](#) for details.

- b. Select the desired key.

NOTE The CTE keys must be:

- > AES128, AES-256, ARIA-128, or ARIA-256
- > Shared with the CTE Clients group
- > Set as exportable

Only the clients that support the CBC CS1 encryption mode can have GuardPoints that use a policy with a CBC CS1 key.

- c. Click **Select**. The selected key appears in the Key Name / Current Key Name field.

The next two steps are specific to LDT policies.

4. (Applicable to LDT policies) Select a **Transformation Key Name**. This is a mandatory field.

- a. Click **Select** next to the field. The list of available keys is displayed.

Optionally, you can create a new key by clicking **Create a New Key**. Optionally, specify a **Name** for the key and click **Create**. The newly created key will appear in the keys list.

Alternatively, encryption keys for CTE can be created on the **Keys** page of the **Keys & Access Management** application. Refer to ["Creating a New Key" on page 122](#) for details.

- b. Select the desired key.

NOTE The CTE keys must be:

- > AES128, AES-256, ARIA-128, or ARIA-256
- > Shared with the CTE Clients group
- > Set as exportable

Only the clients that support the CBC CS1 encryption mode can have GuardPoints that use a policy with a CBC CS1 key.

- c. Click **Select**. The selected key appears in the Transformation Key Name field.

5. Click **Add**. The newly created key rule appears in the list of key rules.

Similarly, you can add multiple key rules to the policy by clicking **Create Key Rule**. To delete a key rule, click **Delete** next to the rule.

6. Click **Next**.

- > For Live Data Transformation and Cloud Object Storage policies, the Confirmation screen is displayed. Verify policy details, as described in ["Step 5: Confirm Details" on page 122](#).
- > For Standard policies, the following screen is displayed:

- **Data Transformation:** If you selected the Data Transformation check box on the General Info screen of the Create Policy wizard. Add data transformation rules, as described in ["Step 4: Add Data Transformation Rules"](#) below.
- **Confirmation:** If you cleared the Data Transformation check box. Verify policy details, as described in ["Step 5: Confirm Details"](#) on the next page.

Step 4: Add Data Transformation Rules

This step is applicable to Standard policies if you selected the Data Transformation check box on the General Info screen of the Create Policy wizard.

1. Click **Create Data Transformation Rule**. The Create Data Transformation Rule dialog box is displayed.
2. (Optional) Select a **Resource Set**.
 - a. Click **Select** next to the Resource Set field. The list of available resource sets is displayed.
Optionally, you can add a new resource set by clicking **Create Resource Set**. The newly created resource set will appear in the resource sets list.
 - b. Select a resource set.
 - c. Click **Select**. The selected resource set appears in the Resource Set field.
3. Select the **Transformation Key Name**. This is a mandatory field.
 - a. Click **Select** next to the Transformation Key Name field. The list of available keys is displayed.
Optionally, you can create a new key by clicking **Create a New Key**. Optionally, specify a **Name** for the key and click **Create**. The newly created key will appear in the keys list.
Alternatively, encryption keys for CTE can be created on the **Keys** page of the **Keys & Access Management** application. Refer to ["Creating a New Key"](#) on the next page for details.
 - b. Select the desired key.

NOTE The CTE keys must be:

- > AES128, AES-256, ARIA-128, or ARIA-256
 - > Shared with the CTE Clients group
 - > Set as exportable

Only the clients that support the CBC CS1 encryption mode can have GuardPoints that use a policy with a CBC CS1 key.
- c. Click **Select**. The selected key appears in the Transformation Key field.
4. Click **Add**. The newly created data transformation rule appears in the list of rules.
Similarly, you can add multiple rules to the policy by clicking **Create Data Transformation Rule**. To delete a rule, click **Delete** next to the rule.
5. Click **Next**. The Confirmation screen is displayed.

Step 5: Confirm Details

1. Verify the policy details. The Confirmation screen displays general information about the policy and details of the security and key rules added to the policy.

If the details are incorrect or you want to modify them, click **Back** and update the details.

Sample confirmation

2. Click **Save**.

The newly created policy appears in the policies list on the Policies page. Similarly, add as many policies as required. A sample list of policies is shown below:

	Name	Type	Version	Updated At	Description	
☐	testcospic	Cloud Object Storage	1	18 Aug 2020, 17:35	Test COS policy	...
☐	ldtpic	Live Data Transformation	1	18 Aug 2020, 17:32		...
☐	testpolicy	Standard	1	18 Aug 2020, 17:30		...

Creating a New Key

When creating a key rule for a policy, you can either select an existing key or create a new key. The list of available keys is displayed on the Select Key dialog box. The new keys that you create on this dialog box appear under the keys list.

Alternatively, encryption keys for CTE can be created on the **Keys** page of the **Keys & Access Management** application, as described below.

NOTE The CTE keys must be:

- > AES128, AES-256, ARIA-128, or ARIA-256
- > Shared with the CTE Clients group
- > Set as exportable

Only the clients that support the CBC CS1 encryption mode can have GuardPoints that use a policy with a CBC CS1 key.

To create a new key:

1. Open the **Keys & Access Management** application.
2. On the Keys page, click **Create a New Key**.
3. Specify the **Key Name**.
4. Select the **Algorithm** from the drop-down list. The default algorithm is AES. CTE supports AES and ARIA algorithms.
5. Select the key **Size** from the drop-down list. The default size is 256.

6. Under the **Key Metadata** section, type **CTE** in the **Groups for Key sharing** box to filter the groups. The CTE Admins and CTE Users groups are displayed.

Groups for Key sharing

Group Names	Key Shared?	
CTE Admins	☐	<button>Add</button>
CTE Clients	☐	<button>Add</button>

7. Click **Add** next to the **CTE Clients** group.
8. Select the **CTE Key Properties** check box. The following fields appear:

☒ CTE Key Properties

☒ CTE Versioned ☐ Persistent on Client

Encryption Mode

- **CTE Versioned:** Specify whether the key is versioned. By default, the key is set as versioned.
 - For Standard and COS policies, clear the **CTE Versioned** check box. This makes sure that the is displayed in the keys list when you add the key rule to the policy.
 - For LDT policies, make sure that the **CTE Versioned** check box is selected.
- **Persistent on Client:** Specify whether the key is stored in persistent memory on the client.
 - When the check box is selected, the key is downloaded and stored (in an encrypted form) in persistent memory on the client.
 - When the check box is left clear, the key is downloaded to non-persistent memory on the client. Every time the key is needed, the client retrieves it from the CipherTrust Manager. This is the default setting.
- **Encryption Mode:** Encryption mode of the key. The options are:
 - CBC
 - CBC CS1
 - XTS

Encryption using the XTS and CBC CS1 keys is known as enhanced encryption. Refer to the CTE Agent Advanced Configuration and Integration Guide specific to your platform for details.

9. Scroll down to the **Key Behaviors** section.
10. Clear **Prevent this key from being exported**. This makes sure that the is displayed in the keys list when you add the key rule to the policy.

Key Behaviors

☒ Prevent this key from being deleted ☐ Prevent this key from being exported

11. Click **Create**.

The newly created key appears in the keys list.

NOTE

- > Only CTE Administrators (users of the CTE Admins group) can delete the CTE keys.
- > An in-use CTE key cannot be deleted. Before you delete a CTE key, make sure that no security rule is using the key.

Displaying Policies

The Policies page shows the list of configured policies with their details such as names, types, and versions. You can view the version history of policies from the Policies page. Additionally, you can delete policies from this page. In the detail view, you can view types of rules linked with the policies.

Name	Type	Version	Updated At: ↓	Description	
☐ testcospic	Cloud Object Storage	0	18 Aug 2020, 17:35	Test COS policy	---
☐ ldtplc	Live Data Transformation	0	18 Aug 2020, 17:32		---
☐ testpolicy	Standard	0	18 Aug 2020, 17:30		---

This section covers the following information:

- > ["Viewing Policies" below](#)
- > ["Viewing Details of Policies" on the next page](#)
- > ["Viewing Policy Version History" on page 127](#)

Viewing Policies

To view the complete list of configured policies:

1. Open the **CTE** application.
2. Click **Policies**. The Policies page shows the following details:

Column	Description
Name	Unique name of the policy.

Column	Description
Type	Type of the policy can be: > STANDARD > LDT > CLOUD OBJECT STORAGE
Version	Version of the policy. Click to view the version history of the policy. Refer to " Viewing Policy Version History " on page 127 for details.
Updated At	Time when the policy is created or updated.
Description	Optional description of the policy.

By default, the policies are displayed in descending order by Updated At. By default, 10 records per page are displayed. Adjust pagination and/or the number of records to display per page to view more records.

To add a new policy, click **Create Policy**. Refer to "[Creating Policies](#)" on page 114 for details.

Viewing Details of Policies

To view the details of a policy:

1. Open the **CTE** application.
2. Click **Policies**. The list of configured policies is displayed.
3. Under **Name**, click the desired policy. The rules linked with the policy are displayed on the following tabs:
 - Security Rules
 - Key Rules
 - Data Transformation Rules (Applicable to Standard policies that contain data transformation rules)

NOTE If a policy is in Learn Mode, a warning banner stating the following is displayed at the top of the page:

Warning: This Policy is in Learn Mode

To disable the Learn Mode, turn off the **Learn Mode** toggle on the right.

4. Click the **Security Rules** tab. This tab displays the following details:

Column	Description
Order	Sequence to enforce security rules. Rules higher in the order take higher priority.
Resource Set	(Not applicable to Cloud Object Storage policies) Resource set linked with the rule.
User Set	User set linked with the rule.

Column	Description
Process Set	Process set linked with the rule.
Action	Action applied to the rule. Refer to "Actions" on page 27 for the complete list of supported actions.
Effect	Effect applied to the rule.
Browsing	Whether browsing of directories under the GuardPoint down to the resources in the rule is allowed. For Cloud Object Storage policies, No is displayed.

To add a new security rule, refer to ["Step 2: Add Security Rules" on page 117](#) for details.

- Click the **Key Rules** tab. This tab displays the following details:

NOTE For Cloud Object Storage policies, only **Key Id** is displayed.

Column	Description
Order	Sequence to enforce key rules. Rules higher in the order take higher priority.
Resource Set	Resource set linked with the key rule.
Key Name / Current Key Name	Encryption key currently applied to the resource. For LDT and Data Transformation policies, the name is Current Key Name.
Transformation Key Name	(Applicable to LDT policies) Encryption key to perform data transformation for LDT policies.
Exclusion Rule	(Applicable to LDT policies) Whether to exclude the resource set from the policy.

To add a new security rule, refer to ["Step 3: Add Key Rules" on page 119](#) for details.

- Click the **Data Transformation Rules** tab. This tab is displayed if the policy contains data transformation rules. This tab displays the following details:

Column	Description
Order	Sequence to enforce key rules. Rules higher in the order take higher priority.
Resource Set	Resource linked with the key rule.
Transformation Key Name	Transformation key to use for rekeying.

To add a new data transformation rule, refer to ["Step 4: Add Data Transformation Rules" on page 121](#) for details.

Viewing Policy Version History

The policy version defines the number of times a policy has been changed. This number indicates the current revision only. It cannot be used to roll back to a previous version. Restore a backup to revert to a previous online policy version. The version count starts at zero when the policy is initially created and increments by one each time it is saved thereafter.

Policy Version History

Version	Date	Author	Comment
4	07/28/20	admin	Delete LDT Key Rule
2	07/28/20	admin	LDT Key Rule Created
2	07/28/20	admin	Dataform Rule Created
1	07/28/20	admin	Key Rule Created
0	07/28/20	admin	Policy Created
0	07/28/20	admin	LDT Key Rule Created
0	07/28/20	admin	Dataform Rule Created
0	07/28/20	admin	Key Rule Created
0	07/28/20	admin	Security Rule Created

9 Policy Audit Records 10 per page +

To view the version history of a policy:

1. Open the **CTE** application.
2. In the left pane, click **Policies**.
3. Click the version number of the policy. The Policy Version History popup displays the following details:

Field	Description
Version	Version of the policy.
Date	Date when the version is created.
Author	User who changed the policy.
Comment	Description of change.

4. Click **OK**.

Modifying Policies and Rules

On the Policies page, you can update the description of policies and delete policies that are no longer needed. Additionally, you can modify the key and security rules linked to the policy. Information in this section is divided into the following topics:

- > ["Updating Policy Description" on the next page](#)

- > "Cloning a Policy" below
- > "Adding New Security Rules" on the next page
- > "Adding New Key Rules" on the next page
- > "Adding New Data Transformation Rules" on page 130
- > "Modifying Security Rules" on page 130
- > "Modifying Key Rules" on page 131
- > "Modifying Data Transformation Rules" on page 133
- > "Deleting Policies" on page 134

Updating Policy Description

To update the description of a policy:

1. Open the **CTE** application.
2. In the left pane, click **Policies**.
3. Click the overflow icon () corresponding to the desired policy.
4. Click **Edit**.
5. Add or modify the **Description**. The policy Name and Type cannot be modified.
6. Click **Update**.

The updated description appears in the policies list.

Cloning a Policy

Cloning is an efficient and simple method to create a copy of an existing policy. The clone is a separate policy and contains all the configurations of its parent policy. When cloning a policy, specify a new unique name for the clone. Also, enable or disable Learn Mode for the clone, if required.

To duplicate a policy:

1. Open the **CTE** application.
2. In the left pane, click **Policies**.
3. Click the overflow icon () corresponding to the desired policy.

4. Click **Clone**.
5. Enter a unique **Name** for the clone.
6. (Optional) Provide a **Description** for the clone.

7. (Optional) Turn on/off the **Learn Mode** toggle. Refer to ["Learn Mode" on page 31](#) for details.

Duplicating policy ldtpic

clone-pic

Description

A copy of ldtpic

Learn Mode: ☐

The clone with the specified name appears at the top of the policies list.

	Name	Type	Version	Updated At	Description	
☐	clone-pic	Live Data Transformation	1	18 Aug 2020, 20:12	A copy of ldtpic	⋮

Adding New Security Rules

To add a new security rule to a policy:

1. Open the **CTE** application.
2. In the left pane, click **Policies**.
3. Click the desired policy.
4. On the **Security Rules** tab, click **Add Security Rule**. The Add Security Rule dialog box is displayed.
5. Specify the required details. The fields on the Add Security Rule dialog box are same as the fields on the Create Security Rule dialog box. Refer to ["Step 2: Add Security Rules" on page 117](#) for details.
6. Click **Add**.

The newly added security rule appears in the security rules list. Similarly, you can add more security rules to the policy.

Adding New Key Rules

To add a new key rule to a policy:

1. Open the **CTE** application.
2. In the left pane, click **Policies**.
3. Click the desired policy.
4. Click the **Key Rules** tab.
5. Click **Add Key Rule**.
6. Specify the required details. The fields on the Add Key Rule dialog box are same as the fields on the Create Key Rule dialog box. Refer to ["Step 3: Add Key Rules" on page 119](#) for details.
7. Click **Add**.

The newly added key rule appears in the key rules list. Similarly, you can add more key rules to the policy.

Adding New Data Transformation Rules

To add a new data transformation rule to a policy:

1. Open the **CTE** application.
2. In the left pane, click **Policies**.
3. Click the desired policy.
4. Click the **Data Transformation Rules** tab.
5. Click **Add Data Transformation Rule**. The Add Data Transformation Rule dialog box is displayed.
6. Specify the required details. The fields on the Add Data Transformation Rule dialog box are same as the fields on the Create Data Transformation Rule dialog box. Refer to ["Step 4: Add Data Transformation Rules" on page 121](#) for details.
7. Click **Add**.

The newly added data transformation rule appears in the data transformation rules list. Similarly, you can add more rules to the policy.

Modifying Security Rules

- > ["Editing Security Rules" below](#)
- > ["Changing Order of Security Rules" below](#)
- > ["Deleting Security Rules" on the next page](#)

Editing Security Rules

To edit a security rule in a policy:

1. Open the **CTE** application.
2. In the left pane, click **Policies**.
3. Click the desired policy.
4. Click the **Security Rules** tab.
5. Click the overflow icon () corresponding to the desired rule.
6. Click **Edit**. The Edit Security Rule dialog box is displayed.
7. Change the required fields. The fields on the Edit Security Rule dialog box are the same the fields on the Create Security Rule dialog box. Refer to ["Step 2: Add Security Rules" on page 117](#) for details.
8. Click **Update**.

The updated details appear in the security rules list.

Changing Order of Security Rules

To change the order of a security key rule in a policy:

1. Open the **CTE** application.
2. In the left pane, click **Policies**.

3. Click the desired policy.
4. Click the **Security Rules** tab.
5. Select the desired rule. Depending on the current order, the following ordering icons are activated.

Icon	Description
Bottom (⇓)	Move the rule to the bottom. Unavailable for the rule at the bottom.
Down (↓)	Move the rule one place lower. Unavailable for the rule at the bottom.
Up (↑)	Move the rule one place higher. Unavailable for the rule at the top.
Top (⇑)	Move the rule to the top. Unavailable for the rule at the top.

6. Click the desired icon.

The rules list shows the updated order.

Deleting Security Rules

To delete security rules from a policy:

1. Open the **CTE** application.
2. In the left pane, click **Policies**.
3. Click the desired policy.
4. Click the **Security Rules** tab.
5. Select the check boxes corresponding to the desired rules.

To select all rules visible on the page for deletion, select the top check box to the left of the Order heading.

6. Click the delete icon (■).

The selected rules are removed from the security rules list.

Modifying Key Rules

Modifying key rules linked with a policy involves:

- > ["Editing Key Rules" below](#)
- > ["Changing Order of Key Rules" on the next page](#)
- > ["Deleting Key Rules" on the next page](#)

Editing Key Rules

To edit a key rule in a policy:

1. Open the **CTE** application.
2. In the left pane, click **Policies**.
3. Click the desired policy.
4. Click the **Key Rules** tab.

5. Click the overflow icon () corresponding to the desired rule.
6. Click **Edit**. The Edit Key Rule dialog box is displayed.
7. Change the required fields. The fields on the Edit Key Rule dialog box are the same the fields on the Create Key Rule dialog box. Refer to ["Step 3: Add Key Rules" on page 119](#) for details.
8. Click **Update**.

The updated details appear in the key rules list.

Changing Order of Key Rules

To change the order of a key rule in a policy:

1. Open the **CTE** application.
2. In the left pane, click **Policies**.
3. Click the desired policy.
4. Click the **Key Rules** tab.
5. Select the desired rule. Depending on the current order, the following ordering icons are activated.

Icon	Description
Bottom ()	Move the rule to the bottom. Unavailable for the rule at the bottom.
Down ()	Move the rule one place lower. Unavailable for the rule at the bottom.
Up ()	Move the rule one place higher. Unavailable for the rule at the top.
Top ()	Move the rule to the top. Unavailable for the rule at the top.

6. Click the desired icon.

The key rules list shows the updated order.

Deleting Key Rules

To delete key rules from a policy:

1. Open the **CTE** application.
2. In the left pane, click **Policies**.
3. Click the desired policy.
4. Click the **Key Rules** tab.
5. Select the check boxes corresponding to the desired rules.

To select all rules visible on the page for deletion, select the top check box to the left of the Order heading.

6. Click the delete icon ()

The selected rules are removed from the key rules list.

Modifying Data Transformation Rules

Modifying data transformation rules linked with a policy involves:

- > ["Editing Data Transformation Rules" below](#)
- > ["Changing Order of Data Transformation Rules" below](#)
- > ["Deleting Data Transformation Rules" on the next page](#)

Editing Data Transformation Rules

To edit a data transformation rule in a policy:

1. Open the **CTE** application.
2. In the left pane, click **Policies**.
3. Click the desired policy.
4. Click the **Data Transformation Rules** tab.
5. Click the overflow icon () corresponding to the desired rule.
6. Click **Edit**. The Edit Data Transformation Rule dialog box is displayed.
7. Change the required fields. The fields on the Edit Data Transformation Rule dialog box are the same the fields on the Create Data Transformation Rule dialog box. Refer to ["Step 4: Add Data Transformation Rules" on page 121](#) for details.
8. Click **Update**.

The updated details appear in the data transformation rules list.

Changing Order of Data Transformation Rules

To change the order of a data transformation rule in a policy:

1. Open the **CTE** application.
2. In the left pane, click **Policies**.
3. Click the desired policy.
4. Click the **Data Transformation Rules** tab.
5. Select the desired rule. Depending on the current order, the following ordering icons are activated.

Icon	Description
Bottom ()	Move the rule to the bottom. Unavailable for the rule at the bottom.
Down ()	Move the rule one place lower. Unavailable for the rule at the bottom.
Up ()	Move the rule one place higher. Unavailable for the rule at the top.
Top ()	Move the rule to the top. Unavailable for the rule at the top.

6. Click the desired icon.

The rules list shows the updated order.

Deleting Data Transformation Rules

To delete data transformation rules from a policy:

1. Open the **CTE** application.
2. In the left pane, click **Policies**.
3. Click the desired policy.
4. Click the **Data Transformation Rules** tab.
5. Select the check boxes corresponding to the desired rules.

To select all rules visible on the page for deletion, select the top check box to the left of the Order heading.

6. Click the delete icon ().

The selected rules are removed from the data transformation rules list.

Deleting Policies

CipherTrust Manager provides options to delete single or multiple policies.

Deleting Single Policies

To delete a single policy:

1. Open the **CTE** application.
2. In the left pane, click **Policies**.
3. Click the overflow icon () corresponding to the desired policy.
4. Click **Delete**.

The selected policy is removed from the policies list.

Deleting Multiple Policies

To delete single or multiple policies:

1. Open the **CTE** application.
2. In the left pane, click **Policies**.
3. Select the check boxes corresponding to the desired policies.

To select all policies visible on the page for deletion, select the top check box corresponding to the left of the Name heading.

4. Click the delete icon ().

The selected policies are removed from the policies list.

CHAPTER 9: Managing GuardPoints

A GuardPoint specifies the list of folders that contains paths to be protected. Access to files and encryption of files under the GuardPoint is controlled by security policies.

This chapter contains the following sections:

- > ["Overview" below](#)
- > ["Secure Start GuardPoints" on the next page](#)
- > ["Considerations Before Creating GuardPoints" on the next page](#)
- > ["Creating Standard GuardPoints on Clients" on page 138](#)
- > ["Creating LDT GuardPoints on Clients" on page 140](#)
- > ["Creating Cloud Object Storage GuardPoints on Clients" on page 143](#)
- > ["Enabling Secure Start for GuardPoints" on page 144](#)
- > ["Creating GuardPoints on Client Groups" on page 145](#)
- > ["Automatic and Manual GuardPoints" on page 151](#)
- > ["Viewing GuardPoints" on page 154](#)
- > ["Viewing GuardPoint Status" on page 155](#)
- > ["Configuring Windows Network Drives" on page 156](#)
- > ["Deleting GuardPoints" on page 157](#)

Overview

Before you apply GuardPoints:

- > A CTE Agent must be installed on the client system and registered with CipherTrust Manager. Refer to the CTE Agent Quick Start Guide specific to your platform for details.
- > A client must be added to the CipherTrust Manager. The client is automatically added to the CipherTrust Manager on successful registration with the CipherTrust Manager.
- > Policies must be created using the encryption keys on the CipherTrust Manager. This involves creation of policy elements and encryption keys. Refer to ["Managing Policies" on page 101](#) for details.
- > A GuardPoint must be created. No one must be using the directory to be guarded before making it a GuardPoint.

If users are working on the directory when it is made a GuardPoint, they can continue to use data in memory rather than use the actual data in the GuardPoint. Inform users to:

- > Save their work
- > Close applications that are running on the directory
- > Exit the directory before applying the GuardPoint

When the users re-enter the directory, they will use protected data and the CTE Agent will work appropriately.

Secure Start GuardPoints

NOTE The Secure Start feature is supported on Windows clients.

Secure Start offers a new type of GuardPoint that offers data protection for applications that start earlier in the boot sequence than VMD (CTE Agent daemon). For example, an AD (Active Directory) or a SQL Server service starts very early. A Secure Start GuardPoint starts before the AD and SQL services, and can, therefore, encrypt those services.

For more information on protecting such applications using Secure Start, refer to the CTE Agent for Windows Advanced Configuration and Integration Guide. To determine whether other applications qualify for Secure Start, contact Thales Customer Support.

Considerations Before Creating GuardPoints

- > If a client is to be added to a client group, do not apply a GuardPoint at the client level, rather, apply the GuardPoint at the client group level. You can do both, but it is harder to keep track of GuardPoints applied at the client group level and custom GuardPoints applied at the client level.
- > Certain directories are protected against guarding. So plan your GuardPoints accordingly:

Windows Platforms

- The following folders cannot be guarded because a GuardPoint cannot be applied to a folder that contains open files.
 - The top-level "Program Data" folder on Windows Vista and Windows 2008
 - The top-level "Documents and Settings" folder on all other Windows platforms
 - The "Users" folder
- The CTE Agent opens and continually maintains log files in subfolders under "ProgramData" and "Documents and Settings". Other subfolders below these folders can be guarded as long as no files are open in any subfolder at the time the GuardPoint is applied.
- Be especially careful when specifying paths for Windows agents. Cross-guarding the same folder with different policies and encryption keys returns unexpected results and corrupts the files in that folder.
- GuardPoint paths must use standard Windows path notation and delimiters.
 - Incorrect notation and delimiters are ignored and discarded by the Windows agent. Therefore, it is possible to enter two paths that resolve to the same Windows folder and successfully guard both of them. The CipherTrust Manager reports that it is guarding two unique folders when, in fact, it is guarding the same folder twice.
 - Do not use any of the following characters as path delimiters: | ? < > : * " / ,
For example, both `C : \gp\` and `C : \gp\/` are allowed by the CipherTrust Manager. When the second GuardPoint is applied, the extraneous "/" is discarded by the Windows CTE Agent and the Windows CTE Agent applies a GuardPoint to `C : \gp\` a second time.

Linux Platforms

- The following directories cannot be guarded:
 - `<secfs install root>/agent/secfs/`
 - `<install root>/agent/secfs/bin` and everything under it
 - `<secfs install root>/agent/vmd` and everything under it
 - `/etc/vormetric` and everything under it
 - `/etc`
 - `/etc/pam.d` and everything under it
 - `/etc/security` and everything under it
 - `/usr`
 - `/usr/lib`
 - `/usr/lib/pam`
 - `/usr/lib/security` and everything under it
 - `/etc/rc*` and everything under it
 - `/var/log/vormetric`
- You cannot apply CTE Agent protection to already mounted and guarded directories, nor can you nest GuardPoints.
 - The `/opt/vormetric/DataSecurityExpert/agent/secfs/.sec` directory is automatically mounted and guarded by `secfs` when the CTE Agent process starts on the client.
 - You cannot apply a GuardPoint to `/opt` because it contains the existing GuardPoint, `/opt/vormetric/DataSecurityExpert/agent/secfs/.sec`; however, you can guard a directory like `/opt/myapps` because it is in a different hierarchy and has no impact on `/opt/vormetric`.
 - Mounted and guarded directories can be displayed using the `df` command.
- > Both CipherTrust Manager and CTE support a new enhanced encryption mode (CBC-CS1). If your client groups contain clients with older versions of CTE, you cannot apply policies containing keys that use this new encryption mode. The action fails with an error message informing you that all clients in the client group do not support the key's encryption mode. Refer to the CTE Agent Advanced Configuration and Integration Guide specific to your platform for details.

When Changing a Policy or Rekeying a GuardPoint

- > To change a policy or rekey a GuardPoint, be prepared to temporarily stop access to the GuardPoint. Changing policies for a GuardPoint requires an interruption of service because the transition process entails disabling one policy and then enabling another policy. The GuardPoint must be inactive during the transition period to ensure GuardPoint integrity. The same rule applies to moving a client between client groups when it includes a change in policies. Coordinate policy changes during a maintenance outage window.
- > If LDT is enabled on your clients, encryption and rekeying of GuardPoint data is done without blocking user or application access to the data. LDT is a separately licensed feature, refer to ["Enabling Live Data Transformation" on page 57](#).

Creating Standard GuardPoints on Clients

Steps to create GuardPoints on individual clients and client groups are similar. GuardPoints can be created on the GuardPoints tab of individual clients and client groups.

To create a GuardPoint:

1. Open the **CTE** application.
2. Click **Clients > Clients**. The list of registered clients is displayed.
3. Under **Client Name**, click the client on which you want to create a GuardPoint.
4. On the **GuardPoints** tab, click **Create GuardPoint**.
5. Select a **Policy**. This is a mandatory field.
 - a. Click **Select** next to the Policy field.
 - b. Select a *Standard* policy. If no policy exists, create one, as described in ["Creating Policies" on page 114](#).

Name	Type	Version
☐ testcosplc	Cloud Object Storage	0
☒ testpolicy	Standard	1
☐ ldtplc	Live Data Transformation	0

- c. Click **Select**.
6. Select the **Type** of device to protect. This is a mandatory field. Depending on the platform, the options for the standard policy are:

Type	Windows	Linux	Description
Auto Directory	Yes	Yes	Select for file system directories.
Manual Directory	No	Yes	Select for file system directories to be guarded manually.
Auto Raw or Block Device	Yes	Yes	Select for standard policies for raw (block) devices.
Manual Raw or Block Device	No	Yes	Select for standard policies for raw (block) devices to be guarded manually.

NOTE Manual Directory and Manual Raw or Block Device are guarded and unguarded (for example, mounted and unmounted) by running the `secfsd -guard` and `secfsd -unguard` commands. Do not run the `mount` and `umount` commands to swap GuardPoint nodes in a cluster configuration.

7. Specify the **Path** to be protected. This is a mandatory field.

- Click **Browse** to select a path by browsing the client file system. This method prevents typographical errors and verifies client availability. This is the recommended method to specify the path.
- Alternatively, if you know the path, manually enter full paths of one or more directories. Enter one path per line.

NOTE

- > If a manually entered path does not exist yet, be sure to enter the path correctly. The CipherTrust Manager does not parse manually entered paths for correct syntax.
- > See ["Considerations Before Creating GuardPoints" on page 136](#) for what to be aware of before creating a GuardPoint.
- > If multiple paths are specified, they will all be protected by the same policy.

8. (Optional, Linux only) Select **Auto Mount** to specify an automount path. For a regular (non-auto) mount path, make sure that the check box is clear.

The screenshot shows the 'Create GuardPoint' dialog box. It has a title bar with a close button (X). The dialog contains three main sections: 'Policy' with a text field containing 'testpolicy' and a 'Select' button; 'Type' with a dropdown menu showing 'Auto Directory'; and 'Path' with a text area containing '/opt/cie-test/Files' and a 'Browse' button. At the bottom, there is an 'Auto Mount' checkbox which is checked.

9. (Optional, Windows only) Select **Secure Start** to enable the Secure Start feature. By default, the check box is clear.

If you plan not to enable the Secure Start now, you can do that later, as described in ["Enabling Secure Start for GuardPoints" on page 144](#).

10. Click **Create**. A message appears prompting to confirm the reuse the GuardPoint settings on another path.

- Click **Yes** to use the same settings on another path. The Use Settings on Another Path dialog box is displayed. Perform the following steps:
 - i. Specify a new **Path**.
 - ii. Click **Add Path**.
 - iii. Click **OK**.
- Click **No** if you do not want to use the same settings on another path.

Depending on the number of paths you add to a GuardPoint, a status information message may appear. Refer to ["GuardPoint Status Information" on the next page](#) for details.

The newly created GuardPoint appears on the GuardPoints tab. The status remains `Unknown` until the client sends the response after processing the GuardPoint request. Click the **Refresh GuardPoints** icon (↻) to view the updated status.

Status of a GuardPoint can be checked at any time on the GuardPoints tab. Refer to "[Viewing GuardPoint Status](#)" on page 155 for details.

GuardPoint Status Information

> When you add multiple paths to a GuardPoint:

- If GuardPoint is created successfully for all paths, a message is displayed at the top right corner of the screen.
- If GuardPoint is disabled or failed for at least one of the paths (for example, when a path is already guarded), a warning message similar to the following appears:

> When you add only one path, and the GuardPoint for that path fails, then an error message is displayed stating the reason of failure.

Creating LDT GuardPoints on Clients

To create an LDT GuardPoint on a client:

1. Open the **CTE** application.
2. Click **Clients > Clients**.
3. Under **Client Name**, click the LDT client on which you want to create a GuardPoint.
4. On the **GuardPoints** tab, click **Create GuardPoint**.
5. Select a **Policy**. This is a mandatory field.
 - a. Click **Select** next to the Policy field. The Select Policy dialog box is displayed.
 - b. Select a *Live Data Transformation* policy. If no policy exists, create one, as described in "[Creating Policies](#)" on page 114.

Name	Type	Version
☐ testcospic	Cloud Object Storage	0
☐ testpolicy	Standard	1
☒ ldtpic	Live Data Transformation	0

c. Click **Select**.

6. Select the **Type** of device to protect. This is a mandatory field. Depending on the platform, the options for an *LDT* policy are:

Type	Windows	Linux	Description
Auto Directory	Yes	Yes	Select for file system directories.
Manual Directory	No	Yes	Select for file system directories to be guarded manually.

NOTE Manual Directory is guarded and unguarded (for example, `mounted` and `unmounted`) by running the `secfsd -guard` and `secfsd-unguard` commands. Do not run the `mount` and `umount` commands to swap GuardPoint nodes in a cluster configuration.

7. Specify the **Path** to be protected. This is a mandatory field.
- Click **Browse** to select a path by browsing the client file system. This method prevents typographical errors and verifies client availability. This is the recommended method to specify the path.
 - Alternatively, if you know the path, manually enter full paths of one or more directories. Enter one path per line.

NOTE

- > If a manually entered path does not exist yet, be sure to enter the path correctly. The CipherTrust Manager does not parse manually entered paths for correct syntax.
- > See "[Considerations Before Creating GuardPoints](#)" on page 136 for what to be aware of before creating a GuardPoint.
- > If multiple paths are specified, they will all be protected by the same policy.

8. Configure the **Preserve Sparse Region** toggle. The toggle is turned on by default.

CAUTION! If you turn off the **Preserve Sparse Region** toggle, you are prompted to confirm the action. This is an irreversible action.

9. (Optional, Windows only) Select **Secure Start** to enable the Secure Start feature. By default, the check box is clear.

If you plan not to enable the Secure Start now, you can do that later, as described in ["Enabling Secure Start for GuardPoints" on page 144](#).

10. Click **Create**. A message appears prompting to confirm the reuse the GuardPoint settings on another path.

- Click **Yes** to use the same settings on another path. The Use Settings on Another Path dialog box is displayed. Perform the following steps:
 - i. Specify a new **Path**.
 - ii. Click **Add Path**.
 - iii. Click **OK**.
- Click **No** if you do not want to use the same settings on another path.

Depending on the number of paths you add to a GuardPoint, a status information message may appear. Refer to ["GuardPoint Status Information" on page 140](#) for details.

The newly created GuardPoint appears on the GuardPoints tab. The status remains **Unknown** until the client sends the response after processing the GuardPoint request. Click the **Refresh GuardPoints** icon (↻) to view the updated status.

Status of a GuardPoint can be checked at any time on the GuardPoints tab. Refer to ["Viewing GuardPoint Status" on page 155](#) for details.

An LDT GuardPoint is applied automatically according to the QoS settings configured in the linked profile. Refer to ["Creating a Profile" on page 42](#) and ["Setting Quality of Service Configuration" on page 50](#).

Creating Cloud Object Storage GuardPoints on Clients

Steps to create GuardPoints on individual clients and client groups are similar. GuardPoints can be created on the GuardPoints tab of individual clients and client groups.

To create a Cloud Object Storage GuardPoint:

1. Open the **CTE** application.
2. Click **Clients > Clients**.
3. Under **Client Name**, click the client on which you want to create a GuardPoint.
4. On the **GuardPoints** tab, click **Create GuardPoint**.
5. Select a **Policy**. This is a mandatory field.
 - a. Click **Select** next to the Policy field. The Select Policy dialog box is displayed.
 - b. Select a *Cloud Object Storage* policy. If no policy exists, create one, as described in "[Creating Policies](#)" on page 114.

Name	Type	Version
☒ testcoospic	Cloud Object Storage	0
☐ testpolicy	Standard	1
☐ idtpic	Live Data Transformation	0

- c. Click **Select**.
6. Select the **Type** of device to protect. This is a mandatory field. The options are:
 - **Auto Cloud Storage**: Select for Cloud Storage policies.
 - **Manual Cloud Storage**: Select for Cloud Storage policies to be guarded manually.

NOTE Manual Cloud Storage are guarded and unguarded (for example, mounted and unmounted) by running the `secfsd -guard` and `secfsd-unguard` commands. Do not run the `mount` and `umount` commands to swap GuardPoint nodes in a cluster configuration.

7. Select the **Cloud Storage Type**. The available option is **Amazon S3 Bucket**.
8. Specify the **URL** of the S3 bucket to be protected. The URL format is `http://s3.amazonaws.com/[bucket_name]`.

9. Click **Validate** to check whether the S3 bucket exists. The Create GuardPoint - Validate Connection dialog box is displayed.
 - a. Enter your AWS account credentials:
 - **Access Key**: Key to access the bucket.
 - **Secret Key**: Secret key to access the bucket.
 - **Region Code**: Code of your AWS region.
 - **URL**: S3 bucket URL that you entered (populated automatically).
 - b. Click **Connect**.
 - c. Click **OK**.

10. Click **Create**.

Depending on the number of paths you add to a GuardPoint, a status information message may appear. Refer to "[GuardPoint Status Information](#)" on page 140 for details.

The newly created GuardPoint appears on the GuardPoints tab. The status remains `Unknown` until the client sends the response after processing the GuardPoint request. Click the **Refresh GuardPoints** icon (↻) to view the updated status.

Status of a GuardPoint can be checked at any time on the GuardPoints tab. Refer to "[Viewing GuardPoint Status](#)" on page 155 for details.

Enabling Secure Start for GuardPoints

NOTE Information in this section is applicable to Windows clients.

Access to a Secure Start GuardPoint is permitted only during the boot sequence and for a short period. After the VMD is up and running, it performs normal agent initialization and communicates with the CipherTrust Manager to access files within a GuardPoint location.

A CipherTrust Manager administrator can enable Secure Start either when creating a GuardPoint or later by modifying the GuardPoint.

To enable Secure Start for a GuardPoint:

1. Open the **CTE** application.
2. Click **Clients > Clients**.
3. Under **Client Name**, click the desired Windows.
4. Click the **GuardPoints** tab.
5. Click the overflow icon () corresponding to the desired GuardPoint.
6. Click **View/Edit**. The Edit GuardPoint dialog box is displayed. In the edit mode, you can enable or disable the Secure Start and Preserve Sparse Region toggles.
7. Turn on the **Secure Start** toggle. By default, the toggle is off.

8. Click **Save**.

Refer to the CTE Agent for Windows Advanced Configuration and Integration Guide for details about using the Secure Start feature.

NOTE To disable Secure Start for a GuardPoint, clear the **Secure Start** check box in the Edit GuardPoint dialog box.

Creating GuardPoints on Client Groups

GuardPoints created on a client group are applied to all members of the group. Additionally, you can apply client group configuration settings (except the password, Agent Lock, System Lock, and Communication Enabled settings) to all clients in a client group. It is important to keep this in mind when adding clients to a client group.

For example, if you create a Linux file system GuardPoint on a client group, and then you add a Windows client to that client group, the Windows client will not be protected by that GuardPoint.

If you create a client group and add a non-LDT client to the group but you create LDT GuardPoints on the client group, then those GuardPoints are not propagated to the non-LDT client. However, if you subsequently enable LDT on the client in that group (assuming you have a license for this feature), the LDT GuardPoint is now propagated to the client.

This section covers the following information:

- > ["Create Standard GuardPoints on Client Groups" on the next page](#)
- > ["Creating LDT GuardPoints on Client Groups" on page 148](#)
- > ["Creating Cloud Object Storage GuardPoints on Client Groups" on page 150](#)

Create Standard GuardPoints on Client Groups

Steps to create GuardPoints on individual clients and client groups are similar. GuardPoints can be created on the GuardPoints tab of individual clients and client groups. Client group GuardPoints apply to all clients in the group.

To create a standard GuardPoint:

1. Open the **CTE** application.
2. Click **Clients > Client Groups**.
3. Under **Client Group Name**, click the client group on which you want to create a GuardPoint.
4. On the **GuardPoints** tab, click **Create GuardPoint**.
5. Select a **Policy**. This is a mandatory field.
 - a. Click **Select** next to the Policy field.
 - b. Select a *Standard* policy. If no policy exists, create one, as described in ["Creating Policies" on page 114](#).

Name	Type	Version
☐ testcosplc	Cloud Object Storage	0
☒ testpolicy	Standard	1
☐ ldtplc	Live Data Transformation	0

- c. Click **Select**.
6. Select the **Type** of device to protect. This is a mandatory field. Depending on the platform, the options for the standard policy are:

Type	Windows	Linux	Description
Auto Directory	Yes	Yes	Select for file system directories.
Manual Directory	No	Yes	Select for file system directories to be guarded manually.
Auto Raw or Block Device	Yes	Yes	Select for standard policies for raw (block) devices.
Manual Raw or Block Device	No	Yes	Select for standard policies for raw (block) devices to be guarded manually.

NOTE Manual Directory and Manual Raw or Block Device are guarded and unguarded (for example, mounted and unmounted) by running the `secfsd -guard` and `secfsd -unguard` commands. Do not run the `mount` and `umount` commands to swap GuardPoint nodes in a cluster configuration.

7. Specify the **Path** to be protected. This is a mandatory field.

- Click **Browse** to select a path by browsing the client file system. This method prevents typographical errors and verifies client availability. This is the recommended method to specify the path.
- Alternatively, if you know the path, manually enter full paths of one or more directories. Enter one path per line.

NOTE

- > If a manually entered path does not exist yet, be sure to enter the path correctly. The CipherTrust Manager does not parse manually entered paths for correct syntax.
- > See ["Considerations Before Creating GuardPoints" on page 136](#) for what to be aware of before creating a GuardPoint.
- > If multiple paths are specified, they will all be protected by the same policy.

8. (Optional, Linux only) Select **Auto Mount** to specify an automount path. For a regular (non-auto) mount path, make sure that the check box is clear.

The screenshot shows the 'Create GuardPoint' dialog box. It has a title bar with a close button (X). The dialog contains three main sections: 'Policy:' with a text field containing 'testpolicy' and a 'Select' button; 'Type:' with a dropdown menu showing 'Auto Directory'; and 'Path:' with a large text area containing '/opt/cie-test/Files' and a 'Browse' button. At the bottom, there is an 'Auto Mount:' checkbox which is checked.

9. (Optional, Windows only) Select **Secure Start** to enable the Secure Start feature. By default, the check box is clear.

If you plan not to enable the Secure Start now, you can do that later, as described in ["Enabling Secure Start for GuardPoints" on page 144](#).

10. Click **Create**. A message appears prompting to confirm the reuse the GuardPoint settings on another path.

- Click **Yes** to use the same settings on another path. The Use Settings on Another Path dialog box is displayed. Perform the following steps:
 - i. Specify a new **Path**.
 - ii. Click **Add Path**.
 - iii. Click **OK**.
- Click **No** if you do not want to use the same settings on another path.

Depending on the number of paths you add to a GuardPoint, a status information message may appear. Refer to ["GuardPoint Status Information" on page 140](#) for details.

The newly created GuardPoint appears on the GuardPoints tab. The status remains `Unknown` until the client sends the response after processing the GuardPoint request. Click the **Refresh GuardPoints** icon (↻) to view the updated status.

Status of a GuardPoint can be checked at any time on the GuardPoints tab. Refer to ["Viewing GuardPoint Status" on page 155](#) for details.

Creating LDT GuardPoints on Client Groups

Steps to create GuardPoints on individual clients and client groups are similar. GuardPoints can be created on the GuardPoints tab of individual clients and client groups. Client group GuardPoints apply to all clients in the group.

1. Open the **CTE** application.
2. Click **Clients > Clients**.
3. Under **Client Group Name**, click the LDT client group on which you want to create a GuardPoint.
4. On the **GuardPoints** tab, click **Create GuardPoint**.
5. Select a **Policy**. This is a mandatory field.
 - a. Click **Select** next to the Policy field. The Select Policy dialog box is displayed.
 - b. Select a *Live Data Transformation* policy. If no policy exists, create one, as described in ["Creating Policies" on page 114](#).

Name	Type	Version
☐ testosplc	Cloud Object Storage	0
☐ testpolicy	Standard	1
☒ ldtplc	Live Data Transformation	0

- c. Click **Select**.
6. Select the **Type** of device to protect. This is a mandatory field. Depending on the platform, the options for an *LDT* policy are:

Type	Windows	Linux	Description
Auto Directory	Yes	Yes	Select for file system directories.
Manual Directory	No	Yes	Select for file system directories to be guarded manually.

NOTE Manual Directory is guarded and unguarded (for example, `mounted` and `unmounted`) by running the `secfsd -guard` and `secfsd-unguard` commands. Do not run the `mount` and `umount` commands to swap GuardPoint nodes in a cluster configuration.

7. Specify the **Path** to be protected. This is a mandatory field.

- Click **Browse** to select a path by browsing the client file system. This method prevents typographical errors and verifies client availability. This is the recommended method to specify the path.
- Alternatively, if you know the path, manually enter full paths of one or more directories. Enter one path per line.

NOTE

- > If a manually entered path does not exist yet, be sure to enter the path correctly. The CipherTrust Manager does not parse manually entered paths for correct syntax.
- > See ["Considerations Before Creating GuardPoints" on page 136](#) for what to be aware of before creating a GuardPoint.
- > If multiple paths are specified, they will all be protected by the same policy.

Create GuardPoint

Policy:

Type:

Path:

Preserve Sparse Region: ☒

8. Configure the **Preserve Sparse Region** toggle. The toggle is turned on by default.

CAUTION! If you turn off the **Preserve Sparse Region** toggle, you are prompted to confirm the action. This is an irreversible action.

9. (Optional, Windows only) Select **Secure Start** to enable the Secure Start feature. By default, the check box is clear.

If you plan not to enable the Secure Start now, you can do that later, as described in ["Enabling Secure Start for GuardPoints" on page 144](#).

10. Click **Create**. A message appears prompting to confirm the reuse the GuardPoint settings on another path.
 - Click **Yes** to use the same settings on another path. The Use Settings on Another Path dialog box is displayed. Perform the following steps:
 - i. Specify a new **Path**.
 - ii. Click **Add Path**.
 - iii. Click **OK**.

- Click **No** if you do not want to use the same settings on another path.

Depending on the number of paths you add to a GuardPoint, a status information message may appear. Refer to ["GuardPoint Status Information" on page 140](#) for details.

The newly created GuardPoint appears on the GuardPoints tab. The status remains `Unknown` until the client sends the response after processing the GuardPoint request. Click the **Refresh GuardPoints** icon (↻) to view the updated status.

Status of a GuardPoint can be checked at any time on the GuardPoints tab. Refer to ["Viewing GuardPoint Status" on page 155](#) for details.

An LDT GuardPoint is applied automatically according to the QoS settings configured in the linked profile. Refer to ["Creating a Profile" on page 42](#) and ["Setting Quality of Service Configuration" on page 50](#).

Creating Cloud Object Storage GuardPoints on Client Groups

Steps to create GuardPoints on individual clients and client groups are similar. GuardPoints can be created on the GuardPoints tab of individual clients and client groups. Client group GuardPoints apply to all clients in the group.

To create a Cloud Object Storage GuardPoint:

- Open the **CTE** application.
- Click **Clients > Clients**.
- On the **GuardPoints** tab, click **Create GuardPoint**.
- Select a **Policy**. This is a mandatory field.
 - Click **Select** next to the Policy field. The Select Policy dialog box is displayed.
 - Select a *Cloud Object Storage* policy. If no policy exists, create one, as described in ["Creating Policies" on page 114](#).

Name	Type	Version
☒ testcosplc	Cloud Object Storage	0
☐ testpolicy	Standard	1
☐ ldtplc	Live Data Transformation	0

- Click **Select**.
- Select the **Type** of device to protect. This is a mandatory field. The options are:
 - Auto Cloud Storage**: Select for Cloud Storage policies.
 - Manual Cloud Storage**: Select for Cloud Storage policies to be guarded manually.

NOTE Manual Cloud Storage are guarded and unguarded (for example, mounted and unmounted) by running the `secfsd -guard` and `secfsd-unguard` commands. Do not run the `mount` and `umount` commands to swap GuardPoint nodes in a cluster configuration.

- Select the **Cloud Storage Type**. The available option is **Amazon S3 Bucket**.

7. Specify the **URL** of the S3 bucket to be protected. The URL format is `http://s3.amazonaws.com/[bucket_name]`.

8. Click **Validate** to check whether the S3 bucket exists. The Create GuardPoint - Validate Connection dialog box is displayed.
- Enter your AWS account credentials:
 - **Access Key**: Key to access the bucket.
 - **Secret Key**: Secret key to access the bucket.
 - **Region Code**: Code of your AWS region.
 - **URL**: S3 bucket URL that you entered (populated automatically).
 - Click **Connect**.
 - Click **OK**.
9. Click **Create**.

Depending on the number of paths you add to a GuardPoint, a status information message may appear. Refer to ["GuardPoint Status Information" on page 140](#) for details.

The newly created GuardPoint appears on the GuardPoints tab. The status remains `Unknown` until the client sends the response after processing the GuardPoint request. Click the **Refresh GuardPoints** icon (🔄) to view the updated status.

Status of a GuardPoint can be checked at any time on the GuardPoints tab. Refer to ["Viewing GuardPoint Status" on page 155](#) for details.

Automatic and Manual GuardPoints

The following table lists the type of GuardPoints depending on the platform and type of the policy type:

Type	Windows	Linux	Description
Auto Directory	Yes	Yes	Select for file system directories.
Manual Directory	No	Yes	Select for file system directories to be guarded manually.
Auto Raw or Block Device	Yes	Yes	Select for standard policies for raw (block) devices.
Manual Raw or Block Device	No	Yes	Select for standard policies for raw (block) devices to be guarded manually.
Auto Cloud Storage	No	Yes	Select for Cloud Storage policies.
Manual Cloud Storage	No	Yes	Select for Cloud Storage policies to be guarded manually.

A GuardPoint is usually applied immediately after it is configured on the CipherTrust Manager GUI; however, it can be applied later on the client system.

When would you want to apply the GuardPoint later? Consider the case of a 2-node cluster configured as active/passive in a cluster environment, such VCS, HACMP, or MSCS. There are two nodes, one which is currently active and the other that is currently inactive. Both nodes are locked.

Apply GuardPoint protection to active nodes only. You should never apply a GuardPoint to a passive node. If the active node develops a problem and tries to switch over to the inactive node, the cluster process fails to switch over because the mirror directory on the inactive node is currently mounted on the active node.

The solution is, for the cluster process to unmount (for example, unguard) the currently active node:

1. Place it in an inactive state.
2. Place the old inactive node in an active state.
3. Mount (for example, guard) the mirror directory on the newly active node.

Generally, when you get error messages, check that only active nodes are properly guarded.

When an auto GuardPoint is applied, regardless of whether it is a file system directory or a raw device, the change is pushed to the client system, and the GuardPoint is applied immediately.

Use the `df` command to display `secfs` mounts (for example, GuardPoints) or `secfsd` to display the GuardPoints themselves. The `secfsd` output shows a guard type of local for directories configured with Directory (Auto Guard).

For example:

```
# df
Filesystem      1K-blocks      Used Available Use% Mounted on
/dev/mapper/VolGroup00-LogVol100
40123784        11352236        26733380      30% /
/dev/sda1       101086 14590      81277      16% /boot

none          254492 0          254492 0% /dev/shm
/opt/vormetric/DataSecurityExpert/agent/secfs/.sec
40123784        11352236        26733380      30%
/opt/vormetric/DataSecurityExpert/agent/secfs/.sec
/opt/apps/apps1/tmp      40123784      11352236      26733380      30% /opt/apps/apps1/tmp
/opt/apps/apps1/lib      40123784      11352236      26733380      30% /opt/apps/apps1/lib
```

```

/opt/apps/apps1/doc      40123784      11352236      26733380      30% /opt/apps/apps1/doc
# secfsd -status guard
GuardPoint      Policy      Type      ConfigState      Status      Reason
-----
/opt/apps/apps1/tmp allowAllOps_fs      local      guarded guarded N/A
/opt/apps/apps1/lib allowAllRootUsers_fs      local      guarded guarded N/A
/opt/apps/apps1/doc      allowAllOps-winusers1_fs      local      guarded guarded N/A
#

```

When a manual GuardPoint is applied, regardless if it is a file system directory or a raw device, the change is pushed to the client system only. The client is aware of the GuardPoint but the client does not mount it. This is indicated in the `Type` column of the `secfsd -status guard` command output.

For example, the GuardPoint `/opt/apps/apps2/bin` has been configured with Manual Directory, so the guard type is set to `manual`.

```

# secfsd -status guard
GuardPoint      Policy      Type      ConfigState      Status      Reason
-----
/opt/apps/apps1/tmp allowAllOps_fs      local      guarded guarded N/A
/opt/apps/apps1/lib allowAllRootUsers_fs      local      guarded guarded N/A
/opt/apps/apps1/doc      allowAllOps-winusers1_fs      local      guarded guarded N/A
/opt/apps/apps2/bin      HR_policy01      manual      unguarded      not guarded Inactive
#

```

Note the `Type` value. A `Type` of `manual` indicates a manual GuardPoint. A `Type` of `local` indicates an automatic GuardPoint.

A manually applied GuardPoint remains Inactive until the GuardPoint is applied on the client. After the GuardPoint is applied on the client, and the client communicates the change to the server, the status changes to Active. It returns to the Inactive state when the GuardPoint is manually unguarded.

Use the `secfsd` command to guard and unguard Manual GuardPoints. The `secfsd` syntax is:

```

secfsd -guard path
secfsd -unguard path

```

Example

To manually guard and unguard a file system directory:

1. As CipherTrust Manager administrator, configure a GuardPoint with the type `Manual Directory`.
2. Log on to the client as an administrator with root permissions.
3. Wait until the configuration change is downloaded to the Agent system.
4. Run the status command until the manual GuardPoint is displayed.

For example:

```

# secfsd -status guard
GuardPoint      Policy      Type      ConfigState      Status      Reason
-----
/opt/apps/etc      allowAllOps_fs      manual      unguarded      not guarded N/A
/opt/apps/lib/dx3 allowAllOps_fs      local      guarded guarded N/A
#

```

5. Enable the GuardPoint.

```

# secfsd -guard /opt/apps/apps2/bin
secfsd: Guard initiated
#

```

The manual GuardPoint is active and the policy is enforced.

6. Disable the GuardPoint.

```
# secfsd -unguard /opt/apps/apps2/bin
secfsd: Unguard initiated
#
```

Selecting a GuardPoint Mount Type

- > Under random circumstances, NFS file systems can be mounted before the CTE Agent drivers are loaded. When this occurs, the CTE Agent is unable to protect GuardPoints on the file system. The **Auto Mount** feature prevents this from occurring. Select the **Auto Mount** toggle in the Edit Client window when the GuardPoint is in an automounted file system.
- > When applying file system protection to an automounted file system, do not apply the GuardPoint to the link-target directory. Rather, apply the GuardPoint to the full path to the directory underneath it. For example, if the automounted directory `"/Auto"` mounts a link-target directory named `"/documents"`, do not set the GuardPoint to `"/documents"`. Instead, set the GuardPoint to `"/Auto/documents"`.
- > Do not configure Linux 64-bit clients to automount directories with the `"/net"` option. The automounter uses the automount map associated with each mount point to locate each file system as it is accessed. The CTE Agent cannot resolve file system selections for GuardPoints, including any directories below a GuardPoint, that are configured with the `"/net"` option.

Viewing GuardPoints

The Status Bar on the GuardPoints tab of a client shows the total number of GuardPoints on the client, and inactive, active, and unknown GuardPoints. The Status Bar contains the following tabs:

- > **<N> Total GuardPoints**: Shows the total number of GuardPoints with all types of health status.
- > **<N> Inactive**: Shows the number of inactive GuardPoints.
- > **<N> Active**: Shows the number of active GuardPoints.
- > **<N> Unknown**: Shows the number of GuardPoints whose status is unclear.

Click each tab to filter the GuardPoints. The GuardPoints list displays details of the GuardPoints on the client.

To view the GuardPoints created on a client:

1. Open the **CTE** application.
2. Click **Clients > Clients**.
3. Under **Client Name**, click the desired client. The GuardPoints tab shows the GuardPoints configured on the client.

Status	Policy	Protected Path	Type	Client Group	Rekey Status	Enabled
Active	Idtpic	C:\AnunB	directory_auto		Rekeyed	Yes

The GuardPoints list shows the following details:

Column	Description
Status	Status of the GuardPoint. The status can be: > Inactive > Active > Unknown A status "Processing" is displayed for a brief period until an operation on the GuardPoint completes.
Policy	Policy applied to the GuardPoint.
Protected Path	Path of the protected directory.
Type	Type of the GuardPoint.
Origin	Origin of the GuardPoint. The origin can be: > Client: GuardPoint is created on an individual client. > Client group: GuardPoint is created on a client group.
Rekey Status	Rekey status of the GuardPoint.
Enable	Whether the GuardPoint is enabled.

Viewing GuardPoint Status

Status of GuardPoints can be seen on the CipherTrust Manager and on the client running the CTE Agent. The CipherTrust Manager GUI shows the GuardPoint status as it is configured on the CipherTrust Manager. It is not a real-time indication of the actual status.

Viewing GuardPoint Status on the Client

To view the actual status:

1. Log on to the CTE client as root/administrator.
2. Run the CTE Agent utilities.
3. Compare the GuardPoint status on the client with the status on the CipherTrust Manager GUI. If they do not match, go with the status on the CTE client.

Viewing GuardPoint Status on the GUI

The GuardPoints tab of the Clients page shows the total number of configured GuardPoints with their status. Similarly, status of GuardPoints on a client group can viewed on its GuardPoints tab.

To view the status on the GUI:

1. Open the **CTE** application.
2. Click **Clients > Clients**.

3. Under **Client Name**, click the desired client.
4. Click the **GuardPoints** tab. This tab shows the list of configured GuardPoints.
5. View the **Status** of the GuardPoint. The status can be:
 - **Active**: GuardPoint is deployed successfully and connection to the CTE Agent is healthy.
 - **Inactive**: GuardPoint is enabled but is not yet applied. Possible reasons are:
 - The GuardPoint is manual and is not mounted on the client. To apply manual GuardPoints, the client administrator needs to run the `secfsd -guard` command on the client.
 - A communication error has occurred between the CipherTrust Manager and CTE client.
 - **Unknown**: GuardPoint is created. Awaiting response from the CTE Agent on the GuardPoint request.

To view more details about an **Active** or **Inactive** GuardPoint, click the corresponding status link.

A status "Processing" is displayed for a brief period until an operation on the GuardPoint completes.

Configuring Windows Network Drives

Windows network drives may need user credentials and domain information for the CipherTrust Manager to configure GuardPoints and to push configuration changes to the CTE Agent. The Remote File Browser window enables you to automatically supply the user credentials.

Guard network mapped drives on a Windows client using the complete Universal Naming Convention (UNC) name for each file path. For example:

```
> \\1.2.3.4\ShareName\dirpath
> \\ServerName.DomainName.com\ShareName\dirpath
> \\ServerName\ShareName\dirpath
```

We recommend that you use the CipherTrust Manager IP address instead of the DNS name. GuardPoint protection is still enforced even when the CipherTrust Manager name is used.

To configure a network drive:

1. Open Guard File System window.
2. Click **Browse**. The Remote File Browser window opens.
3. Enable **Network Drive**. Three text-entry boxes are displayed. They are **Username**, **Password**, and **Windows Domain**.
4. Enter the network name of the user who has access permission to the network drive in the **Username** text-entry box.
5. Enter the password for the specified user in the **Password** text-entry box.
6. Enter the domain name of the system hosting the network drive in the **Windows Domain** text-entry box.
7. Select the GuardPoint and apply the policy as you would a non-network resource.

Deleting GuardPoints

GuardPoints can be removed (deleted) from entire client groups or individual clients. When a GuardPoint is removed from a client group, the GuardPoint is automatically removed from all clients in the group.

Before Deleting GuardPoints

The following preliminary steps need to be taken before deleting a GuardPoint:

- > Encrypted data in a GuardPoint will still be encrypted when the GuardPoint is removed. If you are not going to reuse the GuardPoint for any reason, such as uninstalling the CTE Agent software from a client, do either of the following:
 - Copy the encrypted files out of the GuardPoint so that they are saved as unencrypted files.
 - Rekey the encrypted files while the GuardPoint is still applied.
- > Take the GuardPoint out of service so that no user or application is accessing the directories and files in the GuardPoint. A GuardPoint is a mounted file system. Removing a GuardPoint involves unmounting the file system. File systems cannot be unmounted when in use.
- > Delete all the GuardPoints and disable the locks for a client before deleting the client from the CipherTrust Manager. This ensures that there are no residual GuardPoints in effect on the client.
- > For LDT GuardPoints, refer to procedures described in the CTE-Live Data Transformation with CipherTrust Manager to ensure that the data in those GuardPoints remains available.

Deleting a GuardPoint

To delete a GuardPoint:

1. Open the **CTE** application.
2. Select the client or client group from which you want to remove the GuardPoint.
 - Click a client under the **Client Name** column (**Clients > Clients**).
 - Click a client group under the **Client Group Name** column (**Clients > Client Groups**).
3. On the **GuardPoints** tab, select the GuardPoint to be deleted.
4. Click the overflow icon () corresponding to the desired GuardPoint.
5. Click **Remove**. The GuardPoint status becomes Processing. While processing the GuardPoint removal:
 - a. CipherTrust Manager notifies the CTE Agent that the GuardPoint is removed from the CipherTrust Manager.
 - b. CTE Agent removes the mount point from the client.
 - c. CTE Agent notifies the CipherTrust Manager about the GuardPoint removal.
 - d. CipherTrust Manager removes the GuardPoint from the GuardPoints tab.
6. Click the **Refresh GuardPoints** icon () to update the tab.
7. Verify the mount points on the CTE Agent client.
 - On UNIX, run the command `df` or `secfsd -status guard`.
 - On Windows, click the Vormetric icon and **View > File System > GuardPoints**.

CHAPTER 10: Operations

This chapter provides information on operations that the CTE Server Administrator performs on the CipherTrust Manager. These operations include registering CTE clients with the CipherTrust Manager, and protecting file system on a CTE client.

Registering Clients

Registration is the process of configuring a CTE client with a CipherTrust Manager. This process creates SSL certificates for further communication between the CipherTrust Manager and the CTE client.

Registering a CTE client with the CipherTrust Manager requires a registration token. Single registration token can be used to register any number of CTE clients. Refer to the CTE Agent Quick Start Guide specific to your platform for details.

NOTE After a client is registered, you must change the client password using the manual password creation method. Refer to ["Changing Client Password" on page 72](#) for details.

The following diagram shows the process of registering CTE clients with the CipherTrust Manager:

By default, CipherTrust Manager issues a Local CA with Common Name "KeySecure Root CA" which is used by CTE for signing client certificates. This Local CA is, by default, marked as trusted by the "web" interface which is also used by CTE for client authentication. Make sure that the CA whose signature is used for registering CTE clients is trusted by the "web" interface. Refer to the Interfaces section in the CipherTrust Manager documentation for details.

Third party (external) CA certificates can also be used for securing communication between the CipherTrust Manager and CTE clients. Refer to ["Using External CA Certificates" on the next page](#) for details.

Using External CA Certificates

All local and external CAs that participate in securing communication between the CipherTrust Manager and CTE clients must be added to the list of trusted CAs for the "web" interface on the CipherTrust Manager. Refer to the "Operation > Certificate Authority" section in the CipherTrust Manager Administrator Guide for details.

To use an external CA certificate:

1. Create a registration token using the ID of the Local CA signed by the external CA. Refer to "Client Management > Tokens" in the CipherTrust Manager Administrator Guide for details.
2. Register the CTE clients using this registration token. The registration process will automatically use the Local CA signed by the external CA. Refer to the CTE Agent Quick Start Guide specific to your platform for details.

Reregistering CTE Clients

In some cases, you need to change the CA certificate that was used to register a client with the CipherTrust Manager. For example, when the existing CA certificate expires or the certificate needs to be renewed to meet security requirements of your organization, the client must be reregistered with the CipherTrust Manager.

To reregister a client with the CipherTrust Manager:

1. Create a new registration token. Use the ID of the trusted CA that will be used to sign the client certificate. By default, a local CA will be used to issue certificates. Refer to "Client Management > Tokens" in the CipherTrust Manager Administrator Guide for details.
2. Register the client again using the new registration token created in step 1. The client administrator reregisters the client with the CipherTrust Manager. Steps are similar to registering a new client with the CipherTrust Manager.

Protecting Data on Clients

After registration, the client can communicate with the CipherTrust Manager, and is ready for data protection using CTE. This section describes how CTE GuardPoints, policies, and policy elements work together to encrypt file systems.

Refer to ["Common Scenarios" on page 164](#) for prerequisites and procedures to encrypt data in the most common scenarios.

GuardPoints

A GuardPoint specifies the path on the client that is to be protected with different access and encryption policies. GuardPoint is configured by specifying the guard path, policy, and other policy/path specific configuration parameters.

A sample configuration of a GuardPoint is shown below::

Refer to ["Managing GuardPoints" on page 135](#) for details.

Policies

A policy is the resource where all the access privileges and key configuration is done to achieve the required use cases. Policies are categorized as:

> Standard Policies

Depending on the availability of data in GuardPoints, standard policies can be applied in two different scenarios.

- **The GuardPoint does not contain any data.** The data would be created after the GuardPoint is applied. These policies are also called production policies.

A sample production policy is shown below:

- **The GuardPoint already contains data.** The existing data is migrated to encrypted form by using the data transformation (dataxform) policy.

A sample dataxform policy is shown below:

1 General Info

Name: dataxform.plc

Policy Type: Standard

Description:

2 Security Rules

Resource Set	User Set	Process Set	Action	Effect	Browsing
			key.op	permit,applykey	Yes

3 Key Rules

Resource Set	Current Key Name
	clear_key

4 Data Transformation Rules

Resource Set	Transformation Key Name
	key1

After the data is migrated, unguard the dataxform policy, apply the standard policy with same key (as used by the dataxform policy). A sample standard policy applied after unguarding a dataxform policy is shown below:

1 General Info

Name: UC1-Standard

Policy Type: Standard

Description:

2 Security Rules

Resource Set	User Set	Process Set	Action	Effect	Browsing
	User1		all_ops	permit,applykey	Yes
	User2		all_ops	permit	Yes
				deny	Yes

3 Key Rules

Resource Set	Key Name
	key1

Dataxform policies are created by turning on the Data Transformation toggle when creating a Standard policy. These policies require downtime, so they are referred to as offline policies. If you do not want downtime, you can deploy LDT policies.

> LDT Policies

As their name implies, LDT policies perform live transformation of data. They do not require any time downtime, so they are referred to as online policies. You can continue to work while the transformation of your data in GuardPoints is in progress. To benefit from LDT, you need to purchase an Add-On LDT license with the CTE Base license.

LDT policies can handle both these cases:

- The GuardPoint **does not contain** any data. No data is migrated. A production policy is applied to encrypt/decrypt the future data.
- The GuardPoint already **contains** data. The existing data is automatically migrated. After the data is migrated, the data is encrypted/decrypted like a production policy.

A sample LDT policy is shown below:

Name: UC1-LDT
Policy Type: ldt
Description:

2 Security Rules

Resource Set	User Set	Process Set	Action	Effect	Browsing
			key_op	permit,applykey	No
	User1		all_ops	permit,applykey	Yes
	User2		all_ops	permit	Yes
				deny	Yes

3 Key Rules

Resource Set	Current Key Name	Transformation Key Name	Exclusion Rule
	clear_key	testldt	No

> COS Policies

These policies are used to encrypt data and apply access rules on the GuardPoints on cloud. CTE supports Amazon S3 buckets.

A sample COS policy is shown below:

Name: RS3-COSPolicy
Policy Type: cloud_object_storage
Description:

2 Security Rules

User Set	Process Set	Action	Effect	Browsing
		all_ops	permit,applykey	No

3 Key Rules

Key Name
key2

Refer to ["Creating Policies" on page 114](#) for details.

Policy Elements

To achieve different access privileges based on users, processes, and different resources (sub-directory/specific file formats), create these policy elements:

- > **User Sets:** Groups of single or multiple users that can be used as individual entities in policies to grant user specific privileges. A sample user set is shown below:

1 General Info

Name: UserSet1

Description:

2 Users / Groups

uname	UID	gname	GID	OS domain	
User1	1000	group1	1000		 Remove

- > **Process Sets:** Groups of single or multiple processes that can be used as individual entities in policies to grant process specific privileges.

1 General Info

Name: ProcessSet

Description:

2 Processes

Directory	File	Signature
/usr/bin	vi	

- > **Resource Sets:** Groups of single or multiple resources (sub-directory or specific file formats) that can be used as individual entities in policies to grant resource specific privileges.

1 General Info

Name: ResourceSet1

Description:

2 Resources

Directory	File	Include Sub Folders	File System Type
/	*.txt	Yes	Local File System

Refer to ["Creating Policy Elements" on page 103](#) for details.

CHAPTER 11: Common Scenarios

This chapter describes the common encryption scenarios in which paths can be encrypted using the CTE solution. Similarly, you can configure different types of policies with different combinations of policy elements to suit your requirements.

This chapter describes encryption using:

- > ["User-based Access Privileges" below](#)
- > ["Process-based Access Privileges" on page 167](#)
- > ["Signature-based Access Privileges for Processes" on page 168](#)
- > ["Different Access Privileges for Subdirectory or Different File Formats" on page 169](#)
- > ["Different Access Privileges for Combination of Users, Processes, and Resources" on page 170](#)

Prerequisites

- > The CipherTrust Manager is up and running. Refer to the [CipherTrust Manager Deployment Guide](#) for details.
- > A CTE base license is activated and installed. Refer to ["Licensing" on page 21](#) for details.
- > (Optional) Add-on LDT license is activated and installed. This license is needed only if you want to deploy LDT policies. A CTE base license must be activated on the CipherTrust Manager. Refer to ["Licensing" on page 21](#) for details.
- > The CTE Agent is installed on client machines where data is to be protected. The client machines are running a supported platform. Refer to the CTE Agent Quick Start Guide specific to your platform for details.

NOTE Policy elements can be created either in advance or when creating the policy. Refer to ["Creating Policy Elements" on page 103](#) for details.

User-based Access Privileges

Encrypt a local path with the following access privileges:

- > User set `UserSet1` can encrypt/decrypt data in the GuardPoint.
- > User set `UserSet2` can access the ciphertext data but cannot encrypt or decrypt.
- > All other user sets are denied access to the GuardPoint data.

Depending on the data availability (or downtime) and storage requirements in your setup, you can apply any of these policies:

- > ["Standard \(Production\) Policies" on the next page](#)
- > ["Standard \(Dataxform\) Policies" on the next page](#)

> ["LDT Policies" on page 167](#)

Refer to ["Data Transformation Techniques" on page 35](#) for advantages and limitations of data transformation techniques. LDT policies require an add-on license to use them.

Standard (Production) Policies

If the GuardPoint does not contain any existing data, and the data would be created after the GuardPoint is applied:

1. Create a standard policy. Refer to ["Creating Policies" on page 114](#) for details.

The screenshot shows a policy configuration interface with two main sections: 'General Info' and 'Security Rules'.

General Info:

- Name: ProductionPolicy
- Policy Type: Standard
- Description:

Security Rules:

Resource Set	User Set	Process Set	Action	Effect	Browsing
	User1		all_ops	permit,applykey	Yes

Key Rules:

Resource Set	Key Name
	key1

2. Apply a GuardPoint using the standard policy. Refer to ["Creating Standard GuardPoints on Clients" on page 138](#) for details.

Standard (Dataxform) Policies

If the GuardPoint already contains data, and the existing data needs to be migrated to encrypted form by using the dataxform utility:

1. Create a dataxform policy. Refer to ["Creating Policies" on page 114](#) for details.

1 General Info

Name: dataxform.plc

Policy Type: standard

Description:

2 Security Rules

Resource Set	User Set	Process Set	Action	Effect	Browsing
			key_op	permit,applykey	Yes

3 Key Rules

Resource Set	Current Key Name
	clear_key

4 Data Transformation Rules

Resource Set	Transformation Key Name
	key1

- Apply a GuardPoint using the dataxform policy. Refer to ["Creating Standard GuardPoints on Clients" on page 138](#) for details.
- After the existing data is migrated, unguard the dataxform policy from the GuardPoint. Refer to ["Deleting GuardPoints" on page 157](#) for details.
- Create a standard policy with same key (as used by the dataxform policy in the first step). Refer to ["Creating Policies" on page 114](#) for details.

1 General Info

Name: UC1-Standard

Policy Type: Standard

Description:

2 Security Rules

Resource Set	User Set	Process Set	Action	Effect	Browsing
	User1		all_ops	permit,applykey	Yes
	User2		all_ops	permit	Yes
				deny	Yes

3 Key Rules

Resource Set	Key Name
	key1

- Apply the GuardPoint using the standard policy created in the previous step. Refer to ["Creating Standard GuardPoints on Clients" on page 138](#) for details.

LDT Policies

If you have an add-on LDT license, you can achieve the combined effects of the standard production and standard dataxform policies by applying the LDT policies.

- > If the GuardPoint already contains data, the policy migrates the existing data automatically. No need to run the dataxform utility manually. Later, the policy automatically encrypts/decrypts the data similar to a standard policy.
- > If the GuardPoint does not contain any existing data, migration is not required. A standard (production) policy of encryption/decryption is applied automatically.

To apply an LDT policy:

1. Create an LDT policy. Refer to ["Creating Policies" on page 114](#) for details.

Name: UC1-LDT
Policy Type: ldt
Description:

2 Security Rules

Resource Set	User Set	Process Set	Action	Effect	Browsing
			key_op	permit,applykey	No
	User1		all_ops	permit,applykey	Yes
	User2		all_ops	permit	Yes
				deny	Yes

3 Key Rules

Resource Set	Current Key Name	Transformation Key Name	Exclusion Rule
	clear_key	testldt	No

2. Apply the GuardPoint using the LDT policy. Refer to ["Creating LDT GuardPoints on Clients" on page 140](#) for details.

Process-based Access Privileges

Encrypt a local path with the following access privileges:

- > Process set `ProcessSet1` can encrypt/decrypt data in the GuardPoint.
- > Process set `ProcessSet2` can access the ciphertext data but cannot encrypt or decrypt.
- > All other process sets are denied access to the GuardPoint data.

Process-based policies are configured in exactly the same way the user-based policies are configured, as described in ["User-based Access Privileges" on page 164](#). The only difference is that instead of adding user sets add process sets to the Security Rules tab of the policy.

Depending on the data availability (or downtime) and storage requirements in your setup, you can apply any of these policies:

- > ["Standard \(Production\) Policies" on page 165](#)

- > ["Standard \(Dataxform\) Policies" on page 165](#)
- > ["LDT Policies" on the previous page](#)

Refer to ["Data Transformation Techniques" on page 35](#) for advantages and limitations of data transformation techniques. LDT policies require an add-on license to use them.

Signature-based Access Privileges for Processes

Encrypt a local path with the following access privileges:

- > Process `Process1` with a particular signature can encrypt/decrypt data in the GuardPoint.
- > All other processes are denied access to the GuardPoint data.

To apply a signature-based access policy for a process:

1. Create a signature set. When creating the set, add the source path of `Process1`. This process will be signed. Refer to ["Creating Signature Sets" on page 88](#).

The screenshot shows the 'General Info' and 'Sources' tabs of a signature set configuration. Under 'General Info', the 'Name' is 'SignSet1' and the 'Description' is empty. Under 'Sources', the 'Source Directory' is '/usr/bin/xi'.

2. Sign the signature set. Use a CTE client having the desired process to sign the process. Refer to ["Signing Files in a Signature Set" on page 90](#) for details.

The screenshot shows the 'Source' and 'Signature' tabs of the signing interface. The 'Source' tab is active, showing a 'Change Client' button, a client IP address '10.154.13.209', and a 'Sign' button. Below, there is a search bar and a list of sources with checkboxes. The list shows '0 selected | 1 results | 1 source' and includes 'Source Directory' and '/usr/bin/xi'.

3. Create a process set. When creating the set, add the newly created signature set. Refer to ["Creating Process Sets" on page 110](#) for details.

1 General Info

Name: UC-3-ProcessSet

Description:

2 Processes

Directory	File	Signature	
/usr/bin/	vi	signed	...

4. Configure process-based access policies. Refer to ["Process-based Access Privileges" on page 167](#) for details.

Different Access Privileges for Subdirectory or Different File Formats

Encrypt a local path with the following access privileges:

- > Encrypt/decrypt only a subdirectory, `subdir1`, under the GuardPath.
- > Deny access to all other files and directories under the GuardPoint.

To achieve this use case, you need to add a resource set to the policy. In a resource set, you can provide details about the subdirectories or specific file formats that need to be handled differently under a GuardPoint.

To achieve this use case:

1. Create a resource set. Specify the details of the subdirectory (`subdir1`) in the resources. Refer to ["Creating Resource Sets" on page 104](#) for details.

1 General Info

Name: UC4_ResourceSet_SubDir1

Description:

2 Resources

Directory	File	Include Sub Folders	File System Type
/subdir1/	*	Yes	Local File System

NOTE Paths specified in a resource set should be relative to the GuardPath. Do not provide absolute path for the resources.

2. Create the desired policy type. Make sure to add the resource set created in the previous step. This is done to enforce the desired access policy. Refer to ["Creating Policies" on page 114](#) for details.

1 General Info

Name: UC4-Policy

Policy Type: Standard

Description:

2 Security Rules

Resource Set	User Set	Process Set	Action	Effect	Browsing
UC4_ResourceSet_SubDir1			all_ops	permit,applykey	Yes
				deny	Yes

3 Key Rules

Resource Set	Key Name
UC4_ResourceSet_SubDir1	Key1

3. Apply the GuardPoint using the policy created in the previous step. Refer to ["Managing GuardPoints" on page 135](#) for details.

Different Access Privileges for Combination of Users, Processes, and Resources

Encrypt a local path with the following access privileges:

- > Allow only the process `usrbin.exe` being run by `User1` to encrypt/decrypt text files (*.txt) present under the GuardPath.
- > Deny access to all other users and processes.

To achieve this use case:

1. Created the required resource set. Refer to ["Creating Resource Sets" on page 104](#) for details.
2. Create the required user set. Refer to ["Creating User Sets" on page 105](#) for details.
3. Create the required process set. Refer to ["Creating Process Sets" on page 110](#) for details.
4. Create the desired policy type using the resource set, the user set, and the process set created above. Refer to ["Creating Policies" on page 114](#) for details.

1 General Info**Name:** UCS-Combination-Policy**Policy Type:** Standard**Description:****2 Security Rules**

Resource Set	User Set	Process Set	Action	Effect	Browsing
Text_ResourceSet	User1	UsrBin_ProcessSet	allOps	permitApplyKey	Yes
				deny	Yes

3 Key Rules

Resource Set	Key Name
Text_ResourceSet	Key1

5. Apply the GuardPoint using the policy created in the previous step. Refer to ["Managing GuardPoints" on page 135](#) for details.

APPENDIX A: Troubleshooting

This chapter describes how to handle the issues that you might face when using CTE with the CipherTrust Manager. These issues are categorized as:

- > ["Connection Issues" below](#)
- > ["Registration Issues" below](#)
- > ["Licensing Issues" on the next page](#)
- > ["Configuration Issues" on the next page](#)

Connection Issues

Symptoms	Possible Cause and Remediation
> Client status is Error > Configuration changes are not pushed to the client > Requests like Browse file system are failing	Analyze the CTE logs, identify connection failure reasons, and rectify them: 1. Look for the issues in the <code>/var/log/vormetric/server_comms.log</code> file on the CTE agent. This file contains information about the CipherTrust Manager's communication with the client. 2. Identify the cause of the issue. 3. Take appropriate action to resolve the issue. For example, you might need to: • Restart <code>vmd</code> to get the latest <code>init</code>. • Enable the connection timeout on the CipherTrust Manager to resolve registration token related errors.

Registration Issues

Symptoms	Possible Cause and Remediation
Registration fails with conflict errors	Conflict errors occur when a client with the given name already exists on the CipherTrust Manager. To fix these issues: > Delete the existing client entry from the CipherTrust Manager. > Unenroll the existing client if you want to register it with another CipherTrust Manager.
Reregistration fails with capabilities related errors	Reregistration requires the state of the CTE Agent capabilities such as LDT and COS is the same as it was before unenrollment. After a client is registered, these capabilities can be enabled on the CipherTrust Manager GUI. To disable the CTE Agent capabilities, delete the client from the CipherTrust Manager and register again with these capabilities disabled.

Licensing Issues

Symptoms	Possible Cause and Remediation
> Registration fails with licensing errors > LDT feature cannot be used > CTE configurations are read-only	> Registration can fail if the number of purchased licenses are consumed or the validity of a license is expired. This is applicable for both types of licenses: the base license (CTE - TransparentEncryption) and the add-on license (CTE - LiveDataTransformation). > To enable LDT at the time of registration (or later), make sure that you have a valid base license and a valid add-on LDT license. > After a license is expired: • A new client cannot be registered. • Existing operations on registered clients remain in tact. Their existing security configurations are pushed as and when required. • Creation of new GuardPoints with decryption policies is allowed. • Existing resources on the CipherTrust Manager become read only. Only existing records can be viewed.

Configuration Issues

Symptoms	Possible Cause and Remediation
Mismatched log levels between the CipherTrust Manager configuration and client logs	Try these: > Check the configuration in the linked profile on the CipherTrust Manager. > Validate the <code>vmd</code> configuration on the CTE client by running: <code>vmsec vmdconfig</code>

CipherTrust Transparent Encryption

Challenge: securing sensitive data across changing environments and increasing threats

Safeguarding sensitive data requires much more than just securing a data center's on-premises databases and files. The typical enterprise today uses three or more IaaS or PaaS providers, along with fifty or more SaaS applications, big data environments, container technologies, and their own internal virtual environments and private clouds.

To further complicate the problem, cyber-attacks have grown in sophistication and power. New compliance and regulatory mandates around protection of sensitive information keep on coming, and existing regulations have become more stringent.

Solution: CipherTrust Transparent Encryption

CipherTrust Transparent Encryption delivers data-at-rest encryption with centralized key management, privileged user access control, and detailed data access audit logging that helps organizations meet compliance and best practice requirements for protecting data, wherever it resides. The FIPS 140-2 compliant CipherTrust Transparent Encryption agent resides at the operating file-system or device layer, and encryption and decryption is transparent to all applications that run above it. CipherTrust Transparent Encryption

provides rich access controls, which allow organizations to determine who can access data, when they can access it, and what type of access they have.

Securing sensitive data-at-rest wherever it resides

- Meet compliance and best practice requirements for encryption, access control, and data access logging using a proven hardware accelerated encryption solution, that secures files, volumes and linked cloud storage while enabling access control and data access audit logging in physical, virtual, and cloud environments.
- Deployment is simple, scalable and fast with centralized key management, encryption, and access policies that reach across multiple clouds, on-premises, and within big data, and container environments.
- Easily implement privileged user access controls to enable administrators to work as usual but protect against users and groups that are potential threats to data.

CipherTrust Transparent Encryption

- Leverage detailed, actionable security event logs that provide unprecedented insight into file access activities to identify and stop threats faster.
- Broadest platform support in the industry. Protects structured and unstructured data accessed by Linux, AIX and Windows systems, as well as transparent encryption and access control for data residing in S3 buckets.
- Eliminate the downtime required for initial encryption and re-keying operations by adding the Live Data Transformation option. There is no other data encryption solution that offers this unique capability.

Key advantages

Transparent data protection. Continuously enforces file-level encryption that protects against unauthorized access by users and processes and creates detailed data access audit logs of all activities without requiring changes to applications, infrastructure, systems management tasks, or business practices.

Seamless and easy to deploy. CipherTrust Transparent Encryption agents are deployed on servers at the file system or volume-level and support both local disks as well as cloud storage environments, such as Amazon S3 and Azure Files.

Define granular access controls. Apply granular, least-privileged user access policies that protect data from external attacks and misuse by privileged users. Specific policies can be applied by users and groups from systems, LDAP/Active Directory, Hadoop and containers. Controls also include access by process, file type, time of day, and other parameters.

High-performance hardware accelerated encryption. CipherTrust Transparent Encryption only employs strong, standard-based encryption protocols, such as the Advanced Encryption Standard (AES) for data encryption and Elliptic Curve Cryptography (ECC) for key exchange. Encryption overhead is minimized using the AES hardware encryption capabilities available in modern CPUs.

Comprehensive security intelligence. Identify and stop threats faster with detailed data access audit logs that not only satisfy compliance requirements, but also enable data security analytics.

In addition, security intelligence logs and reports streamline compliance reporting and speed up threat detection using leading security information and event management (SIEM) systems.

Broadest system and environment support. The agent is available for a broad selection of Windows, Linux, and AIX platforms, and can be used in physical, virtual, cloud, container, and big data environments, regardless of the underlying storage technology.

Advanced security

Zero-downtime data transformation. Live Data Transformation option eliminates the downtime required for initial encryption and scheduled rekeying operations. This patented technology allows for databases or files to be encrypted or re-keyed with a new encryption key while the data is in use without taking applications off-line.

Advanced access controls for big data (Hadoop). When implemented in Hadoop environments, access controls are extended to Hadoop users and groups.

SAP HANA qualified. SAP has qualified CipherTrust Transparent Encryption with HANA v2.0 to deliver data encryption, key management, privileged user access control, and granular file access audit logs.

CipherTrust Transparent Encryption UserSpace. Provides scalable and robust file encryption solution based on Linux FUSE that is not affected by kernel upgrades on Linux servers.

Solution architecture

Deployments consist of CipherTrust Transparent Encryption agents and CipherTrust Manager appliances. Policy and key management is centralized at the CipherTrust Manager. The CipherTrust Manager is available as a FIPS 140-2 level 1, 2 or 3 compliant appliance.

CipherTrust Data Security Platform

CipherTrust Transparent Encryption is part of the CipherTrust Data Security Platform. The CipherTrust platform unifies data discovery, classification, data protection, and provides unprecedented granular access controls, all with centralized key management. This simplifies data security operations, accelerates time to compliance, secures cloud migrations, and reduces risk across your business. You can rely on Thales CipherTrust Data Security Platform to help you discover, protect and control your organization's sensitive data, wherever it resides.

About Thales

The people you rely on to protect your privacy rely on Thales to protect their data. When it comes to data security, organizations are faced with an increasing number of decisive moments. Whether the moment is building an encryption strategy, moving to the cloud, or meeting compliance mandates, you can rely on Thales to secure your digital transformation.

Decisive technology for decisive moments.

Introduction

Enterprise digital transformation and increasingly sophisticated IT security threats have resulted in a progressively more dangerous environment for enterprises with sensitive data, even as compliance and regulatory requirements for sensitive data protection rise. With attacks adapting on a daily or even hourly basis, even next-generation network and endpoint defenses consistently fail to stop enterprise network penetration. At the same time, digital transformation is expanding the attack surface available to adversaries beyond traditional enterprise boundaries, as organizations embrace the business advantages available from these new solutions.

Just as no single attack method is responsible for all increased threats to enterprise data, no single digital transformation technology is responsible for all increased risks from these new environments – as each technology adopted presents unique data security challenges. However, the number and complexity of these new technologies and the individualized approach required to secure data throughout each environment combine to compound the problem.

Within this environment of increased risks to sensitive data, enterprises require the ability to limit access to sensitive information to only those users, groups, and processes that require the use of the data – and no more. This need extends across traditional data centers, cloud environments, SaaS implementations, and to the data stores of every digitally transformative environment. What is required is a way to make sensitive data useless (and valueless) when not in use and then to control access to the levers that make the data useful again, when it is needed by a legitimate user. This is what transparent encryption with user access control does.

CipherTrust Transparent Encryption enables quick, effective and transparent protection of data at the system level without derailing business processes, user tasks, and administrative workflows. With a single set of data security controls, information stored within physical and virtual systems, big data environments, containers, and linked cloud storage are protected at the file system or volume level across data centers and cloud environments. The result is greatly reduced risk, and an enhanced capability to meet compliance and regulatory data security requirements.

The CipherTrust Data Security Platform from Thales

The CipherTrust Data Security Platform is composed of an integrated suite of products built on a common, extensible infrastructure with efficient, centralized key and policy management. As a result, your security teams can address your data security policies, compliance mandates, and best practices, while reducing administration effort and total cost of ownership. The platform offers capabilities for protecting and controlling access to databases, files and containers—and can secure assets residing in cloud, virtual, big data and physical environments. This scalable, efficient data security platform enables you to address your urgent requirements, and it prepares your organization to nimbly respond when the next security challenge or compliance requirement arises.

Simplify Data Security

Discover, protect, and control sensitive data anywhere with next-generation unified data protection. The CipherTrust Data Security Platform simplifies data security administration with 'single pane of glass' centralized management console that equips organizations with powerful tools to discover and classify sensitive data, combat external threats, guard against insider abuse, and establish persistent controls, even when data is stored in the cloud or in any external provider's infrastructure. Organizations can easily uncover and close privacy gaps, prioritize protection, and make informed decisions about privacy and security mandates before a digital transformation implementation.

Accelerate Time to Compliance

Regulators and auditors require organizations to have control of regulated and sensitive data and reports to prove it. CipherTrust Data Security Platform capabilities, such as data discovery and classification, encryption, access control, audit logs, tokenization, and key management support ubiquitous data security and privacy requirements. These controls can be quickly added to new deployments or in response to evolving compliance requirements. The centralized and extensible nature of the platform enables new controls to be added quickly through the addition of licenses and scripted deployment of the needed connectors in response to new data protection requirements.

Secure Cloud Migrations

The CipherTrust Data Security Platform offers advanced encryption and centralized key management solutions that enable organizations to safely store sensitive data in the cloud. The platform offers advanced multi-cloud Bring Your Own Encryption (BYOE) solutions to avoid cloud vendor encryption lock-in and ensure the data mobility to efficiently secure data across multiple cloud vendors with centralized, independent encryption key management. Organizations that cannot bring their own encryption can still follow industry best practices by managing keys externally using the CipherTrust Cloud Key Manager. The CipherTrust Cloud Key Manager supports Bring Your Own Key (BYOK) use-cases across multiple cloud infrastructures and SaaS applications. With the CipherTrust Data Security Platform, the strongest safeguards protect an enterprise's sensitive data and applications in the cloud, helping the organization meet compliance requirements and gain greater control over data, wherever it is created, used, or stored.

The CipherTrust Transparent Encryption Solution

Introduction

CipherTrust Transparent Encryption software for enterprises delivers data-at-rest encryption with centralized key management, privileged user access control, and detailed data access audit logging. This protects data wherever it resides -- on-premises, across multiple clouds and within big data and container environments.

The deployment is simple, scalable and fast, with agents installed at operating file system or device layer, and encryption and decryption is transparent to all applications that run above it. CipherTrust Transparent Encryption is designed to meet data security compliance and best practice requirements with minimal disruption, effort, and cost. Implementation of the encryption software is seamless keeping both business and operational processes working without changes even during deployment and roll out.

Meet compliance requirements for encryption and access control

Encryption, access controls, and data access logging are basic requirements or recommended best practices for almost all compliance and data privacy standards and mandates, including PCI DSS, HIPAA/Hitech, GDPR and many others. CipherTrust Transparent Encryption delivers the controls required without operational or business process changes.

Scalable encryption

The CipherTrust Transparent Encryption agent runs at the file system or volume level on a server. The agent is available for a broad selection of Windows, Linux, and AIX platforms and can be used in physical, virtual, cloud, container, and big data environments – regardless of the underlying storage technology. Administrators perform all policy and key administration through the CipherTrust Manager. Encryption takes place on the server, eliminating bottlenecks that plague legacy, proxy-based solutions. Performance and scalability are further enhanced by leveraging cryptographic hardware modules that are built into such modern CPUs as Intel AES-NI and IBM POWER9.

Protect data on-premises or in-cloud

Keep control of your data by managing encryption keys and access policies from your local data center for both your on-premises and cloud data, even in hybrid environment deployments.

Figure 2. CipherTrust Data Security Platform – Risks and Protection Layers for Transparent Encryption

Advanced capabilities

- **Zero-downtime data transformation.** The Live Data Transformation option eliminates the downtime required for initial encryption and scheduled rekeying operations. This patented technology allows for databases or files to be encrypted or re-keyed with a new encryption key while the data is in use without taking applications off-line.
- **Advanced access controls for big data (Hadoop).** When implemented in Hadoop environments, access controls are extended to Hadoop users and groups.
- **SAP HANA reviewed and qualified.** SAP has qualified CipherTrust Transparent Encryption with HANA v2.0 to deliver data encryption, privileged user access control, and granular file access audit logs.

Key features

- **Transparent data protection.** Continuously enforces file-level encryption that protects against unauthorized access by users and processes and creates detailed data access audit logs of all activities without requiring changes to applications, infrastructure, systems management tasks, or business practices.
- **Seamless and easy to deploy.** CipherTrust Transparent Encryption agents are deployed on servers at the file system or volume level and support both local disks as well as cloud storage environments, such as Amazon S3 and Azure Files.
- **Define granular access controls.** Apply granular, least-privileged user access policies that protect data from external attacks and misuse by privileged users. Specific policies can be applied by users and groups from systems, LDAP/Active Directory, Hadoop and containers. Controls also include access by process, file type, time of day, and other parameters.
- **High-performance hardware accelerated encryption.** CipherTrust Transparent Encryption only employs strong, standard-based encryption protocols, such as the Advanced Encryption Standard (AES) for data encryption and Elliptic Curve Cryptography (ECC) for key exchange. Encryption overhead is minimized using the AES hardware encryption capabilities available in modern CPUs.
- **Comprehensive security intelligence.** Identify and stop threats faster with detailed data access audit logs that not only satisfy compliance requirements, but also enable data security analytics. In addition, security intelligence logs and reports streamline compliance reporting and speed up threat detection using leading security information and event management (SIEM) systems.
- **Broadest system and environment support.** The agent is available for a broad selection of Windows, Linux, and AIX platforms and can be used in physical, virtual, cloud, container, and big data environments, regardless of the underlying storage technology.

Optional extensions and additions:

- **Live Data Transformation.** Perform initial encryption and data re-keying without taking applications using data stores offline. This extension is enabled with an additional license.
- **SAP HANA qualified.** CipherTrust Transparent Encryption provides a proven approach to safeguarding SAP HANA data. This solution meets rigorous security, data governance, and compliance requirements. The solution can be quickly deployed, requiring no changes to SAP HANA or the underlying database or hardware infrastructure. With the solution, organizations can encrypt SAP HANA data and log volumes and establish strong governance and separation of duties.

A simple CipherTrust Transparent Encryption deployment scenario for file system or volume data within a local data center includes:

- A CipherTrust Transparent Encryption agent deployed to the host systems or virtual machines
- Two CipherTrust Manager appliances. Two appliances are required for clustering and failover capabilities that enable solution uptime.

Additional options extend the solution's functionality.

CipherTrust Transparent Encryption Agent

CipherTrust Transparent Encryption agents are kernel level drivers that sit above file systems or volumes in the OS stack. Agents perform encryption, decryption, policy-based access control, and data access audit logging.

Policies administered by agents employ logic and fine-grained access control settings configured at the CipherTrust Manager to evaluate attempts to access protected data, and then either grant or deny access.

Controls include who is enabled to access data, what and where information is available to them, when access can be performed, and what processes are allowed to access plaintext, copy encrypted files, or even view file system metadata.

This fine-grained policy control enables operation that lets administrators and system level users perform their work (such as system backups, updates, and hardware maintenance), without having access to decrypted sensitive information.

All activities are logged. Logs are available from the local system or the CipherTrust Manager and can be integrated with leading SIEM systems. See the section of this white paper on Security Intelligence for further detail.

Application uptime, for the solutions whose data CipherTrust Transparent Encryption protects, is supported with an easily available failover capability. Simply deploy agents at the primary and failover locations and keep encrypted data stores in sync with standard processes. When top level application failover is required, enable the same policy used at the primary location at the failover location. Sensitive information is continuously protected, and business operations continue with standard failover operation.

CipherTrust Transparent Encryption is designed to minimize impact on overall system performance. The AES-256 hardware-accelerated encryption capabilities available from modern CPUs are used by the agent regardless of the environment. AIX, Linux, and Windows deployments to physical servers, virtual environments, cloud, and even container environments all benefit from the extremely low overhead on encryption and decryption available from hardware acceleration.

Figure 4. CipherTrust Transparent Encryption encrypts, enforces access policies, and logs all file, volume and linked cloud storage access

Environment Support

OS Support Microsoft: Windows Server 2012, 2016, and 2019 Linux: Red Hat Enterprise Linux (RHEL), SuSE Linux Enterprise Server, AWS Linux and Ubuntu, UNIX: IBM AIX	Big Data Support Hadoop: Cloudera, Hortonworks, IBM NoSQL: Couchbase, DataStax, MongoDB, SAP HANA
Database Support IBM DB2, Microsoft SQL Server, MySQL, NoSQL, Oracle, Sybase, and others	Encryption Hardware Acceleration AMD and Intel AES-NI, IBM P9 cryptographic coprocessor
Application Support Transparent to all applications, including Documentum, SAP, SharePoint, custom applications, and more	Agent Certification FIPS 140-2 Level 1
File systems Supports most standard file systems for each OS – See your Thales sales representative for a complete and current listing. Cloud Storage Amazon AWS – EBS, EFS, and via the AWS Storage Gateway also supports S3 Standard, S3 Infrequent and S3 Glacier Microsoft Azure – Disk Storage, Azure Files	Users and Groups System, LDAP/AD, Hadoop and Containers

Powerful protection against root and privileged user risks

CipherTrust Transparent Encryption includes highly intelligent protection against root user attacks. The solution will log and control access based on user roles and groups (system, LDAP/AD, Hadoop, Containers), but also has additional capabilities to combat root user attacks. The root user role has the capability to both create system level accounts and to log in to other system level accounts. When root users use these capabilities to change to an account that has access to sensitive data, access to the data will still be denied if the root user is not specifically allowed access by CipherTrust Transparent Encryption policy (as defined at the CipherTrust Manager). The solution will be aware of the original login account as root and deny or allow access based on the policies for that root account.

CipherTrust Manager

The CipherTrust Manager is the common centralized management environment for all CipherTrust Data Security Platform products. It provides policy control as well as secure management and storage of encryption keys, includes a web-based console as well as CLI and REST APIs. The CipherTrust Manager is available as FIPS 140-2 compliant virtual and physical appliances.

The CipherTrust Manager also provides a unified way to manage keys for third-party platforms, such as IBM Guardium Data Encryption (GDE), Oracle Transparent Data Encryption (TDE), Microsoft SQL Server TDE, and KMIP-compliant encryption products. The CipherTrust Manager can also store and manage X.509 certificates, symmetric keys, and asymmetric keys.

Strong Separation of Duties

The CipherTrust Manager can be configured as a multi-tenant device that runs many different virtual CipherTrust Managers, which are called “domains.” The CipherTrust Manager can enforce strong separation of duties by requiring more than one data security administrator to manage or change key and policy permissions. CipherTrust Manager administration can be broken into three categories: system, domain, and security. In this manner, no one person has complete control over security activities, encryption keys, or administration. Also, the CipherTrust Manager supports two-factor authentication for administrative access.

Users and groups for data security management tasks can be based on locally defined users or groups, or imported via LDAP from Active Directory or other directory services and identity management environments.

Figure 5. Multitenant Key Management and Strong Separation of Duties

To further isolate and protect sensitive data, the CipherTrust Manager and CipherTrust Transparent Encryption work in tandem to allow security administrators to create a strong separation of duties between data owners and privileged IT administrators. Users and groups used in policies for access control to data can be based on system level roles, LDAP/AD, Hadoop users/groups/zones as well as container environment users and groups.

If desired, CipherTrust Transparent Encryption can encrypt files while leaving their metadata in the clear. This capability enables IT administrators to perform system administration tasks (such as replication, backup, migration, snapshots, and system updates), without exposure to sensitive data. The CipherTrust Manager also can control basic system commands such as copy, write, and directory listings.

Figure 6. Centralized, integrated policy and encryption key management for all CipherTrust Data Security Platform products

CipherTrust Manager High Availability

CipherTrust Managers can be clustered for High Availability (HA), and Thales recommends this configuration for all implementations with a minimum deployment of two CipherTrust Managers. When configured for HA, one CipherTrust Manager acts as the primary and others are used for failover, scalability, or in additional locations where latency is a concern, such as a remote data center or cloud location.

All configuration settings, including changes to administrators, domains, hosts, keys, and policies, are made on the primary CipherTrust Manager, other CipherTrust Managers are read-only. Configuration changes and updates on the primary CipherTrust Manager are pushed to the other CipherTrust Managers at set intervals using replication.

APIs and interfaces

A web-based UI console and RESTful APIs are available. APIs make it possible to manage CipherTrust Manager functions remotely and are designed to operate in environments that require high levels of automation, such as service providers with cloud environments or highly automated data centers.

CipherTrust Security Intelligence

CipherTrust Transparent Encryption agents and CipherTrust Manager provide extensive logging capabilities detailing successful and attempted access attempts to protected data and the CipherTrust Manager management environment, agent interactions and key operations, as well as the actions of administrators at the CipherTrust Manager. Logs are designed to meet a range of needs for information from the solution. These include:

- Audit level information required by compliance, regulatory mandates, and best practice security reports
- Immediate insight into attempted access events by users and processes that may represent threats
- Detailed historical usage data that can be used to create baselines of expected operation from access pattern recognition

Logs are available in standard formats used by security information and event management (SIEM) systems (RFC5424, CEF and LEEF), and are available from CipherTrust Managers as well as from systems hosting CipherTrust Transparent Encryption agents. The primary CipherTrust Manager can be used as a collection point for all logs from CipherTrust Managers and CipherTrust Transparent Encryption agents if desired.

These logs provide deep visibility into data access, which can be used to alert administrators to unauthorized access attempts to protected data that may represent a threat, and to build typical access patterns when combined with other infrastructure and access information. For instance, a user that typically accesses information in small quantities from within a local network, if seen to be accessing large volumes of data from a remote location, would represent a threat that should generate an alert and be investigated.

Detailed logs include information about when users and processes accessed data, under which policies, and if access requests were allowed or denied. The logs will even expose when a privileged user leverages a command like "switch user" to imitate another user. Logs are designed to be able to easily meet the auditing requirements of compliance mandates and regulations as well by delivering the detailed evidence needed to prove to an auditor the encryption, key management, and access policies are appropriate and operating correctly.

Figure 7. CipherTrust Security Intelligence

Live Data Transformation Extension

Deployment and management of data-at-rest encryption can present challenges when transforming clear-text to cipher-text, or when rekeying data that has already been encrypted. Traditionally, these efforts either required planned downtime or labor-intensive data cloning and synchronization efforts. CipherTrust Transparent Encryption Live Data Transformation Extension eliminates these hurdles, enabling encryption and rekeying with unprecedented uptime and administrative efficiency.

Zero-downtime encryption and key rotation.

Live Data Transformation delivers these key capabilities:

- Zero-downtime encryption deployments. The solution enables administrators to encrypt data without downtime or disruption to users, applications or workflows. While encryption is underway, users and processes continue to interact with databases or file systems as usual.
- Seamless, non-disruptive key rotation. Both security best practices and many regulatory mandates require periodic key rotation. Live Data Transformation makes it fast and efficient to address these requirements.

With the solution you can perform key rotation without having to duplicate data or take associated applications offline.

Figure 8. CipherTrust Transparent Encryption with CipherTrust Live Data Transformation Enabled

- Intelligent resource management. Encrypting large data sets can require significant CPU resources for an extended time. Live Data Transformation provides sophisticated CPU use and I/O rate management capabilities so administrators can balance between the resource demands of encryption and other business operations. For example, an administrator can define a resource management rule specifying that, during business hours, encryption can only consume 10% of system CPU, while on nights and weekends, encryption can consume 70% of CPU.
- Versioned backups and archives. With key versioning management, Live Data Transformation offers efficient backup and archive recovery that enable more immediate access. In a data recovery operation, archived encryption keys recovered from the CipherTrust Manager are automatically applied to an older data set. Restored data is encrypted with the current cryptographic key.

CipherTrust Transparent Encryption for SAP HANA

CipherTrust Transparent Encryption provides a proven approach to safeguarding SAP HANA data that meets rigorous security, data governance, and compliance requirements. The solution can be quickly deployed, requiring no changes to SAP HANA, the underlying database, or hardware infrastructure. With this solution, organizations can encrypt SAP HANA data and log volumes, and establish strong governance and separation of duties.

- Enforce strong data encryption on all SAP HANA data and log partitions
- Protect and control access to the SAP HANA persistence layer
- Use granular access controls to prevent privileged users and system administrators from accessing unauthorized data
- Facilitate compliance with new and existing data security mandates
- Maintain key and security policy custody on tenant/customer premises

Secure Import of Data Encryption Keys

As organizations increasingly place business-critical data within multiple cloud environments, the question of who controls the encryption keys that protect sensitive data becomes increasingly important. Enterprises prefer to control and even create the data encryption keys protecting their cloud environment data. Those with the highest levels of IT security requirements may even wish to control the creation of their in-house keys for maximum complexity, randomness, and assurance.

The CipherTrust Data Security platform provides the capability for cloud service providers and enterprises to offer multi-tenanted access to CipherTrust Managers that enables them to create and bring in data encryption keys used with CipherTrust Transparent Encryption agents rather than use the data encryption keys generated by the CipherTrust Manager. Data encryption keys can be created by a trusted hardware device (such as a Thales or third-party Hardware Security Module) or from an existing key management and creation application. Keys imported for use with CipherTrust Transparent Encryption agents can then be used as needed with policies created within the CipherTrust Manager.

Figure 9. Maintain complete control of encryption keys, even within multi-tenant cloud environments

Use cases

Databases and Unstructured Files – Across Data Centers and Cloud Environments

As organizations continue to grow their infrastructure and data sets, they have to deal with a mix of in-house and cloud-based data assets and applications. Regardless of where this data is located, it requires the same level of data security and protection. CipherTrust Transparent Encryption enables enterprises to choose their implementation mode for data security based on their risk tolerance, compliance, and privacy requirements.

Most enterprises will opt for a solution that includes managing and controlling from their local data center encryption keys and access policies for both local data center resources and cloud environments. This approach keeps control of keys firmly within the enterprise, eliminating the risk of remote legal access or compromise at the cloud provider. Enterprises that are “all in” the cloud and make no use of local data center compute resources may opt for a cloud-based deployment of key and policy management. Such organizations can either co-locate cloud key management in the same cloud with data protected by CipherTrust Transparent Encryption, using a secondary cloud environment for the CipherTrust Manager to provide a greater degree of separation and lower risk, or use a co-location or hosting provider for hardware versions of CipherTrust Managers. All of these scenarios are easily supported with CipherTrust Transparent Encryption by locating physical or virtual CipherTrust Managers in local data centers, co-location vendors, hosting solutions, or cloud environments as needed.

Regardless of the deployment model, a typical database protection scenario includes a CipherTrust Transparent Encryption agent deployed to database servers with a simple policy – a signed database process and the database user are allowed cleartext access to the protected data store, all others will only see file metadata and ciphertext. This effectively shields the database access from compromise by root and privileged user-based attacks, local system, and LDAP users and groups while also meeting compliance and best practice requirements for safeguarding the data set with encryption.

For larger data sets, customers will typically purchase the Live Data Transformation extension to CipherTrust Transparent Encryption, enabling immediate encryption of the database without taking critical applications offline and periodic rekeying to meet compliance and best practice requirements without downtime.

We will use a directory for a typical unstructured file system protection example. The CipherTrust Transparent Encryption agent is deployed to the server with separate policies for LDAP/Active Directory user groups. For instance, allowing only finance department members to access critical accounting data, HR to access confidential employee information, and Engineering to access development documents. Each data store section is encrypted with an individual key by policy, effectively limiting the access to only those who require it for their work.

Figure 10. Fully integrated enterprise on-premises and cloud environment deployment

Big Data

With nearly every enterprise embracing big data environments, and with large numbers of these environments implemented in the cloud, the security of the sensitive data within the data lake, source data environments, and the reports that hold high-value correlated results have become an insistent concern.

CipherTrust Transparent Encryption safeguards this information. The solution can be used to protect data at the file system level within compute nodes (and underlying storage), source data locations, as well as the repositories used for logs and reports. And, this protection extends beyond the system level users/ groups and LDAP/AD users and groups that are enforced by CipherTrust Transparent Encryption on a typical server. The solution also enforces policy-based encryption, access controls and data access logging by Hadoop users, groups and zones. This capability provides further protection against privileged users within the big data lake or users within the environment.

A typical deployment includes agents installed on compute nodes, source data servers, and servers accessing log/report repositories. Data is encrypted throughout the environment with appropriate access policies and data access logging controls provided by the CipherTrust Manager. Further, the use of hardware encryption capabilities in underlying compute infrastructure results in minimal overhead from encrypt/decrypt operations. This makes it possible to use the solution even where speed and compute capability are critical.

Further, Thales works with leading big data environment vendors as a partner to ensure solution capability and operation. At the time of this writing, these partners include DataStax, MongoDB, Teradata, IBM, Cloudera, Couchbase, SAP HANA, and Hortonworks.

Figure 11. Protecting data within big data environments using CipherTrust Transparent Encryption

Advanced data protection for Amazon S3

As organizations increasingly use Amazon S3 cloud storage as part of their implementation strategy, as well as for backups and failover environments, they need to protect data within these S3 buckets just as they would if the storage were located within their own data centers.

With advanced data protection for Amazon S3, organizations can apply transparent encryption and access controls to sensitive data in S3 buckets. The CipherTrust Transparent Encryption solution encrypts unstructured files, semi-structured data, or structured databases before they are written to Amazon S3 buckets. This assures that the data is always encrypted in-flight, for example from on-premises hosts or Amazon EC2 instances to the S3 buckets. Decryption only occurs once the data is on the server where it will be used. In addition, CipherTrust Transparent Encryption protection for Amazon S3 features enhanced granular access controls, which, when deployed with custom AWS IAM policies, can enforce additional access controls to limit S3 access only to hosts running the CipherTrust Transparent Encryption for Amazon S3 agent.

Key features of CipherTrust Transparent Encryption for Amazon S3 include:

- **Transparent to applications and Amazon S3 administrators.** Encryption and access controls are completely transparent to applications while Amazon S3 administrative procedures remain unchanged after software agent deployment. The encryption offered by this solution is independent of Amazon S3 server-side encryption.
- **Continuous protection even with misconfigured S3 buckets.** Continuously enforces policies that protect against unauthorized access by users and processes even in the case of Amazon misconfigurations. Data access to protected S3 buckets is tracked through detailed audit logs.
- **Granular controls.** Applies granular, least-privileged user access policies that protect sensitive data in S3 buckets from external attacks and misuse by other privileged users. Security administrators can set up access controls on bucket creation, deletion, and enumeration, as well as for object creation, deletion, and updates. Optional S3 server-side access controls can be enabled with custom IAM policies to restrict S3 bucket access only to hosts configured with CipherTrust Transparent Encryption.
- **Strong data security.** Employs strong, standards-based encryption protocols, such as Advanced Encryption Standard (AES) for data encryption and Elliptic Curve Cryptography (ECC) for key exchange. TLS 1.3 and other NIST recommendations adopted to enforce strong key and data security. The agent is FIPS 140-2 Level 1 validated. The encryption keys are always created and managed by the CipherTrust Manager, a FIPS 140-2 Level 3 compliant appliance.
- **Security intelligence logs.** Identify and stop threats faster with detailed data access audit logs that produce an auditable trail of permitted and denied access attempts from users and processes, delivering unprecedented insight into file access activities.

Summary

The urgent need for data-at-rest encryption continues to grow. Compliance requirements proliferate. Digital transformation expands attack surfaces. And every day we see new internal and external threats to critical IP, PII, customer and citizen information, and more. With CipherTrust Transparent Encryption, organizations can secure their file and volume data wherever it is stored in a wide range of environments and use cases. And, CipherTrust Transparent Encryption is an integral part of a single platform solution that provides comprehensive data-at-rest security across the entire enterprise. The solution helps organizations address their security mandates while minimizing costs and administrative efforts.

Appendix: Performance benchmarks

Intel®, AMD, and PowerPC processor family all include hardware accelerated encryption capabilities that are leveraged by CipherTrust Transparent Encryption agents. For Intel, this includes Intel® Data Protection Technology with Advanced Encryption Standard New Instructions (AES-NI). AES-NI accelerates AES encryption and has been optimized for fast throughput and low latency.

CipherTrust Transparent Encryption uses AES-NI instructions for hardware-based acceleration of data encryption and decryption. In fact, CipherTrust Transparent Encryption has a proprietary encryption engine that is designed to take full advantage of the parallelism that can be achieved with multi-core processor chipsets and it specifically leverages the pipelining capabilities of AES-NI. As a result, the solution delivers the maximum performance possible.

In addition to leveraging hardware-based encryption capabilities, CipherTrust Transparent Encryption is tightly integrated with, and optimized for, each supported operating system kernel. Consequently, CipherTrust Transparent Encryption leverages the latest features available for every platform supported, rather than being coded to a lowest common denominator across multiple platforms. With each new release, Thales continues to add new capabilities that enable the solution to exploit the latest operating system features.

For many applications, the performance overhead that CipherTrust Transparent Encryption introduces is negligible. However, as loads associated with input/output (I/O) increase, there will be increased overhead associated with encryption. Even with demanding, I/O heavy applications, such as databases or big data processing, CipherTrust Transparent Encryption generally introduces less than 10% overhead.

One example can be seen in the chart below. In this example, the Yahoo Cloud Serving Benchmark (YCSB) was run against MongoDB 4.0.3, with the WiredTiger storage engine running on top of CipherTrust Transparent Encryption. YCSB is a generally available open source framework that has a common set of workloads for evaluating the performance of different “key-value” and “cloud” serving stores. The workload was configured so that less than one-half of the data set could fit in memory, causing a heavy I/O load. As the chart illustrates, CipherTrust Transparent Encryption only introduced minimal overhead.

Figure 12. Even when testing in a scenario with a heavy I/O load, CipherTrust Transparent Encryption introduces minimal performance overhead.

About Thales

The people you rely on to protect your privacy rely on Thales to protect their data. When it comes to data security, organizations are faced with an increasing number of decisive moments. Whether the moment is building an encryption strategy, moving to the cloud, or meeting compliance mandates, you can rely on Thales to secure your digital transformation.

Decisive technology for decisive moments.

CipherTrust Transparent Encryption (CTE)

This document describes the CipherTrust Manager interfaces to use CTE. The document explains the CTE concepts such as clients and client groups, signature sets, security rules, and GuardPoints. Next, the document describes how to manage clients and client groups, signature sets, security policies on the CipherTrust Manager. Finally, the document describes how to manage GuardPoints.

- It is assumed, for this document, that you have already configured the CipherTrust Manager appliance. Refer to the CipherTrust Manager product documentation for instructions.
- The next step is to activate and install the CTE license. Refer to [Licensing](#) for details.
- After the license is installed, you can configure CTE Agents. Refer to the [CTE Agent Quick Start Guide](#) specific to your platform for details. Installation of the CTE Agents is required for protecting directories and files stored on clients.

Organization

This document contains the following sections:

- [Overview](#): Provides a high-level overview of the CTE solution.
- [Interfaces](#): Provides an overview of the CipherTrust Manager interfaces—Command Line Interface (CLI), REST Application Programming Interface (REST API), and Graphical User Interface (GUI).
- [Concepts](#): Describes CTE concepts such as clients, client groups, GuardPoints, policies, and security rules.
- [Data Transformation](#): Provides an overview of the data transformation process.
- [Managing Profiles](#): Describes how to configure client log criteria, client Syslog settings, Quality of Service (QoS), multifactor authentication (MFA), ransomware protection (RWP), and server settings etc.
- [Managing Clients](#): Describes how to add, register, and manage clients on the CipherTrust Manager.
- [Managing LDT Communication Groups](#): Describes how to manage LDT communication groups on the CipherTrust Manager.
- [Managing Client Groups](#): Describes how to manage client groups on the CipherTrust Manager.
- [Managing Signature Sets](#): Describes how to create signature sets and how to sign and re-sign files in a signature set. The chapter also describes how to stop file signing and how to delete signatures and signature sets on the CipherTrust Manager.
- [Managing Policies](#): Describes rules and effects of security policies, and provides instructions to create, configure, import, and export security policies on the CipherTrust Manager.
- [Managing GuardPoints](#): Describes how to create, view, and delete GuardPoints on the CipherTrust Manager. The chapter provides information on automatic and manual GuardPoints and provides steps to configure

Windows network drives.

- **Managing Kubernetes Storage Groups and Clients:** Describes how to manage Kubernetes (K8s) storage groups, manage K8s clients, apply GuardPolicies to storage groups, and protect K8s clients.
- **Sharing Resources Across Domains:** Describes how to share CTE resources across CipherTrust Manager domains.
- **Multifactor Authentication:** Describes how Multifactor Authentication (MFA) works for CTE clients and GuardPoints.
- **Communication with CipherTrust Manager:** Describes how communication takes place between the CTE clients and CipherTrust Manager.
- **Configuring Cluster Node Preference:** Describes how to configure preferred nodes of a CipherTrust Manager cluster for sending status updates from CTE clients.
- **Backup and Restore:** Describes how to back up CTE policies and restore them to other CipherTrust Managers.
- **Integrating CTE Logging with Splunk:** Describes how to integrate the CTE audit logging with Splunk.
- **Migrating CTE Configuration from Data Security Manager:** Describes how to migrate CTE configuration from the DSM to the CipherTrust Manager.
- **Migration Summary:** Provides a summary of the CTE resources migrated from the DSM to CipherTrust Manager, mapping of the resources that are handled differently between the two key managers. Also, the section provides any constraints applicable to the migrated resources and describes how to interpret the migration status.
- **Migrating ProtectFile to CipherTrust Transparent Encryption:** Thales CipherTrust Transparent Encryption solutions provide state-of-the-art encryption solutions that cover all of the use cases for ProtectFile and other legacy applications. This guide helps you to migrate from ProtectFile and legacy applications, to CipherTrust Transparent Encryption or CipherTrust Transparent Encryption Userspace. The PFMigrate docs have been moved to their own site. This site contains the documentation for all use cases for PFMigrate.
- **Permissions:** Describes the complete permissions required to perform create, read, update, and delete operations on CTE resources.
- **Quorum Control:** Describes the quorum control for CTE operations and resources.
- **Confidential Computing:** Describes support for Confidential Computing with Intel Trust Domain Extensions (TDX) attestation.
- **Ransomware Protection:** Describes how to protect CTE clients from Ransomware.
- **Unique to Client Keys:** Describes how to make a key unique to a client.
- **Load Balancer:** Describes how to configure the load balancer for CTE on CipherTrust Manager.

-
- **Operations:** Describes the operations that the CTE Server Administrator performs on the CipherTrust Manager. These operations include registering CTE clients with the CipherTrust Manager, using external CA certificates, re-registering the clients, and protecting file system on a CTE client.
 - **Certificate Renewal:** Describes how the CTE clients are automatically notified of any changes in the client certificate or the web interface certificate.
 - **Common Scenarios:** Describes the common encryption scenarios in which the paths can be encrypted using the CTE solution.
 - **Reports:** Describes how to generate and download CTE reports.
 - **Troubleshooting:** Describes how to handle the issues that you might face when using CTE with the CipherTrust Manager.
 - **API Examples:** Provides examples to use CTE APIs to perform tasks such as decrypting LDT-protected GuardPoints.
 - **API Response Codes:** Describes the response codes returned by the CTE APIs with corresponding messages, and possible corrective actions to be taken for them.
 - **How to Configure the External CA for CTE:** Describes how to configure an external CA for CTE.
 - **How to Change Local CA or External CA for CTE:** Describes how to change a local or an external CA for CTE.

Overview

CTE protects data at rest, residing on Direct Attached Storage (DAS), Network Attached Storage (NAS), and Storage Area Networks (SAN). This can be a mapped drive or mounted disk, as well as through Universal Naming Convention paths.

CTE secures data with little impact to application performance. It requires no changes to your existing infrastructure and supports separation of duties between data owners, system administrators, and security administrators.

The CTE solution consists of two parts:

- The CTE Agent software that resides on each protected virtual or physical machine (client). The CTE Agent performs the required data encryption and enforces the access policies sent to it by the CipherTrust Manager. The communication between the CTE Agent and the CipherTrust Manager is encrypted and secure.

The clients contain the directories and drives you want to protect. These clients can be onsite, in the cloud, or a hybrid of both.

- The CipherTrust Manager that stores and manages data encryption keys, data access policies, administrative domains, and administrator profiles. After you install the CTE Agent on a client and register it with a CipherTrust Manager, you can use the CipherTrust Manager to specify which devices on the client you want to protect, what encryption keys are used to protect those devices, and what access policies are enforced on those devices.

How CTE Protects Data

CTE uses policies created in the CipherTrust Manager to protect data. You can create policies to specify file encryption, data access, and auditing on specific directories and drives on your clients. These directories or devices are called GuardPoints. Each GuardPoint must have one and only one associated policy, but each policy can be associated with any number of GuardPoints.

Policies specify:

- Whether or not the resting files are encrypted.
- Who can access decrypted files.
- What level of file access auditing is applied when generating fine-grained audit trails.

A security administrator accesses the CipherTrust Manager through a web browser. You must have administrator privileges to create policies using the CipherTrust Manager. The CTE Agent then implements the policies once they are pushed to the client.

CTE can only enforce security and key selection rules on files inside a guarded directory. If a GuardPoint is disabled, access to data in the directory goes undetected and ungoverned. Disabling a GuardPoint and then allowing unrestricted access to that GuardPoint can result in data corruption.

Workflow

The following diagram shows the basic flow of the CTE solution:

1. A client administrator installs the CTE Agent on the client machine. Refer to these sections in the [CTE Agent Quick Start Guide](#) for your platform:
 - [Installation Prerequisites](#)
 - [Installing and Registering CTE](#)

2. The client administrator registers the client with the CipherTrust Manager. Refer to the "Installing and Registering CTE" section in the [CTE Agent Quick Start Guide](#) for your platform:

A registration token is required to register the client with the CipherTrust Manager. The CTE administrator creates the registration token. Refer to [Creating a Registration Token](#) for details.

After successful registration, the client is added to the CipherTrust Manager. Alternatively, you can manually create a client on the CipherTrust Manager without registration, and register it later. Refer to [Adding Clients Manually](#) for details.

3. The CTE administrator identifies and creates a policy for the device or directory that specifies the access controls and the encryption keys to use for the device or directory. Refer to [Creating Policies](#) for details.

When creating the policy, the CTE administrator identifies and creates the encryption key that CTE will use to encrypt the data on the device or directory. Alternatively, encryption keys for CTE can be created on the Keys page of the CipherTrust Manager GUI. Refer to [Creating a New Key](#) for details.

4. The CTE administrator assigns a GuardPoint to the device or directory. When a GuardPoint is created, the security configuration is prepared and pushed to the CTE client. Refer to [Managing GuardPoints](#) for details.

The above workflow shows high-level and mandatory steps of the CTE solution. It is recommended to read related sections thoroughly (refer to [Organization](#)). These sections provide useful information to help you customize/configure the CTE solution to suit your requirements.

Interfaces

This section provides an overview of the CipherTrust Manager interfaces.

CLI

The CipherTrust Manager includes a CLI tool, named `ksctl`, that can be downloaded and run locally to control a remote CipherTrust Manager appliance. `ksctl` exclusively uses the REST API to communicate with the CipherTrust Manager, so anything that you can do with the tool, you can also do directly with the REST API. Conversely, `ksctl` exposes most of the functionality of the REST API. It can perform management functions, such as managing registration tokens and clients.

Note

`ksctl` is designed to be run from a remote system, not on the CipherTrust Manager itself.

To use the CLI:

1. Open the **CipherTrust Manager** URL in a browser.
2. Click the **API & CLI Documentation** link. The API playground is displayed.
3. At the top left, click **CLI Guide**. The CLI documentation is displayed.
4. At the top right, click the **CLI** download button. This downloads the **ksctl_images.zip** file.
5. Unzip the **ksctl_images.zip** file. The extracted files contain platform specific files. For example, the file for Windows is **ksctl-win-amd64**, and for Linux, the file is **ksctl-linux-amd64**.
6. Set up the `ksctl<os>` file for your system. Refer to the CipherTrust Manager CLI documentation for details.
7. Run `ksctl cte` to run CipherTrust Transparent Encryption specific commands.

Refer to the CipherTrust Manager documentation for details. For details on commands related to CipherTrust Transparent Encryption, refer to the online documentation of `ksctl cte`.

Authenticating to the Embedded API Guide

The embedded API Guide shares authentication with the CipherTrust Web UI. To authenticate to both the API Guide and the CipherTrust Web UI, visit `https://<ciphertrust_manager_IP_or_hostname>` in a web browser. Alternatively, click the **Log In** link in the top right corner of the API Guide when you are unauthenticated.

The simplest login is with a username and password. This authenticates a local user to the root domain. There can be additional login options to [authenticate to another domain](#), [authenticate with a certificate](#), [authenticate using LDAP](#), or [authenticate using OIDC](#). These options require additional user management configuration from a user in the User Admins group.

After login, the API Guide is accessible through the **API** button in the upper right corner.

There, you can make API calls in the established authentication context. You are logged out after 10 minutes of inactivity with the API Guide open. If you close the browser window, you are logged out after 30 minutes of your last login.

Manual API Token Generation for User Credentials

You can generate an API token with a user's username and password for a given domain, outside of the embedded API guide. This is useful if you have created a custom REST API client.

To copy and paste the following example commands, set an environment variable to point to your CipherTrust Manager instance:

```
$ export KSCTL_URL=https://{addr}          # sh/bash
$ set -x KSCTL_URL=https://{addr}         # fish
```

For example, this command will use the root admin's credentials to create an API token:

```
$ curl -k -X POST $KSCTL_URL/api/v1/auth/tokens/ \
  -H "Content-Type: application/json" \
  -d '{"name":"admin","password":"admin"}'
```

Note

By default, this command creates a token for the root domain. You can specify a [child domain](#) to log in to with `'{"name":"domain_user","password":"domain_user_password","domain":"domain_name"}'`

The response:

```
{
  "jwt": "eyJhbGciOiJIUzI1NiIsInR5cCI6IkpXVCJ9.eyJhdWQiOiJkMzEzZjJ0ZlNy1hN2ZlLTQ1YzEtOWU1OS0zYmUxNTRkMTZjYmQiLCJpc3MiOiJreWxvIiwiaWF0IjoiYXNja3lsbyIsImN1c3QiOi0nsiZ3JvdXBzIjpbImFkbWwluI191LCJpYXQiOiJ0e00DExMjQxMzcsImV4cCI6Ij00MTQ4MTEyNDQzN30.Z9GU0Yy0ImHmdPmbZx66vL0NLQfeLvNGkyGkZpVbfx4",
  "duration": 300
}
```

```
}
```

Copy the value of the `jwt` property into another environment variable:

```
(sh) $ export KSCTL_JWT=eyJhbGciOiJIUzI1NiIsInR5cCI6IkpXVCJ9.eyJhdwQiOiJkMzEzYzcwZS01NmYyLTQ5MTU0OGJkNy01ZmMyYmUyNzk2YzEiLCJzdwIiOiJsb2Nhbmh4Im2ZjOGZlNy1hN2ZlLTQ1YzEtOWU1OS0zYmUxNTRkMTZjYmQiLCJpc3MiOiJreWxvIiwiaWVhbnJlIjoia3lsbyIsImN1c3QiOi0nsiZ3JvdXBzIjpbImFkbWluIl19LCJpYXQiOiJE00DEXMjQxMzcsImV4cCI6MTQ4MTEyNDQzN30.Z9GU0Yy0ImHMDPmbZx66vL0NLQfeLvNGkyGkZpVbfx4
(fish)$ set -x KSCTL_JWT eyJhbGciOiJIUzI1NiIsInR5cCI6IkpXVCJ9.eyJhdwQiOiJkMzEzYzcwZS01NmYyLTQ5MTU0OGJkNy01ZmMyYmUyNzk2YzEiLCJzdwIiOiJsb2Nhbmh4Im2ZjOGZlNy1hN2ZlLTQ1YzEtOWU1OS0zYmUxNTRkMTZjYmQiLCJpc3MiOiJreWxvIiwiaWVhbnJlIjoia3lsbyIsImN1c3QiOi0nsiZ3JvdXBzIjpbImFkbWluIl19LCJpYXQiOiJE00DEXMjQxMzcsImV4cCI6MTQ4MTEyNDQzN30.Z9GU0Yy0ImHMDPmbZx66vL0NLQfeLvNGkyGkZpVbfx4
```

Using the `jq` tool, we can fetch, extract, and export the token in a single shell command:

```
(sh) $ export KSCTL_JWT=$(curl -k -X POST $KSCTL_URL/api/v1/auth/tokens/ \
-H "Content-Type: application/json" \
-d '{"name":"admin","password":"admin"}' | jq -r '.jwt')
(fish)$ set -x KSCTL_JWT (curl -k -X POST $KSCTL_URL/api/v1/auth/tokens/ \
-H "Content-Type: application/json" \
-d '{"name":"admin","password":"admin"}' | jq -r '.jwt')
```

We can use that API token to make other calls:

```
$ curl -k "$KSCTL_URL/api/v1/vault/keys2?limit=20" \
-H "Authorization: Bearer $KSCTL_JWT"
```

Making an API Call

To make an API call, find the API in the left pane and click it. In the right pane, specify the required parameters, and click an appropriate button (for example, **POST**, **GET**, **DELETE**, or **Curl**). For example, to create a CTE policy on CipherTrust Manager:

1. In the left pane of the API playground, click **CTE/Policies**.
2. Under **cte/policies**, click **Create**. The Create section of the API playground is displayed in the right pane.
3. In the **body** field, specify required parameters with their values, as shown below.

```
{
  "name": "TestPolicy",
  "policy_type": "Standard",
  "never_deny": false,
  "security_rules": [
    {
```

```

        "effect": "permit",
        "action": "all_ops",
        "partial_match": false,
        "resource_set_id": "TestResourceSet",
        "exclude_resource_set": true
    }
]
}

```

Expand **schema** under the **body** field for names and types of fields. Hover your mouse over each field to view its description. The parameter names and casing in the **body** field must match with those shown in the schema. Also, ensure that parameters and their values are specified in double quotes.

4. Click **POST**.

Alternatively, to get an equivalent `curl` command, click the **Curl** button. The `curl` equivalent will be shown in the text field below. Use the `curl` tool to run the command to make the REST API call.

Similarly, all API calls can be made by referring to the schema shown in the playground.

GUI

Use the CipherTrust Manager's GUI (also called the Management Console) to perform management functions such as managing profiles, policies, clients and client groups, and GuardPoints. These functions can also be performed using the CLI tool or the REST API.

To use the GUI:

1. Open the **CipherTrust Manager** URL in a browser.
2. Enter **Username** and **Password**.
3. Click **Log In**. By default, the Products page is displayed.
4. Click **Transparent Encryption** to open the application.

The Clients page of the Transparent Encryption GUI is displayed, as shown below.

The main components of a Transparent Encryption GUI are:

- Header
- Left Pane
- Page
- Notifications

Header

Element	Description
	App switcher. Click to view and switch to another application such as Access Management and Admin Settings .
THALES	Thales logo.
Transparent Encryption	Application name. For CTE, Transparent Encryption is displayed.
	Version and Server Info icon. Click to view the name, appliance name, and version of the CipherTrust Manager.
API	Link to the API playground.
	Link to the CipherTrust Manager product documentation.
admin	Logged in user. Click to switch domains, view and update user settings (Email address and password), and log out.

Left Pane

Contains links to manage CTE resources - clients, policies, reports, and settings etc.

Element	Description
Clients	Click to manage clients and client groups. The Clients page is the displayed by default. Refer to Managing Clients and Managing Client Groups for details.
Policies	Click to manage policies and policy elements—resource sets, user sets, process sets, and signature sets. Refer to Managing Policies for details.
Reports	Click to manage reports. Refer to Reports for details.
Settings	Click to manage settings such as profiles. Refer to Managing Profiles for details.

Page

A page is the main working area that provides options to manage CTE resources. Depending on the selected option in the left pane, the page shows different types of information. These options are described in this document, where appropriate.

At any time, a page can either be in the list view or in the edit view. A sample screenshot of the list view of the Clients page is shown below. Most pages follow the similar pattern except that they show different content based on the resource being managed.

Client Name Search by Client Name

☐ 0 Selected 2 Results | 2 Clients

[Compatibility Matrix](#) [+ Create Client](#)

	Status	Client Name	Client Type	Protection Mode	OS Type	FAM State	Agent Ver
	☐ Healthy	10.154.13.209	FS	CTE	LINUX	DISABLED	7.2.1
	☐ Healthy	AGWin	FS	CTE	WINDOWS	DISABLED	7.2.1

2 Clients 10 per page

The sample page shown above can be divided into the following elements:

Element	Description
Title	Shows the page name.
Status bar	Shows the total number of clients added to the CipherTrust Manager, the number of clients with errors, warnings, healthy state. The status bar also shows the number of unregistered and expunged clients on the CipherTrust Manager. The status bar also acts as a filter. Click a health status to see the list of clients with that status.
Search box (Search)	Filters clients based on their partial or full names. Search is case-insensitive.
List	Shows the clients based on the selected health status. By default, all the clients added to the CipherTrust Manager are displayed.
Compatibility Matrix button	Provides an option to upload the kernel compatibility matrix.
Create Client button	Provides an option to add a new client even before a CTE Agent is installed on it.
Delete icon ()	Deletes the selected clients. A message is prompted to confirm the action.
Check box (☐)	Provides an option to select a client for deletion or modification. Multiple clients can be selected to perform the delete operation on them. Use the check box provided just under the Search box to select all clients visible on the page.
Expand icon ()	Shows mini detail view of a client in the clients list.
Custom View icon ()	Hides/shows optional columns. For example, click this icon on the Clients page shows:

Element	Description
	 ☒ Status ☒ OS type ☒ Kernel Version ☒ Agent Version ☒ Description ☐ Encryption Modes ☐ Upgrade On Reboot OK Reset Select or clear the desired column and click OK.
Overflow icon ()	Shows additional options. Depending on the current state of a client, the options can vary.
Pagination	Helps configure the number of records to display. By default, 10 records per page are displayed. 
Tooltip icon()	Shows the basic description about an element when the mouse pointer is moved over the tooltip icon. Click the Learn More link in the tooltip to view the related documentation.

Notifications

CTE prompts toast notifications at the top right corner of the main page area. These notifications are shown when operations such as creation or deletion of an entity is performed.

Green success toast notifications are displayed for successful operations.

Red error notifications are displayed for failed operations.

Concepts

This section describes important concepts for CTE.

Clients

A client is a computer system where the data needs to be protected. A compatible CTE Agent software is installed on the client. The CTE Agent can protect data on the client or devices connected to it. A client can be associated with multiple GuardPoints for encryption of various paths (refer to [Managing GuardPoints](#) for details).

CTE also supports Kubernetes (K8s) clients. Refer to [Kubernetes Clients](#).

Client Groups

A client group is used to group one or more clients to simplify configuration and administration. GuardPoints created on a client group are applied to all members of the group. Additionally, you can apply client group configuration settings to all clients in a client group. A client can be a member of multiple client groups.

If you have created a group of one type of clients, then you should only add similar clients to the group. Same configuration settings can only be applied to clients of the type with which the client group is created. If a different type of client is added, configuration settings cannot be applied to that client.

Refer to [Managing GuardPoints](#) for details on creating GuardPoints on client groups.

Kubernetes Clients

Unlike a traditional CTE Agent, a Kubernetes (K8s) client runs as a K8s pod. Multiple pods can run on a single K8s node. Every pod protects the K8s persistent volumes attached to it using a CTE for Kubernetes policy received from the CipherTrust Manager.

The name of a K8s client is a combination of:

- The node on which the K8s client is running
- The linked K8s StorageClass
- The namespace where the K8s client pod runs
- A random string attached automatically

So, the format of K8s client name is `<node-name>_<csi-storage-class>_<csi-namespace>_<random-string>`, for example, `node1_K8sStorageClass1_K8sNamespace1_f2eaa752`.

Kubernetes Storage Groups

A Kubernetes (K8s) storage group is a logical group of multiple K8s clients with the same K8s namespace and K8s StorageClass. The group helps simplify K8s configuration and administration across K8s clients. GuardPolicies created on a storage group are applied to all members of the group.

A K8s client can be a member of one storage group only.

GuardPoints

A GuardPoint specifies the list of folders that contains paths to be protected. Access to files and encryption of files under the GuardPoint is controlled by security policies.

Refer to [Managing GuardPoints](#) for details.

GuardPolicies

A GuardPolicy, which is similar to a CTE GuardPoint, can be attached to a K8s storage group only. It is inherited by the K8s clients attached to the storage group.

Only the policies of type [CTE for Kubernetes](#) can be included in a K8s GuardPolicy. As CTE for K8s protects a volume not a specific path, the GuardPath is automatically set to the CTE for Kubernetes policy name prefixed with a slash (/).

Policies

A policy is a collection of rules that govern data access and encryption. Think of a policy as an if-then statement. Policy rules are processed sequentially. If the criteria of rule one are not met, the policy enforcement engine moves on to the second rule and so on.

Policies specify:

- **Actors:** Users, groups, and processes that are permitted/denied access to protected data.
- **Actions:** What actions authorized actors are allowed to perform. For example create/delete, read/write, decrypt, modify permissions, and so on.
- **Files acted upon:** Policy rules may apply to entire directories and mount points, or only to files named in a specific way (for example, .docx files may be encrypted and restricted to read-only access by designated users, while other files may be stored clear and read and written by anyone).

Additionally, each CTE policy specifies one or more encryption keys used to encrypt blocks of file data when applications write them, and decrypt them when they are read.

CTE encryption is transparent to applications. This means that the CTE Agent encrypts blocks of data as they are written, and decrypts data when they are read by authorized users and applications. This architecture separates administration of files from access to the data in them. Backup programs, for example, may be authorized to read files, but not view the data in them. Therefore, data can be backed up and taken offsite while remaining encrypted so that security is not breached.

A policy comprises Security Rules, Key Rules, and Data Transformation Rules.

CTE supports the following policy types:

- **Standard:** Access to data is blocked during initial encryption or rekeying of data.
- **Live Data Transformation (LDT):** Encryption and rekeying of data takes place in the background, without disrupting user or application access to that data.
- **Cloud Object Storage (COS):** Applicable to GuardPoints in Amazon S3 buckets. Access to data is blocked during initial encryption or rekeying of data.
- **In-place Data Transformation (IDT):** Access to data is blocked during encryption or rekeying of data. This policy type is needed for creating GuardPoints for Teradata clusters.
- **CTE for Kubernetes:** Applicable to GuardPolicies for CTE for Kubernetes clients. Access to data is blocked during initial encryption or rekeying of data.

The following diagram shows the main components of a policy:

Refer to [Managing Policies](#) for details.

Security Rules

A security rule defines:

- Who can access the data (User or Group)
- What they can do with the data (Action)
- What applications or executables have access to the data (Process)

- Where the data is located (Resource)
- How the data can be accessed (Effect)
- Whether it can be enforced on the subdirectories of the GuardPoint (Browsing)

Security Rule Criteria

Security rules consist of five criteria. They specify the attributes of an access attempt, and effects, which define whether that access is permitted or denied, and whether encryption/decryption is required. The following table lists policy rule criteria.

Criteria	Description
Resource	Specifies which files and/or directories in a GuardPoint are to be protected. For example, /secure_dir/financials.
User	Specifies a which users or groups of users can access the files.
Process	Specifies executables that can operate on the files.
Action	Specifies the allowed file action. Action could be read, write, remove, rename, and make directory. Refer to Actions for the complete list of supported actions.
Effect	Describes the type of access granted or denied according to the rule. Refer to Security Rule Effects for the list of supported effects.

Actions

An action is an attempt to access protected data in some way. Action specifies the type of file and directory action (read, write, delete, and rename etc.) allowed on a GuardPoint. A policy provides a wide range of access methods to specify the action required for the security rule. The action is identified, evaluated, and used as a factor in determining whether or not to grant access. Specifying an access method is optional. If you do not specify one, the policy defaults to **all_ops**, or "all operations".

Any action that starts with **d_** applies to directories. Any action that starts with **f_** applies to files. Only a few actions are available for COS and IDT policies.

The following table lists all basic and advanced actions:

Basic Actions

Action	Description	Policy Types
all_ops	All operations. Users can access the data using any method. all_ops is the default action (when no action is specified).	All
read	Read operations. This is a collection of actions related to reading files, directories, and their	Standard, IDT, LDT

Action	Description	Policy Types
	attributes. The read action comprises f_rd , f_rd_attr , f_rd_sec , d_rd , d_rd_attr , and d_rd_sec .	
write	Write operations. This is a collection of actions related to writing to files, directories, and their attributes. The write action comprises f_wr , f_cre , f_ren , f_rm , f_link , f_chg_attr , f_chg_sec , d_ren , d_chg_attr , d_chg_sec , d_mkdir , and d_rmdir .	Standard, IDT, LDT
key_op	Key operations. It requires <i>two</i> keys. One key is specified on the Add Security Rules screen and the other on the Add Data Transformation Rules screen. The encryption keys for the <i>current</i> security rule are specified on the Add Security Rules screen. The keys to migrate data from an encrypted form to a non-encrypted form or to change the encryption keys used to access the data are specified on the Data Transformation Rules screen.	Standard, LDT

Advanced Actions

Action	Description	Policy Types
f_rd	Read a file.	Standard, LDT, COS
f_wr	Write to an existing file.	Standard, LDT, COS
f_wr_app	Append data to a file.	Standard, LDT
f_cre	Create a new file.	Standard, LDT
f_ren	Rename a file.	Standard, LDT
f_link	Link to a file (for example, <code>ln file_name link_name</code>).	Standard, LDT
f_rm	Remove/delete a file.	Standard, LDT, COS
f_rd_attr	Read the attributes of a file (for example, <code>ls -l file</code>).	Standard, LDT
f_chg_attr	Change file attributes (for example, <code>chmod</code>).	Standard, LDT
f_rd_sec	View the security properties of a file.	Standard, LDT

Action	Description	Policy Types
f_chg_sec	Change any security property of a file.	Standard, LDT
d_rd	View directory contents (for example, <code>ls dir; cd dir</code>).	Standard, LDT, COS
d_ren	Rename a directory (for example, <code>mv dir1 dir2</code>).	Standard, LDT
d_rd_att	Read the attributes of a directory (for example, <code>ls -la dir1</code>).	Standard, LDT
d_chg_att	Change directory attributes (for example, <code>chown usr dir1</code>).	Standard, LDT
d_rd_sec	View the security properties of a directory.	Standard, LDT
d_chg_sec	Change any security property of a directory.	Standard, LDT
d_mkdir	Make a new directory.	Standard, LDT
d_rmdir	Delete a directory (for example, <code>rm -r dir1</code>).	Standard, LDT

Security Rule Effects

An effect describes the type of access granted or denied according to the rule. The following table lists policy effects that can be applied to GuardPoints.

Effect	Description
Permit	Allows access attempts to the resource. For example, you can specify an effect that allows writing to a directory.
Deny	Denies access attempts to the resource. For example, you can specify an effect that denies any attempts to access a resource.
ApplyKey	Applies an encryption key to the data in a GuardPoint. When applied, the data copied to the GuardPoint is encrypted with the specified key. When the data in the GuardPoint is accessed, it is decrypted using the same key.
Audit	Creates a message log entry for each qualifying event that records who is accessing what information and when.

How Security Policy Works

Every time a user's application tries to access a GuardPoint file, the security policy tests that access attempt against the criteria of each rule. For example, suppose a user, Harry, wants to access and modify a file called secret, using the command `cp`. For Harry to be successful, there must be a rule that allows access to secret (resource), by user Harry (user), using the command `cp` (process), and includes the permission write (action).

-
- If criteria is not specified, a value of All is used.
 - If resource is not specified, the rule applies to all resources.
 - If user is not specified, the rule applies to all users.
 - If process is not specified, the rules apply to all executables, and so on.
 - Effect cannot be left unspecified. It must have at least a permit (allow access) or deny (disallow access).

A policy can have multiple rules. Rules are evaluated much like firewall rules. They are evaluated in order, from first to last. Evaluation stops when a rule is found for which all the criteria are met. The effect for that rule is then enforced. Therefore, you must carefully order a policy's rules to achieve the desired result.

Resource Sets

A resource is a combination of a directory, a file, and patterns or special variables. A resource set is a named collection of directories, files, or both, that a user or process will be permitted or denied access to.

Refer to [Creating Resource Sets](#) for details on creating resource sets.

User Sets

A user set is a collection of users and user groups that you want to grant or deny access to GuardPoints. User sets are configured in policies. Policies can be applied to user sets, not to individual users.

Refer to [Creating User Sets](#) for details on creating user sets.

Signature Sets

A signature set is a collection of hashes of processes and executables that you want to grant or deny access to GuardPoints. A signature set can be configured in a policy as part of a process set to verify the integrity of a process before it is allowed access to guarded data. Policies are applied to signature sets, not to individual signatures.

A cryptographic hash is created for each file in a signature set that meets a specific criterion. It would take longer, bloat the CipherTrust Manager database, and reduce performance to sign all the files in a signature set, especially when the set comprises top-level directories. The criteria is listed below. All other files are skipped.

Executables accessing a GuardPoint can be inside or outside the GuardPoint. If they are inside:

- On a Windows client, all files in a signature set that are inside a GuardPoint are signed. Only the compiled Windows executables in the signature set that are outside the GuardPoint are signed. Non-executables outside the GuardPoint are not signed.
- On a UNIX client, it makes no difference whether the files are inside or outside a GuardPoint. Only the files in a signature set with one or more execute bits set (for example, `-rwxrwxrwx-`) are signed.
- File extension has no impact. Even files like the following are skipped:
 - [On Windows] `.bat` and Visual Basic programs if they are not inside a GuardPoint

- [On Linux] `.so` files if they do not have an execute bit set

Every instance of a file that is copied to a different location or to a different name will have the same signature. This can be a convenient way to detect duplicate files on your system.

By default, a generic error message is displayed about a non-existent source being detected. The name of the offending file or directory is not specified. However, it is specified in the Agent log on the client. Review the logs to:

- Identify the offending file or directory.
- Determine how many files were affected, what file "is invalid for the signature request".
- Identify the files that were not signed. Look for files with "is invalid for the signature request".

Refer to [Managing Signature Sets](#) for details on the signing process.

Process Sets

A process set is a collection of processes (executables) that you want to grant/deny access to GuardPoints or exempt from RWP monitoring. Like user sets, process sets can be configured in policies. Policies can be applied to process sets, not to individual processes.

In a process set, you can also specify processes with and without signatures and directories to be exempted from RWP monitoring. This process set can be used as a Trusted Process Set in the [Ransomware Protection Configuration](#).

Optionally, file signing can be configured to check the authenticity and integrity of executables and applications before they are allowed to access GuardPoint data. A signature set must already exist before you can configure file signing in a policy for a process set.

Refer to [Creating Process Sets](#) for details on creating process sets.

Key Rules

A key rule defines the encryption key to apply to a specific resource set or the encryption key to use as the default key, if no other key rule matches. The key rule defines the sequence in which the key rules are to be executed (Order), the location of the data to be encrypted (Resource), and the encryption key to be applied to the resource set (Key).

When defining a key rule for an LDT policy, you can select a key that is applied to the resource set (Current Key Name) and the key to use to rekey that resource set (Transformation Key Name).

Note

Keys are created and stored on a CipherTrust Manager appliance.

Data Transformation Rules

Data transformation rules define:

-
- Resources to be protected
 - Symmetric encryption key to use for
 - Rekeying the specified resources from one encryption key to a different key or
 - Rekeying resources into a plaintext format (also referred to as clear, unencrypted, or decrypted)

Signature Rules

A signature rule is a type of signature sets that contains container image signatures. Signature rules can only be associated with CTE for Kubernetes policies.

Profiles

A profile contains the CipherTrust Manager logging criteria for CTE clients, Syslog server configuration, default logging level, LDT Quality of Service (QoS) settings, and other settings that can be used for several CTE clients.

A default profile, **DefaultClientProfile**, is created automatically when either of the following happens:

- On successful registration of the first client if no profile is specified during registration.
- On creation of the first client group. A new client group is automatically linked to **DefaultClientProfile**.

When registering a CTE client, the installer prompts to specify a profile for the client. If not specified, **DefaultClientProfile** is automatically linked to the client on successful registration. The linked profile can be modified later.

Tip

It is recommended to not delete or modify **DefaultClientProfile**.

Refer to [Managing Profiles](#).

Learn Mode

Learn Mode permits a policy to be tested without actually denying access to the GuardPoint. In Learn Mode, all actions that would have been denied are instead permitted, but logged. This allows you to test policies by tracking how rules are evaluated, without enforcing the policy. Monitor the log to determine how data is being accessed, then modify the policy accordingly.

In Learn Mode:

- If the policy contains a security rule with the effect permission Permit and the effect option ApplyKey, then a security rule with the permission Deny MUST include the option ApplyKey. If it does not include the option ApplyKey, a user with the Deny permission can overwrite or edit data, which can corrupt the data.
- Effect permission Deny has the same effect as Permit, and Deny ApplyKey has the same effect as Permit

ApplyKey.

This option generates an ERROR log every time an access attempt is made that matches any security rule in the policy. The ERROR log is labeled [LEARN MODE] and can be viewed in the CTE Agent logs or under Records on the CipherTrust Manager GUI (if the log level is configured as ERROR).

Learn Mode is recommended for policies that restrict applications (process sets). Many applications use multiple binaries that may not be known to the creator of the policy at the time of creation. So, Learn Mode should be enabled when creating policies for such applications.

Note

Use Learn Mode to analyze access patterns and make informed decisions about final encryption policies. Do not keep Learn Mode running for long time.

User Roles

CTE has the [CTE Admins](#) and [CTE Clients](#) users with different responsibilities in administering and using the system.

Caution

It is critical that credentials of these users are kept in a secure location. If a credential is compromised, an attacker could gain access to sensitive data.

Note

Additionally, the CipherTrust Manager provides an option to create customized groups for CTE to control permissions on CTE resources. Refer to [Customized Groups for CTE](#) for details.

CTE Admins

Initially, there is a System Defined Group named "CTE Admins". Users within the "CTE Admins" group are CTE Administrators.

A CTE Administrator is responsible for creating and managing the following resources:

- Clients and client groups
- Profiles, policy elements, and policies
- GuardPoints
- Client registration tokens (with additional rights of System Defined Group named "Client Admins")

Note

Only the users of the "CTE Admins" group can delete CTE keys.

CTE Clients

There is a System Defined Group named "CTE Clients". CTE clients registered with the CipherTrust Manager are part of this group.

Cluster Node Preference

A CTE administrator can configure preferred nodes of a CipherTrust Manager cluster for sending status updates from CTE clients. The administrator assigns a priority to every node of the cluster.

The cluster nodes can be categorized into tiers on the CipherTrust Manager GUI, with every tier assigned a priority. For example, Tier 1 is assigned higher priority than Tier 2. All tiers (for example, Tier 1 + Tier 2) can have a total of 20 nodes. This preference is configured through server settings in profiles. If not configured, the CipherTrust Manager continues working with the default settings. Refer to [Communication with CipherTrust Manager](#) for the default behavior.

After the server settings are configured, the CTE clients associated with the profile first try to send status updates to the top tier. If none of the nodes in the tier is reachable, the CTE clients try to send updates to the next tier.

This feature is applicable to the CipherTrust Manager clusters.

Multifactor Authentication

In Multifactor Authentication (MFA), access to the requested data is granted only after the requester satisfies two or more authentication criteria.

CTE adds an extra layer of security before granting access to the protected GuardPoints. If MFA is enabled, the users performing specific tasks on the configured GuardPoints need to perform an additional OpenID Connect (OIDC) based authentication.

MFA can be helpful in scenarios such as when the credentials of a client machine are compromised. As an additional level of authentication is enforced, the data security cannot be breached.

Refer to [Multifactor Authentication](#) for details.

Data Transformation

This section provides an overview of the data transformation process. It covers the following information:

- The Data Transformation Process
- Data Transformation Techniques
- Protection Policies

The Data Transformation Process

Data transformation is the process of transforming GuardPoint data from:

- Plaintext (clear) to encrypted with a key
- Encrypted with a key to plaintext
- Encrypted with one (old) key to encrypted with another (new) key

Tip

Refer to [CTE Agent Data Transformation](#) for detailed instructions on how to use CTE on clients to transform GuardPoint data from clear text to encrypted text or from encrypted text to clear text.

This section covers the following information:

- Uses of Data Transformation
- How CTE Protects Files
- Components of the CTE Solution
- Properties of Data Transformation

Uses of Data Transformation

- **Initial Data transformation:** Encrypting GuardPoint data for the first time.
- **Rekeying:** Changing the encryption key for GuardPoint data, also called key rotation.
- **Reverse Transformation:** Decrypting GuardPoint data to clear text (not a common procedure).
- **Convert:** Non-LDT GuardPoints to LDT GuardPoints.

Note

Data transformation is complex and disruptive to data center operations. It is strongly recommended that you read and understand this section before you proceed to the initial data transformation and rekey.

How CTE Protects Files

The CTE Agent encrypts the data within a file one block at a time. It does not encrypt file metadata such as a file's name or size. This enables administrators to manage files without being able to view or modify their contents. Whether initially encrypting files, rekeying them, or decrypting them, the CTE Agent must therefore:

-
- **Read** each block of file data to be transformed.
 - **Transform** the block by encrypting, decrypting, or rekeying it.
 - **Write** the transformed block, either to its original location, or to an alternate one.

Components of the CTE Solution

CTE protects data either at the file level or at the storage device level. CTE file-level protection consists of two main components:

- **CipherTrust Manager**

An appliance that manages a database of the file sets protected by CTE GuardPoints, the encryption keys that protect them, policies that specify access rights and encryption protections that can be applied to GuardPoints. The CipherTrust Manager is also a central point for logging events related to accessing protected files.

- **CTE Agents**

Software components that run on clients with file sets to be protected. A CTE Agent manages the files behind a GuardPoint by enforcing the policy associated with it, and communicates data access events to the CipherTrust Manager for logging.

A GuardPoint is usually associated with a Linux mount point or a Windows volume, but may also be associated with a directory subtree. The CTE Agent sits between applications and the file system that clients files within the GuardPoint. It intercepts every file access request, and enforces the access and encryption rules defined in the GuardPoint's policy.

Properties of Data Transformation

For large file sets (hundreds of GBs or more), bulk transformation is time-consuming. Managing transformation time is important, because file set content must be frozen (inaccessible to applications) throughout the transformation process. Once transformation starts, it must continue until complete. So transformation time determines the window of data unavailability. Two major components contribute to transformation time:

- **Number of Blocks of File Data**

Because CTE must read, transform, and rewrite each block of file data, this component can be estimated by multiplying the number of file blocks to be transformed by the average read, transformation, and write time for a block.

- **Number of Files**

Because the CTE Agent transforms data file by file, each file must be "looked up," opened, and closed during transformation, using underlying file system mechanisms. This typically requires multiple disk accesses. Therefore, file sets that consist of many small files, per file overhead, can actually exceed file block transformation time.

Other factors, such as file system fragmentation, and load from concurrent applications, may also affect transformation time. Mainly, the number of blocks and number of files to be transformed are fundamental because they cannot be reduced or eliminated.

Data Transformation Techniques

Three methods to initially encrypt and rekey files are:

- **The Copy/Restore Method:** Using the operating system file copy utility, the client administrator can copy unprotected files to a location protected by a CTE GuardPoint with a standard/production policy.
- **The CTE Dataxform Utility Method:** Every CTE Agent includes a utility program that can encrypt or transform protected files. The `dataxform` utility encrypts, rekeys, or decrypts data in-place. Refer to the [CTE Agent Data Transformation](#) for details.
- **The Live Data Transformation (LDT):** The CipherTrust Manager Security Administrators can encrypt or rekey GuardPoint data without blocking the user or application access to that data. Refer to the [CTE-Live Data Transformation](#) with CipherTrust Manager for details.

These methods have advantages and limitations that make them suitable in different scenarios. These are discussed in the subsequent sections.

Apart from encrypting data, you can reverse the transformation, that is, decrypt the data to plaintext. To decrypt protected files, copy them to an unprotected location.

Note

CTE can also be configured to protect data at the disk level. For data protected in this way, only the copy transformation technique is available for encryption.

The Copy Method

Properties of the Copy Method

The copy method performs initial encryption, rekeying, and decryption by copying data from one directory, or GuardPoint, to another directory or GuardPoint.

- **Initial Encryption**

The client administrator encrypts a file set by copying it to a directory protected by a CTE GuardPoint with a standard policy. Encryption is transparent to the copy utility.

- **Rekeying Protected Data**

Encrypted files protected by a CTE GuardPoint are rekeyed by copying them to a directory protected by another GuardPoint with a different encryption key. Both decryption and re-encryption are transparent to copy utilities.

- **Decrypting Data by Copying**

Decrypt a protected file set by copying files from their protected location to unprotected directories. The CTE Agent decrypts file blocks before delivery to the copy utility for rewriting.

Caution

If the governing policy does not authorize the copy utility user to access data, CTE delivers encrypted file blocks to it.

Advantages of the Copy Method

- **Simplicity**

After an Agent is installed and GuardPoints are activated on a client, the client's administrator can encrypt, decrypt, or rekey file sets simply by copying them from one location to another. There are no procedures to learn, and no requirements to coordinate with the CipherTrust Manager Security Administrator. Data transformation is simply another routine administrative task.

- **Recoverability**

If a copy-based transformation is interrupted, for example, by a power failure or a system crash, the transformation resumes at or prior to the point of interruption. This is because the source files remain available and can be recopied, overwriting files at the destination that may have been only partially re-encrypted.

Limitations of the Copy Method

- **Storage Resource Consumption**

Copying a file set requires that both source and destination files exist simultaneously. Storage capacity sufficient for both must be available during initial encryption. For very large protected data sets, "extra" temporary storage may be a significant expense. However, a greater concern is likely to be the impact of moving production file sets as they are transformed. File data is unprotected while in the copy utility's buffers.

- **Impact on Operating Procedures**

Original and copied file sets have different path names and/or network addresses. After transformation, either both file sets must be renamed (the old path to a new name, and the new path to the old name), or applications must be adapted to process the transformed data set at the new directory. For a small data center with a few protected file sets, some combination of these options is usually practical. For data centers with hundreds of protected file sets, the administrative complexity and consequent chance of error make copying a complex option.

The Restore Method

A variation of the copy method is to make a backup of the files for transformation and restore the backup to the destination location. This works because:

- Backing up data causes it to be read and decrypted.

- Restoring data causes it to be written (re-encrypting it with an alternative key).
- CTE protection is transparent to backup programs.

This technique also creates a backup of the data set. However, a disadvantage is the time required to copy data twice (once from the source location to backup, and once from backup to destination location).

These considerations suggest that copying data to transform it is more suitable for initial encryption (and final decryption), and less so for rekeying. Additionally, the simplicity of recovering an interrupted transformation makes the copy/restore method useful in situations where the probability of interruption during transformation is significant.

The Datasform Utility Method

The **datasform** utility transforms data-in-place and contains two components:

- User mode that controls the overall operation
- Kernel mode that transforms files block-by-block

Advantages of the Datasform Utility

Transforming data in place has two advantages:

- **Minimal Storage Requirements**

Because the **datasform** utility transforms files in place, where they reside, it does not require temporary file storage. However, the utility does need storage in which to create a list of files for transformation.

▪ Security

The period of time that the data transformed by the **dataxform** utility appears in memory, outside the GuardPoint and therefore, unprotected, is shorter than with copying. This is significant for rekeying (compared to copying), which holds clear file data in memory between reading and rewriting. Moreover, **dataxform** requires coordination between the client and CipherTrust Manager Security Administrators, so that no one individual can subvert security during transformation.

Limitations of the Dataxform Utility

Offsetting the advantages of the **dataxform** utility method is the complexity of recovering from an interrupted **dataxform** run. Because **dataxform** transforms files in-place, data in a file undergoing transformation at the time of a failure may be only partly transformed. There is no way to determine which blocks have been transformed and which have not. These files must be recreated after the **dataxform** utility runs from a backup copy. The client administrator must:

1. Determine (by examining the **dataxform** logs) which files may have been incompletely transformed.
2. Delete them from the transformed file set.
3. Recreate them by selective copying from a backup.

Live Data Transformation

The CipherTrust Manager security administrators can encrypt or rekey the GuardPoint data without blocking the user or application access to that data.

After enabling GuardPoints, LDT performs initial encryption or rekeying in the background, unnoticed by users. The data stays live and available. This accelerates CTE deployments and eliminates the need to block application and user access to data during encryption or rekey operations, which can seriously inconvenience users and affect operational efficiency.

Phases of LDT runtime operation:

1. Initial data transformation starts or key expires

Live Data Transformation begins when an LDT policy is first applied to a GuardPoint, or when a current key version expires. The CipherTrust Manager pushes the new policy, or the notification of a key version change, to the clients that are protected by those policies.

2. New key version triggers a rekey on the affected GuardPoints

On each client, CTE determines which GuardPoints are using the key that has just rotated to a new version. CTE starts an LDT rekey on each of those GuardPoints. (If another rekey is already underway on that GuardPoint, the new rekey is rejected).

3. Scan for files

On each GuardPoint where CTE has started a rekey, LDT determines which files to transform. LDT takes inventory of files encrypted with earlier versions of the rotated key and makes a persistent list of the files for transformation. During this phase, the rekey status of the GuardPoint becomes starting, then scanning.

The scan phase might be interrupted, such as by a client reboot. In this case, when the client reboots and the GuardPoint is enabled again, the scan operation starts over from the beginning.

4. Rekey/Key Rotation

- a. Each file, from the persistent list of files, is decrypted using the old version of the key. The old key is applied to each file and then re-encrypted using the new version of the key. Note that new files created during the LDT process do not need to be rekeyed, as they inherit the new version of the key. Multiple files and multiple regions of files are rekeyed simultaneously.
- b. The LDT extended attribute of each file is updated.
- c. The LDT rekey operation can be suspended and resumed manually, or through the QoS schedule.

This manages the impact LDT has on other applications and processes. During this phase, the rekey status of the GuardPoint is rekeying or suspended.

If system errors occur during rekeying, such as IO errors or crashes, LDT can manage and recover from them after the system error is fixed.

5. Finish

When all of the required files in the GuardPoint have been rekeyed, the system and storage resources used by LDT are released, except for the storage required for the extended attributes. Upon completion of rekey, the rekey status of the GuardPoint is rekeyed.

Summary

The following table summarizes the strengths and weaknesses of the two file set transformation methods.

Factor	Copy Method	The dataxform Utility Method	Live Data Transformation
Temporary storage required	Equal to size of file set.	Sufficient to hold a list of path names of files in file set.	Additional space is required to store LDT metadata only.
Security	File data is unprotected while in copy utility's buffers.	File data is never outside the CTE GuardPoint.	File data is never outside the CTE GuardPoint.
Initial encryption	Files can be copied directly from source directory to a CTE-protected directory.	Files must be in a protected location before transformation.	Files must be in a protected location before transformation.
Operational impact	No access to files during transformation. Path names or operating procedures must be adjusted after transformation.	No access to files during transformation.	No other impact on operating procedures.
Recoverability	Restart copy operation at,	Files undergoing	Transformation process

Factor	Copy Method	The dataxform Utility Method	Live Data Transformation
	or prior to, point of failure.	transformation at the point of failure must be discovered from the dataxform logs and restored from backup.	automatically restarts from the point of failure.

Protection Policies

The basic unit of CTE data protection policy application is the GuardPoint. GuardPoints are typically associated with file system mount points, but may also be associated with directory sub-trees.

Note

Nested mount points within a directory, or mount points protected by a GuardPoint, are also protected in Linux environments.

All files in the directory hierarchy, below a GuardPoint, are subject to the GuardPoint's policy, which consists of rules that specify:

-
- **Protected files:** Filenames or filename patterns (example: *.dat) to which the policy applies.
 - **Authorized users:** User(s) group(s), and application(s) permitted to access the protected files.
 - **Permissions:** Actions permitted to users (example: create/delete, read/write, rename, decrypt).

Policies also specify the name of an encryption algorithm and a key for encrypting protected files. For example, a policy might specify that all Excel workbooks protected by a GuardPoint be encrypted using an AES256 key called EXCEL-KEY. Additionally, only users in group 128 have access to the files. All other files that are not encrypted, are freely accessible to all users.

Types of Policies

CTE Agents use two types of policies:

- **Initial Data Transformation**

The data transformation policies contain the elements listed above, plus a data transformation key, used by the `dataxform` utility to rekey file data. Transformation policies contain strict access control rules that prevent application and user access to files during transformation. CTE only uses the data transformation policies for the initial transformation. Afterwards, you replace it with a production policy.

The `dataxform` utility operates on a per-GuardPoint basis. For initial encryption, the data transformation policy specifies a clear production key (meaning that the utility does not decrypt data because the data is unencrypted) and a new data transformation key to encrypt the data.

- **Production/Standard**

Production policies contain the elements listed above. They protect data within GuardPoint(s) during day-to-day IT operations.

For decryption, the policy specifies a clear data transformation key (that is, the utility does not re-encrypt files as it rewrites them) and the current production key.

A rekeying transformation policy specifies both a current production ("old") key and a transformation ("new") key.

Managing Profiles

A profile contains the CipherTrust Manager logging criteria for CTE clients, Syslog server configuration, default logging level, LDT Quality of Service (QoS) settings, server settings, Multifactor Authentication (MFA) settings, Ransomware protection settings, and additional settings that can be used for several CTE clients.

A default profile, `DefaultClientProfile`, is created automatically when either of the following happens:

- On successful registration of the first client if no profile is specified during registration.
- On creation of the first client group. A new client group is automatically linked to `DefaultClientProfile`.

When registering a CTE client, the installer prompts to specify a profile for the client. If not specified, `DefaultClientProfile` is automatically linked to the client on successful registration. The linked profile can be modified later. It is recommended to not delete or modify `DefaultClientProfile`.

Creating a Profile

After you have created a profile, you can define client logging criteria, Syslog configurations, QoS configurations, Ransomware protection settings, MFA configurations, and server settings. These configurations apply to the clients and client groups linked to this profile. Refer to the subsequent sections for details.

Create a profile in WebUI

To create a profile:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Settings > Profiles**.
3. Click **Create Profile**.
4. Specify a unique **Name** for the profile. This is a mandatory field.
5. Provide a **Description** for the profile.
6. Click **Create**.

The newly created profile appears in the profiles list.

Profiles

Search			
☐ 0 selected 3 results 3 Profiles  + Create Profile			
	Name	Description	
☐	TestProfile	Test profile	...
☐	DefaultClientProfile		...
☐	abc		...

Create a profile in ksctl CLI

You can create a profile as a CTE Administrator in the ksctl CLI. The only required setting is a profile name, `--cte-profile-name`. Consult the embedded CLI Guide for full description of options.

You can label a client profile dedicated to **FAM**, using the parameter `labels "ncryptify-reserved/dsf-managed": "true"`.

Example command to create a profile dedicated to FAM:

```
ksctl cte profiles create --cte-profile-name FAMprofile --labels "ncryptify-reserved/dsf-managed": "true"
```

Setting Client Log Configuration

Client log configuration includes basic information such as the level of logs to capture, whether to enable the Syslog server, settings to upload logs to the CipherTrust Manager, and settings to store logs on clients.

To define client log configurations for a profile:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Settings > Profiles**.
3. Under **Name**, click the desired profile. The edit view of the profile is displayed. Profile settings are divided into three categories, as shown below:

Expand All	
CLIENT LOGGING CONFIGURATION	+
CLIENT SYSLOG CONFIGURATION	+
QUALITY OF SERVICE CONFIGURATION	+
RANSOMWARE PROTECTION CONFIGURATION	+
MULTIFACTOR AUTHENTICATION	+
SERVER SETTINGS	+

4. Click **CLIENT LOGGING CONFIGURATION** to expand it. The client log configuration settings are categorized into basic, log upload to key manager, and log to the file on the clients.

Log Level	ERROR	☐ Log Upload to Key Manager	☒ Log to File
Duplications	SUPPRESS	Upload Log Level	ERROR
Threshold (1-100)	5	Connection Timeout (sec) 1-60	75
Suppress interval (sec) 1-1000	600	☐ Drop if Busy	Max File Size (1-1000 MB)
☐ Enable Concise Logging		Upload Timeout (sec) 1-900	600
☐ Syslog Enabled		Max Interval (sec) 1-1000	20
		Min interval (sec) 1-30	10
		Message Upload Range (100-1000)	1000
		Cache Settings	
		Max Files	100
		Max Space (MB)	100
		☐ Allow Purge	Max Old Files (1-100)
			100

Basic Settings

5. Specify the basic settings:

Field	Description
Log Level	Level of logs to generate. It defines the detail and extent of information to be logged by the linked agents. In sequence, the options are: • DEBUG: Fine-grained informational events that are targeted towards support engineers and developers. • INFO: Informational messages that highlight the progress of the application at coarse- grained level. • WARN: Potentially harmful situations. • ERROR: Error events that might still allow the application to continue running. This is the default log level. • FATAL: Severe error events that will presumably lead the application to abort. Log levels are cumulative. The level that you select not only generates log entries for events that occur at that level, but all the levels below. For example, the WARN level also includes events that occur on the ERROR and FATAL levels.
Duplicates	Treatment for duplicate logs. The options are: • SUPPRESS: Messages follow the configured Threshold as to how many times duplicate messages are sent to the CipherTrust Manager during the given

Field	Description
	Interval. • ALLOW : All duplicate messages are captured and displayed in the log.
Threshold (1-100)	(Used when the Duplicates field is set to SUPPRESS .) Maximum number of duplicate messages the CTE Agent can send to the CipherTrust Manager within the time specified by Suppress Interval (see below). The default value is 5 messages.
Suppress Interval (sec) 1-1000	(Used when the Duplicates field is set to SUPPRESS .) Time in which the number of duplicate messages, specified by Threshold, can be uploaded to the CipherTrust Manager. When Suppress Interval exceeds, the count specified by Threshold starts again. The default interval is 600 seconds (10 minutes).
Enable Concise Logging	Whether to enable Concise Logging for the linked clients. Select to enable, clear to disable. By default, Concise Logging is disabled. When enabled, a reduced number of audit log messages are captured. Refer to Concise Logging for details.
Syslog Enabled	Whether the Syslog server is enabled. Select to enable, clear to disable. When you select Syslog Enabled , make sure that client Syslog configurations are defined. Refer to Setting Client Syslog Configuration for details. When the Syslog server is disabled, the logs are sent to the client messages file such as <code>/var/adm/messages</code> . On a Windows client, the messages are sent to the Event Viewer (Application events).

Log Upload Settings

6. Configure settings to upload logs to the CipherTrust Manager:

Field	Description
Log Upload to Key Manager	Whether to enable log upload to the CipherTrust Manager. Select to enable, clear to disable. When this option is selected, you can configure the settings

Field	Description
	listed below. The logs are displayed under the Client Records page of the CipherTrust Manager GUI.
Upload Log Level	Level of logs to upload. In sequence, the options are: • DEBUG: Fine-grained informational events that are targeted towards support engineers and developers. • INFO: Informational messages that highlight the progress of the application at coarse- grained level. • WARN: Potentially harmful situations. • ERROR: Error events that might still allow the application to continue running. This is the default log level. • FATAL: Severe error events that will presumably lead the application to abort. Log levels are cumulative. The level that you select not only generates log entries for events that occur at that level, but all the levels below. For example, the WARN level also includes events that occur on the ERROR and FATAL levels.
Connection Timeout (sec) 1-60	Interval after which the connection attempt to the key manager expires. The default value is 59 seconds.
Drop if Busy	Whether to slow log generation and drop log files during periods of extreme logging (that is, when the server is busy). Select to drop, clear to keep trying. This setting is clear by default.
Upload Timeout (sec) 1-900	Interval after which the log upload attempt expires. The default period is 600 seconds (10 minutes).
Max Interval (sec) 1-1000	Maximum interval to wait before the CTE Agent can upload messages to the CipherTrust Manager. Use this option to update the log viewer even when the Message Upload Range has not been reached. Lower the interval if there is little CTE Agent activity. The default maximum interval is 20 seconds.
Min Interval (sec) 1-30	Minimum interval to wait before the CTE Agent can upload messages to the CipherTrust Manager. Increase the interval if there is considerable CTE Agent activity, so the agents do not flood the network with log messages. The minimum interval is 10 seconds.

Field	Description
Message Upload Range (100-1000)	Maximum number of logs to upload at one time. When the specified number of logs is reached, they are uploaded to the CipherTrust Manager. The default number is 1000 .
Cache Settings	Settings to cache logs. The options are: • Max Files: Maximum number of log files to cache. The default number is 200. • Max Space (MB): Maximum log size to cache. The default value is 100 MB.

Log to File Settings

7. Configure settings to gather logs in files on clients:

Field	Description
Log to File	Whether to write logs to files on clients. This option is selected by default. This means that, by default, the logs are written to files on clients. The logs are sent to the <code>/var/log/vormetric/vorvmd_root.log</code> file of a UNIX client, or a Windows equivalent, such as <code>\Documents and Settings\All Users or WINDOWS\Application\ Data\Vormetric\DataSecurityExpert\agent\log\vorvmd.log</code> . When the Log to File option is selected, you can configure the settings listed below.
File Log Level	Level of logs to capture in the log file. In sequence, the options are: • DEBUG: Fine-grained informational events that are targeted towards support engineers and developers. • INFO: Informational messages that highlight the progress of the application at coarse- grained level. • WARN: Potentially harmful situations. • ERROR: Error events that might still allow the application to continue running. This is the default log level. • FATAL: Severe error events that will presumably lead the application to abort. Log levels are cumulative. The level that you select not only generates log entries for events that occur

Field	Description
	at that level, but all the levels below. For example, the WARN level also includes events that occur on the ERROR and FATAL levels.
Max File Size (1-1000 MB)	Maximum size of a log file. The CTE Agent starts a new, empty log file when the specified limit is exceeded. The default maximum file size is 1000 MB.
Max Old Files (1-100)	The maximum number of old log files to keep. The default number is 100 .
Allow Purge	Whether to allow purging the old log files. Select to allow purge, clear to disallow. This option works in conjunction with the Max Old Files option (see above). For example, set Max Old Files to 3 and select the Allow Purge check box. After 3 log files are generated, the first log file, log1, is deleted and a new log file, log4, is created. If the Allow Purge check box is clear, log files continue to accumulate in the server database and you have to remove them manually.

8. Click **Update**.

The changes are effective immediately and apply to the clients linked with the profile.

The CTE client logs can be seen on the **Records > Client Records** page of the CipherTrust Manager GUI. Filter the records by **Client Type** and look for the **CTE** records, as shown below.

Client	Client Type	Timestamp	Severity	Event	Details
364859	CTE	Aug 31st 2020 - 13:04:08	ERROR	RedGridPath NotExist	<pre>{ "log": "CGA", "uid": "CGA21345", "pid": 1213, "args": [{ "go": "/Non-Existent-Path" }], "message": "Not guarding path [/Non-Existent-Path] (Reason: Exec not exist)", "version": "7.0.0.50", "filename": "SetFS_upload_3.04.05.0.140", "hostname": "3.04.05.0", "client_id": "79cb51d0-25c2-4fed-8e88-c0720c7f3163" }</pre>

Refer to [Records](#) for details.

Setting Client Syslog Configuration

When you have Syslog servers up and running in your environment, you can redirect your client logs to them. A CipherTrust Manager administrator can configure profiles to redirect client logs to Syslog servers.

To configure Syslog settings in a profile:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Settings > Profiles**.
3. Under **Name**, click the desired profile.
4. Expand **CLIENT SYSLOG CONFIGURATION**.

5. Specify the following details:

Note

- You can configure up to four servers, labeled as **Server 1**, **Server 2**, **Server 3**, and **Server 4**. By default, **Server 1** and **Server 2** are visible. To view **Server 3** and **Server 4**, click **Show Additional Servers**.
- This document describes steps to configure one server, **Server 1**. Extend the steps to suit your setup requirements.

Field	Description
Log Level	Level of logs to redirect. In sequence, the options are: • DEBUG: Fine-grained informational events that are targeted towards support engineers and developers. • INFO: Informational messages that highlight the progress of the application at coarse- grained level. • WARN: Potentially harmful situations. • ERROR: Error events that might still allow the application to continue running. This is the default log level. • FATAL: Severe error events that will presumably

Field	Description
	lead the application to abort. Log levels are cumulative. The level that you select not only generates log entries for events that occur at that level, but all the levels below. For example, the WARN level also includes events that occur on the ERROR and FATAL levels.
Local	Whether logs are sent to the client. If selected, the logs are saved on the client at <code>/var/log/messages</code> . By default, the option is clear.
Server 1	
Hostname or IP	Hostname or IP address of the Syslog server.
Port	Port of the Syslog server.
Message Format	Format in which the log messages are transferred to the Syslog server. The options are: • Plain Message • CEF • RFC5424 • LEEF The default log format is RFC5424. This format adheres to the Syslog Protocol RFC 5424 guidelines.
Protocol	Transport protocol for the Syslog connection. The options are UDP, TCP, and TLS. The default protocol is TCP. When you select TLS, the following fields appear: • CA Certificate: Click Browse to select the CA certificate. • Certificate: Click Browse to select the certificate. • Private Key: Click Browse to select the private key.

6. Click **Update**.

The Syslog server settings are configured.

Setting Quality of Service Configuration

The QoS configuration settings apply to clients that have the LDT feature enabled on them. Administrators use these settings to maintain operational efficiencies in their systems in conjunction with LDT operations. They can specify percentage of CPU usage or a rekey rate and schedules for LDT operations. Refer to the [CTE-Live Data Transformation](#) with CipherTrust Manager for best practices about using LDT and QoS.

A CipherTrust Manager administrator can configure LDT QoS on the CipherTrust Manager.

To configure LDT QoS settings in a profile:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Settings > Profiles**.
3. Under **Name**, click the desired profile.
4. Expand **QUALITY OF SERVICE CONFIGURATION**.

☒ Rekey by Rate
 ☐ Rekey by CPU

LDT Status Check Rate (In minutes) ?

QoS Schedules

LDT QoS Schedule:

ANYTIME
 ▼

Create New QoS Schedule

Name	Time Ranges
ANYTIME	Sunday 12:00 AM - Saturday 11:59 PM

5. Specify the rekey option. The options are:

- **Rekey by Rate:** Select to rekey by rate (in MB/s). This is the default setting. Specify the LDT QoS Rekey Rate. The default value is 0.
- **Rekey by CPU:** Select to rekey by CPU usage. By default, LDT operations use all of the available CPU memory.

Optionally, you can reserve percentage of the clients' CPU for LDT rekey operations. To do so:

- a. Select **Cap CPU Allocation**. The **CPU Percentage** field becomes editable.
- b. Enter the **CPU Percentage**. The value must be greater than 0.

- **LDT Status Check Rate:** Select the frequency to check and update the LDT status on the CipherTrust

Manager. The valid value ranges from 10 to 1440 minutes. The default value is 60 minutes.

6. Specify a QoS schedule to run LDT. Under **QoS Schedules**, select an **LDT QoS Schedule**. The options are:

Name	Time Ranges	Description
ANYTIME	Sunday 12:00 AM - Saturday 11:59 PM	LDT runs any day at any time of the week
WEEKNIGHTS	Monday 12:00 AM - Monday 07:00 AM Monday 09:00 PM - Tuesday 07:00 AM Tuesday 09:00 PM - Wednesday 07:00 AM Wednesday 09:00 PM - Thursday 07:00 AM Thursday 09:00 PM - Friday 07:00 AM Friday 09:00 PM - Friday 11:59 PM	LDT runs between midnight to 7:00 AM from Monday to Friday
WEEKENDS	Sunday 12:00 AM - Monday 07:00 AM Friday 09:00 PM - Saturday 11:59 PM	LDT runs between 9:00 PM Friday to 7:00 AM on Monday
CUSTOM	< Custom Range >	LDT runs at a custom schedule (described below)

Creating a Custom LDT Schedule

To create a custom LDT schedule:

- a. Select **CUSTOM** from the **LDT QoS Schedule** drop-down list. Now, the **Create New QoS Schedule** button is available.

The screenshot shows the 'QoS Schedules' configuration area. Under 'LDT QoS Schedule', the 'CUSTOM' option is selected in a dropdown menu. To the right, a blue button labeled 'Create New QoS Schedule' is visible. Below these, there are two input fields: 'Name' and 'Time Ranges', each with a placeholder text and a small icon.

- b. Click **Create New QoS Schedule**. The Create QoS Schedule dialog box is displayed.

Create QoS Schedule

Starting Day:

Ending Day:

Starting Time: :

Ending Time: :

- Select the **Starting Day**. The LDT process will start on this day of the week. The default starting day is Monday.
 - Specify the **Starting Time** in the **HH:MM AM/PM** format. Use the arrows to select time in hours (1 to 11) and minutes (00 to 59). Select AM or PM from the drop-down list. The default starting time is **1:00 AM**.
 - Select the **Ending Day**. The LDT process will end on this day of the week. The default ending day is Monday.
 - Specify the **Ending Time** in the **HH:MM AM/PM** format. The default ending time is **2:00 AM**.
- Click **Create**. The custom LDT QoS schedule is displayed on the screen. The specified Time Ranges are also displayed.

QoS Schedules

LDT QoS Schedule:

...

- Click **Update**. The configuration is saved successfully.

Note

- To create a new custom schedule, click Create New QoS Schedule.
- To delete a custom schedule, click Delete corresponding to the schedule you want to delete.

Setting Ransomware Protection Configuration

Common Ransomware Protection settings for clients and client groups is configured in profiles. In the profile,

specify the process set to be excluded from monitoring and the action to be taken on all other processes that attempt to access the sensitive data. You can also disable the Ransomware Protection for all GuardPoints on the linked clients from a profile.

To configure Ransomware Protection settings in a profile:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Settings > Profiles**.
3. Under **Name**, click the desired profile.
4. Expand **RANSOMWARE PROTECTION CONFIGURATION**.

RANSOMWARE PROTECTION CONFIGURATION

Trusted Process Set?

Select process set

Select

Operation

Block

Update

5. Specify the Ransomware Protection configuration.
 - a. Next to **Trusted Process Set**, click **Select**. The Select Process Set dialog box shows the list of available process sets.
 - a. Select the process set to be *excluded from monitoring*.
 - b. Click **Select**. The CTE Agent will ignore the processes in the selected process set. All other process sets will be monitored for suspicious behavior.
 - b. Select the **Operation** to be performed on the monitored processes. The available operations are:
 - **Block**: Logs an audit message that a suspicious activity has been detected, and **blocks** its access to the sensitive data. This is the default setting.
 - **Monitor**: Logs an audit message that a suspicious activity has been detected, and **allows** the activity on the sensitive data.
 - **Disable**: Disables Ransomware Protection for all GuardPoints on the clients linked with this profile.

Note

- When you change the operation to **Disable** in a profile, Ransomware Protection for all GuardPoints on the linked clients is disabled.
- When you change the *profile* of a client to another profile with the operation set to **Disable**, Ransomware Protection for all GuardPoints on the client is disabled.

- c. Enable the **Alarm** on clients linked with the profile.

Note

If Ransomware is detected, an [alarm](#) and a [record](#) will be generated on CipherTrust Manager.

- d. Click **Update**.

Setting MFA Configuration

Common MFA configuration for clients and client groups is configured in profiles. When the security configuration for a client is built, the MFA configuration is fetched from the associated profile.

To set up MFA configuration, specify an OIDC connection and the set of exempted users. MFA will not be enforced for users in the exempted user set. By default, MFA is enforced for all users of the associated clients.

To configure MFA settings in a profile:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Settings > Profiles**.
3. Under **Name**, click the desired profile.
4. Expand **MULTIFACTOR AUTHENTICATION**.

MULTIFACTOR AUTHENTICATION

Select OIDC Connection:

Select OIDC Connection

Select MFA Exempted User Set:

Select Userset

i The selected user set will be exempted from MFA enforcement. MFA will not be enforced on the users of this set.

Update

5. Specify the MFA configuration.

- **Select OIDC Connection** from the drop-down list. This is the OIDC connection over which MFA configurations will be enforced. OIDC connections are created on the CipherTrust Manager. Refer to [Connection Manager](#) for details.
- **Select MFA Exempted User Set** from the drop-down list. This user set will be exempted from MFA. MFA will not be enforced on the users of this set.

Note

- A CipherTrust Manager administrator with sufficient privileges can delete an OIDC connection being used by a profile. When an in-use OIDC connection is deleted, the security configuration for the associated clients cannot be built and pushed to the clients. The errors are logged in audit records. The CTE Agent continues working with the current configuration until the connection is restored.
- You can delete the existing OIDC connection and MFA Exempted User set by clicking **Delete (X)**.

6. Click **Update**.

Configuring Server Settings

A CTE administrator can configure preferred nodes of a CipherTrust Manager cluster for sending status updates from CTE clients. The administrator assigns a priority to every node of the cluster.

The cluster nodes can be categorized into tiers on the CipherTrust Manager GUI, with every tier assigned a priority. For example, Tier 1 is assigned higher priority than Tier 2. All tiers (for example, Tier 1 + Tier 2) can have a total of 20 nodes. This preference is configured through server settings in profiles. If not configured, the CipherTrust Manager continues working with the default settings. Refer to [Communication with CipherTrust Manager](#) for the default behavior.

After the server settings are configured, the CTE clients associated with the profile first try to send status updates to the top tier. If none of the nodes in the tier is reachable, the CTE clients try to send updates to the next tier.

To configure the cluster node preference in a profile:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Settings > Profiles**.
3. Under **Name**, click the desired profile.
4. Expand **SERVER SETTINGS**.
5. Click **Configure Settings**.

Before proceeding, make sure the CipherTrust Manager is part of a cluster. Refer to [Clusters and Nodes](#) for information on CipherTrust Manager clusters and nodes.

When the CipherTrust Manager is part of a cluster, the Server Settings section displays cluster nodes grouped into tiers.

6. Add/modify cluster node preference as appropriate.
 - To add/modify the priority of a cluster node, drag it from one tier and drop to another. Alternatively, click the add button () in the target tier and select the node from the displayed list.
 - To remove a node from a tier:
 - a. Click the delete icon () in the node name. A message box appears prompting to confirm the action.
 - b. Click **Yes** to confirm.

The change will be effective only after you click **Update** in the SERVER SETTINGS section of the Profiles page.

- To add a new tier, click **Add Another Tier**. By default, one tier is visible. You can set preference for all nodes of a CipherTrust Manager cluster.

A maximum of 20 tiers can be added.

- To delete a tier, click the delete button (). Tier 1 cannot be deleted.

7. Click **Update**. The server settings are saved successfully.

The Update button is enabled only when the tier list is modified and every tier has at least one node.

Configuring Attestation Settings

After performing the initial attestation to [activate the confidential computing on a CTE client](#), you can perform the reattestation at a certain frequency in a profile.

To configure the Attestation settings in a profile:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Settings > Profiles**.
3. Under **Name**, click the desired profile.
4. Expand **ATTESTATION SETTINGS**.
5. Turn on the **Enable Reattestation** toggle.
6. Set the **FREQUENCY**.
 - a. Enter the **Frequency**. Frequency can be set from 1 to 30 days or 1 to 720 hours.
 - b. Select the unit of frequency, which can be **Hours** or **Days**.
7. Set the **RETRY ON FAIL**.
 - a. Select the **Interval** minutes.
 - b. Select the **Retry Attempts**.
8. Click **Update**.

On successful updating of the attestation settings, a "Profile updated successfully" message will be displayed.

Concise Logging

CTE's standard operational logging sends audit messages for every file system operation. An audit message is sent every time a file is opened, read, updated, or written. Standard logging can generate high volumes of log data. Security administrators might not need most of these logs to monitor file system activities on the protected clients.

A CipherTrust Manager administrator can enable or disable Concise Logging for a profile. After Concise Logging is enabled or disabled, CTE Agent generates a log message to record that event:

```
"[CGA] [INFO] [CGA3201I] [08/07/2020 10:57:18] Concise logging enabled"
"[CGA] [INFO] [CGA3202I] [08/07/2020 10:57:27] Concise logging disabled"
```

Advantages

Concise Logging:

- Helps security administrators to focus on relevant audit messages and important actionable messages such as errors and warnings.
- Can eliminate repetitive and unimportant audit messages generated by read and write activities on a file, read and write directory attributes, and other file system activities.
- Eliminates audit messages:

-
- For each block read by a user or an application. Only one audit message is sent for every read/write activity.
 - That read the attributes, basic information of file set attributes, and other event-based messages.
 - For directory open, read directory attributes, and directory close.

Considerations

Concise Logging:

- Changes the set of messages that are sent to Security Information and Event Management (SIEM) software systems. If this results in loss of data required for customer reports, then disable Concise Logging.
- Applies to all GuardPoints and for all users of the clients linked with a profile. There is no fine-grained control such as per GuardPoint, user, or message type.
- Applies to the existing clients and the new clients to be linked with the profile subsequently.
- Is supported by CTE **secfs** only.
- Should not be used with Learn Mode.

Modifying Profiles

To modify a profile:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Settings > Profiles**.
3. Under **Name**, click the desired profile.

Alternatively, click the overflow icon () corresponding to the desired profile and click **Edit**.

4. Expand **CLIENT LOGGING CONFIGURATION**.
 - a. Modify the settings, as appropriate. Refer to [Setting Client Log Configuration](#) for details.
 - b. Click **Update**.
5. Expand **CLIENT SYSLOG CONFIGURATION**.
 - a. Modify the settings, as appropriate. Refer to [Setting Client Syslog Configuration](#) for details.
 - b. Click **Update**.
6. Expand **QUALITY OF SERVICE CONFIGURATION**.
 - a. Modify the settings, as appropriate. Refer to [Setting Quality of Service Configuration](#) for details.

-
- b. Click **Update**.
 7. Expand **RANSOMWARE PROTECTION CONFIGURATION**.
 - a. Modify the settings, as appropriate. Refer to [Setting Ransomware Protection Configuration](#) for details.
 - b. Click **Update**.
 8. Expand **MULTIFACTOR AUTHENTICATION**.
 - a. Modify the settings, as appropriate. Refer to [Setting MFA Configuration](#) for details.
 - b. Click **Update**.
 9. Expand **SERVER SETTINGS**.
 - a. Modify the settings, as appropriate. Refer to [Configuring Server Settings](#) for details.
 - b. Click **Update**.

The profile settings are updated.

You can also modify or delete a CUSTOM QoS.

Modifying a CUSTOM LDT QoS Schedule

To modify a CUSTOM schedule:

1. Click the overflow icon () corresponding to the desired custom QoS schedule.
2. Click **Edit**. The Create QoS Schedule dialog box is displayed.
3. Modify the schedule, as appropriate. Refer to [Creating a Custom LDT Schedule](#) for details.
4. Click **Update**.

The CUSTOM LDT QoS schedule is modified.

Deleting a CUSTOM LDT QoS Schedule

To delete a CUSTOM schedule:

1. Click the overflow icon () corresponding to the desired custom QoS schedule.
2. Click **Delete**.
3. Click **Yes** to confirm the deletion.

The CUSTOM LDT QoS schedule is deleted.

Deleting Profiles

Single or multiple profiles can be deleted from the CipherTrust Manager GUI in one go. Before deleting a profile

make sure that no clients or client groups are linked to it.

Deleting Individual Profiles

To delete a profile:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Settings > Profiles**.
3. Click the overflow icon () corresponding to the desired profile.

Alternatively, select the desired profile and click the delete icon ().

4. Click **Delete**.

The selected profile is removed from the profiles list.

Deleting Multiple Profiles

To delete multiple profiles:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Settings > Profiles**.
3. Select the check boxes corresponding the desired profiles.

To select all profiles visible on the page for deletion, select the top check box to the left of the **Name** heading.

4. Click the delete icon (). A dialog box appears prompting to confirm the action.
5. Click **Delete**.

Managing Clients

A client is a computer system where the data needs to be protected. A compatible CTE Agent software is installed on the client. The CTE Agent can protect data on the client or devices connected to it. A client can be associated with multiple GuardPoints for encryption of various paths (refer to [Managing GuardPoints](#) for details).

The Clients page of the CipherTrust Manager GUI displays all clients protected by encryption Agents.

The K8s Clients page of the CipherTrust Manager GUI displays all the registered [Kubernetes Clients](#).

Registering Clients

Note

Before proceeding, make sure that:

- A compatible CTE Agent is installed on the client.
- The client is registered with the CipherTrust Manager.

Refer to the [CTE Agent Quick Start Guide](#) specific to your platform for information on installing and configuring CTE Agents.

Note

When CTE clients are restored on the CipherTrust Manager from the backup file of another CipherTrust Manager, you must unenroll the client before proceeding with reregistration.

When CTE clients are registered, they are automatically added to the CipherTrust Manager GUI. Refer to the [CTE Agent Quick Start Guide](#) specific to your platform for information on installing and configuring CTE Agents.

Similarly, all the registered [Kubernetes Clients](#) are displayed on the K8s Clients page of the CipherTrust Manager GUI.

Adding Clients Manually

Optionally, the CipherTrust Manager administrator can manually add a client to the CipherTrust Manager GUI - even before the CTE Agent is installed on it.

Note

CTE for Kubernetes clients cannot be added manually. They are automatically added to the CipherTrust Manager on registration.

To add the client manually:

1. Log on to the CipherTrust Manager GUI as administrator.
2. Open the **Transparent Encryption** application. The Clients page is displayed.
3. Click **Create Client**. The General Info screen of the Create Client wizard is displayed.

General Info

1. Specify a unique **Name** for the client.
2. Set the **Password Generation Method**. The options are:
 - **Generate**: A password is generated automatically by CipherTrust Manager. This is the default method.
 - **Manual**: Set the password manually.
 - a. Select **Manual**.
 - b. Enter the new password in the **Password** and **Confirm Password** fields. The password must match in both fields.

Note

The password must contain minimum eight characters including at least:

- One capital letter
- One number
- One of these special characters: ! @ # \$ % ^ & * () { } []

Refer to [Changing Client Password](#) for details.

3. Provide a **Description** for the client.
4. Specify the following, as appropriate:
 - **UserSpace Client**: Ensure that the check box is clear. This check box specifies whether the client will be a CTE UserSpace client.
 - **Registration Allowed**: Whether to allow client's registration with the CipherTrust Manager. Select to allow, clear to deny registration. By default, the registration is not allowed.
 - **Communication Enabled**: Whether to enable the client's communication with the CipherTrust Manager. Select to enable, clear to disable communication. By default, the communication is disabled. This can only be enabled when **Registration Allowed** is enabled.
5. Click **Next**. The Add GuardPoints screen is displayed.

Add GuardPoints (Optional)

Optionally, you can create GuardPoints on the manually added client. CTE supports creation of all types of GuardPoints on such clients.

1. Click **Create GuardPoint**.

2. Select a **Policy**. Refer to **Policy Type** under **Creating Policies > Step 1: Specify General Information** for details.
3. Specify the **Type** of the GuardPoint. Refer to [Automatic and Manual GuardPoints](#) for details on types of GuardPoints.
4. Specify the **Path** (or **Cloud Object Storage URL** for a COS GuardPoint) to be protected. Refer to [Managing GuardPoints](#) for details.
5. Configure **Preserve Sparse Region**, **In-Place Data Transformation**, and/or **Auto Mount** as appropriate. The options vary based on the selected policy, as follows:
 - **Preserve Sparse Region** pre-selected for an LDT policy.
 - **In-Place Data Transformation** pre-selected for an IDT policy.
 - **Auto Mount** for a Standard policy and an LDT policy.

Note

- The Secure Start option cannot be enabled for GuardPoints on manually added clients.
- The Multifactor Authentication option is unavailable for GuardPoints on manually added clients.
- Auto Mount can be enabled only for the Auto Directory GuardPoint.

6. Click **Create**. The newly created GuardPoint appears in the list.
7. Click **Next**. The Confirmation screen is displayed.

Confirmation

1. Verify the client details. The Confirmation screen displays general information about the client and details of the GuardPoints added to the client.

If the details are incorrect or you want to modify them, click **Back** and update the details.

2. Click **Save**.

The newly created client appears in the clients list.

Searching Clients

The Clients page on the CipherTrust Manager GUI shows the list of registered clients.

To search for a registered client:

1. Log on to the CipherTrust Manager GUI as administrator.

2. Open the **Transparent Encryption** application. The Clients page is displayed. This page lists the clients added to this CipherTrust Manager appliance.
3. In the **Search** box, enter the client name. Search is case-insensitive. You can enter all or part of a client name. A partial client name displays every client with a name that contains the specified string.

Viewing Clients

The Clients page shows the total number of clients, clients with errors, clients with warnings, healthy clients, unregistered clients. The Status Bar contains the following tabs:

- **Total Clients:** Shows the total number of registered and unregistered clients with all types of health status.
- **Errors:** Shows the number of clients with errors.
- **Warnings:** Shows the number of clients with warnings.
- **Healthy:** Shows the number of healthy clients.
- **Unregistered:** Shows the number of unregistered clients.
- **Expunged:** Shows the number of expunged clients.

Note

The Unregistered and Expunged states are not applicable to the CTE for Kubernetes clients.

Refer to [Client States](#) for details.

Click each tab to filter the clients. The clients list displays names of clients in the CipherTrust Manager database and details about their configuration.

To view the clients added to the CipherTrust Manager:

1. Open the **Transparent Encryption** application.
2. Click **Clients > Clients**. The clients list shows the following details:

Status	Client Name ↑	Client Type	Protection Mode	OS Type ↑	FAM State	Agent Version	Description	⚙
▸ ☐  Healthy	P_1	CTE-U	CTE	LINUX	DISABLED	9.5.0.20	TestHost CTE-U	...
▸ ☐  Healthy	P_10	FS	CTE	LINUX	DISABLED	7.2.0.90	TestHost	...
▸ ☐  Healthy	P_11	FS	CTE	LINUX	DISABLED	7.2.0.90	TestHost	...
▸ ☐  Healthy	P_12	FS	CTE	LINUX	DISABLED	7.2.0.90	TestHost	...
▸ ☐  Healthy	P_2	FS	RWP	WINDOWS	DISABLED	7.4.0.0	TestHost	...

Column	Description
Status	Health status of the client: • Healthy • Error • Warning • Unregistered • Expunged The Unregistered and Expunged states are not applicable to the CTE for Kubernetes clients. Refer to Client States for details.
Client Name	Name link of the client on the CipherTrust Manager.
Client Type	The type of the client: • FS (a CTE client) • CTE-U (a CTE UserSpace client)
Protection Mode	The protection mode of the client: • CTE (File system protection, unregistered clients) • RWP (Ransomware protection, Windows clients) • CTE RWP (Both file system and Ransomware protection, Windows clients) When you unenroll (unregister) a client, its Protection Mode does not change. For example, if the Protection Mode of a client before unenrolling is CTE RWP, the mode remains CTE RWP after the client is unenrolled.

Column	Description
OS Type	OS running on the client: • AIX • LINUX • WINDOWS • UNKNOWN • FREEBSD UNKNOWN is displayed for unregistered or manually added clients. FREEBSD is supported by CTE UserSpace.
FAM Status	Whether FAM is ENABLED or DISABLED for the client.
Agent Version	Version of the CTE Agent installed on the client. For unregistered or manually added clients, the field is empty.
Description	Description to identify the client.
Encryption Modes	Encryption mode(s) used to protect GuardPoints on the client, for example, CBC, CBC_CS1, and XTS.
LDT Enabled	Whether LDT is enabled on the client.
Profile	Profile linked to the client.
Domain Sharing Enabled	Whether the client is shared across domains - Yes or No . Refer to Sharing a Client Across Domains for details.
Sharing	Sharing status of the client. • External: The client is external to the current domain. The client is created and shared from another domain. • Shared: The client is shared across other domains. The current domain is the native domain of the client. • -: The client is neither Shared nor External. The field is left blank for clients that were registered with a previous version of the CipherTrust Manager. Such clients can also be shared across domains. Refer to Sharing a Client Across Domains for details.

The **Encryption Modes**, **LDT Enabled**, **Profile**, **Domain Sharing Enabled**, and **Sharing** columns are hidden by default. To show/hide a column, click the custom view icon () , select/clear the desired column, and click **OK**.

Viewing Details of a Client

To view the details of a client:

1. Open the **Transparent Encryption** application.
2. Click **Clients > Clients**. The list of available CTE clients is displayed.
3. Under **Client Name**, click the desired client. The client details page is displayed.

You can see the details of GuardPoints, FAM, Settings, Membership, and Challenge Response associated with the client.

Warning

If potential ransomware activities are detected, the warning will be displayed at the top of the page.

FAM

Note

You can see the FAM details only if the FAM is enabled for that client.

1. Click the **FAM** tab.
2. Expand **ATTRIBUTE** to view the attribute details such as Destination Name, Duplicates, Threshold, and Suppress Threshold.

Note

After the client has enabled FAM, the attribute can be created. You can create only one attribute for a client.

3. Expand **POLICIES** to view the list of FAM policies linked with the client.

Note

- A client can have multiple FAM policies.
- The FAM policies are reusable. One FAM policy can be linked with multiple clients.

Client States

- **Healthy:** Client is registered with the CipherTrust Manager without any errors, that is, `init` is received from Agent without any issues.
- **Error:** Client's communication is broken with the CipherTrust Manager for more than five minutes.
- **Warning:** Client's communication is broken with the CipherTrust Manager or a GuardPoint is inactive due to any reasons.
- **Unregistered:** Client is unenrolled from the CipherTrust Manager.
- **Expunged:** Client's delete operation is triggered, but its confirmation is not yet received from the Agent.

Note

The Unregistered and Expunged states are not applicable to the CTE for Kubernetes clients. When a CTE for Kubernetes client is deleted or unenrolled (from the client), its entry is automatically removed from the CipherTrust Manager.

Getting Latest Client Status

By default, the status of a registered client is updated on the CipherTrust Manager when the configuration of the client changes. However, if needed, you can manually fetch the latest status of the client at any time.

Note

- The latest status of only a *registered* client can be fetched.
- Request to fetch the latest status can be reattempted after 30 minutes of the previous attempt.
- After registering a new client, wait for 30 minutes to fetch the latest status.

To get the latest status of a client:

1. Open the **Transparent Encryption** application.
2. Click **Clients > Clients**.
3. Click the overflow icon () corresponding to the desired client.
4. Click **Refresh**.

The client status on the Clients page is refreshed.

Unenrolling Clients

A registered CTE client can be unenrolled from the CipherTrust Manager. When the client is unenrolled (unregistered), the communication between the CTE Agent and the CipherTrust Manager is removed. The CTE Agent can no longer communicate with the CipherTrust Manager. However, the CipherTrust Manager still maintains the client configuration to allow re-registration.

Important Notes

- A CTE client with Active LDT GuardPoints cannot be unenrolled (unregistered).
- After unenrolling, the client's GuardPoints will still be displayed on the CipherTrust Manager. However, their status will be displayed as Unknown.
- The status of the client capabilities, for example, LDT, will not change on the CipherTrust Manager. They will be displayed the same as they were before unenrolling the client.
- The associated client under the Client-Management section of the API playground is deleted after unenrolling. If the client is not deleted automatically, you can delete it manually.
- The status of the unenrolled client will be displayed as Unregistered on the CipherTrust Manager.

Note

An unenrolled client requires re-registration to enroll with the CipherTrust Manager again.

Note

When deleting a pod running on a registered CTE for Kubernetes client, you might notice some unwanted error messages. To avoid such messages, it is recommended to unenroll the CTE for Kubernetes client before attempting to delete the pod.

To unenroll a client from the CipherTrust Manager:

1. Open the **Transparent Encryption** application.

-
2. Click **Clients > Clients**.
 3. Click the overflow icon () corresponding to the desired client.
 4. Click **UnEnroll**. A dialog box appears prompting to confirm the action.

An unenrolled client requires re-registration to enroll with the CipherTrust Manager again.

5. Click **UnEnroll**.

The selected client is unenrolled from the CipherTrust Manager. Its status on the CipherTrust Manager becomes Unregistered.

Reregistering Clients

An unenrolled client requires reregistration to enroll with the CipherTrust Manager again.

When you try to reregister a client, you must enable the same set of capabilities that were enabled on the client before reregistration. Also, specify name of at least one client group (if the client was associated with any groups). Refer to [Reregistering CTE Clients](#) for details.

Deleting Clients

A CTE client can be deleted when it is no longer required to be associated with the CipherTrust Manager.

Clients with the Healthy, Unregistered, Warning, and Error states can be deleted from the CipherTrust Manager.

After you initiate the client deletion operation, the operation:

1. Waits for confirmation from the CTE Agent before deleting anything from the CipherTrust Manager.
2. Changes the client status to Expunged on the CipherTrust Manager.
3. After receiving confirmation from the Agent:
 - Deletes all entries, capabilities, and GuardPoints associated with the client.
 - Removes the client record from the CipherTrust Manager.

However, in some cases, due to network issues or any other reasons, the CipherTrust Manager does not receive confirmation from the CTE Agent. In such cases, the client configurations cannot be deleted from the CipherTrust Manager and the client remains stuck at the Expunged state. Such clients need to be deleted manually. Refer to [Deleting Expunged Clients Manually](#) for details.

4. Deletes the associated client from the Client-Management section of the API playground.

Before proceeding with client deletion, read and understand the additional information provided on client deletion, Agent uninstallation, clients with System and Agent locks, and deletion indicators in [Deleting Clients](#).

The CipherTrust Manager provides options to delete individual clients or multiple clients in one go. To delete the client from the CipherTrust Manager GUI.

Note

Before deleting the client, ensure that the Unique to client key is not associated. If the key is associated, decrypt the data. Refer to [Data Transformation](#) for details.

Warning

It is important to decrypt the data. If you don't decrypt it, the data will be lost and cannot be recovered.

1. Open the **Transparent Encryption** application.
2. Click **Clients > Clients**.
3. Click the desired tab to view the instructions.

Individual Clients

- a. Under **Client Name**, click the overflow icon () corresponding to the client you want to delete.
- b. Click **Delete**. A dialog box appears prompting to confirm the action.
- c. Click **Delete**.

The selected client is deleted and its entry is removed from the Clients page after the CipherTrust Manager receives confirmation from the CTE Agents.

Multiple Clients

A maximum of 200 clients can be deleted at once.

- a. Select the desired clients.

To select all clients visible on the page, select the top check box to the left of the Status heading.

- b. Click the delete icon (). A dialog box appears prompting to confirm the action.
- c. Click **Delete**.

The selected clients are deleted and their entries are removed from the Clients page after the CipherTrust Manager receives confirmation from the CTE Agents.

Refer to [Deleting Expunged Clients Manually](#) for details on deleting Expunged clients.

Deleting Expunged Clients Manually

If due to any reasons, the CipherTrust Manager does not receive the deletion confirmation from the CTE Agent, the client remains stuck in the Expunged state. The client cannot be deleted automatically from the CipherTrust Manager.

To manually delete an Expunged client and its configurations from the CipherTrust Manager, run the `/v1/transparent-encryption/clients/{id}/delete` API with the force delete option ("force_del_client").

When running the API, set `"force_del_client": true`. Refer to the API playground documentation for details.

Sharing a Client Across Domains

A shared client will be visible in read-only mode in all the domains where it is shared. The GuardPoints can be created on the shared client from any of the linked domains. These GuardPoints will be visible in read-only mode in all the linked domains except their native domains (where the GuardPoints are created). All the valid operations on the GuardPoints will be allowed from the native domains.

This functionality is transparent to the CTE client, that is, the client will receive a single security configuration having GuardPoint details of all the domains.

The following diagram shows the client-sharing workflow:

To share a client across domains:

1. Open the **Transparent Encryption** application.

2. Click **Clients > Clients**. The list of available CTE clients is displayed.
3. click the **Name** link of the desired client. The details page of the client is displayed.
4. Click the **Settings** tab.
5. Expand **GENERAL SETTINGS**.
6. Enable **Domain Sharing**.
7. Click **Update**.

Removing Client Sharing from Domains

You can remove client sharing from individual domains or from multiple domains in one go.

1. Open the **Transparent Encryption** application. The Clients page is displayed.
2. Click **Clients > Clients**.
3. Under **Client Name**, click the desired client. The detail view of the Clients page is displayed.
4. Click the **Sharing** tab.
5. Click the desired tab to view the instructions.

From Individual Domains

- a. Under **Domain Name**, select the check box corresponding to the desired domain.
- b. Click **Remove**. A dialog box appears prompting to confirm the action. Deleting this domain is permanent and cannot be undone.

From Multiple Domains

- a. Under **Domain Name**, select the check box corresponding to the desired domains. To select all domains visible on the page, select the top check box to the left of the Domain Name heading.
- b. Click the delete icon (). A dialog box appears stating that deleting the selected domains is permanent and cannot be undone.

6. Click **Delete**.

The client is no longer shared with the selected domain(s).

Enabling Live Data Transformation

The Live Data Transformation (LDT) feature enables the CipherTrust Manager Security Administrators to encrypt or rekey GuardPoint data without blocking the user or application access to that data.

In standard CTE deployments, data access is blocked during the initial encryption or rekeying of the data, and each rekey operation requires guarding your data under separate production and offline data transformation policies. With LDT, encryption and rekeying of the data takes place in the background using one policy, without disrupting user or application access.

Prerequisites

To use LDT, you must have the following:

- CTE Agent license. The feature is called *CTE - TransparentEncryption* on the Licensing page.
- CTE LDT add-on license. The feature is called *CTE - LiveDataTransformation* on the Licensing page.
- CTE Agent installed on a client. Refer to the [CTE Agents Quick Start Guide](#) specific to your platform for information about installing and registering CTE clients.

Refer to the [CTE-Live Data Transformation with CipherTrust Manager](#) and the CipherTrust Manager [Compatibility Matrices](28,186: Refer to the [CTE-Live Data Transformation with CipherTrust Manager](#) and the CipherTrust Manager [Compatibility Matrices](#) for information about implementing LDT and the supported platforms.

Important Notes

- If the CipherTrust Manager fails, all keys that were automatically rotated after the last backup would be lost, making all data encrypted with those keys unusable or unrecoverable. Therefore, it is recommended that the LDT feature is used in a high availability CipherTrust Manager deployment.
- If LDT must be used in a single CipherTrust Manager configuration, it is recommended to:
 - Set "Persistent on Client" to "Yes" for all keys that are created.
 - Set the password creation method to "Manual" for all clients.
 - If the standalone CipherTrust Manager fails or is unavailable, the data on the client can still be accessed by entering the known passphrase. The data is accessible as the encryption keys are cached on the client.

Enable LDT

Enable the LDT support for a client either during registration or after registration with the CipherTrust Manager.

- If LDT is enabled during registration, the Live Data Transformation check box appears selected by default on the CipherTrust Manager GUI.
- If LDT is not enabled during registration, you can enable it on the CipherTrust Manager GUI, as described below.

To enable LDT on a client after CTE installation:

1. Open the **Transparent Encryption** application.
2. Click **Clients > Clients**.

3. Under **Client Name**, click the desired client.
4. Select **Live Data Transformation**.

By default, LDT performs rekey operations on the LDT protected GuardPoints as soon as GuardPoints are enabled. To pause LDT rekey operations, click the Suspend Live Data Transformation icon (⏸). The icon changes to Resume Live Data Transformation (▶).

5. Click **Apply**. LDT is now enabled on the client.

After LDT has been enabled, it cannot be disabled. To remove the feature, you must migrate existing data protected under LDT policies, unregister the client, and delete the client. Then, you can reregister the client without enabling the feature. This allows you reclaim the license for use on another client.

Refer to [Managing GuardPoints](#) for details on creating LDT GuardPoints. For details about how LDT works, guidelines, and best practices for using the feature, refer to the [CTE-Live Data Transformation with the CipherTrust Manager](#) documentation.

Setting Client Locks

Agent Lock and System Lock are used to protect the CTE Agent and certain system files. CTE Agent protection includes preventing:

- Certain changes to the CTE Agent installation directory.
- Unauthorized termination of the CTE Agent processes.

These locks can be applied to individual clients or client groups. By default, the Agent Lock and System Lock are disabled.

Note

Uninstallation of the Agent software might fail when the Agent Lock and System Lock are enabled. It is recommended to disable the:

- Agent Lock before uninstalling the Agent software on the client system.
- Agent Lock before deleting the client records from the CipherTrust Manager GUI.
- System Lock before updating, deleting, or modifying the protected system files.

Agent Lock

Agent Lock locks the contents of the CTE Agent directories on the client. These directories are `/etc/ciphertrust`

`root>/agent/secfs` and `/<install root>/agent/vmd`.

Files in these directories cannot be modified or removed when Agent Lock is enabled; however, the CipherTrust Manager can still propagate updates to the client system.

Note

The CTE Agent directories `secfs/.sec/conf/` (on Linux) and `secfs\sec\conf\` (on Windows) contain sensitive configuration files. It is highly recommended to enable the Agent Lock to avoid data exposure to unauthorized users.

When Agent Lock is Disabled

- CTE Agent software on the client is not protected

Note

Do not unregister or delete the CTE Agent while locks are applied. The locks stay in effect after the Agent is unregistered, and without Agent credentials, the CipherTrust Manager can neither administer that Agent nor disable the locks. You must boot the client into single-user mode and manually modify the Agent configuration to disable the locks.

When Agent Lock is Enabled

- Certificates are exchanged and the client is bound to the CipherTrust Manager
- CTE Agent installation directory cannot be deleted or overwritten
- CTE Agent services cannot be stopped
- CTE Agent GuardPoints cannot be forcefully unmounted
- On **Linux** systems:
 - All operations are permitted on the following directory:

```
/<install root>/agent/secfs/tmp
```

- Following directories cannot be removed or renamed, and directory and file creation will fail.

```
/<install root>/agent/secfs/bin
/<install root>/agent/vmd
```

- File creations and other operations will work for the following directory, but the directory cannot be removed or renamed.

```
/<install root>/agent/secfs/
```

- On **AIX** systems:

- Contents of the following directories cannot be changed or moved.

```
/<install root>/agent/vmd
```

- Contents of the following files and directories can be modified, but not removed or renamed.

```
/<install root>/agent/secfs/  
/<install root>/agent/secfs/tmp
```

- On **Windows** systems:

- Following folder cannot be moved and its contents cannot be modified.

```
C:\Program Files\Vormetric\DataSecurityExpert\Agent\secfs\sec
```

- CTE Agent entries in the registry cannot be modified or deleted.

System Lock

System Lock applies an internal policy to the client to lock client system directories, such as `/var`, `/bin`, and `/etc`.

Note

System Lock must be disabled before upgrading or installing third-party software, adding new applications, opening SSH sessions remotely, or modifying system directories.

Note

(Windows only) Verify that the volume letter and the path for the Windows system are correct before proceeding. When the CTE Agent is installed, the volume letter defaults to `C:`. The executables on the Client Settings tab may be on a different volume or in a different folder. If the volume or path information is incorrect, the CipherTrust Manager cannot sign the applications and apply Agent Lock and System Lock.

When System Lock is Disabled

- The internal policy is disabled.
- You can install or update system software.

When System Lock is Enabled

- Agent Lock is automatically enabled.
- Operating system directories on the client are protected.
- Microsoft Update cannot be run on Windows systems to protect the client. Microsoft update and other installation-related executables are specifically blocked. Executables like `wuacuc.lt.exe` and `msiexec.exe` cannot be run.
- The installation utility checks if System Lock is enabled on the client system. If it is, the utility aborts installation and displays a message informing you to **unlock system before running install/update program**. Other third-party installation utilities do not check whether System Lock is enabled, and are not prevented from installing software.
- New file or directory creation inside a protected directory is not allowed.

The following files, directories, and subdirectories are, by default, automatically protected when System Lock is enabled. Asterisks (*) indicate pattern matching.

- On **Linux** systems:
 - Following files and the contents of the following directories cannot be changed or moved.
 - `/etc/pam.d`
 - `/etc/rc*`
 - `/etc/security`
 - `/usr/lib/security`
 - Contents of the following files and directories can be modified, but not removed or renamed.
 - `/etc`
 - `/etc/init.d/secfs`
 - `/usr`
 - `/usr/bin/vmd`
 - `/usr/bin/vmsec`
 - `/usr/bin/secfsd`

-
- /usr/bin/dataxform
 - /usr/lib
 - /usr/lib/pam
 - /usr/lib/security
 - /var/log/vormetric
- On **AIX** systems:
 - Following files and the contents of the following directories cannot be changed or moved when System Lock is enabled.
 - /etc/rc.d
 - /etc/security
 - /usr/lib/security
 - /sbin/helpers/mount_secfs
 - Contents of the following files and directories can be modified, but not removed or renamed when System Lock is enabled.
 - /var/log/vormetric
 - On **Windows** systems:
 - Files with the following extensions in the Windows OS installation folder (for instance: `\Windows`, `\WinNT`, and so on) cannot be moved or modified:
 - .exe
 - .dll
 - .sys
 - .cmd
 - .com

When System Lock is applied, a protected file or path cannot be renamed or deleted; however, if it is a directory, other files may be added to it. For example, `/etc` cannot be deleted nor renamed, though you can add files to it. A file that cannot be modified cannot be opened and edited in any way.

Setting Locks

You can apply locks to individual clients or to client groups. To apply the locks:

1. Make sure that no one is currently in or accessing the Agent installation directories; otherwise, the CipherTrust Manager might not lock the Agent software.
2. Open the **Transparent Encryption** application.
3. Click the desired tab to view the instructions.

On an Individual Client

- a. Click **Clients > Clients**. The list of available CTE clients is displayed.
- b. Click the **Name** link of the desired client. The details page of the client is displayed.
- c. Click the **Settings** tab.
- d. Expand **SECURITY SETTINGS**.
- e. On the lock bar, click **Agent Lock**. This protects the CTE Agent files from modification and deletion.

- f. Click **System Lock**. This protects a set of system files from modification and deletion.

Agent Lock is automatically enabled when System Lock is enabled. You can manually enable or disable Agent Lock only when System Lock is disabled.

- g. Click **Update**.

On a Client Group

- a. Click **Clients > Client Groups**.
- b. Under **Client Group Name**, click the desired client group.
- c. On the lock bar, click **Agent Lock**. This protects the CTE Agent files from modification and deletion.

- d. Click **System Lock**. This protects a set of system files from modification and deletion.

Agent Lock is automatically enabled when System Lock is enabled. You can manually enable or disable Agent Lock only when System Lock is disabled.

- e. Click **Apply**.

4. Verify the locks. Refer to [Verifying Locks on Clients](#).

Note

To disable the locks on a client group, select the client, click **Unlock**, and click **Apply**.

Verifying Locks on Clients

A client administrator can verify that the locks are applied to the Agent on the client.

To verify the locks:

1. Log on to the client system.
2. Run the `secfsd` command with the `lockstat` argument:

```
# secfsd -status lockstat
FS Agent Lock: true
System Lock: true
```

Note

Sometimes, the CipherTrust Manager reports the CTE Agent configuration different than the actual configuration. This can be because of the delay between log uploads to the CipherTrust Manager, or because a GuardPoint is in use when the lock is applied.

In some cases, when the locks are enabled, the CipherTrust Manager cannot administer the client. In such cases, after changing authentication credentials or removing the certificate fingerprint, the client administrator must unlock the client manually.

Unlocking Clients Manually

Unlocking Linux Clients

To unlock the client manually:

1. Boot the client into single-user mode.
2. Edit the `secfs/.sec/conf/configuration/secfs_config` file.
3. Set both `coreguard_locked` and `system_locked` to `false`.
4. Save the file.
5. Boot the system into multi-user mode.

You can now administer the client again.

Unlocking Windows Clients

To unlock the client manually:

1. Boot in safe mode.
2. Rename `C:\Windows\system32\drivers\vmgmt.sys` and `.\drivers\vmfiltr.sys` to something else.
3. Boot in regular mode.

You can now administer the client again.

Disabling Locks

To disable the locks on a client:

1. Open the **Transparent Encryption** application.
2. Click **Clients > Clients**. The list of available CTE clients is displayed.
3. Click the **Name** link of the desired client. The details page of the client is displayed.
4. Click the **Settings** tab.
5. Expand **SECURITY SETTINGS**.
6. Click **Unlock**. The lock bar should look like the following:

7. Click **Update**.

To disable the locks on a client group, select the client group, click **Unlock**, and click **Apply**. The lock bar should look like the following:

Administering Locking Issues

The client administrator must inform the Security Administrator of changes to the system hierarchy.

- **Example 1:** The client system administrator can request to have the locks temporarily disabled to do administrative functions.
- **Example 2:** The client system administrator can remove directories and files, then, later when the lock is reapplied, the CipherTrust Manager protects non-existent data.
- Another common administrative issue pertains to mounted GuardPoints. The client system administrator can remove or unmount an unlocked, non-automounted GuardPoint. The CipherTrust Manager GUI is not aware of this change and does not issue a warning when you reapply the lock to the now non-existent mounted GuardPoint.
- To recover an unmounted GuardPoint:
 - a. Disable the GuardPoint for the file system on the CipherTrust Manager GUI.
 - b. Mount the file system on the client.
 - c. Enable the GuardPoint for the file system.

Client Settings

Applications such as `su`, `sshd`, and `login` authenticate users' identity by requesting user credentials (user name and password). These are signed applications that identify and authenticate before a child process is executed.

GuardPoints can have an associated policy that restricts access to the data stored in them. For a process to access the data, the user's associated identity must be authorized. This authorization can be done by adding an entry to the Settings field on the Client Settings tab. This entry specifies a program, such as mentioned above, with a keyword that indicates the type of authorization that is applied.

Client settings configured on the CipherTrust Manager are pushed to the clients periodically.

Any changes to the client settings are not automatically signed. Signatures of the newly added processes are compared against the signatures in the existing settings. If they differ, an error message is generated. Refer to [Re-Sign Settings](#) for steps to configure this setting. Refer to the [CTE Agent Advanced Configuration and Integration Guide](#) specific to your platform for details about this feature.

Client settings can also be configured at the client group level, refer to [Inheritance of Client Group Settings](#) for details.

Note

Refer to [CTE Linux Authentication and Client Settings](#) for detailed and additional information on authentication and client settings.

Client Settings for Linux

Specify the authentication mechanisms in place for certain binaries on the client machine.

Default Settings for Linux

```
|authenticator|/usr/sbin/sshd
|authenticator|/usr/sbin/in.rlogind
|authenticator|/bin/login
|authenticator|/usr/bin/gdm-binary
|authenticator|/usr/bin/kdm
|authenticator_euid|/usr/sbin/vsftpd
```

Add, edit, or modify authentication settings as appropriate.

Additional Settings for HDFS (Linux Clients)

Depending on the Hadoop security authentication mode, additional settings are needed for CTE clients in an HDFS cluster. Add the following settings as appropriate.

Note

`/usr/jdk64/jdk1.8.0_40/bin/java` is the Java executable used to launch the HDFS services. Change the Java jdk path to reflect your end-user environment.

- Sample setup when `hadoop.security.authentication` mode is simple.

```
|authenticator+arg+=class=org.apache.hadoop.hdfs.server.namenode.NameNode|/usr/
jdk64/jdk1.8.0_40/bin/java
|authenticator+arg+=class=org.apache.hadoop.hdfs.server.datanode.DataNode|/usr/
jdk64/jdk1.8.0_40/bin/java
```

- Sample setup when `hadoop.security.authentication` mode is Kerberos.

```
|authenticator+arg=+class=org.apache.hadoop.hdfs.server.namenode.NameNode|/usr/
jdk64/jdk1.8.0_40/bin/java
|authenticator+arg=+class=org.apache.hadoop.hdfs.server.datanode.SecureDataNode
Starter|/usr/lib/bigtop-utils/jsvc
```

Authentication Settings for Signature Sets (Linux Clients)

The CipherTrust Manager provides an option to configure authentication of CTE client binaries. If a binary, whose path matches a client setting entry, is executed on the CTE client, the operation is validated using the binary signature stored in a signature set on the CipherTrust Manager. Based on the authenticity of the binary, the operation is validated as "User Authenticated" or "User Not Authenticated" as appropriate.

The format to specify authentication settings for a signature set is:

```
|privilege+sig=<signature-set-name>|/path/to/binary
```

For example, to specify authentication settings for a signature set `test-sign-set` for a binary stored at `/home/test/run-test`, add the entry:

```
|authenticator+sig=test-sign-set|/home/test/run-test
```

The wildcard character asterisk (*) can also be used to specify paths in client settings as:

```
|keyword+sig=<signature-set name>|/path/to/binary/*`
```

For example, to specify authentication settings for all binaries under `/home/test/`, add the entry:

```
|authenticator+sig=test-sign-set|/home/test/*
```

Note

The wildcard character * is supported for Linux clients only.

Specify Authentication Settings

To specify authentication settings for the client:

1. Open the **Transparent Encryption** application.
2. Click **Clients > Clients**. The list of available CTE clients is displayed.
3. Click the **Name** link of the desired client. The details page of the client is displayed.

4. Click the **Settings** tab.
5. Expand **CLIENT SETTINGS**. The Settings text box contains the authentication settings.

CLIENT SETTINGS

Settings

```

| C:\WINDOWS\system32\winlogon.exe
|lock| C:\WINDOWS\system32\msiexec.exe
|lock| C:\WINDOWS\system32\wuauclt.exe
|lock| C:\WINDOWS\system32\wupdmgr.exe
|lock| C:\Program Files\Wormetric\DataSecurityExpert\Agent\Secfs\sec\bin\wminstall.exe
|exempt| C:\WINDOWS\explorer.exe
|exempt| C:\WINDOWS\regedit.exe
|exempt| C:\WINDOWS\system32\regedt32.exe
|exempt| C:\WINDOWS\system32\svchost.exe
|exempt| C:\WINDOWS\system32\services.exe
|exempt| C:\WINDOWS\system32\smss.exe

```

☐ Re-sign Settings (This toggle resets after a push to the CTE agent.)

Note

- To delete the client settings, delete the content in the Settings box and click Update.
- To edit the client settings, modify the content in the Settings box and click Update. When editing the settings strings, follow the format `|privilege|file name`.

Update

Each line has the format:

```
|privilege|/path/to/binary
```

The format to specify authentication settings for a signature set is:

```
|privilege+sig=<signature-set-name>|/path/to/binary
```

Refer to [Client Settings Keywords](#) for keywords.

6. In the **Settings** box, specify the authentication mechanism.

Note

- To delete the settings, delete the content and click **Update**.

- To edit the settings, modify the content and click **Update**. When editing the setting strings, follow the format `|privilege|binary`.

7. Click **Update**.

Client Settings for Windows

For applications running under **WOW64** that require some form of user authentication, create entries on the Client Settings tab. The **syswow64** paths are created by default when the CTE Agent is installed. **Windows** is for Windows XP and Windows Itanium operating systems.

In **WOW64**, all file access to **C:\Windows\System32** is redirected to **C:\Windows\syswow64**, and is implemented using the File System. Redirected **syswow64** paths are effective only for 64-bit Windows file agents. This is the path where programs compiled for 32-bits are stored to run on a 64-bit system.

Before proceeding, verify that the volume letter and the path for the Windows system are correct. When the CTE Agent is installed, the volume letter defaults to **C:**. It is possible that the executables on the Client Settings tab are on a different volume or in a different folder. If the volume or path information is incorrect, the CipherTrust Manager cannot sign the applications, and it cannot apply Agent Lock and System Lock.

Default Settings for Windows

```
| | C:\WINDOWS\system32\winlogon.exe
| lock| C:\WINDOWS\system32\msiexec.exe
| lock| C:\WINDOWS\system32\wuauclt.exe
| lock| C:\WINDOWS\system32\wupdmgr.exe
| lock| C:\Program Files\Vormetric\DataSecurityExpert\Agent\Secfs\sec\bin\vminstal
l.exe
| exempt| C:\WINDOWS\explorer.exe
| exempt| C:\WINDOWS\regedit.exe
| exempt| C:\WINDOWS\system32\regedt32.exe
| exempt| C:\WINDOWS\system32\svchost.exe
| exempt| C:\WINDOWS\system32\services.exe
| exempt| C:\WINDOWS\system32\smss.exe
```

Add, edit, or modify authentication settings as appropriate.

Specify Authentication Settings

To specify authentication settings for the client:

1. Open the **Transparent Encryption** application.
2. Click **Clients > Clients**. The list of available CTE clients is displayed.
3. Click the **Name** link of the desired client. The details page of the client is displayed.
4. Click the **Settings** tab.

- Expand **CLIENT SETTINGS**. The Settings text box contains the authentication settings.

CLIENT SETTINGS

Settings

```

| | C:\WINDOWS\system32\winlogon.exe
| lock | C:\WINDOWS\system32\msiexec.exe
| lock | C:\WINDOWS\system32\wuauclt.exe
| lock | C:\WINDOWS\system32\wupdmgr.exe
| lock | C:\Program Files\Vormetric\DataSecurityExpert\Agent\Secfs\sec\bin\vminstall.exe
| exempt | C:\WINDOWS\explorer.exe
| exempt | C:\WINDOWS\regedit.exe
| exempt | C:\WINDOWS\system32\regedt32.exe
| exempt | C:\WINDOWS\system32\svchost.exe
| exempt | C:\WINDOWS\system32\services.exe
| exempt | C:\WINDOWS\system32\smss.exe

```

☐ Re-sign Settings (This toggle resets after a push to the CTE agent.)

Note

- To delete the client settings, delete the content in the Settings box and click Update.
- To edit the client settings, modify the content in the Settings box and click Update. When editing the settings strings, follow the format |privilege|file name.

Update

Each line has the format:

```
|privilege|/path/to/binary
```

Refer to [Client Settings Keywords](#) for keywords.

- In the **Settings** box, specify the authentication mechanism.

Note

- To delete the settings, delete the content and click **Update**.
- To edit the settings, modify the content and click **Update**. When editing the setting strings, follow the format |privilege|binary.

- Click **Update**.

Oracle Database in a Guarded NFS Mount on AIX

To locate your Oracle database in a guarded NFS mount:

1. Open the **Transparent Encryption** application.
2. Click **Clients > Clients**. The list of available CTE clients is displayed.
3. Click the **Name** link of the desired client. The details page of the client is displayed.
4. Click the **Settings** tab.
5. Expand **CLIENT SETTINGS**. The Settings text box contains the authentication settings. Each line has the format:

```
|privilege|/path/to/binary
```

6. In the **Settings** text box, add the following entries:

```
|vfsnumber|<path to>/oracle
|vfsnumber|<path to>/dbca
```

Example:

```
|vfsnumber|/u01/app/oracle/dbhome_1/bin/oracle
|vfsnumber|/u01/app/oracle/dbhome_1/bin/dbca
```

7. Click **Update**.

Client Settings Keywords

The following table lists the keywords that you can enter on the Client Settings tab. These keywords override different authentication requirements:

Keyword	Description
authenticator	(UNIX only) Authenticates based upon the real user ID (ruid) credentials of a process. The indicates that the given binary is trusted to authenticate users. For example, the sshd process on UNIX is a good authenticator . It takes incoming network connections and authenticates the user that attempts to log on to the system. All child processes from this session are trusted as the original user.
authenticator_euid	(UNIX only) Authenticates based upon the effective user ID (euid) credentials of a process. The keyword is used to authenticate the credentials of a setuid

Keyword	Description
	process with the <code>euid</code> value rather than the <code>ruuid</code> value.
<code> vfsnumber </code>	(AIX [all supported]/Oracle 10gR2) Use when Oracle RMAN backups fail on NFS as a result of not receiving underlying file system identifiers. Apply <code> vfsnumber </code> to the Oracle binaries directory.
<code> realfsid </code>	(AIX [All supported]) Use if the <code>cp</code> operation fails while copying files with extent attributes on guarded Veritas file systems. The failure occurs because the underlying file system identifier is not received.
<code> lock </code>	(Windows only) Specifies an application that cannot be executed on the client. An application defined with <code>lock</code> does not go through an internal policy check. The application is not allowed to run at all. A default set of applications is locked on Windows clients to prevent their execution and potential failure during bootup. The same effect can be achieved by configuring the resource and process security rule attributes in a policy. However, certain default applications are automatically locked on the Client Settings tab as a precautionary measure. Those applications must be included in the policy. Sometimes, problems such as installation failure or application lockup occur when installing software on a locked client. In such cases, identify the locked processes, unlock them, and retry installation. The failure goes away. For example: <code> lock c:\winnt\system32\msiexec.exe</code>
<code> exempt </code>	(Windows only) When processes or applications are started, the internal policy and regular policies are checked locally or by the CipherTrust Manager. When a policy check is performed and <code>exempt</code> is applied to the process, a six second timeout is imposed on the check. Without <code>exempt</code> , an application can wait indefinitely for a policy access check to complete, as when the CipherTrust Manager is required but is inaccessible. If the check times out because the CipherTrust Manager is unavailable for any reason, access is denied. <code>Exempt</code> client processes are also "exempt" from popup messages that describe the occurrence of access violations. An example of what causes such popup messages is an application that tries to memory map a file for which it does not have encryption permission (for instance, memory map with no view ability key on Windows). The only reasons to include <code>exempt</code> in the configuration are shorter wait periods and blocked popup messages.
<code> su_root_no_auth </code>	(UNIX only) Assigned only to the <code>su</code> process for tracking root users issuing unauthenticated <code>su</code> logins. The <code> su_root_no_auth /usr/bin/su</code> host setting in conjunction with <code> authenticator /usr/</code>

Keyword	Description
	<code>lib/ssh/sshd</code> prevents root from being authorized as another user. Non-root users using <code>su</code> to log on as another user after authentication, that is, after providing a password are not affected.
<code> path_no_trust </code>	(UNIX only) Any executable path that is marked with a <code> path_no_trust </code> client setting marks the process, and all child processes, as not trusted. Non-trusted processes are treated as "User Not Authenticated" to prevent access on user-based policies. CTE prevents overrides from other client settings authenticators, using the <code> path_no_trust </code> status. If a user runs the <code>su</code> command from a non-trusted shell, that new shell is still marked as <code> path_no_trust </code> , even if <code> authenticator /usr/bin/su</code> is specified in the client settings. The <code> path_no_trust </code> feature overrides any and all authenticators under client settings.
<code> protect </code>	When a file is marked as protected in the client host settings, that file is protected from being modified or deleted, (even from a root process). It is not guarded and the file can be external to a GuardPoint. If the file marked as <code> protect </code> does not exist, then CipherTrust Transparent Encryption creates a 0-length file in its place. This provides an efficient means to identify and implement file protection. When the agent is stopped or uninstalled, these 0-length files are deleted and then re-created if the agent is restarted. Additionally, an audit record is generated when a file operation is denied. The <code> protect </code> status is displayed using the command <code>secfsd -status auth.</code>

The following table shows different results you get when using `authenticator` or `authenticator_euid` to verify user identities.

Product	Application	Client Setting	User
Oracle	oracle	<code>authenticator_euid</code>	"oracle"
Oracle	oracle	<code>authenticator</code>	*

* indicates the real uid of the user who starts the application. This means that if the policy is configured to check the user ID, a security rule must be generated for every possible user.

Note

Apply the `|authenticator_euid|` keyword to the oracle binary on the Client Settings tab to authenticate the `oracle` user because regardless of who starts the oracle process, the `EUID` is always `oracle`.

Configuring Application Authentication Credentials

To configure application authentication credentials:

1. Open the **Transparent Encryption** application.
2. Click **Clients > Clients**. The list of available CTE clients is displayed.
3. Click the **Name** link of the desired client. The details page of the client is displayed.
4. Click the **Settings** tab.
5. Expand **CLIENT SETTINGS**. The Settings box displays the default set of system applications that may require authentication entries.
6. In the **Settings** box, add, modify, or delete entries to control their access permissions. When you add more processes, you must include the entire path.

Note

A keyword such as `|authenticator|` must be used in front of a process, otherwise, the entry is ignored by the CipherTrust Manager GUI.

7. Click **Update**.

Client users currently logged on to the client must log off and log on again to refresh their user authentication credentials. They can verify the change by logging on to the client, accessing a GuardPoint, and checking the user information in the message logs.

Inheriting Client Settings from a Client Group

To inherit client settings from a client group:

1. Open the **Transparent Encryption** application.
2. Under **Client Name**, click the desired client.
3. Click the **Client Settings** tab.
4. Select the desired client group from the **Inherit Client Setting From** drop-down list. This drop-down shows the list of client groups the client is a member of. The drop-down is not available for standalone clients.
5. Click **Apply**.

The client now inherits client settings from the selected client group. Refer to [Inheritance of Client Group Settings](#) for details on inheritance.

Note

An unregistered client cannot inherit client settings from its client groups.

Re-Sign Settings

If you add another process to the set of trusted applications on the Client Settings tab, enable the Re-sign Settings toggle. This ensures that the new process is signed and authenticated by the client.

Subsequently, when the client settings are pushed to the CTE Agent, the updated settings are re-signed. The Re-sign Settings toggle is turned off (or reset).

To ensure that new processes are signed and authenticated by the client:

1. Open the **Transparent Encryption** application.
2. Click **Clients > Clients**. The list of available CTE clients is displayed.
3. Click the **Name** link of the desired client. The details page of the client is displayed.
4. Click the **Settings** tab.
5. Expand **CLIENT SETTINGS**. The Settings text box contains the authentication settings.

CLIENT SETTINGS

Settings

| C:\WINDOWS\system32\winlogon.exe
| lock | C:\WINDOWS\system32\msiexec.exe
| lock | C:\WINDOWS\system32\wuauclt.exe
| lock | C:\WINDOWS\system32\wupdmgr.exe
| lock | C:\Program Files\Wormetric\DataSecurityExpert\Agent\Secfs\sec\bin\wminstall.exe
| exempt | C:\WINDOWS\explorer.exe
| exempt | C:\WINDOWS\regedit.exe
| exempt | C:\WINDOWS\system32\regedt32.exe
| exempt | C:\WINDOWS\system32\svchost.exe
| exempt | C:\WINDOWS\system32\services.exe
| exempt | C:\WINDOWS\system32\smss.exe

☐ Re-sign Settings (This toggle resets after a push to the CTE agent.)

Note

1 To delete the client settings, delete the content in the Settings box and click Update.
2 To edit the client settings, modify the content in the Settings box and click Update. When editing the settings strings, follow the format | privilege | file name.

Update

6. In the **Settings** box, update settings as appropriate.
7. Turn on the **Re-sign Settings** toggle.

☒ **Re-sign Settings** (This toggle resets after a push to the CTE agent.)

8. Click **Update**.

Enabling the Re-sign Settings toggle forces a signature update. On subsequent push of the client settings to the CTE Agent, the updated settings are re-signed and the Re-sign Settings toggle is turned off (or reset). If you do not turn on this toggle after adding a new process, the client ignores the newly added process.

Modifying Client Configuration

To modify the client configuration:

1. Open the **Transparent Encryption** application.
2. Click **Clients > Clients**. The list of available CTE clients is displayed.
3. Click the **Name** link of the desired client. The details page of the client is displayed.
4. Click the **Settings** tab.

Note

Any data protection related fields such as Live Data Transformation and LDT Access Only and Multifactor Authentication are unavailable for Windows clients with the RWP protection mode.

1. Modify the following, as appropriate:
 - **Live Data Transformation:** Enabled or disabled based on the feature selection during registration. By default, LDT performs rekey operations on the LDT protected GuardPoints as soon as GuardPoints are enabled. To pause LDT rekey operations, expand the **ADVANCE SETTINGS** and enable **Live Data Transformation**.

After LDT has been enabled, it cannot be disabled. To remove the feature, you must migrate existing data protected under LDT policies, unregister the client, and delete the client. Then, you can reregister the client without enabling the feature. This allows you reclaim the license for use on another client.
 - **LDT Passive Mode:** By default, LDT Passive Mode is disabled. To enable LDT Passive Mode, expand **ADVANCE SETTINGS** and enable **LDT Passive Mode**. After you enable it, you can't disable it.

Note

- If the client supports LDT_P, this field appears.
- If Live Data Transformation is enabled, this field is hidden.

- **LDT Access Only:** (Windows only) Whether the client can be added to an LDT communication group.
 - If the check box is clear, the client can be added to or removed from an LDT communication group.
 - If the check box is selected, the client cannot be added to an LDT communication group.
- **Encryption Key Protection:** Enable or disable protection of encryption keys stored in the cache memory on the CTE client. The field is available to registered clients only.

When enabled, keys are removed from the cache after three minutes of inactivity and memory is overwritten with random data any time after a key is used.

When keys are cached in memory, they are encrypted in the cache and only decrypted when used. This adds a small overhead but extra security. The in-memory key cache is held in the operating system kernel and is not accessible to any user-space applications. Furthermore, Thales recommends that CTE only be run on operating systems that have been patched to prevent Meltdown and Spectre attacks. Subsequent releases will prevent the CTE agent from running if patches are not in place.

If a kernel crash dump is initiated, any clear-text key information (used to derive keys from encrypted cached key counterparts) is erased from memory before the crash dump is taken.

- **Cloud Object Storage:** (Non-editable, Linux only) Enabled or disabled based on the feature selection during registration. From the GUI, you can neither disable nor enable the Cloud Object Storage feature. To enable or disable it, register the client again and opt or opt out of the Cloud Object Storage feature. Refer to the [CTE Agent for Linux Quick Start Guide](#) for details.
- **File Header Supported (FHS):** (Non-editable, Windows only) Enabled or disabled based on the feature selection during Agent installation. When this feature is enabled, you can apply GuardPoints to SMB shares.

After FHS has been enabled, it cannot be disabled from the CipherTrust Manager. To turn off the feature, you must migrate existing data protected under LDT policies, unregister the client, and delete the client. Then, you can reinstall the client with the *LDT on CIFS* (File Header Support, FHS) capability *turned off*, and register with the CipherTrust Manager.

- **Secure Start:** (Non-editable, Windows only) Enabled or disabled based on the installed Agent capability. If the Agent supports the Secure Start feature, then this option is enabled, otherwise, the option is disabled.

To enable Secure Start, expand **ADVANCE SETTINGS** and enable **Secure Start**.

-
- **Multifactor Authentication (MFA):** Available based on the installed Agent capability.
 - If the Agent supports MFA, you can enable or disable the feature. By default, the feature is disabled. To enable MFA on the client, expand **ADVANCE SETTINGS** and enable **Multifactor Authentication**. To disable, clear the check box.

When enabled, access to the requested data is granted only after the requester satisfies configured authentication criteria. Refer to [Multifactor Authentication](#) for details.

 - If the Agent does not support MFA, the option is disabled and cannot be modified.
- **In-place Data Transformation - Device:** (Non-editable, Linux only) Enabled or disabled based on the installed Agent capability. If the Agent supports the feature, then this option is enabled, otherwise, the option is disabled.
 - **Domain Sharing:** Allow or deny sharing the client resources across domains. Refer to [Sharing Resources Across Domains](#) for details.
 - **Unlock:** Unlock Agent Lock and System Lock.
 - **Agent Lock:** Lock the contents of the CTE Agent directories on the client.
 - **System Lock:** Apply an internal policy to the client to lock client system directories, like `/var`, `/bin`, `/etc`. Enabling System Lock automatically enables Agent Lock.
 - **Communication Enabled:** Whether to enable the client's communication with the CipherTrust Manager. Expand **GENERAL SETTINGS**, select to enable and clear to disable communication. By default, the communication is enabled. For manually added unregistered clients, this option is editable if **Registration Allowed** is selected.
 - **Registration Allowed:** (Manually added unregistered clients) Whether to allow client's registration with the CipherTrust Manager. Expand **GENERAL SETTINGS**, select to allow and clear to deny registration. By default, the registration is not allowed.
 - **Password Creation Method:** Set the password creation method—Manual or Generate. Refer to [Changing Client Password](#) for details.
 - **Protection Mode:** (Editable for Windows clients) Set the protection mode for the Windows client.

To change the protection mode:

- a. Expand **ADVANCE SETTINGS**.
- b. Select the desired **Protection Mode**.

Note that changing the protection mode from RWP (Ransomware Protection) to CTE RWP is irreversible. Review your decision before proceeding with this change.

- c. Click **Update**.
-

Note

For non-Windows CTE clients and unregistered clients, the Protection Mode is **CTE**.

- **Supports Unique to Client keys:** Enable to generate the key-salt. To enable Unique to Client keys, expand **ADVANCE SETTINGS** and enable **Supports Unique to Client keys**.

The default state of this field depends on the CipherTrust Manager version used to create/register the client:

- Version 2.13 or later: The field is enabled by default.
- Version 2.12 or earlier: If the client uses [unique to client keys](#), this field is disabled. Follow the steps below to enable it.
 - a. Ensure that the client is ready to enable the **Supports Unique to Client keys** field.

Warning

The client functions correctly without the "Supports Unique to Client keys" enabled. Enable this field only when the client status is healthy and ready, that is, the client has no GuardPoints using the unique to client keys. Applying it to a client in another state may cause configuration conflicts or unexpected behavior.

- b. Identify the GuardPoints that are using a unique to client key.
 - If no GuardPoints are found, skip to the next step to enable the **Supports Unique to Client keys** field.
 - If the GuardPoints are found, unguard the GuardPoints using the unique to client keys.

Warning

It is important to decrypt the data. If you don't decrypt it, the data will be lost. After all the GuardPoints are unguarded, proceed to the next step.

- c. Enable the **Supports Unique to Client keys** field. Once this field is enabled, you cannot disable it.
- d. Guard the GuardPoints that you've unguarded above.

e. Perform the above steps for all the clients.

- **Client Profile:** Select a profile for the client. The default profile is DefaultClientProfile. If you did not specify a profile during registration, the client is linked with default profile. To change the client profile, refer to [Changing the Profile](#) for details.
- **Advanced Security Configuration:** View or edit the client's security configuration parameters. Refer to [Changing Security Configuration Parameters](#) for details.
- **Details (Read-only):** Shows the versions of the platform and kernel installed on the client, for example, RHEL7.8 - 3.10.0-1127.el7.x86_64. For unregistered or manually added clients, a hyphen (-) is displayed. For Windows clients, the field is empty.
- **Upgrade On Reboot (Read-only):** Displays when the next upgrade of the CTE Agent is scheduled. None is displayed if the upgrade is not scheduled. For unregistered clients, the field remains blank.
- **Agent Information:** Collect and download the Agent information (**agentinfo**) from the CTE Agent.
 - **Collect:** Informs the CTE client to collect the Agent information and send it back to the CipherTrust Manager. This is the default link.

After the Agent information is successfully received, the link changes to **Recollect** and **Download**.

- **Recollect:** Collects the latest Agent information from the CTE Agent.
- **Download:** Downloads the Agent information from the CipherTrust Manager in a tar file. After the download, the Agent information is removed from the CipherTrust Manager. In a CipherTrust Manager cluster, the information will be downloaded from the node where the Agent information is requested.

Refer to [Collecting Agent Information](#) for details.

- **Confidential Computing:** Enabled or disabled based on the feature selection during registration. If enabled, the all the data executions takes place within a trusted environment, safeguarding user's data from software attacks. For more information, see [Confidential Computing](#).
 - **ATTESTED:** Indicates that Confidential Computing is enabled and attestation is successful.
 - **NOT ATTESTED:** Indicates that Confidential Computing is enabled but attestation has failed.

After confidential computing has been enabled, it cannot be disabled. To remove the feature, you must unregister and delete the client. Then, you can re-register the client without enabling the feature. This allows you to reclaim the license for using on another client.

Note

If Confidential Computing feature is not opted during client registration, the **Confidential Computing**

field will display '-' as status.

- **FAM:** Whether FAM is enabled on the client. For more information, see [File Activity Monitoring \(FAM\)](#).

2. Click **Update**.

Changing the Profile

To change the client profile:

1. Open the **Transparent Encryption** application.
2. Click **Clients** > **Clients**. The list of available CTE clients is displayed.
3. Click the **Name** link of the desired client. The details page of the client is displayed.
4. Click the **Settings** tab.
5. Expand **GENERAL SETTINGS**. The Client Profile section shows the current client profile and Rekey Option, Rekey Rate, and Schedule of the selected profile.

The screenshot shows the 'Client Profile' section with a dropdown menu currently set to 'DefaultClientProfile'. Below the dropdown, there are four status indicators: 'Log Level: ERROR', 'Rekey Option: RekeyRate', 'Rekey Rate: 0', and 'Schedule: ANY_TIME'. A blue link 'Go to the Selected Profile' is located to the right of these indicators.

6. From the **Profile** drop-down list, select the desired profile.
7. Click **Update**. The selected profile is linked successfully.

Changing Security Configuration Parameters

The CipherTrust Manager provides options to modify certain security configuration parameters configured on the CTE client. The list of editable configuration parameters can vary based on the capabilities supported by the CTE Agent installed on the client. Refer to the [CTE Agent documentation](#) for compatible versions and dynamic parameters.

To view or change the security configuration parameters:

1. Open the **Transparent Encryption** application.
2. Under **Client Name**, click the desired client.
3. Next to **Advanced Security Configuration**, click the **View/Edit Settings** link. The Advanced Security

Configuration dialog box lists the security configuration parameters that can be updated after the CTE client is registered with the CipherTrust Manager. Every parameter has the fixed set of values.

Note

The `PTRACE_PROTECTION` feature is not applicable to CTE for Windows Agents.

4. Change the security configuration, as appropriate.
5. Click **Save**. The security configuration is changed successfully.

CTE Linux Authentication and Client Settings

CTE Linux client (also known as host) settings, which ensure CTE user access controls and systems protection, is a CipherTrust encryption feature that is often difficult to understand and configure. This section provides an updated description of CTE Linux 7.1.1 client settings, authentication, and different authenticators.

The intended audience of this information are CTE and CipherTrust Manager administrators. It is assumed that they are knowledgeable on Linux/Unix concepts, techniques, and security features. Additionally, it is assumed that they have read the CTE and CipherTrust Manager administration documents and are familiar with the CipherTrust Manager security policies and capabilities.

Root Privileges

Users with root privileges on Linux systems have unrestrained capabilities to override all file access and execution permissions imposed by the system. `setuid` programs running with root permissions and privileges can create, remove, or modify any files in the system. By exploiting the ability to escalate privileges, adversaries can subvert system controls and access and steal confidential data.

CTE Access Controls

Use CTE access controls to:

- Curtail privileges of root users and `setuid` programs.
- Specify policies to restrict "who, *the client system users or groups*" and "what, *the application processes or binaries*" access to protected data within CTE GuardPoints.

Individual users (including root) accessing the CTE GuardPoint data can therefore be granted or denied access.

The CipherTrust Manager policies track and prevent privileged users (including `setuid` root programs) from reading, modifying, or executing files and directories residing in the GuardPoints owned by normal/unprivileged users.

For every running operating system process, CTE maintains a separate trusted ID distinct from each process' real and effective UIDs. This trusted ID is used for making decisions based on user-related policy evaluations. One such example is CTE differentiating between:

-
- A user who logs in, and is therefore explicitly authorized, as root.

AND

- A user who logs in, is authorized as a normal/unprivileged user, and subsequently runs a potentially malicious `setuid` program like `su` to gain root privileges.

System (and in some cases, certain classes of users) applications on the CTE client such as `sshd`, `login`, and `su` etc. authenticate a user's identity by requesting user credentials, authorizing the user, and spawning child processes.

Therefore, for a process to access protected data, the user's identity must be established as authenticated and authorized by these special authenticator binaries. Processes (including their descendants) spawned by authenticators like `sshd` and `login` are treated as authorized and therefore trusted. The real (or in some cases, effective) UID of the progeny is recorded for granting access. Processes continue to be tracked and identified with the original trusted ID even though its operating system UID and effective user ID (EUID) may change without proper authorization. Invocation of a `setuid` root program to acquire root privileges or a root user issuing `su` to become another user are some examples of unauthorized (and possibly malicious) transitions.

For example, `sshd` runs as user root. When a user logs into a system using `sshd`, it forks off a child process, changes the UID of that process to the logged in user (say, `alice`), and then executes a process like `bash`. Because `sshd` is tagged with `|authenticator|`, CTE records the trusted user ID of the new process and of every process that it spawns with `alice`'s real UID. If `alice` tries to change its UID to root by running a `setuid` root program, it changes according to the operating system, but not according to CTE. From a policy evaluation standpoint, CTE still treats the `setuid`-escalated root process with user ID `alice`. If the GuardPoint policy prevents root accesses, CTE denies this root-escalated process from accessing the GuardPoint as an unauthorized operation. In this case, CTE terms the root user as a fake user and logs it as such.

By default, the CTE Agent does NOT trust any process as authenticated. Any attempt to access a resource by any process is therefore flagged with a `User Not Authenticated` notification. Therefore, the CTE Agent is to be instructed to trust the authenticator process progeny. For example, `/usr/sbin/sshd` is a process that can be trusted to authenticate the user to the system and to CTE.

CTE client settings are the means by which an administrator configures user authorization. Client settings are tags or keywords with pipe (|) delimiters specifying full-system binary paths to trusted programs (referred to as authenticators) on the CTE client. The subsequent sections describe the client settings tags, their properties and behavior, and the equivalent binaries and best practices.

Enabling CTE Client Settings for Authenticator Programs on the CipherTrust Manager

Client settings can be enabled for individual clients or client groups with the CipherTrust Manager GUI or REST API. On the CipherTrust Manager GUI, the Client Settings tab of clients is used to configure client settings.

Refer to [Client Settings](#) for details.

The client settings provided by the default installation are examples. It is recommended to *remove* all unnecessary client settings, as these may pose *security risks*.

Adding, Removing, or Modifying Client Settings

When client settings are modified, it is recommended to verify the updated settings after some time (a few minutes later). This can be done by running `secfsd -status auth`. Also, before applying the new client settings, the dependent applications, if any, should be *stopped*.

Description of Authenticators

authenticator

The `authenticator` keyword is used to specify the full path of the authenticator program authorizing the real UID of the process progeny. The real UID of the process and its descendants are used to set CTE's trusted UID. Therefore, CTE follows and authorizes the real UID of the user authenticator process and its descendants. In general, programs that use user name and password pairs (for example, `sshd` and `login`) are candidates for being authenticators.

Example of client settings:

```
|authenticator|/usr/sbin/sshd
|authenticator|/usr/sbin/in.rlogind
|authenticator|/bin/login
|authenticator|/usr/bin/gdm-binary
|authenticator|/usr/bin/kdm
```

Programs that do not authenticate users should not be tagged as authenticators. Examples of such programs include `su` invoking `setuid/seteuid` or `setgid/setegid` system calls. Tagging `/usr/bin/su` with the

authenticator keyword authorizes a root user to become a non-privileged user even without authentication. Therefore, `/usr/bin/su` should not be set as an authenticator.

`/usr/bin/su` can be set as an authenticator in cases where a root administrator legitimately uses `su` to temporarily switch privileges. This mode should be used *sparingly*.

authenticator_euid

The **authenticator_euid** keyword works similar to **authenticator**, but instead of the real UID, the CTE access control uses EUID for granting access. Specifically for Oracle, the database process (**oracle**) is started by the root process and then a **setuid** system call forces the service account user ID of either **oracle** or **orauser**. For such processes, CTE should rely on the EUID of the process for authentication.

The `|authenticator_euid|` keyword is applied as follows:

```
|authenticator_euid|/u01/app/oracle/dbhome_1/bin/oracle
|authenticator_euid|/u01/app/grid/bin/grid
```

Similarly, DB2's **db2start** application binary should have the **authenticator_euid** tag.

su_root_no_auth

The **su_root_no_auth** keyword is applicable only to the `/usr/bin/su` binary and should be deployed with the **sshd** authenticator:

```
|authenticator| /usr/bin/sshd
|su_root_no_auth| /usr/bin/su
```

With **su_root_no_auth**, a non-root user is permitted to log in as another user through `su`. The new user is authorized after authentication, that is, after providing the new user's password. However, root is prevented from being authorized as another user.

path_no_trust

The **path_no_trust** keyword instructs CTE to not trust, that is, not authorize a binary's process and its progeny. Therefore, users associated with these processes are unauthorized and flagged as such when accessing CTE GuardPoint data.

For example, `/usr/bin/ksh` is tagged as **path_no_trust** while `/usr/bin/su` is tagged as **authenticator**. A user who runs `/usr/bin/su` from this non-trusted `ksh` is unauthorized even though `/usr/bin/su` is a valid authenticator.

The **path_no_trust** keyword can be used to disallow selected executables from a large pool, for example, to trust all client binaries except three specific ones. This is achieved as follows:

```
|trust|*
|path_no_trust| /usr/bin/su
|path_no_trust| /usr/bin/ksh
|path_no_trust| /usr/bin/login
```

These client settings allow all client binaries to be trusted except `/usr/bin/su`, `/usr/bin/ksh`, and `/usr/`

`bin/login`.

It is important to note the `path_no_trust` authenticator overrides any previous authenticator tags placed on the same binary. For example, when tagging the `/usr/bin/su` binary, `path_no_trust` overrides any authenticator tags already set on `/usr/bin/su`.

The behavior described above is applicable to CTE 7.1.1 and higher versions. For older CTE versions, `|trust|*` overrides all other authenticator tags.

trust

The `trust` keyword is a carryover from older CTE versions and retained for legacy/backwards compatibility. The `|trust|*` authenticator allows users to be trusted regardless of the authentication method.

This mode, however, weakens against attacks by root users (that is, system administrators). Its use is *strongly discouraged*.

Conclusion

CTE access controls require correct specification of client setting authenticators for proper authorization. This document highlights various authenticators supported by CTE 7.1.1 and their use cases. Future releases of CTE will continue to expand access controls and authenticator capabilities.

Appendix 1: Deploying the Correct Authenticator

Here are the basic questions for determining what client setting authenticators to apply to the process.

- Does the process authenticate users, having them supplied credentials?

YES:

```
|authenticator|<path-to-binary>/<binary-name>
```

- Is the process started and run as a service account, specifically by the root account?

YES:

```
|authenticator_euid|<path-to-binary>/<binary-name>
```

- Does the process run with a specific user ID, and whether no other user IDs should be allowed?
-

YES:

```
|authenticator_euid|<path-to-binary>/<binary-name>
```

- Should root be prevented from becoming any other user to access data?

YES:

```
|authenticator|/usr/bin/sshd
|su_root_no_auth|/bin/su
```

- How do I use authenticator keywords with Java applications?

Java runtime binary file can be set as follows:

```
|authenticator_euid|<path-to-binary>/java
```

Contact [Thales Customer Support](#) for specifying arguments to Java programs.

Appendix 2: Related Non Authenticator Client Settings

protect

The `|protect|` keyword protects the system credential files from tracking and preventing malicious updates. Refer to the [CTE Agent Advanced Configuration and Integration](#) documentation for additional details on these client settings.

Appendix 3: Description of Common Audit Messages

User Not Authenticated

This message indicates CTE is unable to establish the user's authorization status due to incomplete information from authenticator application processes.

```
2021-04-07 03:46:06.728 [CGP] [ERROR] [5206] [CGP2602E] [ALARM] Policy[host-sett
ings-policy] User[root,uid=0,euid=0 (User Not Authenticated) (bash[pid=5058,ui
d=0,euid=0] : sshd[pid=5035,uid=0,euid=0]:sshd[pid=4991,uid=0,euid=0] : systemd[p
id=1,uid=0,euid=0]]) Process[/usr/bin/cat]Action[read_file]Res[/home/bob/gp/testf
ile]Key[None] Effect[PERMITTED Code (1A,2U,3M)]
```

Possible reasons include:

- The user logging in even before CTE started.
- A misconfigured authenticator client setting (possibly due to incorrect paths).

Therefore, a policy restricting specific user accesses to GuardPoints fails evaluation.

User Impersonation

```
2021-04-07 04:10:24.714 [CGP] [ERROR] [7865] [CGP2602E] [ALARM] Policy[host-sett
ings policy] User[root,uid=0,euid=1004,gid=0\\root\\ (faked as(bob,1004)) (bash[p
id=7819,uid=1004,euid=1004] : su[pid=7818,uid=0,euid=0] : bash[pid=7736,uid=0,eui
d=0] : sshd[pid=7724,uid=0,euid=0] : sshd[pid=7697,uid=0,euid=0]]) Process[/usr/b
in/cat] Action[read_file] Res[/home/bob/gp/testfile] Key[None] Effect[FAKED USE
R!! DENIED Code (1A,2U,3M)]
```

A user (in this case, root) logs in and is authorized by an authenticator application. A descendant process subsequently runs an unauthorized (non-client setting authenticator) `setuid` binary to change to another user named bob without authentication. Therefore, the process is still authorized as root and not bob. Therefore, bob is termed a fake user.

Cron

Cron is started by the `init` process during system boot. It runs as a root process, processes the `crontab` jobs, and runs the requests as the designated user. A root user could cause a cron entry to be run as any other user without that user being authenticated or authorized. Cron-based authentication is not supported.

Changing Client Password

Offline Password

CTE supports the offline password feature. This feature is designed to enable retrieval of the keys being used to protect data in a GuardPoint. When communication between the CipherTrust Manager and the CTE Agent are lost, the GuardPoint continues to encrypt/decrypt data with the current last known key and policy. However, if the communication is lost and the protected client is rebooted, the CTE Agent attempts to validate it using the latest keys and policies, but fails. Therefore, a password can be used by the isolated CTE Agent to retrieve the last known key and policy to enable the GuardPoint to continue with encryption/decryption operations. After the communication is re-established, any policy or key changes can be applied.

The offline password feature enables access to encryption keys that are stored locally on a client. This keeps the data secure when the CipherTrust Manager is inaccessible. To access the data, provide the offline password. Then, the CTE Agent encrypts/decrypts the guarded data according to the applied policy.

Password Types

The client password is initially set when the client is added to the CipherTrust Manager. Passwords can be set on a client-by-client or client group basis. The CipherTrust Manager supports two types of offline passwords:

- **Manual** (Static): A password is specified manually.
- **Generate** (Dynamic): A password is generated automatically by the CipherTrust Manager.

Changing the Password

You can change the password manually or dynamically. To change the password:

1. Open the **Transparent Encryption** application.

2. Click **Clients > Clients**. The list of available CTE clients is displayed.
3. Click the **Name** link of the desired client. The details page of the client is displayed.
4. Click the **Settings** tab.
5. Expand **SECURITY SETTINGS**.
6. Click the desired tab to view the instructions.

Change Password Manually

- a. In the **Password Creation Method** section, select **Manual**. The **Regenerate Password** button is replaced by **Change Password**.

- b. Click **Change Password**.
- c. Enter the new password in the **Password** and **Confirm Password** fields. The password must match in both the fields.

Note

The password must contain minimum eight characters including at least:

- One capital letter
- One number
- One of these special characters: ! @ # \$ % ^ & * () { } []

- d. Click **Update**.

When changing a static password or modifying a client to use a static password instead of a dynamic password, provide the new static password to the client users. Without the password, they cannot access encrypted data when there is no network connection between the client and the CipherTrust Manager.

The users can access the data stored in GuardPoints on the client by either running the `vmsec password` command or using the [challenge-response](#) method.

Change Password Dynamically

- a. In the **Password Creation Method** section, select **Generate**. This is the default method.
- b. Click **Regenerate Password**.

A new generated password is downloaded to the client.

Note

When modifying a client to use a dynamic password instead of a static password, inform the client users that challenge-response authentication is enabled and they need to run `vmsec challenge` on UNIX/Linux clients or select **Password...** on the Windows etray when the client cannot connect to the CipherTrust Manager.

Accessing GuardPoints in Offline Mode

This section is applicable to the CTE client administrators. This information is given here to show the end-to-end flow of the challenge-response process.

When the CipherTrust Manager is unreachable from a protected client, the data stored in GuardPoints on the client cannot be accessed without the challenge-response.

To access the GuardPoints in offline mode:

1. Log on to the offline CTE client.
2. Depending on your platform, do the following:
 - On UNIX/Linux, run the command, `vmsec challenge`.

```
vmsec challenge
Contact your CM administrator for assistance.
Your hostname is 10.164.14.207
Your challenge is: FHEH-ICPL-2MCZ-2AHI
Response (part 1) ->
```

- On Windows, select **Password...** on the Windows etray, then select **Challenge... > Response...**. The CipherTrust Transparent Encryption Challenge/Response dialog box is displayed, as shown below.

Your CipherTrust Manager administrator will need the hostname of your client and the challenge shown above in the command output (for Linux/AIX) and in the screenshot (for Windows).

3. Contact your CipherTrust Manager administrator.
4. Provide the challenge (for example, **FHEH-ICPL-2MCZ-2AHI**) to the administrator.

The CipherTrust Manager administrator generates responses in four parts on the CipherTrust Manager. Refer to [Generating Response for a Challenge](#) for details. Contact the CipherTrust Manager administrator for the response codes.

5. Enter the response (part 1 through 4) on the `vmsec challenge` command prompt (on Linux/AIX) or on the CipherTrust Transparent Encryption Challenge/Response dialog box (on Windows). The responses must be entered in the given order. For example:

```
Response (part 1) -> STYB-JAZE-C2PB-6FLU
Response (part 2) -> F7ME-R3MG-BQB5-5MXB
Response (part 3) -> QN26-0A6F-5ZKA-T5LG
Response (part 4) -> BI4Y-53AI-30XZ-N2EC
Success!
```

The client users can now access protected GuardPoints on the client.

Generating Response for a Challenge

To generate a response for a challenge:

1. Log on to the **CipherTrust Manager** GUI.

-
2. Open the **Transparent Encryption** application.
 3. Click **Clients > Clients**.
 4. Click the desired client.
 5. Click the **Challenge Response** tab.
 6. In the **Challenge From the Client** box, enter the challenge provided by the client administrator.
 7. Click **Submit**.

A set of four responses (part 1 through 4) for the provided challenge is shown on the GUI. Provide those to the client administrator.

Managing Membership

View and manage the client group memberships of a client on the Membership tab. The Membership tab is divided into CLIENT GROUPS and LDT COMMUNICATION GROUP sections. The CLIENT GROUPS section provides an option to remove the client from individual or multiple client groups. The LDT COMMUNICATION GROUP section provides an option to add or change the LDT communication group membership for the client.

Viewing Group Membership of a Client

To view the client groups of a client:

1. Open the **Transparent Encryption** application.
2. Click **Clients > Clients**.
3. Under **Client Name**, click the desired client.
4. Click the **Membership** tab.
5. Expand the **CLIENT GROUPS** section. The section shows the client groups the client is a member of.

Removing a Client

As part of the CipherTrust Manager maintenance, you occasionally need to remove a client from its client groups. The CipherTrust Manager provides options to remove a client from individual client groups or from multiple client groups in one go.

To remove the client:

1. Open the **Transparent Encryption** application.
2. Click **Clients > Clients**.
3. Under **Client Name**, click the desired client.
4. Click the **Membership** tab.
5. Expand the **CLIENT GROUPS** section, if needed.

CLIENT GROUPS

Search

☐ 0 Selected 1 Result | 1 Client Group

Client Group Name		
☐	A1	...

6. Click the desired tab to view instructions.

From a Single Client Group

- Under **Client Group Name**, select the group from which you want to remove the client.
- Click the delete icon ().

Alternatively, click the overflow icon () corresponding to the desired client group, and click **Remove**. A dialog box appears prompting to confirm the action. Click **Remove** to remove the client.

- Click **Delete**.

The client is removed from the selected client group. Also, the client group is removed from the CLIENT GROUPS section of the client's Membership tab.

From Multiple Client Groups

- Under **Client Group Name**, select the groups from which you want to remove the client.

To select all client groups visible on the page, select the top check box to the left of the Client Group Name heading.

- Click the delete icon ().

A dialog box appears prompting to confirm the action.

- Click **Delete**.

The client is removed from the selected client groups. Also, the client groups are removed from the CLIENT

GROUPS section of the client's Membership tab.

Viewing LDT Communication Group Membership of a Client

To view the LDT communication group of a client:

1. Open the **Transparent Encryption** application.
2. Click **Clients > Clients**.
3. Under **Client Name**, click the desired client.
4. Click the **Membership** tab.
5. Expand the **LDT COMMUNICATION GROUP** section. The LDT Communication Group drop-down list shows the LDT communication group the client is a member of.

Update

Adding or Changing LDT Communication Group Membership of a Client

Clients can be added to an LDT communication group when creating or updating the group. You can also add or change the LDT membership of a client on the Membership tab. A client can be added to only one LDT communication group at a time.

The Windows clients that have the **LDT Access Only** check box selected cannot be added to the LDT communication group.

To add or change the LDT communication group of a client:

1. Open the **Transparent Encryption** application.

-
2. Click **Clients > Clients**.
 3. Under **Client Name**, click the desired client.
 4. Click the **Membership** tab.
 5. Expand the **LDT COMMUNICATION GROUP** section, if needed.
 6. Select the desired **LDT Communication Group** from the drop-down list.
 7. Click **Update**.

The selected LDT communication group is linked with the client.

Removing LDT Communication Group Membership of a Client

To remove the LDT communication group membership of a client:

1. Open the **Transparent Encryption** application.
2. Click **Clients > Clients**.
3. Under **Client Name**, click the desired client.
4. Click the **Membership** tab.
5. Expand the **LDT COMMUNICATION GROUP** section, if needed.
6. Click the remove icon () next to the LDT Communication Group drop-down list.

The LDT communication group membership is removed from the client.

Deleting Clients

Only CipherTrust Manager administrators can delete clients. When a client is deleted from the CipherTrust Manager, the client moves to the [Expunged state](#) and the CTE Agent is notified to drop client configuration. The CTE Agent installations on the client continue to run, complete with the applied policies. To completely remove a CTE Agent from the client, uninstall the Agent from the client system.

When Agent uninstallation is initiated, the client record is deleted from the CipherTrust Manager. The CipherTrust Manager pushes the configuration change to the CTE Agent running on that client. As a result, the following occur on the client:

- CTE Agent certificates are deleted.
- The URL line is removed from the `agent.conf` file.
- The GuardPoints are removed.
- The client is no longer recognized by the CipherTrust Manager. If the CTE Agent tries to communicate with the CipherTrust Manager, the connection is refused.

Deleting Clients with System Lock or Agent Lock

Do not unregister or delete the CTE client while locks are applied. The locks remain effective after the client is unregistered. Without client credentials, the CipherTrust Manager cannot administer that CTE Agent and cannot disable the locks. You must boot the client in single-user mode and manually modify the Agent configuration to disable the locks.

To remove everything associated with a client (including the CTE Agent):

1. Apply a rekey policy and run `dataxform` on the client to decrypt encrypted files.
2. Disable the locks on the client. Refer to [Disabling Locks](#).
3. Remove all the GuardPoints from the client.
4. Click **Clients > Clients**.
5. Under **Client Name**, click the overflow icon () corresponding to the desired client.
6. Click **Delete**. A dialog box appears prompting to confirm the action.
7. Click **Delete**.

The client administrator with root permissions must log on to the client system and uninstall the CTE Agent.

Refer to [Deleting Clients](#) for more information on deleting clients from the CipherTrust Manager.

Deleted Client Indicators

A client is successfully deleted from the CipherTrust Manager GUI if:

- CipherTrust Manager URL is deleted from the CTE Agent `agent.conf` file.
- Certificates are removed from the `./agent/pem` directory.

However, if the client is deleted and its identity is changed while it is *offline*:

- The GuardPoints are not removed
- The certificates remain intact in the `./agent/pem` directory
- The `agent.conf` file remains unchanged
- But the Agent and CipherTrust Manager still cannot communicate with each other.

Logging for the CTE Agent on the CipherTrust Manager is also affected if an offline client is deleted. When the client comes online, log messages about the denied connection can be viewed only by CipherTrust Manager administrators of type System or All (when not in a domain). This is because the CipherTrust Manager:

- No longer has the client's record.
- Does not know which domain and the group the client belongs to.

- Cannot send messages to the appropriate log service.

Kernel Compatibility Matrix

A registered CTE Linux client should be running a compatible kernel. Refer to the latest [Compatibility Matrix](#) for the list of supported kernels.

You can also upload the latest Compatibility Matrix (a .tgz file) to the CipherTrust Manager so it automatically matches the kernels running on the registered clients. If a client is running an incompatible kernel, its status becomes Warning on the GUI.

Note

After upgrading CipherTrust Manager to version 2.21 or later, the **Uploaded File Creation Date (Local Timezone)** label incorrectly displays the upload time of the previously uploaded compatibility matrix, instead of its creation time.

When you reupload the old or new compatibility matrix, the original creation time is shown.

Uploading Compatibility Matrix

To upload the Compatibility Matrix:

1. Download the latest [Compatibility Matrix](#) file.
2. Open the **Transparent Encryption** application.
3. Click **Clients > Clients**.
4. Click **Compatibility Matrix**. The Compatibility Matrix dialog box is displayed.

Compatibility Matrix

The CipherTrust Manager uses the compatibility matrix to display warning for the clients running unsupported kernels.

Upload Compatibility Matrix

Browse

5. Click **Browse** to locate and select the Compatibility Matrix file.
6. Click **Save**.

After the matrix is uploaded, the CipherTrust Manager starts matching the kernels running on the registered

clients. Depending on the number of registered clients, the Status may take some time to update.

Note

When you upload a compatibility matrix to a domain, it will automatically be inherited by any subdomains that don't have their matrix. This inheritance continues down the hierarchy from domain to subdomain to sub-subdomain, and so on until a domain with its matrix is found.

If a domain doesn't have a compatibility matrix, it will inherit the compatibility matrix of its nearest ancestor. For example, if a domain is a sub-subdomain, it will inherit the compatibility matrix of the subdomain, not the domain.

Replacing the Compatibility Matrix

Whenever a new version of the Compatibility Matrix is available, you can replace the existing matrix with the new one. The Compatibility Matrix dialog box shows details of the currently uploaded matrix, with the uploaded file creation date (local timezone).

To replace the matrix:

1. Download the latest [Compatibility Matrix](#) file.
2. Open the **Transparent Encryption** application.
3. Click **Clients > Clients**.
4. Click **Compatibility Matrix**. The Compatibility Matrix dialog box is displayed.
5. Under REPLACE/UPLOAD NEW FILE, click **Browse** to locate the latest Compatibility Matrix file.
6. Click **Save**.

The old Compatibility Matrix is now replaced with the latest version. The CipherTrust Manager now starts matching the kernels running on the registered clients with those in the new matrix. Depending on the number of registered clients, the Status may take some time to update.

Downloading the Compatibility Matrix

Whenever needed, you can download the Compatibility Matrix uploaded to the CipherTrust Manager.

To download the matrix from the CipherTrust Manager:

1. Open the **Transparent Encryption** application.
2. Click **Clients > Clients**.
3. Click **Compatibility Matrix**. The Compatibility Matrix dialog box is displayed.
4. Under EXISTING FILE DETAILS, click the Overflow Icon (), and click **Download**.

The uploaded Compatibility Matrix is now downloaded to your local machine.

Removing the Compatibility Matrix

Whenever needed, you can remove the Compatibility Matrix uploaded to the CipherTrust Manager.

To remove the matrix from the CipherTrust Manager:

1. Open the **Transparent Encryption** application.
2. Click **Clients > Clients**.
3. Click **Compatibility Matrix**. The Compatibility Matrix dialog box is displayed.
4. Under EXISTING FILE DETAILS, click the Overflow Icon (), and click **Remove**.

The Compatibility Matrix is now removed. The CipherTrust Manager no longer matches the kernels running on the registered clients.

Collecting Agent Information

A CTE Agent provides the **agentinfo** utility to collect system and CTE configuration data. The **agentinfo** utility takes a configuration snapshot of the system that you can send to Thales Customer Support to debug an issue.

The latest information about individual CTE Agents can also be collected and downloaded on the CipherTrust Manager GUI. The collected information about all the CTE Agents is stored in a dedicated volume on the CipherTrust Manager. An option is provided to clean the Agent information about all the CTE Agents from the volume.

Collecting the CTE Agent Information

To collect the latest CTE Agent information:

1. Open the **Transparent Encryption** application.
2. Click **Clients > Clients**. The list of available CTE clients is displayed.
3. Click the **Name** link of the desired client. The details page of the client is displayed.
4. Click the **Settings** tab.
5. Expand **GENERAL SETTINGS**.
6. Click **Collect Agent Information**. A request is sent to the CTE Agent to send the latest Agent information to the CipherTrust Manager.

Note

If the connection between CM and Agent is not established, the agent information will not be available for the client.

Fetching the latest Agent information from the CTE Agent might take some time. You need to *refresh* the page to download the latest Agent information. As soon as the information is available, the **Collect Agent Information** link is replaced with the **Recollect Agent Information** and **Download Agent Information** links.

Recollecting the CTE Agent Information

After you have fetched the CTE Agent information from the CTE client, a CTE Client Administrator might make some confirmation changes. To get the updated CTE Agent configuration on the CipherTrust Manager, use the Recollect option.

To recollect the updated CTE Agent information:

1. Open the **Transparent Encryption** application.
2. Click **Clients > Clients**. The list of available CTE clients is displayed.
3. Click the **Name** link of the desired client. The details page of the client is displayed.
4. Click the **Settings** tab.
5. Expand **GENERAL SETTINGS**.
6. Click **Recollect Agent Information**. A request is sent to the CTE Agent to send the updated Agent information to the CipherTrust Manager.

Fetching the latest Agent information from the CTE Agent might take some time. The **Recollect Agent Information** and **Download Agent Information** links are replaced with **Collect Agent Information**. You need to *refresh* the page to download the latest Agent information. As soon as the information is available, the **Collect Agent Information** link is replaced with the **Recollect Agent Information** and **Download Agent Information** links.

Downloading the CTE Agent Information

After you have fetched the Agent information from a CTE client, you can download this information from the CipherTrust Manager GUI. The information is downloaded in a tar file.

After the download, the Agent information is removed from the CipherTrust Manager.

In a CipherTrust Manager cluster, the information will be downloaded from the node where the Agent information is requested.

To download the CTE Agent information:

1. Open the **Transparent Encryption** application.

2. Click **Clients > Clients**. The list of available CTE clients is displayed.
3. Click the **Name** link of the desired client. The details page of the client is displayed.
4. Click the **Settings** tab.
5. Expand **GENERAL SETTINGS**.
6. Click **Download Agent Information**.

The CTE Agent information currently available on the CipherTrust Manager is downloaded in a tar file, and removed from the CipherTrust Manager. The **Recollect Agent Information** and **Download Agent Information** links are again replaced with **Collect Agent Information**.

Cleaning the CTE Agent Information Volume

When you fetch the CTE Agent information from a CTE Agent, this information is stored in a file in a dedicated volume on the CipherTrust Manager. This volume contains information about all the CTE Agents from which you have collected the information.

The CipherTrust Manager provides an option to [clean the Agent information volume any time](#) to remove all the files containing the Agent information from the CipherTrust Manager. Also, when the [volume is 80% full](#), you are prompted to clean it while collecting the latest Agent information from clients.

Clean the Volume Any Time

To clean the volume containing the CTE Agent information:

1. Log on to the **CipherTrust Manager** GUI.
2. Open the **Transparent Encryption** application.
3. Navigate to **Settings > Client Information and Capabilities**.
4. Under **Empty CTE Agent Information Log Volume**, click **Remove Agent Information**. A warning message is displayed.

Warning

The Agent information currently available on the CipherTrust Manager will be removed. You will have to regenerate the Agent information.

5. Select **Yes, clean up the entire volume containing the Agent information**.
6. Click **Clean**.

Clean the Volume When 80% Full

When the volume containing the Agent information is 80% full, a warning message is displayed while collecting the Agent information from a client. You need to clean the volume to collect the latest information.

To clean the volume, click **Clear Volume**. All the files containing the Agent information are removed from the volume. You can now retry collecting the latest Agent information.

Fetching Latest Capabilities from Clients

Note

This feature will be available from CTE 7.5.0.

CipherTrust Manager 2.14 and Lower

When a CTE Agent supports a capability but the CipherTrust Manager with which the Agent is registered doesn't, the CipherTrust Manager ignores the unsupported capability. After the CipherTrust Manager is upgraded to 2.14 or a lower version, the CipherTrust Manager requires the CTE Agent restart to fetch the latest capabilities from the client.

CipherTrust Manager 2.15 and Higher

When a CTE Agent supports a capability but the CipherTrust Manager with which the Agent is registered doesn't, the CipherTrust Manager ignores the unsupported capability. After the CipherTrust Manager is upgraded, the CipherTrust Manager administrator can fetch the latest capabilities from all the active clients present in the current domain without requiring the Agent restart.

Note

When a CipherTrust Manager that doesn't support the CTE Confidential Computing (CC) capability is upgraded to a version that supports the capability, you must unenroll and re-register any CC-capable CTE Agents already registered with the CipherTrust Manager to use CC.

To fetch the latest capabilities from active clients of the current domain:

1. Log on to the **CipherTrust Manager** GUI.
2. Switch to the desired domain.
3. Open the **Transparent Encryption** application.
4. Navigate to **Settings > Client Information and Capabilities**.
5. Under **Request Capabilities from All Clients**, click **Get Capability**.

A confirmation message appears stating that this is a time intensive operation and would run in the

background. This process may take a few minutes to complete depending on the number of active clients in the current domain. The active CTE clients will continue working with no impact. Do you want to continue?

6. Click **Get Capability**.

The latest capabilities are fetched from all the active CTE clients present in the current domain. Update Client Capability audit records are generated on the CipherTrust Manager. Review the records on the Server Records tab of the Loki Audit Records page (**Records > Loki Audit Records**).

Note

When a request to fetch the latest client capabilities is in progress, triggering the operation again will lead to an error message.

Managing LDT Communication Groups

An LDT communication group contains a group of LDT-enabled CTE clients that can communicate with each other. An LDT communication group is mandatory when using a multi-node solution for LDT over NFS/CIFS. The CipherTrust Manager pushes the LDT communication group details to all clients in the group.

Note

- The LDT communication groups are applicable to the LDT-enabled CTE clients.
- A client can be added to only one LDT communication group at a time.
- For successful communication among clients in an LDT communication group, make sure that clients are registered with the CipherTrust Manager using their hostnames or IP addresses.

Warning

All the clients guarding a common share must be part of the same LDT communication group, otherwise, data may be corrupted. If you need to change the LDT communication group of a client, ensure that the client no longer guards the common share.

For example, if 10 clients will be guarding a common share, add all of them to the same LDT communication group only. To change the LDT communication group of one of these clients, ensure that the client no longer guards the share. However, to change the LDT communication group of all 10 clients, it is recommended to take the GuardPoint offline, change the LDT communication group, and reapply the GuardPoint.

Creating an LDT Communication Group

To create an LDT communication group:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Clients > LDT Communication Groups**.
3. Click **Create LDT Communication Group**. The Create LDT Communication Group wizard is displayed.
4. On the General Info screen:
 - a. Specify a **Name** for the LDT communication group. The name must start with a letter or number and can only have alphanumeric characters, periods (.), underscores (_), pipes (|), and hyphens (-).
 - b. Provide a **Description** for the LDT communication group.
 - c. Click **Next**.
5. On the Add Clients screen:
 - a. Select the clients to be added to the LDT communication group. Use the Client Name filter to search for the desired clients. Only the clients that are not part of an LDT communication group are displayed. Also, the Windows clients that have the **LDT Access Only** check box selected cannot be added to the LDT communication group.

To select all clients visible on the page, select the top check box to the left of the Client Name heading.
 - b. Click **Next**. The Confirmation screen is displayed.
6. Verify the group details.

If the details are incorrect or you want to modify them, click Back and update the details.
7. Click **Create**. The LDT communication group is created and displayed in the LDT communication groups list.

An association is created between the CTE clients that you selected for the group and the LDT communication group. The LDT communication group is listed under the LDT COMMUNICATION GROUP section on the Membership tab of the client.

Viewing LDT Communication Groups

To view an LDT communication group:

1. Open the **Transparent Encryption** application.
2. Click **Clients > LDT Communication Groups**. A list of existing LDT communication groups appears. The LDT Communication Groups page displays the following details:

Field	Description
Status	Status of the LDT communication group. Can be Healthy or Unhealthy.
Name	Alias of the LDT communication group. A unique, user-friendly name that helps in searching for specific LDT communication groups.
Created At	The time when the LDT communication group was created.
Updated At	The time when the LDT communication group was last updated.
Description	A brief explanation of the LDT communication group.

Editing an LDT Communication Group

After an LDT communication group is created, you can modify its description. The name of the group cannot be modified.

To edit an existing LDT communication group:

1. Open the **Transparent Encryption** application.
2. Click **Clients > LDT Communication Groups**. The list of existing LDT communication groups is displayed.
3. Under **Name**, click the overflow icon () corresponding to the desired LDT communication group.
4. Click **Edit**.
5. Change the **Description** of the group.
6. Click **Update**.

The LDT communication group description is updated.

Viewing Group Status Reports

To view a group status report:

1. Open the **Transparent Encryption** application.
2. Click **Clients > LDT Communication Groups**. A list of existing LDT communication groups appears.
3. Under **Name**, click the overflow icon () for the desired LDT communication group.
4. Select **View Group Status Report**. The Group Status Report wizard opens.

The report shows the status of the LDT communication service on the master and replica nodes.

Adding Clients to an LDT Communication Group

You can add clients to an LDT communication group during or after the group creation. A client can be added to only one LDT communication group at a time.

To add clients to an existing LDT communication group:

1. Open the **Transparent Encryption** application.
2. Click **Clients > LDT Communication Groups**. The list of existing LDT communication groups is displayed.
3. Under **Name**, click the desired LDT communication group. The Member Clients list shows the list of clients in the group.
4. Click **Add Clients**. The Add Clients dialog box is displayed.
5. Select the clients to be added to the LDT communication group. Use the Client Name filter to search for the desired clients. Only the clients that are not part of an LDT communication group are displayed. Also, the Windows clients that have the **LDT Access Only** check box selected cannot be added to the LDT communication group.

If no client exists, you can create one by clicking **Create Client**. Refer to [Adding Clients Manually](#) for details.

To select all clients visible on the page, select the top check box to the left of the Client Name heading.

6. Click **Save**.

The selected clients are added to the LDT communication group and are displayed in the Member Clients list.

Note

Client association with the LDT communication group is restricted based on the operating system of the clients. An LDT communication group can associate with only a single type of operating system, it can be Windows or Linux.

If an existing LDT communication group has clients running different operating systems, move clients running different operating systems to different LDT groups. For example, if the existing group has two clients, WinClient and LinxClient, running Windows and Linux respectively, then, it is recommended to move WinClient to an LDT communication group of Windows clients. Similarly, move the LinxClient to an LDT communication group of Linux clients.

Removing Clients from an LDT Communication Group

If needed, you can remove LDT clients from an LDT communication group. However, if a client associated with an LDT communication group contains an active LDT over NFS/SMB GuardPoint, **do not** remove the client from the LDT communication group directly.

Note

To remove a client from an LDT communication group gracefully:

1. Disable or unguard the LDT over NFS/SMB GuardPoint on the client. Refer to [Disabling GuardPoints](#) and [Removing GuardPoints](#) for details.
2. Remove the client from the LDT communication group, as described below.

To remove clients from an existing LDT communication group:

1. Open the **Transparent Encryption** application.
2. Click **Clients > LDT Communication Groups**. The list of existing LDT communication groups is displayed.
3. Under **Name**, click the desired LDT communication group. The Member Clients list shows the list of clients in the group.
4. Click the overflow icon () corresponding to the client you want to remove from the group.
5. Click **Remove**. Removal of a client is permanent and cannot be undone.
6. Click **Remove** to confirm the action.

The client is removed from the LDT communication group.

Deleting an LDT Communication Group

To delete an LDT communication group:

1. Open the **CipherTrust Transparent Encryption** application.
2. In the left pane, click **Clients > LDT Communication Groups**. The list of existing LDT communication groups is displayed.
3. Under **Name**, click the overflow icon () corresponding to the desired LDT communication group.
4. Click **Delete**. Deletion of an LDT communication group is permanent and cannot be undone.
5. Click **Delete** to confirm the action.

The LDT communication group is deleted.

Managing Client Groups

A client group is used to group one or more clients to simplify configuration and administration. GuardPoints created on a client group are applied to all members of the group. Additionally, you can apply client group configuration settings to all clients in a client group. A client can be a member of multiple client groups.

CTE supports two types of client groups, clustered and non-clustered. A clustered client group contains clients that are members of a cluster with a cluster file system. A non-clustered client group contains members that are not members of a cluster. A client can be a member of multiple client groups. However, membership in a cluster group is exclusive, so a client that belongs to a cluster, cannot join another cluster group or client group.

If you have created a group of one type of clients, then you should only add similar clients to the group. Same configuration settings can only be applied to clients of the type with which the client group is created. If a different type of client is added, configuration settings cannot be applied to that client.

Creating a Client Group

To create a client group:

1. Open the **Transparent Encryption** application.
2. Click **Clients > Client Groups**.
3. Click **Create Client Group**. The General Info screen of the Create Client Group wizard is displayed.

Add General Info

On the **General Info** screen:

1. Specify a unique **Name** for the client group.
2. Select the **Cluster Type**. The options are:
 - **NON CLUSTER**: Create a non-clustered client group.
 - **HDFS**: Create a clustered client group. An HDFS client group is required to apply GuardPoints on CTE clients in an HDFS cluster.
3. Set the **Password Generation Method**. The options are:
 - **Generate**: A password is generated automatically by CipherTrust Manager. This is the default method.
 - **Manual**: Set the password manually.
 - a. Select **Manual**.
 - b. Enter the new password in the **Password** and **Confirm Password** fields. The password must match in both fields.

Note

The password must contain minimum eight characters including at least:

- One capital letter

- One number
- One of these special characters: ! @ # \$ % ^ & * () { } []

Refer to [Changing Client Group Password](#) for details.

4. Select **NON CLUSTER** as the **Cluster Type**. CTE UserSpace does not support HDFS client groups.
5. (Optional, if a profile already exists) From the **Client Profile** drop-down list, select the desired client profile. The default profile is **DefaultClientProfile**.

If the **DefaultClientProfile** does not exist, it is created as soon as the first client group is created.

6. (Optional) Provide **Description** to identify the client group. The maximum length can be 256 characters.

Name: *

Password Creation Method: *

Cluster Type: *

Client Profile:

Description:

Communication Enabled: ☒

7. (Optional) Specify whether to enable the client's communication with the CipherTrust Manager. Select **Communication Enabled** to enable, clear to disable communication. By default, the communication is disabled.
8. Click **Next**. The Add Clients screen is displayed.

Add Clients (Optional)

Optionally, you can add clients to the group. The Add Clients screen shows the list of clients added to the CipherTrust Manager.

On the **Add Clients** screen:

1. Select the clients to be added to the group. Filter the clients by using the Client Name text box.

If no client exists, you can add one by clicking **Create Client**. Refer to the [Adding Clients Manually](#). The newly created client is added to the clients list.

2. Click **Next**. A dialog box is displayed asking you to confirm inheritance settings.
3. Confirm whether the selected clients should inherit settings from the client group. The options are:
 - **Inherit Client Group Settings:** This is the default and recommended option. Clients inherit the following properties of the group except the password:
 - Client Settings
 - Agent Lock
 - System Lock
 - Communication Enabled
 - Profile Settings
 - QoS Settings
 - GuardPoints

Refer to [Inheritance of Client Group Settings](#) for details.

- **Do not Inherit Client Group Settings:** Clients retain their individual settings. Selecting this option can introduce configuration conflicts. *This is not the recommended option.* Read the instructions carefully before selecting this option.

Note

When a client is added to a client group, the password generation method of the client remains unchanged. However, when the client group's password or password generation method is updated in the future, this change is applied to all the clients in the client group. This is true irrespective of whether the clients inherit settings from the client group or not.

4. Click **OK**. The Add GuardPoint screen is displayed.

Add GuardPoints (Optional)

Optionally, you can create GuardPoints on the manually added client. CTE supports creation of all types of supported GuardPoints on such clients.

On the **Add GuardPoint** screen:

1. Click **Create GuardPoint**. The Add GuardPoints > Create GuardPoints screen is displayed.
2. Select a **Policy**. The Select Policy dialog box displays the available policies.
3. Select the desired policy.

If no policy exists, you can create one by clicking **Create Policy**. Refer to **Creating Policies > Creating Policies** for details.

4. Click **Select**. The selected policy appears in the Policy field.
5. Specify the **Type** of the GuardPoint. Refer to **Automatic and Manual GuardPoints** for details on types of GuardPoints.
6. (COS GuardPoints only) Select the **Cloud Storage Type**. CTE UserSpace does not support COS GuardPoints.
7. Specify the **Path** (or **URL** for a COS GuardPoint) to be protected. Refer to **Managing GuardPoints** for details.
8. Configure **Preserve Sparse Region**, **Secure Start**, and/or **Auto Mount** as appropriate. The options vary based on the selected policy.

The Multifactor Authentication option is unavailable for manually added clients.

9. Click **Create**. The newly created GuardPoint appears in the list.

To remove a GuardPoint, click **Remove** corresponding to it.

10. Click **Next**. The Confirmation screen is displayed.

Confirmation

On the **Confirmation** screen:

1. Verify the client group details. The Confirmation screen displays general information about the client group, the list of clients in it, and details of the GuardPoints added to the group.

If the details are incorrect or you want to modify them, click **Back** and update the details.

2. Click **Create**.

The newly created client group appears in the client groups list.

Adding Clients to a Client Group

Clients can be added to a client group either manually or by specifying the group when registering clients with the CipherTrust Manager. If you specify a client group during client registration, the client automatically appears under the client group on the CipherTrust Manager GUI. Refer to the [CTE Agent Clients Guide](#) for information on the registration process.

When protecting an HDFS cluster, the CTE clients with the HDFS configuration must be added to an HDFS client group on the CipherTrust Manager.

To manually add clients to a client group:

1. Open the **Transparent Encryption** application.
2. Click **Clients > Client Groups**.
3. Under **Client Group Name**, click the expand icon () to the left of the desired client group.

Note

Select an HDFS client group if the CTE client to be added is in an HDFS cluster.

Alternatively, click the desired client group and click the **Membership** tab.

4. Click **Add Client**. The Add Client to Client Group <ClientGroupName> dialog box is displayed with the list of available clients, if any. At least, one client must already exist.

Add Client to Client Group A1

Search					
☐ 1 Selected 7 Results 7 Clients					
	Status	Name	Client Type	OS Type	Description
☐	 Healthy	P_1	CTE-U	LINUX	TestHost
☒	 Healthy	P_10	FS	LINUX	TestHost
☐	 Healthy	P_11	FS	LINUX	TestHost

5. Select the desired clients.
6. Click **Add**. A dialog box is displayed asking you to confirm settings inheritance.

7. Confirm whether the selected clients should inherit settings from the client group. The options are:

- **Inherit Client Group Settings:** This is the default and recommended option. Clients inherit the following properties of the group except the password:
 - Client Settings
 - Agent Lock
 - System Lock
 - Communication Enabled
 - Profile Settings
 - QoS Settings
 - GuardPoints

Refer to [Inheritance of Client Group Settings](#) for details.

- **Do not Inherit Client Group Settings:** Clients retain their individual settings. Selecting this option can introduce configuration conflicts. *This is not the recommended option.* Read the instructions carefully before selecting this option.

Note

When a client is added to a client group, the password generation method of the client remains unchanged. However, when the client group's password or password generation method is updated in the future, this change is applied to all the clients in the client group. This is true irrespective of whether the clients inherit settings from the client group or not.

8. Click **OK**.

The selected clients are added to the group. They are displayed in the mini view and on the Membership tab of the client.

Displaying Client Groups

To view the list of client groups:

1. Open the **Transparent Encryption** application.
2. Click **Clients > Client Groups**. The list of available client groups is displayed.

Client Group Name	Created At	Cluster Type	Description	Sharing	Native Domain
☐ A1	09 Sep 2021, 16:20	NON-CLUSTER	A test client group	-	root
☐ A10	09 Sep 2021, 16:21	HDFS	A test client group	-	root
☐ A11	09 Sep 2021, 16:22	NON-CLUSTER	A test client group	-	root

The client groups list shows the following details:

Column	Description
Client Group Name	Name link of the client group on CipherTrust Manager. Click the link to open client group details in edit mode. The edit mode shows additional details and configuration settings. In the edit mode, you can also view and add clients, GuardPoints, and Client Group Settings.
Created At	When the client group is created.
Cluster Type	Cluster type of the client group. • NON CLUSTER: A non-clustered client group. • HDFS: A clustered client group.
Description	(Optional) Description to identify the client group.
Sharing	Sharing status of the client group. • External: The client group is external to the current domain. The client group is created and shared from another domain. • Shared: The client group is shared across other domains. The current domain is the native domain of the client group. • -: The client group is neither Shared nor External. The field is left blank for client groups that were created on a previous version of the CipherTrust Manager. Such client groups can also be shared across domains. Refer to Sharing a Client Group Across Domains for details.
Native Domain	Name of the native domain of the client group. If the

Column	Description
	client group is not external, the current domain is the native domain of the client group.

Modifying Client Groups

After you have created a client group, you can update group details and configuration settings. You can make the following changes:

- Enable or disable Agent communication for the clients in the group
- Lock or unlock the CTE Agent files on the clients in the group
- Change the CTE Agent password for the clients in the group
- Change the linked profile
- Add new clients to the group
- Remove clients from the group
- Enable the LDT Passive Mode
- Share the group across domains
- Remove the group sharing from a domain

The cluster type of a client group cannot be modified after it is created.

To modify a client group:

1. Open the **Transparent Encryption** application.
2. Click **Clients > Client Groups**.
3. Under **Client Group Name**, click the expand icon () to the left of the desired client group.

4. Modify the required details:
 - **Unlock:** Unlock Agent Lock and System Lock.
 - **Agent Lock:** Lock the contents of the CTE Agent directories on the clients.
 - **System Lock:** Apply an internal policy to the clients to lock system directories like `/var`, `/bin`, and `/etc`. Enabling System Lock automatically enables Agent Lock.

- **Communication Enabled:** Whether to enable clients' communication with the CipherTrust Manager. Select to enable, clear to disable communication.
- **Live Data Transformation:** Initiates the suspend/resume rekey operation on LDT protected GuardPoints on LDT clients in the group. By default, the rekey operation is initiated. However, to get the actual state of the rekey operation, check the status on individual clients.
 - To suspend the LDT rekey operations, click the **Suspend Live Data Transformation** icon (⏸). The icon changes to **Resume Live Data Transformation** (▶).
 - To resume the LDT rekey operations, click the **Resume Live Data Transformation** (▶) icon. The icon changes to **Suspend Live Data Transformation** icon (⏸).

Note

When ⏸ or ▶ is clicked, an error is generated on non-LDT clients in the client group. To view the error details, go to **Records > Server Records** on the CipherTrust Manager GUI.

- **LDT Passive Mode:** By default, LDT Passive Mode is disabled. After you enable it, you can't disable it.
- **Password Creation Method:** Set the password creation method — **Generate** or **Manual**. Refer to [Changing Client Group Password](#) for details.
- **Client Profile:** Select a profile for the client group. The default profile is **DefaultClientProfile**. To change the client profile, refer to [Changing the Profile](#) for details.

5. Click **Apply**.

Additionally, you can define GuardPoints for the clients in the group. Refer to [Managing GuardPoints](#).

Managing Designated Primary Set

A Designated Primary Set (DPS) is used to create a group of clients from which you can select a primary client to perform key rotation and versioning.

Adding Designated Primary Set to a Client Group

Before creating a Designated Primary Set:

- Ensure that a CIFS connection is configured.
- Ensure that clients that you want to add are part of the LDT Communication Group and Client Group. See [Managing LDT Communication Groups](#) to create an LDT Communication Group clients.

Note

- Modifications made to the Designated Primary Set list will not be updated to the clients that are associated with a Client Group for which inheritance is disabled. See [Inheritance of Client Group Settings](#) for more details on Client Group inheritance.
- The clients associated with the Designated Primary Set must inherit properties from the client group. This ensures that any changes made to the Designated Primary Set are pushed to the associated clients.
- A Designated Primary Set (DPS) is fully enforced when all members of the client group are DPS-capable (that is, running CTE Agent 7.7.0 or higher). If a client group with DPS enabled has non-DPS capable members, the GuardPoints will not be pushed to those members.

To create a Designated Primary Set:

1. Click **Clients > Client Groups**.
2. Click the desired client group name.
3. Select the **Designated Primary Set** tab.

It shows the list of Designated Primary Sets. Expand the desired Designated Primary Set to see its details.

4. Click **Create Designated Primary Set**.
5. In the **General Info** screen, provide a name for the Designated Primary Set and select an LDT Communication Group.
6. Click **Next**.
7. In the **Add Clients** screen, select the clients for the primary set.

Use the search box to search for a particular client.

Note

- A Designated Primary Set should contain at least one client.
- Add two or more clients to the Designated Primary Set to prevent issues during LDT primary failover.

8. In the **Confirmation** screen, review the details of Designated Primary Set.
9. Click **Create**.

The screen will display a message indicating whether the Designated Primary Set was created successfully.

10. Click **Close** to close the screen.

The Designated Primary Set will appear in the **Designated Primary Set** tab.

After you have created a Designated Primary Set for a client group, you can create a corresponding LDT guard point for it. See [Creating LDT GuardPoints on SMB/NFS Paths](#) for details.

Removing Designated Primary Set

To remove a Designated Primary Set:

1. Click the **Remove** icon next to the desired Designated Primary Set name.
2. In the confirmation dialog box, click **Remove**.

Adding New Clients to a Designated Primary Set

To add new clients to an existing Designated Primary Set:

1. Under **Clients > Client Groups**, click the desired client group name.
2. Select the **Designated Primary Set** tab.
3. Expand the desired Designated Primary Set.

It displays the list of clients.

4. Click **Add Clients**.
5. Select the checkboxes for the desired client names.
6. Click **Add**.

Removing Clients from a Designated Primary Set

To remove a client from a designated primary set:

1. Under **Clients > Client Groups**, click the desired client group name.
2. Select the **Designated Primary Set** tab.
3. Expand the desired Designated Primary Set.

It displays the list of clients.

4. Click the **Remove** icon next to the client name.
5. In the confirmation dialog box, click **Remove**.

Removing Multiple Clients from a Client Group

As part of the CipherTrust Manager maintenance, you occasionally need to remove clients from their client groups.

To remove clients from a client group:

1. Open the **Transparent Encryption** application.
2. Click **Clients > Client Groups**.
3. Under **Client Group Name**, click the expand icon () to the left of the desired client group.

Alternatively, click the desired client group and click the **Membership** tab.

4. Select the clients that you want to remove from the group.

To select all clients visible on the page, select the top check box to the left of the Status heading.

5. Click the delete icon ().

A warning message appears stating that deleting the selected clients is permanent and cannot be undone.

6. Click **Delete**.

The selected clients are removed from the client group. Also, the client group is removed from the Membership tab of the linked clients.

Removing a Client from a Client Group

As part of the CipherTrust Manager maintenance, you occasionally need to remove a client from its client group.

To remove an individual client from a client group:

1. Open the **Transparent Encryption** application.
2. Click **Clients > Client Groups**.
3. Under **Client Group Name**, click the expand icon () to the left of the desired client group.

Alternatively, click the desired client group and click the **Membership** tab.

4. Select the client that you want to remove from the group.

5. Click the delete icon ().

Alternatively, click the overflow icon (), and click **Remove**. When prompted, click **Remove**.

A warning message appears stating that deleting the selected clients is permanent and cannot be undone.

6. Click **Delete**.

The selected client is removed from the client group. Also, the client group is removed from the Membership tab of the client.

Changing the Profile

To change the profile:

1. Open the **Transparent Encryption** application.
2. Click **Clients > Client Groups**.
3. Under **Client Group Name**, click the expand icon () to the left of the desired client group.
4. Next to **Client Profile**, click the profile link (for example, **DefaultClientProfile**). The Select Profile dialog box shows the current client profile, Log Level, Rekey Option, Rekey Rate, and Schedule of the selected profile.

5. From the **Profile** drop-down list, select the desired profile.
6. Click **OK**. The selected profile is linked successfully.

Changing Client Group Password

The CipherTrust Manager allows for client password management using client groups. For large scale deployments where the CipherTrust Manager must manage several hundreds or thousands of agents, administering passwords on a per-client basis becomes untenable and burdensome. Using a common password across all the clients in a client group mitigates the administrative burden.

This feature is also useful for offline agent recovery. If a remote agent reboots (planned or unplanned) and cannot communicate with the CipherTrust Manager in the central office, it prompts the administrator at the remote site to enter the client password. The remote site administrator typically calls the corporate help desk for the password. Using the password provided by the help desk personnel, the remote site administrator enables offline agent recovery and the resumption of services. As the password is now known to the remote site administrator and the help desk personnel, it may result in a breach of security and/or render the IT operations non-compliant with respect to guaranteeing data privacy.

To remedy the compromised situation, the security administrators should change the password (rotate the password) according to existing security practices. The client group password management feature allows changing the password on all the clients in the client group when the password is compromised.

The use cases for client group password feature can be summarized as follows:

1. Set a common password for all clients in a client group.

- Reset the common password for all clients in a client group (if the password is provided to a remote CTE Agent administrator for offline agent recovery).

This feature is best suited for large scale deployments when many agents are under the management of a CipherTrust Manager cluster.

Note

When a client group's password or password generation method is updated, this change is applied to all the clients in the client group. This is true irrespective of whether the clients inherit settings from the client group or not.

Changing the Password Manually

Note

The manual password creation method is recommended for disaster recovery scenarios.

To change the password:

- Open the **Transparent Encryption** application.
- Click **Clients > Client Groups**.
- Under **Client Group Name**, click the expand icon () to the left of the desired client group.

- From the **Password Creation Method** drop-down list, select **Manual**. The **Regenerate Password** button is replaced by **Change Password**.

- Click **Change Password**.
- Enter the new password in the **Password** and **Confirm Password** fields. The password must match in both the fields.

The password must contain minimum eight characters including at least:

- One capital letter
- One number
- One of these special characters: ! @ # \$ % ^ & * () { } []

To cancel the password change, click **Cancel Change Password**.

7. Click **Apply**.

When the new password is applied, the server pushes the password to all clients in the client group. Clients that are removed from the client group retain the password set for the group. Clients added to the group later do not receive the new password.

Changing the Password Dynamically

To change the password:

1. Open the **Transparent Encryption** application.
2. Click **Clients > Client Groups**.
3. Under **Client Group Name**, click the expand icon (▸) to the left of the desired client group.

4. From the **Password Creation Method** drop-down list, select **Generate**. This is the default method.
5. Click **Regenerate Password**.
6. Click **Apply**.

A new generated password is downloaded to the client.

Inheritance of Client Group Settings

Instead of specifying settings for applications running on multiple clients individually, configure them at the client group level. Those settings can be automatically applied to all clients in the group. Refer to [Client Settings](#) for details on client settings.

Caution

Take care when defining client settings at the client group level. If a group contains clients running different operating systems (for example, Linux and Windows) that inherit client settings from the group, conflicts and issues may be observed with file and user access permissions.

-
- A client that joins a client group can opt to inherit client group configuration including the client settings.
 - If the client settings are not defined at the group level, the client retains its own settings.
 - If the client settings at the group level are modified later, the updated settings apply to all group members that inherit configuration from the group.
 - Individual clients in the group have client settings overwritten by the group's client settings.

For example:

- a. `clientA` has client settings defined, joins `clientGroup1` and inherits its group configuration. `clientB` also joins `clientGroup1` but does not inherit its group configuration. `clientGroup1`, however, does not have any client settings defined. In this case, both `clientA` and `clientB` retain their own client settings.
 - b. Now, client settings of `clientGroup1` are modified. This overwrites the client settings of all clients that inherit group configuration from `clientGroup1`. So `clientA` inherits the modified group configuration but `clientB` does not, as it does not inherit client group configuration.
 - c. `clientB` is modified to inherit settings from `clientGroup1`. The next time `clientGroup1` updates its client settings, the changes apply to both `clientA` and `clientB`.
- A client can be a member of more than one client groups. If the client inherits client group configuration from the first client group it joins, and the next groups it joins subsequently, the client inherits the client settings from the last group that it joins.

For example:

- a. `clientC` joins `clientGroup2` and inherits the client group configuration. `clientC` now has `clientGroup2` client settings.
 - b. `clientC` is added to `clientGroup1` and set to inherit client group configuration. So, `clientC` gets `clientGroup1` client settings.
- If client settings of a client group are emptied, member clients that inherit settings from the group retain the last defined client settings.

For example:

- a. `clientGroup1` deletes its client settings. All member clients (`clientA`, `clientB`, and `clientC`) retain the last client settings defined for `clientGroup1`— blank client settings are not passed to members of the group.
 - b. `clientB` leaves `clientGroup1`. Now, `clientB` retains the client settings it last inherited from `clientGroup1`.
- If the client settings of a member of a client group are modified, that client no longer inherits client settings from
-

the client group.

For example, client settings on `clientB` are modified. Then, the client settings for `clientGroup1` are modified, all members except `clientB` inherit the changes made to the client settings for `clientGroup1`.

Configuring Client Group Settings

To configure client settings at group level:

1. Open the **Transparent Encryption** application.
2. Click **Clients > Client Groups**.
3. Under **Client Group Name**, click the desired client group.
4. Click the **Settings** tab.
5. Expand **CLIENT GROUP SETTINGS**. The Settings text box contains the authentication settings.

6. In the **Settings** text box, add `|authenticator|` before the path of the binary. For example, `|authenticator|/bin/su` to allow `su` to be a trusted method of authentication. For further consideration of authentication options, refer to [Client Settings](#).
7. (Optional, if you add another process to the set of trusted applications) Enable **Re-sign Settings** to ensure

that the new process is signed and authenticated by the client. The next time the client settings are pushed to the CTE Agent, the updated client settings are re-signed and the **Re-sign Settings** toggle is disabled (or reset).

If, after adding a new process, you do not enable **Re-sign Settings**, the client ignores the newly added process. See [Re-Sign Settings](#) for more information.

8. Click **Update**.

Deleting Client Groups

As part of the CipherTrust Manager maintenance, you occasionally should remove client groups from the CipherTrust Manager.

- When you delete a client group, only the group is removed from the CipherTrust Manager GUI. Individual clients that are members of the group remain intact.
- If you configured a client group password, the individual clients retain the group password.

Deleting a Client Group

To remove a client group:

1. Make sure that no GuardPoints is applied on the group.
2. Open the **Transparent Encryption** application.
3. Click **Clients > Client Groups**.
4. Under **Client Group Name**, click the overflow icon () corresponding to the desired group.

Alternatively, select the check box corresponding to the desired group, click the delete icon (), and click **Delete**.

5. Click **Delete**. A dialog box appears prompting to confirm the action.
6. Click **Delete**.

The client group is removed from the client groups list. Also, the client group is removed from the Membership tab of the linked clients.

Deleting Multiple Client Groups

The CipherTrust Manager provides an option to delete multiple client groups.

To remove multiple client groups:

1. Make sure that no GuardPoints is applied on the group to be deleted.
 2. Open the **Transparent Encryption** application.
-

3. Click **Clients > Client Groups**.
4. Under **Client Group Name**, select the check boxes corresponding to the desired groups.

To select all client groups visible on the page, select the top check box to the left of the Client Group Name heading.

5. Click the delete icon ().

A warning message appears stating that deleting the selected client groups is permanent and cannot be undone.

6. Click **Delete**.

The client groups are removed from the client groups list. Also, the client groups are removed from the Membership tab of the linked clients.

Sharing a Client Group Across Domains

A shared client group will be visible in read-only mode in all the domains where it is shared. The GuardPoints can be created on the shared client group from any of the linked domains. These GuardPoints will be visible in read-only mode in all the linked domains except their native domains (where the GuardPoints are created). All the valid operations on the GuardPoints will be allowed from the native domains.

Clients can be added to the shared client group from all the linked domains (including the native domain). All the GuardPoints added to the client group (from all the domains) will be propagated to the clients in the group.

Propagation of client settings and other configuration (like LDT suspend/resume) is passed on to all the clients in the group irrespective of the domain.

To share a client group across domains:

1. Open the **Transparent Encryption** application. The Clients page is displayed. This page lists the clients added to this CipherTrust Manager appliance.
2. Click **Clients > Client Groups**.
3. Under **Client Group Name**, click the desired client group.
4. In the mini detail view, select **Domain Sharing**.

Alternatively, to enable domain sharing on a client group, click the expand icon () corresponding to the desired group, select **Domain Sharing** in the mini detail view, and click **Apply**.

5. Click **Apply**. Now, the **Sharing** tab is displayed.
6. On the **Sharing** tab, click **Share With Other Domains**. The Share With Other Domains dialog box is displayed.
7. Under **Domain Name**, select the domains with which you want to share the client group. The dialog box also provides an option to select all the domains, if required.

-
8. Click **Share**.

The client group is shared across selected domains of the CipherTrust Manager.

Note

If a client group is shared across domains, then deleting its native domain member clients returns the "resource not found" error.

Removing Group Sharing from Domains

Removing Individual Domains

To remove group sharing from a domain:

1. Open the **Transparent Encryption** application. The Clients page is displayed.
2. Click **Clients > Client Groups**.
3. Under **Client Group Name**, click the desired client group. The detail view of the Client Groups page is displayed.
4. Click the **Sharing** tab.
5. Under **Domain Name**, select the check box corresponding to the desired domain.
6. Click **Remove**. A dialog box appears stating that deleting the selected domain is permanent and cannot be undone.
7. Click **Delete**.

The client group is no longer shared with the selected domain.

Removing Multiple Domains

To remove group sharing from multiple domains:

1. Open the **Transparent Encryption** application. The Clients page is displayed.
 2. Click **Clients > Client Groups**.
 3. Under **Client Group Name**, click the desired client group. The detail view of the Client Groups page is displayed.
 4. Click the **Sharing** tab.
 5. Under **Domain Name**, select the check box corresponding to the desired domains. To select all domains visible on the page, select the top check box to the left of the Domain Name heading.
-

-
6. Click the delete icon (). A dialog box appears stating that deleting the selected domains is permanent and cannot be undone.
 7. Click **Delete**.

The client group is no longer shared with the selected domains.

Managing Signature Sets

File signing checks the authenticity and integrity of executables and applications before they are allowed to access GuardPoint data. When you initiate file signing on the CipherTrust Manager, the CTE Agent calculates the cryptographic signatures of the executables that are eligible to access GuardPoint data. Files are individually signed as part of a set and the set is configured in a policy that defines the processes to allow.

When an executable tries to access a GuardPoint, the **secfs** service checks the fingerprint, a SHA-2 (Secure Hashing Algorithm) message digest, of the executable against the fingerprint stored in the CTE database. If they match, the executable's authenticity is verified and it can be allowed to access protected data. A hostile or compromised executable, such as a Trojan application, malicious code, or rogue process, with a missing or mismatched signature, is denied access.

Once a set of files to be signed is created, the executables are signed on a selected client and a copy of each signature is stored on the CTE. This is done as a background process on the selected client. The time it takes to complete signing depends upon the number of files to be signed, the response time of the client system, and other load factors. The completion status is indicated in the Signature Sets window.

Completed signature sets are configured in a (CTE Agent) policy so that not only are the executables attempting GuardPoint access identified, but their signatures are checked to ensure that they had not been compromised.

The Signing Process

The basic steps involved in the signature signing process are:

1. The CTE Server Administrator creates signature sets. Refer to [Creating Signature Sets](#) for details.
2. The CTE Server Administrator initiates the signature signing request. The administrator selects the signature set to be signed and the CTE client that will sign the set. Refer to [Signing Files in a Signature Set](#) for details.
3. The CipherTrust Manager forwards the request to the selected CTE client.
4. The CTE client signs the set and sends it to the CipherTrust Manager.
5. The CipherTrust Manager:
 - a. Updates the signatures in the set.
 - b. Updates the affected policies.
 - c. Sends the updated configuration files including the signatures to the clients that are using the affected policies.

In future, if any processes in the signature set are updated, the signature set should be signed again. The CTE Server Administrator can initiate the signature signing process again. This is referred to as the signature re-

signing process.

The following diagram shows the high level signature signing process:

The Signing Process for CTE for Kubernetes

The CTE for Kubernetes clients cannot sign files. So, the signing process is different for CTE for Kubernetes clients. The CTE Server Administrator needs to manually upload the files signed by a Kubernetes image.

The basic steps involved in the signature signing process are:

1. The CTE Server Administrator creates signature sets for Kubernetes clients. Refer to [Creating Signature Sets for Kubernetes Clients](#) for details.
2. The CTE Server Administrator manually adds the signatures to the signature set on the CipherTrust Manager.
3. The CipherTrust Manager:
 - a. Updates the affected policies.
 - b. Sends the updated configuration files to the CTE for Kubernetes clients that are using the affected policies.

In future, if any processes in the signature set are updated, the CTE Server Administrator needs to reupload the latest signatures to the signature set. This is referred to as the signature re-signing process.

Using Signature Sets in a Policy

Policies can be configured to identify the executables trying to access GuardPoint data and to verify that the executables themselves are unchanged since they were signed. You must, however, anticipate the effect of encryption on file signatures.

When a file inside a GuardPoint is copied to a location outside the GuardPoint, the two files have different

signatures. The file in the GuardPoint is encrypted, but the file outside the GuardPoint is not.

- Encryption makes the two files different. The VMD process does not decrypt guarded files before checking their signatures. So, when you rekey guarded files, their signatures also change. Re-sign the files that use the signatures of those files in process sets.
- If both files must access the GuardPoint data, add both files to the signature set and sign them. If encryption is not applied, both files have the same signature; a signature mismatch should not occur.

Creating Signature Sets

A signature set is a collection of hashes of processes and executables that you want to grant or deny access to GuardPoints. You can enter the full path of files and directories manually or use the browser to locate and select them. Specify a directory to sign all the files in that directory and all the subdirectories that it may contain.

Signing many files can take a while. To shorten processing time, verify that the files and directories in the signature set exist. It takes longer to process non-existent files. If they do not exist, it is recommended that you delete them as sources from the signature set. Refer to [Deleting Source from Signature Sets](#) for details.

To create a signature set:

1. Open the **Transparent Encryption** application.
2. Click **Policies > Policy Elements**.
3. Click the **Signature Sets** tab.
4. Click **Create Signature Set**. The General Info screen of the Create Signature Set wizard is displayed.

General Info

1. Enter a unique **Name** for the set.
 - The name must start with a character. The maximum length can be 64 characters.
 - The name can contain alphanumeric characters, underscores (`_`), and dashes (`-`).
 - The name cannot contain the following special characters:
`? : ; | ! @ # $ % ^ & * < = > + ( ) { } ~ , \ / [ ] ' "`
2. Select **Application** as the **Type**. The signature set will have signatures of the running applications.
3. (Optional) Provide a **Description** for the set.
4. Enable or disable the **Add Signatures** toggle. If you enable this option, an **3 - Add Signatures** screen becomes available.
5. Click **Next**. The Add Sources screen is displayed. On this screen, you can add files to be signed, as described below.

Add Sources

Specify path of the directory or file to be signed. If a directory is specified, all files in the directory and its subdirectories are signed.

The CipherTrust Manager provides an option to add multiple sources. A maximum of 200 sources can be added at once.

1. Click **Add Source**.
2. Click **Select Client**. The list of registered clients is displayed.
3. Select the desired client.

Status	Name	OS Type	Description
☒ Healthy	10.164.13.209	LINUX	ABLinux
☐ Healthy	ABWin	WINDOWS	AB Windows Client

4. Click **Select**. The selected client appears next to the Change Client button (previously Select Client).

If needed, change the client by clicking **Change Client**.

5. Specify the path to be signed by either typing manually or using the browser.

Client

Change Client

10.164.13.209

Enter Source:

/usr/bin/

Start Directory

Apply

Select Source:

tmp

tools

usr

bin

To jump to a specific directory, enter the directory path in the **Start Directory** field and click **Apply**. The browser shows the subdirectories and files, as shown below.

Client

Change Client

10.164.13.209

Enter Source:

/usr/bin

Start Directory

/usr/bin

Apply

Select Source:

You cannot browse above the Start Directory. Enter a start point that is higher in the directory hierarchy than all the directories and files that you want to select, or you will have to re-enter start points to locate and select the desired files. The default is the top-level, either slash (Linux) or backslash (Windows).

Alternatively, if you know the directory path, you can enter it manually in the **Path** field.

- Click **Add Source**. The selected source is displayed in the SELECTED SOURCES list.

Client

Select Source:

SELECTED SOURCES

/usr/bin

Remove

Optionally, you can add a new source by clicking **Add Source**. To remove a source, click **Remove** to the right of the source. A signature set must contain at least one source.

- Click **Add**. The selected source is displayed in the Source Directory list.

Optionally, you can add a new source by clicking **Add Source**. To remove a source, click the overflow icon () corresponding to the source and click **Remove**.

- Click **Next**. The Add Signatures screen is displayed. On this screen, you can manually add signatures or upload a CSV file containing signatures.
-

Add Signatures

If you enabled **Add Signatures** on the **General Info** screen, CipherTrust Manager provides options to add signatures to a signature set manually, and to upload the signatures to a signature set through CSV.

Click the desired tab to view the instructions.

Adding Signatures to a Signature Set Manually

1. Click **Create Signature**. The Create Manually tab is displayed.
2. Under **Signature 1**, enter the following details:
 - **Program**: Full path of the file.
 - **Signature**: Signature of the file.

To add multiple signatures, click **+ Add More Signatures**. To remove a signature, click **X**.

3. Click **Add**. The signatures are added to the signature set. The list of programs and their signatures are displayed.

Optionally, you can add more signature(s) by clicking **Create Signature**, and repeating step 2 and 3. To remove a signature, click the overflow icon () corresponding to the signature and click **Remove**.

4. Click **Next**. The Confirmation screen is displayed. The screen shows the General Info, Sources and Signatures details of the signature set.

Uploading Signatures to a Signature Set through CSV

1. Click **Create Signature**. The Create Manually tab is displayed.
2. Click the **Upload** tab.
 - a. Next to **Upload CSV**, click **Browse**.
 - b. Select and upload the CSV file. The Upload CSV field shows the uploaded file.
3. Click **Add**. The signatures from the CSV file are added. The name of the file is displayed.

Optionally, you can change the file by clicking **Create Signature**, and repeating step 2 and 3. To remove the file, click the overflow icon () corresponding to the uploaded CSV file and click **Remove**.

4. Click **Next**. The Confirmation screen is displayed. The screen shows the General Info, Sources and Signatures details of the signature set.

Confirmation

1. Verify the set details. If the details are incorrect or you want to modify them, click **Back** and update the details.
2. Click **Save**.

The newly created set appears on the Signature Sets tab. By default, the signature set has the status **UNSIGNED**.

Name	Type	Signing Status	Updated At ↓	Description	
☐ testsigset	Application	Unsigned	24 Nov 2022, 14:14	Test signature set	...
☐ test	Container Image	Unsigned	24 Nov 2022, 14:12		...

It is recommended that the signature set is signed before you apply policies to processes. This ensures that a tampered with or compromised process executable is not granted permissions to access protected GuardPoints. Refer to [Signing Files in a Signature Set](#) for details.

Creating Signature Sets for Container Images

A signature set is a collection of file names and their signatures. A signature is a hash of a process or an executable file. Through signature sets, a signature can be used to verify the integrity of the process before it is allowed access to the guarded data.

You can enter the full path of files and their signatures manually or use the browser to upload YAML files containing the list of files and their signatures.

To create a signature set for CTE for Container Images:

1. Open the **Transparent Encryption** application.
2. Click **Policies > Policy Elements**.
3. Click the **Signature Sets** tab.
4. Click **Create Signature Set**. The General Info screen of the Create Signature Set wizard is displayed.

General Info

1. Enter a unique **Name** for the set.
 - The name must start with a character. The maximum length can be 64 characters.
 - The name can contain alphanumeric characters, underscores (`_`), and dashes (`-`).
 - The name cannot contain the following special characters:
`? : ; | ! @ # $ % ^ & * < = > + ( ) { } ~ , \ / [ ] ' "`
2. Select **Container Image** as the **Type**. The signature set will have the signatures of containers.
3. (Optional) Provide a **Description** for the set.
4. Enable or disable **Add Signatures**.
5. Click **Next**. The Add Sources screen is displayed. On this screen, you can add source paths or upload the YAML file containing the source paths, as described below.

Add Sources

Specify path of the directory or file to be signed. If a directory is specified, all files in the directory and its subdirectories are signed.

The CipherTrust Manager provides an option to add multiple sources. A maximum of 200 sources can be added at once.

Click the desired tab to view the instructions.

Adding Sources Manually

1. Click **Add Source**. The Create Manually tab is displayed.
2. In the **Enter Source** field, add source for the container images to be trusted.
3. Click **Add**. The sources are added to the signature set. The list of Source Directory is displayed.

Optionally, you can add more sources by clicking **Add Source**, and repeating step 2 and 3. To remove a source, click the overflow icon () corresponding to the source and click **Remove**.

4. Click **Next**. The Add Signatures screen is displayed. On this screen, you can manually add signatures or upload the list of signatures.

Uploading Sources through YAML

1. Click **Add Source**. The Create Manually tab is displayed.
2. Click the **Browse** tab.
 - a. Next to **Upload YAML**, click **Browse**.
 - b. Select and upload the YAML file that contains the source for the container images to be trusted. The Upload YAML field shows the uploaded file.
3. Click **Add**. The sources from the YAML file are added. The name of the file is displayed.

Optionally, you can change the file by clicking **Add Source**, and repeating step 2 and 3. To remove a signature, click the overflow icon () corresponding to the source and click **Remove**.

4. Click **Next**. The Add Signatures screen is displayed. On this screen, you can manually add signatures or upload the list of signatures.

Note

The Add Signatures tabs is displayed if you selected **Add Signatures** on the General Info screen.

Add Signatures

If you enabled **Add Signatures** on the **General Info** screen, CipherTrust Manager provides options to add

signatures to a signature set manually, and to upload the signatures to a signature set through CSV.

Click the desired tab to view the instructions.

Adding Signatures to a Signature Set Manually

1. Click **Create Signature**. The Create Manually tab is displayed.
2. Under **Signature 1**, enter the following details:

- **Program**: Full path of the file.
- **Signature**: Signature of the file.

To add multiple signatures, click **+ Add More Signatures**. To remove a signature, click **X**.

3. Click **Add**. The signatures are added to the signature set. The list of programs and their signatures are displayed.

Optionally, you can add more signature(s) by clicking **Create Signature**, and repeating step 2 and 3. To remove a signature, click the overflow icon () corresponding to the signature and click **Remove**.

4. Click **Next**. The Confirmation screen is displayed. The screen shows the General Info, Sources and Signatures details of the signature set.

Uploading Signatures to a Signature Set through CSV

1. Click **Create Signature**. The Create Manually tab is displayed.
2. Click the **Upload** tab.
 - a. Next to **Upload CSV**, click **Browse**.
 - b. Select and upload the CSV file. The Upload CSV field shows the uploaded file.
3. Click **Add**. The signatures from the CSV file are added. The name of the file is displayed.

Optionally, you can change the file by clicking **Create Signature**, and repeating step 2 and 3. To remove the file, click the overflow icon () corresponding to the uploaded CSV file and click **Remove**.

4. Click **Next**. The Confirmation screen is displayed. The screen shows the General Info, Sources and Signatures details of the signature set.

Confirmation

1. Verify the set details. If the details are incorrect or you want to modify them, click **Back** and update the details.
2. Click **Save**.

The newly created set appears on the Signature Sets tab. By default, the signature set has the status **UNSIGNED**.

Signing Files in a Signature Set

This section is applicable to CTE clients only. CTE for Kubernetes clients do not support signing files.

Signing involves calculating a hash value for a file and storing the value on the CipherTrust Manager. Later, when a policy checks signatures, the signature of the process or executable accessing the GuardPoint is calculated and compared against the value in the CipherTrust Manager. If the two values match, the process or executable satisfies the Process requirement of a policy and may be granted access to the guarded data.

Note

If the executable itself is volatile, or subject to frequent change, it may not be worthwhile to use a file signature as a criteria in a policy because you have to re-sign the executable after each change. If the volatile executables are members of a large signature set, it can take a while to re-sign the files because the signature of every file in the signature set is recalculated. If the volatile files are few, it might be quicker to add the volatile files to a different signature set and sign that set, rather than re-sign all the files in the original signature set.

To sign the files in a signature set:

1. Open the **Transparent Encryption** application.
2. Click **Policies > Policy Elements**.
3. Click the **Signature Sets** tab. The list of configured signature sets is displayed.
4. Click the desired signature set.

5. Select a client to sign the signature set. A signing client is required to start the signing process.
 - a. On the **Source** tab, click **Select Client**. Based on the type of the signature set, the list of registered clients

or sign-capable container images is displayed. Select any client or image to sign the signature set.

b. Select the client.

c. Click **Select**. The selected client appears next to the Select Client button. The Sign icon () is now enabled.

Note

Do not select check boxes when signing a signature set. They are used to select source directories to be deleted from the set.

6. Click the Sign icon (). The signing process starts.

The signing status of the signature set becomes **InProgress**.

- To view the percent completion of the signing process, hover over the Spinner () progress bar.
- To stop the signing process before it completes, click the Stop Signing icon (). Refer to [Stopping the Signing Process](#) for details.

The time for the signing process to complete depends on the number of files being processed. Signing occurs as a background process. So, you can use the CipherTrust Manager GUI for other administrative functions during this process.

When the signing completes, the signing status of the signature set becomes **Finished**. Refer to [Checking Signing Completion Status](#) for details about the signing status.

The resulting signatures are available on the Signature tab of the signature set.

Checking Signing Completion Status

To view the signing completion status of a signature set:

1. Open the **Transparent Encryption** application.
2. Click **Policies > Policy Elements**.
3. Click the **Signature Sets** tab. The list of configured signature sets is displayed.

	Name	Signing Status	Updated At ↓	Description	
☐	testsigset	Finished	18 Aug 2020, 08:04	Test signature set	...
☐	test	Unsigned	18 Aug 2020, 00:55		...

4. View the **Signing Status** for the signature set. The Signing Status can be:

Status	Description
Manual	(Applicable to CTE for Kubernetes clients) Signature set signed manually.
Unsigned	Signature set is unsigned. Either no files exist in the set or no attempt is made to sign them yet.
InProgress	The CipherTrust Manager is actively signing the files in the set. This can take some time depending on the system load, accessibility, and the number of files being signed at one time.
Finished	All the files in the set are signed successfully. The set is ready for use.
FinishedWithWarning	All the files in the set are processed, but one or more files in the set could not be signed. Possible causes are missing files or inadequate access permissions. Check the VMD logs for details: • On Unix, <code>vorvmd_root.log</code>. • On Windows, <code>vorvmd.log</code>. Alternatively, view the logs in Event Viewer > CipherTrust Encryption Expert. Refer to Checking Agent Logs if Signing Fails for details.
Aborted	Signing was started but stopped before completion.

Stopping the Signing Process

This section is applicable to CTE clients only. CTE for Kubernetes clients do not support signing files.

Interrupt the signing process at any time before it completes. Click the Stop Signing () icon on the Source tab of the Signature Sets tab. The CipherTrust Manager does prompt you to verify your choice.

It takes a while for the signing process to stop. After the process is stopped, the Signing Status displayed on the Signature Sets tab is set to abort. All the files that were signed until you stopped the process remain intact and can be viewed on the Signature tab of the signature set.

Displaying Signatures of Files in a Signature Set

CipherTrust Manager provides options to display signatures of all or specific files in a signature set.

Displaying Signatures of All Files in the Signature Set

To display the signatures of all files in a signature set:

1. Open the **Transparent Encryption** application.
2. Click **Policies > Policy Elements**.
3. Click the **Signature Sets** tab. The list of configured signature sets is displayed.
4. Under **Name**, click the desired signature set.
5. Click the **Signature** tab.

Source		Signature
Search		
☐ 0 Selected 10 Results 1758 Signatures		
Program	Signature	
☐ /usr/bin/crash	8849AA3A71BD1D2C3C0A347932E93F7A17F6635380699540975B855E28E1CA62 ***	
☐ /usr/bin/wrwc	56FE294800C9B9895589D1983A556807DA1E06E227E63D611325F81803A9123D ***	
☐ /usr/bin/woradmin	7BB14D0AAAFFD0ED8FCD55D445AEAF4C2418FB830CA3EA00844A013906E3029 ***	

The list of all files (programs) in the signature set with their signatures is displayed. By default, 10 records per page are displayed. Adjust the pagination to view more records.

Displaying Specific Signed Files in the Signature Set

To display specific signed files in a signature set:

1. Open the **Transparent Encryption** application.
2. Click **Policies > Policy Elements**.
3. Click the **Signature Sets** tab. The list of configured signature sets is displayed.
4. Under **Name**, click the desired signature set.
5. Click the **Signature** tab. By default, all signed files in the set are displayed in alphanumeric order.
6. In the **Search** box, enter the string that matches the partial or full name of the program whose signature you are searching for.

The search is case-insensitive. All files that contain the string in their names are displayed.

Detecting Duplicate Files

Unless the content of a file is modified, its signature remains the same regardless of the file name and location. Also, the signature of all copies of a file remains the same. So, to determine the duplicates of a file, display the files based on their signature. If you search using a signature, it is recommended to enter the complete signature.

To detect the duplicates of a file:

1. Open the **Transparent Encryption** application.
2. Click **Policies > Policy Elements**.
3. Click the **Signature Sets** tab. The list of configured signature sets is displayed.
4. Under **Name**, click the signature set in which you want to detect duplicate files.
5. Click the **Signature** tab. The signatures of the files in the set are displayed.
6. Copy the signature of a file from the **Signature** column.
7. Paste the signature in the **Search** box. Remove any extra space, if inserted when pasting.

8. Notice the search result.

If multiple records are displayed, duplicates of the file exist. If a single record is displayed, duplicates of the file do not exist. For example, the following figure shows two files with different names and locations, but with identical content based on their signature.

Source	Signature
Q: 7724722A749E444883B8ACE63C20E688D09C4905EE34D039E

☐ /dir1/o	7724722A749E444883B8ACE63C20E688D09C4905EE34D039E5B734A90E900062

2 Signatures 10 per page

Deleting Signatures from Signature Sets

Delete either individual signatures from a set or the complete signature sets. Refer to [Deleting Signature Sets](#) for information on deleting complete signature sets.

Delete signatures from a signature set when you want to continue to use the signature set to authenticate processes, but you no longer want to authenticate the files that you are deleting from the set.

You can delete signatures individually or one page at a time.

Deleting Single Signatures

To delete a single signature from a signature set:

1. Open the **Transparent Encryption** application.
2. Click **Policies > Policy Elements**.
3. Click the **Signature Sets** tab.
4. Click the desired signature set.
5. Click the **Signature** tab. The list of signatures in the signature set is displayed.
6. Click the overflow icon (**...**) corresponding to the desired signature.

Program	Signature
☐ /usr/bin/crash	8849AA3A71BD1D2C3C0A347932E93F7A17F6635380699540975B855E28E1CA02
☐ /usr/bin/vortc	56FE2948D0C9B98905589D1983A5568D7DA1E06E227E63D611325F81803A0723D

Delete

7. Click **Delete**. A dialog box appears prompting you to confirm the action.
8. Click **Delete**.

The selected signature is removed from the list and the CipherTrust Manager database.

Deleting Multiple Signatures

To delete single or multiple signatures from a signature set:

1. Open the **Transparent Encryption** application.
2. Click **Policies > Policy Elements**.
3. Click the **Signature Sets** tab.
4. Click the desired signature set.
5. Click the **Signature** tab.
6. Select the check boxes corresponding to the signatures you want to delete.

2 Selected 10 Results 1759 Signatures	
Program	Signature
☒ /usr/bin/crash	8849AA3A71BD1D2C3C0A3
☒ /usr/bin/vortc	56FE294800C9B9895589D1

To select all signatures for deletion, select the top check box to the left of the Signature heading.

7. Click the delete icon (). A dialog box appears prompting you to confirm the action.
8. Click **Delete**.

The selected signatures are removed from the list and the CipherTrust Manager database.

Deleting Source from Signature Sets

This section is applicable to CTE clients only. CTE for Kubernetes clients do not support signing files.

Signing many files can take a while. To shorten processing time, verify that the files and directories in the signature set exist. It takes longer to process non-existent files. If they do not exist, it is recommended that you delete them as sources from the signature set.

Deleting Single Sources

To delete a single source from a signature set:

1. Open the **Transparent Encryption** application.
2. Click **Policies > Policy Elements**.
3. Click the **Signature Sets** tab.
4. Click the desired signature set. The Source tab shows the list of source directories.
5. Click the overflow icon () corresponding to the desired source directory.

6. Click **Delete**. A dialog box appears prompting you to confirm the action.
7. Click **Delete**.

The selected source is removed from the list and the CipherTrust Manager database.

Deleting Multiple Sources

To delete single or multiple sources from a signature set:

1. Open the **Transparent Encryption** application.
2. Click **Policies > Policy Elements**.
3. Click the **Signature Sets** tab.
4. Click the desired signature set. The Source tab shows the list of source directories.
5. Select the check boxes corresponding to the desired source directories.

To select all sources for deletion, select the top check box to the left of the Source Directory heading.

6. Click the delete icon (). A dialog box appears prompting you to confirm the action.
7. Click **Delete**.

The selected sources are removed from the list and the CipherTrust Manager database.

Deleting Signature Sets

Delete either individual signatures from a set or the complete signature sets. Refer to [Deleting Signatures from Signature Sets](#) for information on deleting individual signatures.

An active (in use) signature set cannot be deleted. Before deleting a signature set from the CipherTrust Manager, make sure that no policies are using it.

CipherTrust Manager provides options to delete single or multiple signature sets.

Deleting Single Signature Sets

To delete a single signature set:

1. Open the **Transparent Encryption** application.
2. Click **Policies > Policy Elements**.
3. Click the **Signature Sets** tab. The list of configured signature sets is displayed.
4. Click the overflow icon () corresponding to the desired signature set.

	Name	Signing Status	Updated At ↓	Description	
☐	testsigset	Finished	18 Aug 2020, 08:12	Test signature set	
☐	test	Unsigned	18 Aug 2020, 00:55		Edit Delete

5. Click **Delete**. A dialog box appears prompting you to confirm the action.
6. Click **Delete**.

The selected signature set is removed from the list.

Deleting Multiple Signature Sets

To delete single or multiple signature sets:

1. Open the **Transparent Encryption** application.
2. Click **Policies > Policy Elements**.

3. Click the **Signature Sets** tab. The list of configured signature sets is displayed.
4. Select the check boxes corresponding to the desired signature sets.

☒ 2 Selected 2 Results 2 Signature Sets	
Name	Signing Status
☒ testsigset	Finished
☒ test	Unsigned

To select all sets for deletion, select the top check box to the left of the Name column.

5. Click the delete icon (). A dialog box appears prompting you to confirm the action.
6. Click **Delete**.

The selected signature sets are removed from the list.

Re-Signing Files in a Signature Set

Signatures are computed values. Unless the files in a signature set are compromised or modified, the signature always remains the same for a given file. If the files are modified, they must be re-signed to ensure that their signatures match the signatures on the CipherTrust Manager.

To re-sign the files, you can:

- Create and sign a new signature set with the files and directories to be signed. Use this option if the set contains only a few files and directories.
- Create and sign a new signature set with the paths of the directories that contain the files to be signed. Use this option if the directories contain only a few files or most files in the directories need re-signing.
- Open and re-sign the existing signature set that is originally used to sign the files. Use this option if you have the time or the signature set is small.

Computing the signature of every file in a large signature set takes a long time.

Re-signing the files in a set takes longer than signing the files the first time. It requires additional handling to update information on the CipherTrust Manager. If you plan to re-sign a large number of files (say hundreds of thousands), it can be quicker to:

1. Delete the existing signature set. Refer to [Deleting Signature Sets](#) for details.
2. Create the signature set again, from scratch. Refer to [Creating Signature Sets](#) for details.

3. Sign the files of the signature set again. Refer to [Signing Files in a Signature Set](#) for details.

Tip

CTE for Kubernetes clients do not support signing of files. To re-sign files, you need to [delete the signature set](#) and [create the signature set](#) of manually signed files again.

Checking Agent Logs if Signing Fails

If signing fails, or you want more information about the signing process such as which files were skipped, check the CTE Agent logs captured on the client.

Messages are logged to:

- (UNIX) `/var/log/vormetric/vorvmd_root.log` with Log to File enabled and to a Syslog server with Syslog enabled.
- (Windows) `\Documents and Settings\...\agent\log\vorvmd.log` with Log to File enabled.

In the `vorvmd_root.log`/`vorvmd.log` file on the client, look for messages like:

```
[VMD] [WARN ] [3732] [VMD3824W] Failed to create the signature for
E:\apps\lib\dx1\aa_dir\dataxform_auto_config for the signature
request 9, error code 3
```

The following table lists error codes with their description:

Code	Description
0	System is okay.
1	Does not exist.
2	DO NOT USE.
3	Invalid argument.
4	Operation not supported.
5	Out of memory.
6	No space left on device.
7	Timeout reached.
8	I/O error.
9	Interrupted.
10	Permission denied.
11	Too many keys in key group.
12	Error in soap rpc layer.

Code	Description
13	Returned buffer is partially full.
14	Given target buffer is too small.
15	Unable to compress buffer.
16	Internal test failed.
17	Overflow.
18	Error setting up logging.
19	Overloaded error.
20	Server responded to a file upload with "bad request".
21	Unknown user name or bad password.
22	The directory service is not available.

Managing Policies

The primary job of a CipherTrust Manager Security Administrator is to create policies that protect data. Policies govern access to, and encryption of, the files in GuardPoints.

Overview

A policy is a collection of rules that govern data access and encryption. Think of a policy as an if-then statement. Policy rules are processed sequentially. If the criteria of rule one are not met, the policy enforcement engine moves on to the second rule and so on.

Policies specify:

- **Actors:** Users, groups, and processes that are permitted/denied access to protected data.
- **Actions:** What actions authorized actors are allowed to perform. For example create/delete, read/write, decrypt, modify permissions, and so on.
- **Files acted upon:** Policy rules may apply to entire directories and mount points, or only to files named in a specific way (for example, .docx files may be encrypted and restricted to read-only access by designated users, while other files may be stored clear and read and written by anyone).

Additionally, each CTE policy specifies one or more encryption keys used to encrypt blocks of file data when applications write them, and decrypt them when they are read.

CTE encryption is transparent to applications. This means that the CTE Agent encrypts blocks of data as they are written, and decrypts data when they are read by authorized users and applications. This architecture separates administration of files from access to the data in them. Backup programs, for example, may be authorized to read files, but not view the data in them. Therefore, data can be backed up and taken offsite while remaining encrypted so that security is not breached.

The following criteria are processed by the policy enforcement engine:

Criteria	Description
Order	Security rule enforcement sequence.
Resource	Files and/or directories to which the policy will apply, plus key rules that govern those files and directories.
User	Users and user groups authorized to access the resources.
Process	Executables which will access the files.
Action	Type of user access being made (read, write, copy, move etc.). Before you can define Data Transformation Rules, you must select an Action type of Key_op.
Effect	When all the other rules match, this describes the type of access granted or denied per the rule.
Browsing	Allow browsing is enabled by default, while the Enable Communication check box is enabled on the client. This allows the server to browse the client's file system. This option can be deselected even if client communication is still enabled.

A policy comprises [Security Rules](#), [Key Rules](#), [Data Transformation Rules](#), and [Signature Rules](#).

Policy Rule Criteria and Effects

Policy Rules consist of five criteria, which specify the attributes of an access attempt, and effects, which define whether that access is permitted or denied, and whether encryption/decryption is required.

Policy Rule Criteria

Criteria	Action
Resource	Files and/or directories in a GuardPoint to be blocked. Example: <code>/secure_dir/financials</code> .
User	Users or groups of users that can access the files.
Process	Executables that can operate on the files.
Action	Allowed file action. Example: read, write, remove, rename, and make directory.

Policy Rule Effects

Effect	Action
Permit	Allows access to the data.
Deny	Disallows access to the data.
Apply Key	Encrypts data written to a GuardPoint with the specified key. Decrypts data that is accessed using the same key.

Effect	Action
Audit	Creates an entry in the Message Log that describes what is being accessed, when it is being accessed, and the security rule being applied.

Every time a user's application tries to access a GuardPoint file, the security policy tests that access attempt against the criteria of each rule. For example, suppose a user, Harry, wants to access and modify a file called secret, using the command cp. For Harry to be successful, there must be a rule that allows access to the secret (resource), by the user Harry (user), using the command cp (process), and includes the permission write (action).

A blank criteria field specifies a value of All. If User is blank, the rule applies to all users; if Process is blank, the rule applies to all executables, and so on. Effect can never be blank. It must have at least a permit (allow access) or deny (disallow access).

A policy can have multiple rules. Rules are evaluated much like firewall rules. They are evaluated in order, from first to last, and evaluation stops when a rule is found for which all the criteria are met. The effect for that rule is then enforced. So, carefully order a policy's rules to achieve the desired result.

Creating Policy Elements

Policy rule criteria consist of resource sets, user sets, signature sets, process sets, action, and effect, and are called policy elements. These elements should exist on the CipherTrust Manager before you can use them in security policies.

Although you can add policy elements when creating policies, it may be a better approach to have them created in advance. This document describes creation of policy elements separately, before creating policies.

A CipherTrust Manager administrator can create, modify, and delete resource sets, user sets, process sets, and signature sets on the CipherTrust Manager. Actions and effects are preconfigured on the CipherTrust Manager.

After you have created policy elements, you can use them in creating and configuring policies. Refer to [Creating Policies](#) for details.

Note

You can only label a profile for [File Activity Monitoring \(FAM\)](#) in the ksctl CLI.

Creating Resource Sets

A resource is a combination of a directory, a file, and patterns or special variables. A resource set is a named collection of directories, files, or both, that a user or process will be permitted or denied access to.

Use the Create Resource Set wizard to create resource sets.

1. Open the **Transparent Encryption** application.
2. Click **Policies > Policy Elements**.
3. On the **Resource Sets** tab, click **Create Resource Set**. The Create Resource Set wizard is displayed.

4. On the **General Info** screen:

- a. Enter a unique **Name** for the set.
 - The name must start with a character. The maximum length can be 64 characters.
 - The name can contain alphanumeric characters, underscores (`_`), and dashes (`-`).
 - The name cannot contain the following special characters:
`? : ; | ! @ # $ % ^ & * < = > + ( ) { } ~ , \ / [ ] ' "`
- b. Make sure that **Directory** is selected as the **Resource Set Type**.
- c. Provide a **Description** for the set.
- d. Click **Next**. The Add Resources screens is displayed.

5. Specify the resource **Directory**.

Note

- Resource sets must be relative to the guard path. Resource sets created using the absolute paths are not supported.
- The path must end with a slash. For example, a Windows path must end with a `\` (backward slash). A Linux path must end with a `/` (forward slash).

6. Specify a **File** or enter the asterisk (`*`). The asterisk acts as a wild card character.

Note

An asterisk can be used to include all files of a specific extension in the resource set. For example, to include all text files under a resource directory, specify `*.txt`.

Later, a policy with desired permissions can be applied to the resource set. That policy will apply to all files of the specified extension under the specified resource directory.

7. (Optional) Specify whether to include subfolders in the set. Turn on **Include Sub Folders**. By default, the subfolders are not included.

Directory

/cte-test/

File

*

Include Sub Folders: ☒HDFS File System: ☐

8. (Optional, Linux only) Turn on the **HDFS File System** toggle for an HDFS resource. When you turn on this toggle, ensure that **Directory** and **File** contain HDFS paths.

HDFS is applicable to Linux clients. By default, the **HDFS File System** toggle is turned off. Keep it turned off for a non-HDFS resource.

Note

To protect an HDFS resource, the CTE clients (NameNode and DataNodes in the HDFS cluster) must be configured for HDFS. Refer to the "Installing CTE on Hadoop" section in the [CTE Agent for Linux Advanced Configuration](#) document for details.

Note

For the list of supported HDFS systems, refer to the [Compatibility Matrix for CTE Agent with Data Security Manager](#). The matrix also applies to the CTE clients registered with the CipherTrust Manager.

9. Click **Next**. The Confirmation screen is displayed.

The screen shows general information about the set and the selected sources.

Directory	File	Include Sub Folders	File System Type	
/cte-test/	*	Yes	Local FileSystem	...

10. Verify the resource set details.

If the details are incorrect or you want to modify them, click **Back** and update the details. To add another resource, click **Add Another Resource**, and specify the details, as described above.

11. Click **Save**. The resource set is created.

The newly created resource set appears on the Resource Sets tab.

	Name	Type	Updated At ↓	Description	
☐	resourceset	Directory	18 Aug 2020, 11:47	Resource set	...
☐	5G-ResourceSet	Directory	18 Aug 2020, 11:38		...

Creating User Sets

A user set is a collection of users and user groups that you want to grant or deny access to GuardPoints. User sets are configured in policies. Policies can be applied to user sets, not to individual users.

Use the Create User Set wizard to create user sets. The wizard provides two options to add user sets. Specify a user set either by querying the registered client or by manually entering the members (individual members, groups, or group members). If needed, you can manually add AD users to a user set.

Creating User Sets by Browsing the Client

To create a user set:

1. Open the **Transparent Encryption** application.
2. Click **Policies > Policy Elements**.
3. Click the **User Sets** tab.
4. Click **Create User Set**. The Create User Set wizard is displayed.
5. On the **General Info** screen:
 - a. Enter a unique **Name** for the set.
 - The name must start with a character. The maximum length can be 64 characters.
 - The name can contain alphanumeric characters, underscores (`_`), and dashes (`-`).
 - The name cannot contain the following special characters:
`? : ; | ! @ # $ % ^ & * < = > + ( ) { } ~ , \ / [ ] ' "`
 - b. (Optional) Provide a **Description** for the set.
 - c. Click **Next**. The Add Users screen is displayed.
6. On the **Add Users** screen:
 - a. Click **Create User**. By default, the **Manually Add Users** tab is active.

-
- b. Click the **Browse to Add Users** tab.

This tab allows you to browse the client for members. To add members manually, refer to [Creating User Sets by Adding Members Manually](#).

- c. Select a **Connection Type**. You can select either Agent or LDAP. Click the desired tab to view the instructions.

Agent

- a. Click **Select**. The list of registered clients is displayed.
- b. Select the desired client. Members, groups, or group members of this client will be added to the set.
- c. Click **Select**. The IP address or hostname of the selected client is displayed next to the Select button. The **User Type** and **Member Choice** fields are also displayed.

Agent *

Select 10.164.13.209

User Type *

Member Choice *

Select Option

- d. Select the desired **User Type**. The options are:
- **System**: Select to add system users to the user set.
 - From the **Member Choice** drop-down list, select members. The options are:
 - **Users**: Users of the client.
 - **Groups**: User groups of the client.
 - **Group Members**: Group members of the client. When you select this option, the Select Groups field appears. This is a mandatory field. Select a group from the drop-down list. Search will retrieve members of the selected group.
 - Click **Apply**. The search result based on the specified criteria is displayed on the right. A set of sample system users/groups is displayed below.

The screenshot shows a configuration window with the following elements:

- User Type:** A dropdown menu set to "System".
- Member Choice:** A dropdown menu set to "Group Members".
- Select Groups:** A dropdown menu set to "Administrators".
- Apply:** A blue button.
- Search Results:** A table with columns "uname" and "gname". Above the table, it says "0 Selected" and "Administrator" with an unchecked checkbox.

The search can display only the first 100 results. Refine your search by entering the exact name.

- Select the desired members from the list.

The screenshot shows the same configuration window as before, but with the following changes:

- Search Results:** The table now shows one row with a checked checkbox, "Administrator", and empty "uname" and "gname" fields. Above the table, it says "1 Selected".

- **LDAP:** Select to add LDAP users to the user set.
 - From the **Member Choice** drop-down list, select members. The options are:
 - **Users:** Users of the client.
 - **Groups:** User groups of the client.
 - **Group Members:** Group members of the client. When you select this option, the Select Groups field appears. This is a mandatory field. Select a group from the drop-down list. Search will retrieve members of the selected group.
 - Click **Apply**. The LDAP Credentials dialog box is displayed.
 - Specify LDAP credentials to browse LDAP users and groups.
 - **Domain:** User-friendly network address that can be resolved through the Domain Name System (DNS).
 - **Username:** Name of the LDAP user for LDAP authentication.
 - **Password:** Password of the LDAP user for LDAP authentication.
 - Click **Submit**. The search result based on the specified criteria is displayed on the right. A set of sample LDAP users/groups is displayed below.

The search can display only the first 100 results. Refine your search by entering the exact name.

If the specified LDAP credentials are incorrect or you want to change them, click **Edit Credentials** and specify the updated details.

- Select the desired members from the list.

- Click **Create**.

LDAP

- Select LDAP Connection** from the drop-down list.
- Max Number of Entries to Return:** Number of Users, Groups, and Group Mmembers and their records to return in the search results. By default, a maximum of 300 records will be returned. Enter a number from 1 to 10000. For example, if you enter 100:
 - A maximum of 100 users/groups will be displayed when Member Choice is *Users* or *Groups*.
 - A maximum of 100 groups will be displayed in the Select Groups drop-down box when Member Choice is *Group Members*.
 - A maximum of 100 search results based on the specified criteria above is displayed on the right.
- From the **Member Choice** drop-down list, select members. The options are:
 - **Users:** Users of the client.
 - **Groups:** User groups of the client.

- **Group Members:** Group members of the client. When you select this option, the Select Groups field appears, which lists the Common Name (CN) of the groups. This is a mandatory field. Select a group from the drop-down list.

d. (Optional) Enter an **LDAP Query** to filter members meeting specific criteria.

For example, if you select Users in the Member Choice drop-down list, enter `(&(objectClass=posixAccount)(uidNumber=2001))` in the LDAP Query field, and click **Apply**, the search results will only display users with the UID number 2001.

e. Click **Apply**. Search will retrieve members based on the specified search criteria.

f. Select the desired users/groups.

7. Click **Create**.

uname	UID	gname	GID	OS domain
		WseManagedGroups		 Remove
		Administrators		 Remove
		Administrator		 Remove

To add more users, click **Create User**.

You can add System and LDAP users and groups simultaneously.

If you want to remove users from the set, identify the user and click **Remove**.

8. Click **Next**. The Confirmation screen shows general information about the set and the selected members.

9. Verify the set details.

If the details are incorrect or you want to modify them, click **Back** and update the details.

10. Click **Save**. The user set is created.

The newly created set appears on the User Sets tab.

	Name	Updated At ↓	Description	
☐	userset	14 Sep 2022, 12:34	A test user set	...
☐	testuserset	14 Sep 2022, 15:05	Test user set	...

Creating User Sets by Adding Members Manually

This method is useful when you already know the names of users and groups that should be added to a user set. Also, use this method to add AD users and groups to the user set.

Using Variables

You can also use the variables `|uname|` (user name) and `|gname|` (group name) when adding members manually. On the UNIX systems, `|uid|` and `|gid|` can also be used.

When the security rule is applied, the variable is replaced by the actual user name or user group name. For example, if **Directory** is set to `/opt/local/|gname|`, when you later make `/opt/local` the GuardPoint, only the members of the group **engineering** in **Users** are allowed access to `/opt/local/engineering`. `|uname|` and `|gname|` act like macros.

Similarly, if you want to define a policy to protect all of the user directories under `/home`, you don't need to enumerate `/home/user1`, `/home/user2`, `/home/user3`, and so on. You only need to define `/home/|uname|`. When the agent evaluates the policy, it replaces `|uname|` with the actual user. So, when **user1** logs on, the agent evaluates the policy with `/home/user1`. They can't access `/home/user2`.

To create a user set:

1. Open the **Transparent Encryption** application.
2. Click **Policies > Policy Elements**.
3. Click the **User Sets** tab.
4. Click **Create User Set**. The Create User Set wizard is displayed.
5. On the **General Info** screen:
 - a. Enter a unique Name for the set.
 - The name must start with a character. The maximum length can be 64 characters.
 - The name can contain alphanumeric characters, underscores (`_`), and dashes (`-`).
 - The name cannot contain the following special characters:
`? : ; | ! @ # $ % ^ & * < = > + ( ) { } ~ , \ / [ ] ' "`
 - b. (Optional) Provide a **Description** for the set.
 - c. Click **Next**. The Add Users screen is displayed.
 - d. Click **Create User**.

To browse the client for adding members manually, click the **Browse to Add Users** tab. This tab allows you to browse the client for members. Refer to [Creating User Sets by Browsing the Client](#) for details.

6. On the **Manually Add Users** tab, specify the following details, as appropriate:

Element	Description
uname	Login name of the user.
UID	(AIX/Linux only) ID of the user.
gname	Comma-separated list of group names.
GID	(AIX/Linux only) Group ID of the user. Specify only the primary group ID.
OS domain	(Windows only) Network domain of the user. Multiple domain names, separated by commas, can be entered. Specify the string <code>localhost</code> to configure a generic domain.

7. Click **Create**.

To add more users, click **Create User**. You can add different types of users and groups simultaneously.

If you want to remove users from the set, identify the user and click **Remove** next to the user.

8. Click **Next**. The Confirmation screen shows general information about the set and the selected members.

9. Verify the set details.

If the details are incorrect or you want to modify them, click **Back** and update the details.

10. Click **Save**. The user set is created.

The newly created set appears on the User Sets tab.

Creating Signature Sets

A signature set is a collection of hashes of processes and executables that you want to grant or deny access to GuardPoints. A signature set can be configured in a policy as part of a process set to verify the integrity of a process before it is allowed access to guarded data. Policies are applied to signature sets, not to individual signatures.

To create a signature set:

1. Open the **Transparent Encryption** application.
2. Click **Policies > Policy Elements**.
3. Click the **Signature Sets** tab.
4. Click **Create Signature Set**. The General Info screen of the Create Signature Set wizard is displayed.

General Info

1. Enter a unique **Name** for the set.

- The name must start with a character. The maximum length can be 64 characters.
- The name can contain alphanumeric characters, underscores (`_`), and dashes (`-`).
- The name cannot contain the following special characters:
`? : ; | ! @ # $ % ^ & * < = > + ( ) { } ~ , \ / [ ] ' "`

2. Select **Application** as the **Type**. The signature set will have signatures of the running applications.
3. (Optional) Provide a **Description** for the set.
4. Enable or disable the **Add Signatures** toggle. If you enable this option, an **3 - Add Signatures** screen becomes available.
5. Click **Next**. The Add Sources screen is displayed. On this screen, you can add files to be signed, as described below.

Add Sources

Specify path of the directory or file to be signed. If a directory is specified, all files in the directory and its subdirectories are signed.

The CipherTrust Manager provides an option to add multiple sources. A maximum of 200 sources can be added at once.

1. Click **Add Source**.
2. Click **Select Client**. The list of registered clients is displayed.
3. Select the desired client.

Status	Name	OS Type	Description
☒ Healthy	10.164.13.209	LINUX	ABLinux
☐ Healthy	ABWin	WINDOWS	AB Windows Client

4. Click **Select**. The selected client appears next to the Change Client button (previously Select Client).

If needed, change the client by clicking **Change Client**.

5. Specify the path to be signed by either typing manually or using the browser.

Client

SELECTED SOURCES

/usr/bin **Remove**

Enter Source:

Select Source:

usr bin

Optionally, you can add a new source by clicking **Add Source**. To remove a source, click **Remove** to the right of the source. A signature set must contain at least one source.

- Click **Add**. The selected source is displayed in the Source Directory list.

Optionally, you can add a new source by clicking **Add Source**. To remove a source, click the overflow icon () corresponding to the source and click **Remove**.

- Click **Next**. The Add Signatures screen is displayed. On this screen, you can manually add signatures or upload a CSV file containing signatures.

Add Signatures

If you enabled **Add Signatures** on the **General Info** screen, CipherTrust Manager provides options to add signatures to a signature set manually, and to upload the signatures to a signature set through CSV.

Click the desired tab to view the instructions.

Adding Signatures to a Signature Set Manually

- Click **Create Signature**. The Create Manually tab is displayed.
- Under **Signature 1**, enter the following details:
 - Program**: Full path of the file.
 - Signature**: Signature of the file.

To add multiple signatures, click **+ Add More Signatures**. To remove a signature, click **X**.

- Click **Add**. The signatures are added to the signature set. The list of programs and their signatures are displayed.

Optionally, you can add more signature(s) by clicking **Create Signature**, and repeating step 2 and 3. To remove a signature, click the overflow icon () corresponding to the signature and click **Remove**.

- Click **Next**. The Confirmation screen is displayed. The screen shows the General Info, Sources and Signatures details of the signature set.

Uploading Signatures to a Signature Set through CSV

- Click **Create Signature**. The Create Manually tab is displayed.
- Click the **Upload** tab.
 - Next to **Upload CSV**, click **Browse**.
 - Select and upload the CSV file. The Upload CSV field shows the uploaded file.
- Click **Add**. The signatures from the CSV file are added. The name of the file is displayed.

Optionally, you can change the file by clicking **Create Signature**, and repeating step 2 and 3. To remove the file, click the overflow icon () corresponding to the uploaded CSV file and click **Remove**.

- Click **Next**. The Confirmation screen is displayed. The screen shows the General Info, Sources and Signatures details of the signature set.

Confirmation

- Verify the set details. If the details are incorrect or you want to modify them, click **Back** and update the details.
- Click **Save**.

The newly created set appears on the Signature Sets tab. By default, the signature set has the status **UNSIGNED**.

	Name	Type	Signing Status	Updated At ↓	Description	
☐	testsigset	Application	Unsigned	24 Nov 2022, 14:14	Test signature set	
☐	test	Container Image	Unsigned	24 Nov 2022, 14:12		

It is recommended that the signature set is signed before you apply policies to processes. This ensures that a tampered with or compromised process executable is not granted permissions to access protected GuardPoints. Refer to [Signing Files in a Signature Set](#) for details.

Creating Signature Sets for Container Images

A signature set is a collection of file names and their signatures. A signature is a hash of a process or an executable file. Through signature sets, a signature can be used to verify the integrity of the process before it is allowed access to the guarded data.

You can enter the full path of files and their signatures manually or use the browser to upload YAML files containing the list of files and their signatures.

To create a signature set for CTE for Container Images:

1. Open the **Transparent Encryption** application.
2. Click **Policies > Policy Elements**.
3. Click the **Signature Sets** tab.
4. Click **Create Signature Set**. The General Info screen of the Create Signature Set wizard is displayed.

General Info

1. Enter a unique **Name** for the set.
 - The name must start with a character. The maximum length can be 64 characters.
 - The name can contain alphanumeric characters, underscores (`_`), and dashes (`-`).
 - The name cannot contain the following special characters:
`? : ; | ! @ # $ % ^ & * < = > + ( ) { } ~ , \ / [ ] ' "`
2. Select **Container Image** as the **Type**. The signature set will have the signatures of containers.
3. (Optional) Provide a **Description** for the set.
4. Enable or disable **Add Signatures**.
5. Click **Next**. The Add Sources screen is displayed. On this screen, you can add source paths or upload the YAML file containing the source paths, as described below.

Add Sources

Specify path of the directory or file to be signed. If a directory is specified, all files in the directory and its subdirectories are signed.

The CipherTrust Manager provides an option to add multiple sources. A maximum of 200 sources can be added at once.

Click the desired tab to view the instructions.

Adding Sources Manually

1. Click **Add Source**. The Create Manually tab is displayed.
2. In the **Enter Source** field, add source for the container images to be trusted.
3. Click **Add**. The sources are added to the signature set. The list of Source Directory is displayed.

Optionally, you can add more sources by clicking **Add Source**, and repeating step 2 and 3. To remove a source, click the overflow icon () corresponding to the source and click **Remove**.

4. Click **Next**. The Add Signatures screen is displayed. On this screen, you can manually add signatures or upload the list of signatures.
-

Uploading Sources through YAML

1. Click **Add Source**. The Create Manually tab is displayed.
2. Click the **Browse** tab.
 - a. Next to **Upload YAML**, click **Browse**.
 - b. Select and upload the YAML file that contains the source for the container images to be trusted. The Upload YAML field shows the uploaded file.
3. Click **Add**. The sources from the YAML file are added. The name of the file is displayed.

Optionally, you can change the file by clicking **Add Source**, and repeating step 2 and 3. To remove a signature, click the overflow icon () corresponding to the source and click **Remove**.

4. Click **Next**. The Add Signatures screen is displayed. On this screen, you can manually add signatures or upload the list of signatures.

Note

The Add Signatures tabs is displayed if you selected **Add Signatures** on the General Info screen.

Add Signatures

If you enabled **Add Signatures** on the **General Info** screen, CipherTrust Manager provides options to add signatures to a signature set manually, and to upload the signatures to a signature set through CSV.

Click the desired tab to view the instructions.

Adding Signatures to a Signature Set Manually

1. Click **Create Signature**. The Create Manually tab is displayed.
2. Under **Signature 1**, enter the following details:
 - **Program**: Full path of the file.
 - **Signature**: Signature of the file.

To add multiple signatures, click **+ Add More Signatures**. To remove a signature, click **X**.

3. Click **Add**. The signatures are added to the signature set. The list of programs and their signatures are displayed.

Optionally, you can add more signature(s) by clicking **Create Signature**, and repeating step 2 and 3. To remove a signature, click the overflow icon () corresponding to the signature and click **Remove**.

4. Click **Next**. The Confirmation screen is displayed. The screen shows the General Info, Sources and

Signatures details of the signature set.

Uploading Signatures to a Signature Set through CSV

1. Click **Create Signature**. The Create Manually tab is displayed.
2. Click the **Upload** tab.
 - a. Next to **Upload CSV**, click **Browse**.
 - b. Select and upload the CSV file. The Upload CSV field shows the uploaded file.
3. Click **Add**. The signatures from the CSV file are added. The name of the file is displayed.

Optionally, you can change the file by clicking **Create Signature**, and repeating step 2 and 3. To remove the file, click the overflow icon () corresponding to the uploaded CSV file and click **Remove**.

4. Click **Next**. The Confirmation screen is displayed. The screen shows the General Info, Sources and Signatures details of the signature set.

Confirmation

1. Verify the set details. If the details are incorrect or you want to modify them, click **Back** and update the details.
2. Click **Save**.

The newly created set appears on the Signature Sets tab. By default, the signature set has the status **UNSIGNED**.

Creating Process Sets

A process set is a collection of processes (executables) that you want to grant/deny access to GuardPoints or exempt from RWP monitoring. Like user sets, process sets can be configured in policies. Policies can be applied to process sets, not to individual processes.

In a process set, you can also specify processes with and without signatures and directories to be exempted from RWP monitoring. This process set can be used as a Trusted Process Set in the [Ransomware Protection Configuration](#).

Optionally, file signing can be configured to check the authenticity and integrity of executables and applications before they are allowed to access GuardPoint data. A signature set must already exist before you can configure file signing in a policy for a process set.

Use the Create Process Set wizard to create process sets.

To create a process set:

1. Open the **Transparent Encryption** application.
 2. Click **Policies > Policy Elements**.
 3. Click the **Process Sets** tab.
 4. Click **Create Process Set**. The Create Process Set wizard is displayed.
-

5. On the **General Info** screen:

- a. Enter a unique **Name** for the set.
 - The name must start with a character. The maximum length can be 64 characters.
 - The name can contain alphanumeric characters, underscores (`_`), and dashes (`-`).
 - The name cannot contain the following special characters:
`? : ; | ! @ # $ % ^ & * < = > + ( ) { } ~ , \ / [ ] ' "`
- b. Provide a **Description** for the set.
- c. Click **Next**. The Add Processes screen is displayed.

6. On the **Add Processes** screen:

- a. Click **Create Process**.
- b. Click **Select** next to the Directory field. The Browse Path dialog box is displayed.
 - a. Click **Select Client**. The list of registered clients is displayed.
 - b. Select the desired client and click **Add**. The selected client appears next to the **Change Client** button. Click this button to change the client. The dialog box shows the filesystem of the selected client.
- c. Select the directory and file(s). The selected path automatically appears in the Search Local Path field.

Alternatively, specify the process name (with its path) in the **Search Local Path** field. Use `/` (forward slashes) to specify the path. A directory path must end with `/`.

You can also **Add Full Directory** or select multiple files of a single directory individually. Select a file and click **Add Path**.

The selected directory and process appear in the **Selected Directory** and **Selected Files** fields. If a process is not selected, the **Selected Files** field shows an (`*`) asterisk. The asterisk acts as a wild card character.

- d. Click **Add**.

Alternatively, you can update or specify the directory and process in the **Directory** and **File** fields. Use `/` (forward slashes) to specify the path. A directory path must end with `/`.

- c. Link the desired signature set to the process set.
 - a. Click **Select** next to the Signature field. The list of Application type signature sets is displayed.

The signature sets of the Container Image type are not displayed. They are used by the CTE for Kubernetes policies.

Optionally, you can create a new signature set by clicking **Create Signature Set**, and link it with the process set. Refer to [Creating Signature Sets](#) for details.

b. Select the desired signature set.

c. Click **Add**.

The selected signature set appears in the Signature field.

d. Link the desired RWP Exempted Resource to the process set.

Note

It is recommended to add the resource set if the process set is used as the Trusted Process Set in the [Ransomware Protection Configuration](#).

a. Click **Select** next to the RWP Exempted Resource. The list of Application type resource sets is displayed.

b. Select the desired **Resource Set** from the list.

c. Click **Add**.

7. Click **Add**. The Confirmation screen shows general information about the set.

Directory	File	Signature	
/usr/bin/	*	testsigset	...

8. Verify the set details.

If the details are incorrect or you want to modify them, click **Back** and update the details. To add another process, click **Create Process**, and specify the details, as described above.

To remove a process, click the overflow icon () corresponding to the desired process and click **Remove**.

9. Click **Next**.

10. Review the process set details.

11. Click **Save**. The process set is created.

The newly created set appears on the Process Sets tab.

	Name	Updated At ↓	Description	
☐	testprocessset	18-Aug-2020, 12:34	Test process set	...
☐	aprocesstest	18-Aug-2020, 12:34	A process set	...

After you have created policy elements, you can use them in creating and configuring policies. Refer to [Creating Policies](#) for details.

Viewing Policy Elements

The Policy Elements page shows the list of configured policy elements.

Note

Any updates to the policy elements will be applied without confirmation if the linked policy is not in use by any Enabled/Active GuardPoints.

To view the policy elements:

1. Open the **Transparent Encryption** application.
2. Click **Policies > Policy Elements**. The Policy Elements page contains the following tabs:

Column	Description
Resource Sets	Displays the list of configured resource sets. This is the default tab.
User Sets	Displays the list of configured user sets.
Process Sets	Displays the list of configured process sets.
Signature Sets	Displays the list of configured signature sets.

3. Click the **Resource Sets** tab. This tab displays the following details:

	Name	Type	Updated At ↓	Description	
☐	resourceset	Directory	18-Aug-2020, 11:47	Resource set	...
☐	5G-ResourceSet	Directory	18-Aug-2020, 11:38		...

Column	Description
Name	Name of the resource set.
Updated At	Time when the set is created or updated.
Description	Optional description of the resource set.

By default, the records are displayed in descending order by Updated At. To add a new resource set, refer to [Creating Resource Sets](#).

To modify an existing resource set, click the desired set, modify the **Description**, and click **Apply**.

The edit view also provides the **Add Resource** button to add new resources to the set. While saving the new resource details, specify the applicable OS for the resource - Windows or Non Windows.

- Click the **User Sets** tab. This tab displays the following details:

Name	Updated At ↓	Description	
☐ userset	14 Sep 2022, 12:34	A test user set	...
☐ testuserset	14 Sep 2022, 15:05	Test user set	...

Column	Description
Name	Name of the user set.
Updated At	Time when the set is created or updated.
Description	Optional description of the user set.

By default, the records are displayed in descending order by Updated At. To add a new user set, refer to [Creating User Sets](#).

To modify an existing user set, click the desired set, modify the **Description**, and click **Apply**. The edit view also provides the **Browse users** and **Manually add user** buttons to add new users to the set.

- Click the **Process Sets** tab. This tab displays the following details:

Name	Updated At ↓	Description	
☐ testprocessset	18 Aug 2020, 12:34	Test process set	...
☐ aprocessset	18 Aug 2020, 12:34	A process set	...

Column	Description
Name	Name of the process set.
Updated At	Time when the set is created or updated.
Description	Optional description of the process set.

By default, the records are displayed in descending order by Updated At. To add a new process set, refer to [Creating Process Sets](#).

To modify an existing process set, click the desired set, modify the **Description**, and click **Apply**. The edit view also provides the **Add Process** button to add new processes to the set.

6. Click the **Signature Sets** tab. This tab displays the following details:

Name	Type	Signing Status	Updated At ↓	Description	
☐ testsigset	Application	Unsigned	24 Nov 2022, 14:14	Test signature set	...
☐ test	Container Image	Unsigned	24 Nov 2022, 14:12		...

Column	Description
Name	Name of the signature set.
Type	Type of the signature set. The type can be: • Application: The signature set will have signatures of the running applications. • Container Image: The signature set will have the signatures of containers.
Signing Status	Signing status of the signature set. Refer to Checking Signing Completion Status) for details.
Updated At	Time when the set is created or updated.
Description	Optional description of the signature set.

By default, the records are displayed in descending order by Updated At. To add a new signature set, click **Create Signature Set** (refer to [Creating Signature Sets](#)).

To add a new source to an existing signature set, click the desired set, and click **Add Source**. Refer to [Creating Signature Sets](#) for details.

To add a new signature to an existing signature set, click the desired set, click the **Signature** tab, and click **Create Signature**. Refer to [Creating Signature Sets](#) for details.

Creating Policies

A policy is a collection of rules that govern data access and encryption. Think of a policy as an if-then statement. Policy rules are processed sequentially. If the criteria of rule one are not met, the policy enforcement engine moves on to the second rule and so on.

Policies specify:

- **Actors:** Users, groups, and processes that are permitted/denied access to protected data.
- **Actions:** What actions authorized actors are allowed to perform. For example create/delete, read/write, decrypt, modify permissions, and so on.
- **Files acted upon:** Policy rules may apply to entire directories and mount points, or only to files named in a specific way (for example, `.docx` files may be encrypted and restricted to read-only access by designated users, while other files may be stored clear and read and written by anyone).

Additionally, every CTE policy specifies one or more encryption keys used to encrypt blocks of file data when applications write them, and decrypt them when they are read.

CTE encryption is transparent to applications. This means that the CTE Agent encrypts blocks of data as they are written, and decrypts data when they are read by authorized users and applications. This architecture separates administration of files from access to the data in them. Backup programs, for example, may be authorized to read files, but not view the data in them. Therefore, data can be backed up and taken offsite while remaining encrypted so that security is not breached.

The following diagram shows policies and how they relate to the GuardPoints, clients, and the CipherTrust Manager.

Before you can create a policy, policy elements should exist on the CipherTrust Manager. This section assumes that you have already created policy elements, as described in [Creating Policy Elements](#).

When creating a policy, you can specify security rules, key rules, and data transformation rules that apply to the policy. At least one key or security rule must be added to a policy. Use the Create Policy wizard to create a policy.

Step 1: Specify General Information

To specify general information about policy:

1. Open the **Transparent Encryption** application.
2. Click **Policies**. The Policies page shows the list of available policies.
3. Click **Create Policy**.
4. Specify a unique **Name** for the policy. For example, basic-access-policy or ldt-policy.
 - The name must start with a character. The maximum length can be 64 characters.
 - The name can contain alphanumeric characters, underscores (`_`), and dashes (`-`).
 - The name cannot contain the following special characters:
`? : ; | ! @ # $ % ^ & * < = > + ( ) { } ~ , \ / [ ] ' "`
5. Select a **Policy Type**. The options are:
 - **Standard**: Access to data is blocked during initial encryption or rekeying of data. This is the default policy type. Refer to [Creating Standard GuardPoints](#) for details.
 - **Live Data Transformation**: Encryption and rekeying of data takes place in the background, without disrupting user or application access to that data. The LDT policy is available if you have a valid LDT license.

 If you select an LDT policy type, then the first security rule for the policy is created by default. This rule permits key operations on all resources for that policy, without denying user or application access to resources. This allows a rekey operation whenever the encryption key is versioned. This rule is always the first rule in an LDT policy and cannot be edited.
 - Refer to [Enabling Live Data Transformation](#) for more information about LDT.
 - An LDT policy is needed for creating LDT GuardPoints. Refer to [Creating LDT GuardPoints on Clients](#) for details.
 - **Cloud Object Storage (COS)**: Access to data is blocked during initial encryption or rekeying of data. This policy type is needed for creating GuardPoints for cloud storages. Refer to [Creating Cloud Object Storage GuardPoints on Clients](#) for details.
 - **In-place Data Transformation (IDT)**: Access to data is blocked during encryption or rekeying of data. This policy type is needed for creating GuardPoints for Teradata clusters. Refer to [Creating IDT GuardPoints](#) for details.
 - **CTE for Kubernetes**: Applicable to GuardPolicies for CTE for Kubernetes (K8s) clients. Access to data is blocked during initial encryption or rekeying of data. The CTE for Kubernetes policies are used to protect K8s clients. Refer to [Protecting Kubernetes Clients](#) for details.

6. Provide a basic **Description** for the policy.
7. (Optional) Turn on the **Learn Mode** toggle. A warning message is displayed indicating that the policy is in Learn Mode.

Learn Mode:

Warning: This Policy is in Learn Mode [Click here for more details](#)

Refer to [Learn Mode](#) for details. By default, the toggle is turned off.

Note

Learn Mode is not applicable to *In-place Data Transformation* policies.

8. (Optional) Turn on the **Restrict Update** toggle. This option is used to restrict or allow any changes to the policy. By default, the toggle is turned off. This setting can be changed any time after the policy is created. Refer to [Controlling Updates to Policies](#).
9. (Optional, applicable to *Standard* policies) Turn on the **Data Transformation** toggle. This option is used to create a *data transformation* policy. By default, the toggle is turned off.

Note

The Data Transformation option is not applicable to *LDT*, *Cloud Object Storage*, and *In-place Data Transformation* policies. For a data transformation policy, the Create Policy wizard shows five steps including the Data Transformation step, as shown below.

Create Policy [?]

1 General Info 2 Security Rules 3 Key Rules 4 Data Transformation 5 Confirmation

10. Click **Next**. The Security Rules screen is displayed.

For a *standard data transformation* policy, a security rule with the Action **key_op**, the Effect **permit**, **applykey**, and Browsing set to Yes is added automatically. Edit or delete the rule, as appropriate. Click the overflow icon (**⋮**) for options.

Resource Set	User Set	Process Set	Action	Effect	Browsing
			key_op	permit,applykey	Yes

For an *LDT policy*, the default security rule with the Action **key_op**, the Effect **permit, applykey**, and Browsing set to No is added automatically. The rule is *read only*.

Resource Set	User Set	Process Set	Action	Effect	Browsing
			key_op	permit,applykey	No

Step 2: Add Security Rules

1. Click **Add Security Rule**. The Create Security Rule dialog box is displayed. This dialog box contains the following fields:

Field	Description
Resource Set	(Not applicable to <i>COS</i> policies) Resource set for the rule.
User Set	User set for the rule.
Process Set	Process set for the rule.
Action	Actions for the rule. Refer to Actions for the complete list of supported actions.
Effect	Effect permission and options for the rule. This is a mandatory field.
Allow Browsing	(Not applicable to <i>COS</i> and <i>CTE for Kubernetes</i> policies) Whether browsing of directories under the GuardPoint down to the resources in the rule is allowed.

2. (Optional, not applicable to *COS* policies) Select a **Resource Set**.
 - a. Click **Select** next to the Resource Set field. The list of available resource sets is displayed.

Optionally, you can add a new resource set by clicking **Create Resource Set**. Walk through the Create Resource Set wizard, as described in [Creating Resource Sets](#). The newly created resource set appears in the resource sets list.
 - b. Select a resource set.
 - c. (Optional) Select **Exclude Rule** to exclude the resource set from the policy. The security rule does not apply to this resource set.

d. Click **Select**. The selected resource set appears in the Resource Set field.

3. (Optional) Select a **User Set**.

a. Click **Select** next to the User Set field. The list of available user sets is displayed.

Optionally, you can add a new user set by clicking **Create User Set**. Walk through the Create User Set wizard, as described in [Creating User Sets](#). The newly created user set appears in the user sets list.

b. Select a user set.

c. Click **Select**. The selected user set appears in the User Set field.

4. (Optional) Select a **Process Set**.

a. Click **Select** next to the Process Set field. The list of available process sets is displayed.

Optionally, you can add a new process set by clicking **Create Process Set**. Walk through the Create Process Set wizard, as described in [Creating Process Sets](#). The newly created process set appears in the process sets list.

b. Select a process set.

c. (Optional) Select **Exclude Rule** to exclude the process set from the policy. The security rule does not apply to this process set.

d. Click **Select**. The selected process set appears in the Process Set field.

5. (Optional) Select an **Action**. Specify the type of file and directory action allowed on a GuardPoint. To specify *all* actions, leave the **Action** field blank.

a. Click **Select** next to the Action field. By default, the Select Action(s) dialog box displays basic actions.

To view advanced actions, expand **Advanced Options** by clicking **+**. The Select Action(s) dialog box provides the names and brief description of actions. Refer to [Actions](#) for the complete list of supported actions.

b. Select the desired actions.

Note

- For a data transformation policy, the action **key_op** is selected automatically. If you select **key_op**, then you must add a data transformation rule.
- For an IDT policy, the allowed actions are **read**, **write**, and **all_ops**.

c. Click **Select**. The selected actions appear in the Action field.

6. Select an **Effect**. Effect is the action that occurs when the attempted access matches all the criteria in the rule. This is a mandatory field. The default action is Deny.
 - a. Click **Select** next to the Effect field. The Select Effect dialog box displays the available Effect Permissions and Effect Options.
 - b. From the **Effect Permissions** list, select a permission. An effect must have a permission. The available options are:
 - **Deny**: Denies the access attempts to a resource. For example, you can specify an effect that denies any attempts to access a resource.
 - **Permit**: Allows the access attempt to a resource. For example, you can specify an effect that allows writing to a resource.
 - c. From the **Effect Options** list, select appropriate options. The available options are:
 - **ApplyKey**: Applies an encryption key to data in a GuardPoint. When applied, data copied to the GuardPoint is encrypted with the key specified on the Create Key Rule screen and data that is accessed in the GuardPoint is decrypted using the same key. It allows the access attempt to the resource. For example, you can specify an effect that allows writing to a directory.

Note

If you select ApplyKey, you must also specify the key rules to apply for encrypting and decrypting the resources. Refer to [Step 3: Add Key Rules](#) for details.

- **Audit**: Creates a message log entry for each qualifying event. It records what, when, and who is accessing the information.
- d. Click **Select**. The selected effects appear in the Effect field.
7. (Optional, not applicable to *COS* and *CTE for Kubernetes* policies) Specify whether to **Allow Browsing** the directories under the GuardPoint down to the resources in the rule.

By default, the **Allow Browsing** toggle is on. Users that match the criteria set by the security rule can access the directories between the GuardPoint and the resource. If you define a resource, then that resource should exist in the GuardPoint. The files in these directories can be listed like any file in a browser, but they cannot be modified, copied, or deleted.

To prevent users from browsing the directories under the GuardPoint, turn off the **Allow Browsing** toggle.

8. Click **Add**. The newly created security rule appears in the list of security rules.

Similarly, you can add multiple security rules to the policy by clicking **Create Security Rule**. To delete a security rule, click **Delete** next to the rule.

Note

A security rule with the **ApplyKey** Effect must be supported by at least one key rule. Refer to [Step 3: Add Key Rules](#).

9. Click **Next**. The Key Rules screen is displayed.

Step 3: Add Key Rules

If you added a security rule with the Effect **ApplyKey** on the Security Rules screen, then you must add at least one key rule.

Note

For the **IDT** policies, only *one* key rule can be specified. So, you only need to specify the **Current Key** and **Transformation Key**. You can add a `clear_key`, `XTS`, `CBC`, or `CBC_CS1` key as the **Current Key**. After adding the key, click **Next**. Verify the policy details on the Confirmation screen. Refer to [Step 5: Confirm Details](#).

To add a key rule:

1. Click **Create Key Rule**. The Create Key Rule dialog box is displayed.
2. (Optional, not applicable to *COS* policies) Select a **Resource Set**.
 - a. Click **Select** next to the Resource Set field. The list of available resource sets is displayed.

Optionally, you can add a new resource set by clicking **Create Resource Set**. The newly created resource set will appear in the resource sets list.
 - b. Select a resource set.
 - c. Click **Select**. The selected resource set appears in the Resource Set field.
3. Select a **Key Name**. This is a mandatory field. For *LDT* and Data Transformation policies, the field name is **Current Key Name** instead of Key Name.
 - a. Click **Select** next to the field. The Select Key dialog box shows the list of available keys. Optionally, you can create a new `CBC`, `CBC-CS1`, or `XTS` key on this dialog box.

To create a new key

- a. Click **Create a New Key**. The **Key created will be AES 256** section is displayed on the dialog box below.

- b. Specify an optional **Name** for the key.
- c. Select the **Encryption Mode**. The encryption mode can be CBC, CBC-CS1, or XTS. The default mode is CBC.
- d. (Optional, not applicable to COS and CTE for Kubernetes policies) Select **Unique to Client** to make the key a unique to client key.
- e. Click **Create**. The newly created key appears in the keys list.

If you selected the **Unique to Client** check box when creating the key, you will see a check mark for the key under the Unique to Client column. This indicates the key is a unique to client key. Refer to [Unique to Client Keys](#) for details.

Alternatively, encryption keys for CTE can be created on the **Keys** page of the CipherTrust Manager GUI. Refer to [Creating a New Key](#) for details.

Note

When creating the XTS keys using the CipherTrust Manager CLI or the API:

- Set the `xts` flag to `true`.
- Set the key as exportable, that is, set `unexportable` to `false`.
- Share the key with the CTE Users group with the `read_key` and `export_key` permissions.

Refer to the following sample for creating an XTS key:

```
{
  "name": "CTE-XTS-Key",
  "algorithm": "aes",
  "size": 256,
  "undeletable": true,
  "unexportable": false,
  "meta": {
    "ownerId": "local|59ba6797-e5a6-4427-b11c-a5534b5a975e",
    "permissions": {
      "ExportKey": [
        "CTE Clients"
      ],
      "ReadKey": [
        "CTE Clients"
      ]
    }
  }
}
```

```

    },
    "cte": {
      "persistent_on_client": true,
      "encryption_mode": "XTS",
      "cte_versioned": false
    }
  },
  "xts": true,
  "id": "95cc7868-89bf-492b-b868-bbb884a9b379"
}

```

Note

When an XTS key is created, an additional tweak key (<key-name>_xts) is generated with the original key. Make sure that both the original and the tweak keys are part of the CTE Users group with the read key (read_key) and export key (export_key) permissions.

- b. Select the desired key.

Note

For CTE for Kubernetes policies, select a CBC-CS1 key. These policies do not support XTS keys.

- c. Click **Select**. The selected key appears in the Key Name / Current Key Name field.

The next two steps are specific to *LDT* policies.

4. (Applicable to LDT policies) Select a **Transformation Key Name**. This is a mandatory field.

- a. Click **Select** next to the field. The list of available keys is displayed.

Optionally, you can create a new key by clicking **Create a New Key**. Optionally, specify a **Name** for the key and click **Create**. The newly created key will appear in the keys list.

Alternatively, encryption keys for CTE can be created on the **Keys** page of the CipherTrust Manager GUI. Refer to [Creating a New Key](#) for details.

- b. Select the desired key.
- c. Click **Select**. The selected key appears in the Transformation Key Name field.

-
- Click **Add**. The newly created key rule appears in the list of key rules.

Similarly, you can add multiple key rules to the policy by clicking **Create Key Rule**. To delete a key rule, click **Delete** next to the rule.

- Click **Next**.

For *Live Data Transformation*, *Cloud Object Storage*, and *In-place Data Transformation* policies, the Confirmation screen is displayed. Verify policy details, as described in [Step 6: Confirm Details](#).

For *Standard* policies, the following screen is displayed:

- **Data Transformation:** If you selected the **Data Transformation** check box on the **General Info** screen of the Create Policy wizard. Add data transformation rules, as described in [Step 4: Add Data Transformation Rules](#).
- **Confirmation:** If you cleared the **Data Transformation** check box. Verify policy details, as described in [Step 6: Confirm Details](#).

For *CTE for Kubernetes* policies, the following screen is displayed:

- **Data Transformation:** If you selected the **Data Transformation** check box on the **General Info** screen of the Create Policy wizard. Add data transformation rules, as described in [Step 4: Add Data Transformation Rules](#).
- **Signature Rules:** If you cleared the **Data Transformation** check box. Add signature rules, as described in [Step 5: Add Signature Rules](#).

Step 4: Add Data Transformation Rules

This step is applicable to *Standard* and *CTE for Kubernetes* policies if you selected the Data Transformation check box on the General Info screen of the Create Policy wizard.

- Click **Create Data Transformation Rule**. The Create Data Transformation Rule dialog box is displayed.
- (Optional) Select a **Resource Set**.

- Click **Select** next to the Resource Set field. The list of available resource sets is displayed.

Optionally, you can add a new resource set by clicking **Create Resource Set**. The newly created resource set will appear in the resource sets list.

- Select a resource set.
- Click **Select**. The selected resource set appears in the Resource Set field.

- Select the **Transformation Key Name**. This is a mandatory field.

- Click **Select** next to the Transformation Key Name field. The Select Key dialog box shows the list of available keys. Optionally, you can create a new CBC, CBC-CS1, or XTS key on this dialog box.

To create a new key

- a. Click **Create a New Key**. The **Key created will be AES 256** section is displayed on the dialog box below.
- b. Specify an optional **Name** for the key.
- c. Select the **Encryption Mode**. The encryption mode can be CBC, CBC-CS1, or XTS. The default mode is CBC.
- d. (Optional, not applicable to COS and CTE for Kubernetes policies) Select **Unique to Client** to make the key a unique to client key.
- e. Click **Create**. The newly created key appears in the keys list.

If you selected the **Unique to Client** check box when creating the key, you will see a check mark for the key under the Unique to Client column. This indicates the key is a unique to client key. Refer to [Unique to Client Keys](#) for details.

Alternatively, encryption keys for CTE can be created on the **Keys** page of the CipherTrust Manager GUI. Refer to [Creating a New Key](#) for details.

Note

When creating the XTS keys using the CipherTrust Manager CLI or the API:

- Set the `xts` flag to `true`.
- Set the key as exportable, that is, set `unexportable` to `false`.
- Share the key with the CTE Users group with the `read_key` and `export_key` permissions.

Refer to the following sample for creating an XTS key:

```
{
  "name": "CTE-XTS-Key",
  "algorithm": "aes",
  "size": 256,
  "undeletable": true,
  "unexportable": false,
  "meta": {
    "ownerId": "local|59ba6797-e5a6-4427-b11c-a5534b5a975e",
    "permissions": {
      "ExportKey": [
        "CTE Clients"
      ],
    },
  },
}
```

```

    "ReadKey": [
      "CTE Clients"
    ],
  },
  "cte": {
    "persistent_on_client": true,
    "encryption_mode": "XTS",
    "cte_versioned": false
  },
  "xts": true,
  "id": "95cc7868-89bf-492b-b868-bbb884a9b379"
}

```

Note

When an XTS key is created, an additional tweak key (<key-name>_xts) is generated with the original key. Make sure that both the original and the tweak keys are part of the CTE Users group with the read key (read_key) and export key (export_key) permissions.

- b. Select the desired key.
- c. Click **Select**. The selected key appears in the Transformation Key field.
4. Click **Add**. The newly created data transformation rule appears in the list of rules.

Similarly, you can add multiple rules to the policy by clicking **Create Data Transformation Rule**. To delete a rule, click **Delete** next to the rule.

5. Click **Next**. The Confirmation screen is displayed.

Step 5: Add Signature Rules

This step is applicable to *CTE for Kubernetes* policies.

A signature rule is a type of signature sets that contains container image signatures. Signature rules can only be associated with CTE for Kubernetes policies.

1. Click **Add Signature Rule**. The Add Signature Rule dialog box is displayed. The list of available signature rules is displayed.
2. Select the desired signature rules.

Note

Ensure that you have already created a [signature set for container images](#).

- Click **Add**. The newly added rule appears in the list of signature sets on the Signature Rules tab.

Similarly, you can add more rules to the policy by clicking **Add Signature Rule**. To delete a rule, click **Remove** next to the rule.

- Click **Next**. The Confirmation screen is displayed.

Step 6: Confirm Details

- Verify the policy details. The Confirmation screen displays general information about the policy and details of the rules added to the policy.

If the details are incorrect or you want to modify them, click **Back** and update the details.

- Click **Save**.

The newly created policy appears in the policies list on the Policies page. Similarly, add as many policies as required. A sample list of policies is shown below:

	Name	Type		Version	Updated At ↓	Description	Learn Mode	
☐	test-k8s-plc	CTE for Kubernetes		0	20 Jun 2022, 10:17	Test K8s policy		...
☐	test-idt-plc	In-place Data Transformation		1	14 Mar 2022, 12:02	Test IDT policy	N/A	...
☐	testpolicy	Standard		1	14 Mar 2022, 12:02	Test standard...		...
☐	ldtplc	Live Data Transformation		1	14 Mar 2022, 12:01	Test LDT policy		...
☐	testcosplc	Cloud Object Storage		1	14 Mar 2022, 12:01	Test COS policy		...

Creating a New Key

When creating a key rule for a policy, you can either select an existing key or create a new key. The list of available keys is displayed on the Select Key dialog box. The new keys that you create on this dialog box appear under the keys list.

Alternatively, encryption keys for CTE can be created on the **Keys** page of the CipherTrust Manager GUI, as described below. However, XTS keys must be created on the Select Key dialog box only.

Note

The CTE keys must be:

- AES-128, AES-256, ARIA-128, or ARIA-256
- Shared with the CTE Clients group
- Set as exportable

Only the clients that support the CBC CS1 encryption mode can have GuardPoints that use a policy with a CBC CS1 key.

To create a new key:

1. In the top left corner, click the App Switcher icon. The Products page is displayed.
2. In the left pane, click **Keys**. The Keys page is displayed.
3. Click **Add Key**.
4. Specify the **Key Name**.
5. Select the **Algorithm** from the drop-down list. The default algorithm is **AES**. CTE supports **AES** and **ARIA** algorithms.
6. Select the key **Size** from the drop-down list. The default size is **256**.
7. (Optional) Under **Key Properties**, select **XTS/CBC CS1** if you want to create a key for enhanced encryption mode.
8. (Optional) Under **CTE Property**, select **Unique to Client** if you want to create a unique to client key. Refer to [Unique to Client Keys](#) for details on these keys.
9. Click **Add Key** to create the key. The edit view of the key is displayed.

For an enhanced encryption key, a set of two keys is created with names **<key - name>** and **<key - name>_xts**.

10. In the mini detail view, turn on the **Exportable** toggle. This makes sure the key is displayed in the keys list when you add the key rule to the policy.
11. Specify whether the key can be deleted. To make the key deletable, turn on the **Deletable** toggle. By default, the **Deletable** toggle is turned off, that is, the key cannot be deleted.

Owner	local admin	Object Type	Symmetric Key
Created	06 Mar 2021, 22:39	Algorithm	AES
Last Modified	06 Mar 2021, 23:03	Size	256
Exportable	☒	Deletable	☒

12. Expand the **KEY ACCESS** section.

13. On the General tab:

- Make sure that the **Show All Groups** toggle is enabled. It displays the list of available groups.
- In the **Search groups** box, type **CTE Clients** to filter the groups. The **CTE Clients** group is displayed.
- Select the **All** check box. All the available permissions are selected.

KEY ACCESS

Group	Read	Use	Decrypt	Encrypt	Sign	Verify	Export	All
CTE Clients	☒	☒	☒	☒	☒	☒	☒	☒

Show All Groups ☒

1 group 5 per page

d. Click **Update**.

14. Click the **CTE** tab. You need to scroll down the page.

15. Specify the CTE key properties (metadata):

Note

You must be a member of **both** the **CTE Admins** and **Key Admins** groups to update the CTE key

properties.

Refer to [create users](#) and [assign groups](#) to them.

- **CTE Versioned:** Specify whether the key is versioned.
 - For Standard, COS, and IDT policies, clear the **CTE Versioned** check box. This makes sure that the key is displayed in the keys list when you add the key rule to the policy.
 - For LDT policies, make sure that the **CTE Versioned** check box is selected.
- **Unique to Client:** (Read only) Specifies whether the key is a unique to client key. This field is non-editable and its state (selected or clear) depends on how you configured the **Unique to Client** check box under **CTE Property** when creating the key.
- **Persistent on Client:** Specify whether the key is stored in persistent memory on the client.
 - When the check box is selected, the key is downloaded and stored (in an encrypted form) in persistent memory on the client. This can be used in the event that a connection to the CipherTrust Manager is unreliable.

Note

For a unique to client key, the **Persistent on Client** check box is selected automatically and is non-editable.

- When the check box is left clear, the key is only stored on disk inside the CipherTrust Manager. When required, the key is downloaded to the CTE client but only cached in memory. Every time the key is needed, the client retrieves it from the CipherTrust Manager.
- **Encryption Mode:** Encryption mode of the key. The options are:
 - **CBC CS1**
 - **XTS**
 - **CBC**

Note

- For ARIA-128 and ARIA-256 keys, select **CBC** as the encryption mode. These keys don't support the **CBC CS1** encryption mode.
- For CTE for Kubernetes policies, select **CBC CS1**. These policies do not support XTS keys.
- If you selected the **XTS/CBC CS1** check box when creating the key, you must select either **CBC CS1** or XTS as the encryption mode. Encryption using the XTS and **CBC CS1** keys is known as *enhanced encryption*. Refer to [Enhanced Encryption Mode](#) for details.

If you left the **XTS/CBC CS1** check box clear when creating the key, **CBC** is the available encryption mode.

Properties of a sample CTE key are shown below:

KMIP
NAE
CTE
Meta

 **CTE PROPERTIES**

☒ CTE Versioned
☐ Unique to Client
☒ Persistent on Client

Encryption Mode

CBC CS1 ▼

Note

To set Group Permissions for accessing this key, specify the settings on the General tab under the KEY ACCESS section.

16. Click **Update**.

The key is updated for use with CTE.

Note

- Only CTE Administrators (users of the **CTE Admins** group) can delete the CTE keys.
- An in-use CTE key cannot be deleted. Before you delete a CTE key, make sure that no key rule is using the key.

Modifying Policies and Rules

On the Policies page, you can view details of policies, update their description, and delete that policies that are no longer needed. Additionally, you can modify the key and security rules linked to the policy.

Note

Any updates to a policy will be applied without confirmation if the policy is not in use by any Enabled/Active GuardPoints.

Displaying Policies

The Policies page shows the list of configured policies with their details such as names, types, and versions. You can view the version history of policies from the Policies page. Additionally, you can delete policies from this page. In the detail view, you can view types of rules linked with the policies.

Additionally, the Policies page shows a warning banner at the top with the number of policies that have Learn Mode enabled for more than 3 days.

	Name	Type		Version	Updated At ↓	Description	Learn Mode	⚙

This section covers the following information:

- Viewing Policies

- Viewing Details of Policies
- Viewing Policy Version History
- Controlling Updates to Policies
- Updating Policy Description
- Cloning a Policy
- Adding New Security Rules
- Adding New Key Rules
- Adding New Data Transformation Rules
- Adding New Signature Rules
- Modifying Security Rules
- Modifying Key Rules
- Modifying Data Transformation Rules
- Modifying Signature Rules
- Automatic Addition/Removal of ApplyKey Effect for All Security Rules
- Exporting Policies
- Deleting Policies

Viewing Policies

To view the complete list of configured policies:

1. Open the **Transparent Encryption** application.
2. Click **Policies**. The Policies page shows the following details:

Column	Description
Name	Unique name of the policy.
Type	Type of the policy can be: • Standard • Live Data Transformation • Cloud Object Storage • In-place Data Transformation • CTE for Kubernetes

Column	Description
Version	Version of the policy. Click to view the version history of the policy. Refer to Viewing Policy Version History for details.
Updated At	Time when the policy is created or updated.
Description	Optional description of the policy.
Learn Mode	Whether Learn Mode is turned on for the policy. Use the toggle to turn on/off Learn Mode for the policy. Turning Learn Mode on/off automatically inserts/removes the ApplyKey effect for all security rules having the Deny effect. Refer to Automatic Insertion/Removal of ApplyKey Effect for All Security Rules for details. Turn off Learn Mode for the policy for which you have analyzed the valid processes and users.
Restrict Update	Whether the updates to the policy are restricted. Use the toggle to restrict or allow updates to the policy. Turning on the toggle restricts updates to the policy, which can be useful when the policy is in use by GuardPoints. However, turning off the toggle allows updates to the policy. Refer to Controlling Updates to Policies .

The **Restrict Update** column is hidden by default. To show/hide a column, click the custom view icon (⚙️), select/clear the desired column, and click **OK**.

By default, the policies are displayed in descending order by Updated At. By default, 10 records per page are displayed. Adjust pagination and/or the number of records to display per page to view more records.

To add a new policy, click Create Policy. Refer to [Creating Policies](#) for details.

Viewing Details of Policies

The detail view of a policy shows the security rules, key rules, and data transformation rules, as appropriate. The Restrict Update and Learn Mode toggles are also provided. Use these toggles to turn on or off learn mode and updates to the policy.

To view the details of a policy:

1. Open the **Transparent Encryption** application.
2. Click **Policies**. The list of configured policies is displayed.
3. Under **Name**, click the desired policy. The edit view of the policy is displayed. The rules linked with the policy are displayed on the following tabs:

- Security Rules
- Key Rules
- Data Transformation Rules (Applicable to policies that contain data transformation rules)
- Signature Rules (Applicable to CTE for Kubernetes policies)

Note

If a policy is in Learn Mode, a warning banner stating the following is displayed at the top of the page:

Warning: This Policy is in Learn Mode

To disable Learn Mode, turn off the **Learn Mode** toggle on the right.

If the Restrict Update toggle is turned on, updates to a policy that is in use by active GuardPoints are restricted. Security rules and key rules linked with the policy cannot be changed.

4. Click the **Security Rules** tab. This tab displays the following details:

Column	Description
Order	Sequence to enforce security rules. Rules higher in the order take higher priority. Click to edit the rule.
Resource Set	(Not applicable to Cloud Object Storage policies) Resource set linked with the rule. Click the link to edit the resource set.
User Set	User set linked with the rule. To modify an existing user set, click the desired user set link, modify the Description , and click Apply . The edit view also provides the Browse users and Manually add user buttons to add new users to the set.
Process Set	Process set linked with the rule. To modify an existing process set, click the desired process set link, modify the Description , and click Apply . The edit view also provides the Add Process button to add new processes to the set.
Action	Action applied to the rule. Refer to Actions for the complete list of supported actions.
Effect	Effect applied to the rule.

Column	Description
Browsing	Whether browsing of directories under the GuardPoint down to the resources in the rule is allowed. For Cloud Object Storage policies, No is displayed.

To add a new security rule, refer to [Step 2: Add Security Rules](#) for details.

- Click the **Key Rules** tab. This tab displays the following details:

Standard Policies

Column	Description
Order	Sequence to enforce key rules. Rules higher in the order take higher priority. Click to edit the rule.
Resource Set	Resource set linked with the key rule.
Key Name / Current Key Name	Encryption key currently applied to the resource. For Data Transformation policies, the name is Current Key Name .

Live Data Transformation Policies

Column	Description
Order	Sequence to enforce key rules. Rules higher in the order take higher priority. Click to edit the rule.
Resource Set	Resource set linked with the key rule. Click the link to edit the resource set.
Current Key Name	Encryption key currently applied to the resource.
Transformation Key Name	Encryption key to perform data transformation for LDT policies.
Exclusion Rule	Whether to exclude the resource set from the policy.

Cloud Object Storage Policies

Column	Description
Key Name	Name of the key.

In-place Data Transformation Policies

Column	Description
Current Key	Name of the current encryption key.
Transformation Key	Encryption key to perform data transformation for IDT policies.

CTE for Kubernetes Policies

Column	Description
Order	Sequence to enforce key rules. Rules higher in the order take higher priority. Click to edit the rule.
Resource Set	Resource set linked with the key rule. Click the link to edit the resource set.
Key Name	Encryption key currently applied to the resource.

To add a new key rule, refer to [Step 3: Add Key Rules](#) for details.

- Click the **Data Transformation Rules** tab. This tab is displayed if the policy contains data transformation rules. This tab displays the following details:

Column	Description
Order	Sequence to enforce key rules. Rules higher in the order take higher priority. Click to edit the rule.
Resource Set	Resource linked with the key rule. Click the link to edit the resource set.
Transformation Key Name	Transformation key to use for rekeying.

To add a new data transformation rule, refer to [Step 4: Add Data Transformation Rules](#) for details.

- Click the **Signature Rules** tab. This tab is displayed for CTE for Kubernetes policies. This tab displays the following details:

Column	Description
Signature Set Name	Name of the linked signature set (signature rule).
Created At	Time when the signature rule is created.

To add a new signature rule, refer to [Step 5: Add Signature Rules](#) for details.

Viewing Policy Version History

Viewing Policy Version History

The policy version defines the number of times a policy has been changed. This number indicates the current revision only. It cannot be used to roll back to a previous version. Restore a backup to revert to a previous online policy version. The version count starts at zero when the policy is initially created and increments by one each time it is saved thereafter.

Policy Version History

Version	Date	Author	Comment
4	01/05/21	admin	Delete LDT Key Rule
2	01/04/21	admin	LDT Key Rule Created
2	01/04/21	admin	DataXform Rule Created
1	01/04/21	admin	Key Rule Created
0	01/04/21	admin	Policy Created
0	01/04/21	admin	LDT Key Rule Created
0	01/04/21	admin	DataXform Rule Created
0	01/04/21	admin	Key Rule Created
0	01/04/21	admin	Security Rule Created

9 Policy Audit Records 10 per page ▾

To view the version history of a policy:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Policies**.
3. Click the version number of the policy. The Policy Version History popup displays the following details:

Field	Description
Version	Version of the policy.
Date	Date when the version is created.
Author	User who changed the policy.
Comment	Description of change.

4. Click **OK**.

Controlling Updates to Policies

CTE provides options to restrict or allow changes to a policy that is in use by active GuardPoints. When updates are restricted, security rules and key rules linked with the policy cannot be changed.

To restrict or allow changes to a policy:

1. Open the **Transparent Encryption** application.
2. Click **Policies**. The list of configured policies is displayed.
3. Under **Name**, click the desired policy. The edit view of the policy is displayed.
4. Turn on/off the **Restrict Update** toggle.

Note

Before turning on the Restrict Update, ensure that the active GuardPoints are disabled.

Turning on the toggle restricts updates to the policy. Any attempts to change the policy will result in an error. Turning off the Restrict Update toggle allows updates to the policy.

Updating Policy Description

To update the description of a policy:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Policies**.
3. Click the overflow icon () corresponding to the desired policy.
4. Click **Edit**.
5. Add or modify the **Description**. The policy **Name** and **Type** cannot be modified.
6. Click **Update**.

The updated description appears in the policies list.

Cloning a Policy

Cloning is an efficient and simple method to create a copy of an existing policy. The clone is a separate policy and contains all the configurations of its parent policy. When cloning a policy, specify a new unique name for the clone. Also, enable or disable Learn Mode and Restrict Update for the clone, if required.

To duplicate a policy:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Policies**.
3. Click the overflow icon (**⋮**) corresponding to the desired policy.

Name	Type	Version	Updated At	Description	Learn Mode	
☐ Idtplc	Live Data Transformation	0	10 Nov 2021, 12:11		☐	⋮

1 Policy

Edit
 Clone
 Delete

4. Click **Clone**.
5. Enter a unique **Name** for the clone.
6. (Optional) Provide a **Description** for the clone.
7. (Optional) Turn on/off the **Learn Mode** toggle. Refer to [Learn Mode](#) for details.

Cloning policy Idtplc

Name *

clone-plc

Description

A copy of Idtplc

Learn Mode:

Restrict update:

8. (Optional) Turn on/off the **Restrict Update** toggle. Refer to [Controlling Updates to Policies](#) for details.

The clone with the specified name appears at the top of the policies list.

Name	Type	Version	Updated At	Description	Learn Mode	
☐ clone-plc	Live Data Transformation	0	10 Nov 2021, 15:39	A copy of Idtplc	☐	⋮

Adding New Security Rules

To add a new security rule to a policy:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Policies**.
3. Click the desired policy.
4. On the **Security Rules** tab, click **Add Security Rule**. The Add Security Rule dialog box is displayed.
5. Specify the required details. The fields on the Add Security Rule dialog box are same as the fields on the Create Security Rule dialog box. Refer to [Step 2: Add Security Rules](#) for details.
6. Click **Add**.

The newly added security rule appears in the security rules list. Similarly, you can add more security rules to the policy.

Adding New Key Rules

To add a new key rule to a policy:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Policies**.
3. Click the desired policy.
4. Click the **Key Rules** tab.
5. Click **Add Key Rule**.

An IDT policy can have only one key rule. So, the **Add Key Rule** button is not available for IDT key rules.

6. Specify the required details. The fields on the Add Key Rule dialog box are same as the fields on the Create Key Rule dialog box. Refer to [Step 3: Add Key Rules](#) for details.
7. Click **Add**.

The newly added key rule appears in the key rules list. Similarly, you can add more key rules to the policy.

Adding New Data Transformation Rules

This section is applicable to policies that contain data transformation rules.

To add a new data transformation rule to a policy:

1. Open the **Transparent Encryption** application.

-
2. In the left pane, click **Policies**.
 3. Click the desired policy.
 4. Click the **Data Transformation Rules** tab.
 5. Click **Add Data Transformation Rule**. The Add Data Transformation Rule dialog box is displayed.
 6. Specify the required details. The fields on the Add Data Transformation Rule dialog box are same as the fields on the Create Data Transformation Rule dialog box. Refer to [Step 4: Add Data Transformation Rules](#) for details.
 7. Click **Add**.

The newly added data transformation rule appears in the data transformation rules list. Similarly, you can add more rules to the policy.

Adding New Signature Rules

This section is applicable to CTE for Kubernetes policies.

A signature rule is a type of signature sets that contains container-image signatures. Signature rules can only be associated with CTE for Kubernetes policies.

To add a new signature rule to a policy:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Policies**.
3. Click the desired CTE for Kubernetes policy.
4. Click the **Signature Rules** tab.
5. Click **Add Signature Rules**. The Add Signature Rules dialog box is displayed.
6. Select the desired signature rules.

The fields on the Add Signature Rules dialog box are same as the fields on the Add Signature Rules dialog box that appears when creating a CTE for Kubernetes policy. Refer to [Step 5: Add Signature Rules](#) for details.

The signature rules already in use by a policy are read-only, and cannot be selected.

7. Click **Add**.

The newly added signature rule appears in the signature rules list. Similarly, you can add more rules to the policy.

Modifying Security Rules

- [Editing Security Rules](#)

- Changing Order of Security Rules
- Deleting Security Rules

Editing Security Rules

To edit a security rule in a policy:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Policies**.
3. Click the desired policy.
4. Click the **Security Rules** tab.
5. Click the overflow icon () corresponding to the desired rule.
6. Click **Edit**. The Edit Security Rule dialog box is displayed.
7. Change the required fields. The fields on the Edit Security Rule dialog box are the same the fields on the Create Security Rule dialog box. Refer to [Step 2: Add Security Rules](#) for details.
8. Click **Update**.

The updated details appear in the security rules list.

Changing Order of Security Rules

To change the order of a security key rule in a policy:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Policies**.
3. Click the desired policy.
4. Click the **Security Rules** tab.
5. Select the desired rule. Depending on the current order, the following ordering icons are activated.

Icon	Description
Bottom ()	Move the rule to the bottom. Unavailable for the rule at the bottom.
Down ()	Move the rule one place lower. Unavailable for the rule at the bottom.
Up ()	Move the rule one place higher. Unavailable for the rule at the top.

Icon	Description
Top ()	Move the rule to the top. Unavailable for the rule at the top.

6. Click the desired icon.

The rules list shows the updated order.

Deleting Security Rules

To delete security rules from a policy:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Policies**.
3. Click the desired policy.
4. Click the **Security Rules** tab.
5. Select the check boxes corresponding to the desired rules.

To select all rules visible on the page for deletion, select the top check box to the left of the Order heading.

6. Click the delete icon ().

The selected rules are removed from the security rules list.

Modifying Key Rules

Modifying key rules linked with a policy involves:

- [Editing Key Rules](#)
- [Changing Order of Key Rules](#)
- [Deleting Key Rules](#)

Editing Key Rules

To edit a key rule in a policy:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Policies**.
3. Click the desired policy.
4. Click the **Key Rules** tab.

5. Click the overflow icon () corresponding to the desired rule.
6. Click **Edit**. The Edit Key Rule dialog box is displayed.
7. Change the required fields. The fields on the Edit Key Rule dialog box are the same the fields on the Create Key Rule dialog box. Refer to [Step 3: Add Key Rules](#) for details.
8. Click **Update**.

The updated details appear in the key rules list.

Changing Order of Key Rules

To change the order of a key rule in a policy:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Policies**.
3. Click the desired policy.
4. Click the **Key Rules** tab.
5. Select the desired rule. Depending on the current order, the following ordering icons are activated.

Icon	Description
Bottom ()	Move the rule to the bottom. Unavailable for the rule at the bottom.
Down ()	Move the rule one place lower. Unavailable for the rule at the bottom.
Up ()	Move the rule one place higher. Unavailable for the rule at the top.
Top ()	Move the rule to the top. Unavailable for the rule at the top.

6. Click the desired icon.

The key rules list shows the updated order.

Deleting Key Rules

To delete key rules from a policy:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Policies**.

- Click the desired policy.

Note

The key rule linked with an IDT policy cannot be deleted from the CipherTrust Manager. However, you can update the key rule when required (refer to [Editing Key Rules](#)).

- Click the **Key Rules** tab.
- Select the check boxes corresponding to the desired rules.

To select all rules visible on the page for deletion, select the top check box to the left of the Order heading.

- Click the delete icon ().

The selected rules are removed from the key rules list.

Modifying Data Transformation Rules

Modifying data transformation rules linked with a policy involves:

- Editing Data Transformation Rules
- Changing Order of Data Transformation Rules
- Deleting Data Transformation Rules

Editing Data Transformation Rules

To edit a data transformation rule in a policy:

- Open the **Transparent Encryption** application.
- In the left pane, click **Policies**.
- Click the desired policy.
- Click the **Data Transformation Rules** tab.
- Click the overflow icon () corresponding to the desired rule.
- Click **Edit**. The Edit Data Transformation Rule dialog box is displayed.
- Change the required fields. The fields on the Edit Data Transformation Rule dialog box are the same the fields on the Create Data Transformation Rule dialog box. Refer to [Step 4: Add Data Transformation Rules](#) for details.

8. Click **Update**.

The updated details appear in the data transformation rules list.

Changing Order of Data Transformation Rules

To change the order of a data transformation rule in a policy:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Policies**.
3. Click the desired policy.
4. Click the **Data Transformation Rules** tab.
5. Select the desired rule. Depending on the current order, the following ordering icons are activated.

Icon	Description
Bottom ()	Move the rule to the bottom. Unavailable for the rule at the bottom.
Down ()	Move the rule one place lower. Unavailable for the rule at the bottom.
Up ()	Move the rule one place higher. Unavailable for the rule at the top.
Top ()	Move the rule to the top. Unavailable for the rule at the top.

6. Click the desired icon.

The rules list shows the updated order.

Deleting Data Transformation Rules

To delete data transformation rules from a policy:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Policies**.
3. Click the desired policy.
4. Click the **Data Transformation Rules** tab.
5. Select the check boxes corresponding to the desired rules.

To select all rules visible on the page for deletion, select the top check box to the left of the Order heading.

-
6. Click the delete icon ().

The selected rules are removed from the data transformation rules list.

Modifying Signature Rules

Modifying signature rules linked with a policy involves:

- [Editing Signature Rules](#)
- [Deleting Signature Rules](#)

Editing Signature Rules

To edit a signature rule in a policy:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Policies**.
3. Click the desired CTE for Kubernetes policy.
4. Click the **Signature Rules** tab.
5. Click the overflow icon () corresponding to the desired rule.
6. Click **Edit**. The Edit Signature Rule dialog box is displayed.
7. Select the required signature set.

The signature sets already in use by a policy are read-only.

8. Click **Update**.

The updated details appear in the signature rules list.

Deleting Signature Rules

To delete a signature rule from a policy:

1. Open the **Transparent Encryption** application.
 2. In the left pane, click **Policies**.
 3. Click the desired policy.
 4. Click the **Signature Rules** tab.
 5. Click the overflow icon () corresponding to the desired rule.
 6. Click **Delete**. The *<signature-rule> will be deleted* dialog box is displayed.
-

7. Click **Delete**.

The rule is removed from the signature rules list.

Automatic Addition/Removal of ApplyKey Effect for All Security Rules

If you enable Learn Mode on an existing policy, the ApplyKey effect is **added** to *all* the security rules having the Deny effect in the policy. Similarly, if you disable Learn Mode on an existing policy, the ApplyKey effect is **removed** from *all* the security rules having the Deny and ApplyKey effects in the policy.

To automatic add or remove the ApplyKey effect from all security rules of a policy in one go:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Policies > Policies**.
3. Turn on/off the **Learn Mode** toggle corresponding to the desired policy that contains the security rules having the Deny effect.

Alternatively, click the **Name** link corresponding to the desired policy and turn on/off the **Learn Mode** toggle in the mini details view.

Note

When you enable Learn Mode for a policy, the ApplyKey effect will only be inserted if the policy contains at least one key rule.

Refer to [Learn Mode](#) for details.

Exporting Policies

CipherTrust Manager provides options to back up CTE policies and restore them to other CipherTrust Manager appliances. Refer to [Backup and Restore](#) for details.

Deleting Policies

CipherTrust Manager provides options to delete single or multiple policies.

Deleting Single Policy

To delete a single policy:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Policies**.

- Click the overflow icon () corresponding to the desired policy.
- Click **Delete**.

The selected policy is removed from the policies list.

Deleting Multiple Policies

To delete single or multiple policies:

- Open the **Transparent Encryption** application.
- In the left pane, click **Policies**.
- Select the check boxes corresponding to the desired policies.

To select all policies visible on the page for deletion, select the top check box corresponding to the left of the Name heading.

- Click the delete icon ().

The selected policies are removed from the policies list.

Managing FAM Policies and Rules

The primary job of a DSF Hub user is to create policies that protect data. Policies govern access to the files in GuardPoints. FAM policies allow you to manage the FAM audit rules.

Viewing FAM Policies

The FAM Policies page shows the list of configured FAM policies with their details such as names, versions, and descriptions.

To view the complete list of configured FAM policies:

- Open the **Transparent Encryption** application.
- Click **Policies**. The Policies page is displayed
- Click the **FAM Policies** tab. The FAM Policies tab provides the list of added FAM policies. The tab displays the following details:

Column	Description
Name	Unique name of the FAM policy.
Version	Version of the FAM policy. Click to view the version history of the FAM policy.
Created At	The time when the FAM policy is created.

Column	Description
Updated At	The time when the FAM policy is updated.
Description (Optional)	Description of the FAM policy.

By default, the FAM policies are displayed in descending order by Updated At. By default, 10 records per page are displayed. Adjust pagination and/or the number of records to display per page to view more records.

Managing GuardPoints

A GuardPoint specifies the list of folders that contain paths to be protected. Access to files and encryption of files under the GuardPoint is controlled by security policies.

Before you apply GuardPoints:

- A CTE Agent must be installed on the client system and registered with CipherTrust Manager. Refer to the [CTE Agent Quick Start Guide](#) specific to your platform for details.
- A client must be added to the CipherTrust Manager. The client is automatically added to the CipherTrust Manager on successful registration with the CipherTrust Manager.
- Policies must be created using the encryption keys on the CipherTrust Manager. This involves creation of policy elements and encryption keys. Refer to [Managing Policies](#) for details.
- A GuardPoint must be created. No one must be using the directory to be guarded before making it a GuardPoint.

If users are working on the directory when it is made a GuardPoint, they can continue to use data in memory rather than use the actual data in the GuardPoint. Inform users to:

- Save their work
- Close applications that are running on the directory
- Exit the directory before applying the GuardPoint

When the users re-enter the directory, they will use protected data and the CTE Agent will work appropriately.

Secure Start GuardPoints

Note

The Secure Start feature is supported on Windows clients.

Secure Start offers a new type of GuardPoint that offers data protection for applications that start earlier in the boot sequence than VMD (CTE Agent daemon). For example, an AD (Active Directory) or a SQL Server service starts very early. A Secure Start GuardPoint starts before the AD and SQL services, and can, therefore, encrypt those services.

For more information on protecting such applications using Secure Start, refer to the [CTE Agent for Windows Advanced Configuration and Integration Guide](#). To determine whether other applications qualify for Secure Start, contact Thales Customer Support.

Considerations Before Creating GuardPoints

Before creating GuardPoints, consider the following:

- If a client is to be added to a client group, do not apply a GuardPoint at the client level. Rather, apply the GuardPoint at the client group level. You can do both, but it is harder to keep track of GuardPoints applied at the client group level and custom GuardPoints applied at the client level.
- Certain directories are protected against guarding. So plan your GuardPoints accordingly:

Linux Platforms

- The following directories cannot be guarded:
 - `<secfs install root>/agent/secfs/`
 - `<install root>/agent/secfs/bin` and everything under it

-
- `<secfs install root>/agent/vmd` and everything under it
 - `/etc/vormetric` and everything under it
 - `/etc`
 - `/etc/pam.d` and everything under it
 - `/etc/security` and everything under it
 - `/usr`
 - `/usr/lib`
 - `/usr/lib/pam`
 - `/usr/lib/security` and everything under it
 - `/etc/rc*` and everything under it
 - `/var/log/vormetric`
 - You cannot apply CTE Agent protection to already mounted and guarded directories, nor can you nest GuardPoints.
 - The `/opt/vormetric/DataSecurityExpert/agent/secfs/.sec` directory is automatically mounted and guarded by `secfs` when the CTE Agent process starts on the client.
 - You cannot apply a GuardPoint to `/opt` because it contains the existing GuardPoint, `/opt/vormetric/DataSecurityExpert/agent/secfs/.sec`; however, you can guard a directory like `/opt/myapps` because it is in a different hierarchy and has no impact on `/opt/vormetric`.
 - Mounted and guarded directories can be displayed using the `df` command.

Windows Platforms

- Be careful when specifying paths for Windows agents. Cross-guarding the same folder with different policies and encryption keys returns unexpected results and corrupts the files in that folder.
- GuardPoint paths must use standard Windows path notation and delimiters.
 - Incorrect notation and delimiters are ignored and discarded by the Windows agent. Therefore, it is possible to enter two paths that resolve to the same Windows folder and successfully guard both of them. The CipherTrust Manager reports that it is guarding two unique folders when, in fact, it is guarding the same folder twice.
 - Do not use any of the following characters as path delimiters: `| ? < > : * " / ,`

For example, both `C:\gp\` and `C:\gp/` are allowed by the CipherTrust Manager. When the second

GuardPoint is applied, the extraneous / is discarded by the Windows CTE Agent and the Windows CTE Agent applies a GuardPoint to C:\gp\ a second time.

- Both CipherTrust Manager and CTE support a new enhanced encryption mode (CBC-CS1). If your client groups contain clients with older versions of CTE, you cannot apply policies containing keys that use this new encryption mode. The action fails with an error message informing you that all clients in the client group do not support the key's encryption mode. Refer to the [CTE Agent Advanced Configuration and Integration Guide](#) specific to your platform for details.

When Changing a Policy or Rekeying a GuardPoint

- To change a policy or rekey a GuardPoint, be prepared to temporarily stop access to the GuardPoint. Changing policies for a GuardPoint requires an interruption of service because the transition process entails disabling one policy and then enabling another policy. The GuardPoint must be inactive during the transition period to ensure GuardPoint integrity. The same rule applies to moving a client between client groups when it includes a change in policies. Coordinate policy changes during a maintenance outage window.
- If LDT is enabled on your clients, encryption and rekeying of GuardPoint data is done without blocking user or application access to the data. LDT is a separately licensed feature, refer to [Enabling Live Data Transformation](#).

Creating GuardPoints

A GuardPoint is created to enforce protection on a GuardPath according to linked security policy. This is also called guarding a path. For a Ransomware protection GuardPoint, a policy is not required.

Refer to the following sections for information on creating different types of GuardPoints:

- [Creating Standard GuardPoints](#)
- [Creating LDT GuardPoints](#)
- [Creating Cloud Object Storage GuardPoints](#)
- [Creating IDT GuardPoints](#)
- [Creating Ransomware GuardPoints](#)

Creating Standard GuardPoints

Steps to create GuardPoints on individual clients and client groups are similar. GuardPoints can be created on the GuardPoints tab of individual clients and client groups.

Creating Standard GuardPoints on Local Paths

To create a GuardPoint:

1. Open the **Transparent Encryption** application.
-

2. Select the client or client group on which you want to create a GuardPoint.
 - Click a client under the **Client Name** column (**Clients > Clients**).
 - Click a client group under the **Client Group Name** column (**Clients > Client Groups**).
3. On the **GuardPoints** tab, click **Create GuardPoint**.
4. Select a **Policy**. This is a mandatory field.
 - a. Click **Select** next to the Policy field.
 - b. Select a *Standard* policy. If no policy exists, create one, as described in [Creating Policies](#).

Name	Type	Version
☐ testcosplc	Cloud Object Storage	0
☒ testpolicy	Standard	1
☐ idtvlc	Live Data Transformation	0
☐ test-jdt-plc	In-place Data Transformation	0

- c. Click **Select**.
5. Select the **Type** of device to protect. This is a mandatory field. Depending on the platform, the options for a *Standard* policy are:

Type	Windows	Linux	Description
Auto Directory	Yes	Yes	Select for file system directories.
Manual Directory	No	Yes	Select for file system directories to be guarded manually.
Auto Raw or Block Device	Yes	Yes	Select for standard policies for raw (block) devices.
Manual Raw or Block Device	No	Yes	Select for standard policies for raw (block) devices to be guarded manually.

Note

Manual Directory and Manual Raw or Block Device are guarded and unguarded (for example, mounted and unmounted) by running the `secfsd -guard` and `secfsd -unguard` commands. Do not run the `mount` and `umount` commands to swap GuardPoint nodes in a cluster configuration.

Note**Access Rules to Apply for Raw/Block Devices**

When creating a GuardPoint on a raw/block device, ensure that the policy contains a signature set for the following system processes that require access to the guarded devices:

```
/usr/lib/systemd/systemd-udev
/sbin/dmsetup
```

Adjust the above paths as per their location on the file server. On newer systems (for example, RHEL 9.4, SLES 15SP6, and Ubuntu 22.04), include the following paths.

```
/usr/bin/udevadm
/usr/sbin/dmsetup
```

Failure to include the above two processes in the policy might cause the GuardPoint creation to fail with the error `Does not exist`.

6. Specify the **Path** to be protected. This is a mandatory field. Options to specify the GuardPoint paths are:

- **Enter/Browse Path:** Select this option, and enter the GuardPoint paths by either typing or clicking the **Browse** button.

Note

A maximum of 200 GuardPaths can be specified using the **Enter/Browse Path** option.

Browse Method

- a. Click **Browse** to select a path by browsing the client file system. This method prevents typographical

errors and verifies client availability. This is the recommended method to specify individual paths.

File system of a client that is not registered with the CipherTrust Manager cannot be browsed.

- b. In the **Search Local Path** field, specify a starting path and click **Refresh** or select from the on-screen file system browser.
- c. Click **Add**.

Note

If the paths are already guarded, you'll see an active GuardPoint icon before them.

Manual Method

Alternatively, if you know the path, manually enter full paths of one or more directories in the given text box. Enter one path per line.

- **Upload CSV:** Select this option and click **Browse** to upload the CSV file containing the list of one or more directories. This is the recommended method to specify a large number of paths in one step.

Note

- If a manually entered path does not yet exist, be sure to enter the path correctly. The CipherTrust Manager does not parse manually entered paths for correct syntax.
- See [Considerations Before Creating GuardPoints](#) for what to be aware of before creating a GuardPoint.
- If multiple paths are specified, they will all be protected by the same policy.
- A maximum of 1000 GuardPaths per CSV file can be uploaded.
- The following paths are restricted.

Linux: /proc, /usr/bin, /usr/sbin, /sbin, /bin, /opt/vormetric or install directory, /usr, /opt, /tmp, /var/log/vormetric, /lib64, /lib, /proc/*, /usr/bin/*, /usr/lib, /usr/lib/pam, /usr/lib/security, /usr/lib/security/*, /usr/sbin/*, /etc/, /sbin/*, /bin/*, /opt/vormetric/*, /etc/init.d/secfs, /etc/pam.d, /etc/pam.d/*, /etc/rc, /etc/security, /etc/security/*, /etc/ssh/ssh_config, /etc/ssh/sshr, /etc/systemd, /lib/systemd, and /usr/lib/systemd.

Windows: A few folders are restricted in the boot drive. If C:\ is the boot drive, the restricted folders are C:\Windows, C:\Program Files, C:\ProgramData, C:\User, C:\Users, C:\Program Files (x86), and C:\Documents And Settings.

7. (Optional, Linux only) Select **Auto Mount** to specify an automount path. For a regular (non-auto) mount path, make sure that the check box is clear.

Create GuardPoint

☒ Enter/Browse Path ☐ Upload CSV

/opt/cte-test/

Browse

i To apply the same GuardPoint settings to multiple paths, type paths in the Path field or specify them using the Browse button. A maximum of 200 GuardPaths can be specified.

Auto Mount: ☒

8. (Optional, Windows only) Select **Secure Start** to enable the Secure Start feature. By default, the check box is clear.

If you plan not to enable the Secure Start now, you can do that later, as described in [Enabling Secure Start for GuardPoints](#).

9. (Optional) Select **Multifactor Authentication**. Refer to [Multifactor Authentication](#) for details.

10. Click **Create**.

Depending on the number of paths you add to a GuardPoint, a status information message may appear. Refer to [GuardPoint Status Information](#) for details.

The newly created GuardPoint appears on the GuardPoints tab. The status remains **Unknown** until the client sends the response after processing the GuardPoint request. Click the **Refresh GuardPoints** icon () to view the updated status.

Status of a GuardPoint can be checked at any time on the GuardPoints tab. Refer to [Viewing GuardPoint Status](#) for details.

GuardPoint Status Information

- When you add multiple paths to a GuardPoint:
 - If the GuardPoint is created successfully for all paths, a message is displayed at the top right corner of the screen.
 - If the GuardPoint creation failed for all paths, an error message is displayed stating that none of the GuardPoints could be created. Fix the issues and retry for failed GuardPoints.
 - If the GuardPoint is disabled or failed for at least one of the paths (for example, when a path is already guarded), an error message is displayed stating that some of the GuardPoints could not be created. Fix the issues and retry for failed GuardPoints.

The message shows the number of created and failed GuardPoints. The list of failed GuardPaths with their respective failure reasons is also displayed.

Error

Some of the GuardPoints could not be created. Fix the issues and retry for failed GuardPoints. [Save Error Details](#)

Success : 5 GuardPoints

Error : 31 GuardPoints

31 Results | 31 GuardPoints

GuardPath	Reason
/opt/test/gp_3011	Duplicate GuardPath and Policy
/opt/test/gp_3013	Duplicate GuardPath and Policy
/opt/test/gp_3018	Duplicate GuardPath and Policy
/opt/test/gp_3019	Duplicate GuardPath and Policy
/opt/test/gp_3021	Duplicate GuardPath and Policy
/opt/test/gp_3025	Duplicate GuardPath and Policy
/opt/test/gp_3027	Duplicate GuardPath and Policy

To download the CSV file with the list of failed GuardPoints, click the **Save Error Details** link at the top of the error message.

- When you add only one path, and the GuardPoint for that path fails, then an error message is displayed stating the reason of failure.

Refer to [Creating Standard GuardPoints on Network Paths](#) for information on creating Standard GuardPoints on network paths.

Creating Standard GuardPoints on Network Paths

To create a GuardPoint:

1. Open the **Transparent Encryption** application.
2. Click **Clients > Clients**. The list of registered clients is displayed.
3. Under **Client Name**, click the client on which you want to create a GuardPoint.
4. On the **GuardPoints** tab, click **Create GuardPoint**.
5. Select a **Policy**. This is a mandatory field.
 - a. Click **Select** next to the Policy field.
 - b. Select a *Standard* policy. If no policy exists, create one, as described in [Creating Policies](#).

	Name	Type	Version
☐	testcospic	Cloud Object Storage	0
☒	testpolicy	Standard	1
☐	ldtpic	Live Data Transformation	0
☐	test-jdt-pic	In-place Data Transformation	0

- c. Click **Select**.
6. Select the **Type** of device to protect. This is a mandatory field. Depending on the platform, the options for a *Standard* policy are:

Type	Windows	Linux	Description
Auto Directory	Yes	Yes	Select for file system directories.
Manual Directory	No	Yes	Select for file system

Type	Windows	Linux	Description
			directories to be guarded manually.
Auto Raw or Block Device	Yes	Yes	Select for standard policies for raw (block) devices.
Manual Raw or Block Device	No	Yes	Select for standard policies for raw (block) devices to be guarded manually.

Note

Manual Directory and Manual Raw or Block Device are guarded and unguarded (for example, mounted and unmounted) by running the `secfsd -guard` and `secfsd -unguard` commands. Do not run the `mount` and `umount` commands to swap GuardPoint nodes in a cluster configuration.

7. Specify the **Path** to be protected. This is a mandatory field. Options to specify the GuardPoint paths are:

- **Enter/Browse Path:** Select this option, and enter the GuardPoint paths by either typing or clicking the **Browse** button.

Note

A maximum of 200 GuardPaths can be specified using the **Enter/Browse Path** option.

Browse Method

- In the text box, type the Windows network share (in the format, `\\nas-machine-hostname\share` or `\\nas-machine-ip\share`).
- Click **Browse** if you want to specify a lower-level network path. This method prevents typographical errors and verifies client availability. This is the recommended method to specify individual paths.

File system of a client that is not registered with the CipherTrust Manager cannot be browsed.

- Select **Network Path** as the **Path Type**.
- Specify the **User Name** and **Password** to access the desired network path on the NAS machine.

-
- e. (Optional) Specify the **Domain** where the NAS machine exists.
 - f. In the **Search Network Path** field, specify a starting path and click **Refresh** or select from the on-screen network path browser.
 - g. Click **Add**.

Manual Method

Alternatively, if you know the network path, manually enter full network paths in the given text box. Enter one path per line.

- **Upload CSV:** Select this option and click **Browse** to upload the CSV file containing the list of one or more directories. This is the recommended method to specify a large number of paths in one step.

Note

- If a manually entered path does not yet exist, be sure to enter the path correctly. The CipherTrust Manager does not parse manually entered paths for correct syntax.
- See [Considerations Before Creating GuardPoints](#) for what to be aware of before creating a GuardPoint.
- If multiple paths are specified, they will all be protected by the same policy.
- A maximum of 1000 GuardPaths per CSV file can be uploaded.

8. (Optional, Linux only) Select **Auto Mount** to specify an automount path. For a regular (non-auto) mount path, make sure that the check box is clear.

local filesystem paths.

Creating LDT GuardPoints

Steps to create GuardPoints on individual clients and client groups are similar. GuardPoints can be created on the GuardPoints tab of individual clients and client groups.

Creating LDT GuardPoints on Local Paths

To create an LDT GuardPoint on a client:

1. Open the **Transparent Encryption** application.
2. Select the client or client group on which you want to create a GuardPoint.
 - Click a client under the **Client Name** column (**Clients > Clients**).
 - Click a client group under the **Client Group Name** column (**Clients > Client Groups**).
3. On the **GuardPoints** tab, click **Create GuardPoint**.
4. Select a **Policy**. This is a mandatory field.
 - a. Click **Select** next to the Policy field.
 - b. Select a *Live Data Transformation* policy. If no policy exists, create one, as described in [Creating Policies](#).

Name	Type	Version
☐ testcospic	Cloud Object Storage	0
☐ testpolicy	Standard	1
☒ ldtpic	Live Data Transformation	0
☐ test-jdt-plc	In-place Data Transformation	0

- c. Click **Select**.
5. Select the **Type** of device to protect. This is a mandatory field. Depending on the platform, the options for an *LDT* policy are:

Type	Windows	Linux	Description
Auto Directory	Yes	Yes	Select for file system directories.
Manual Directory	No	Yes	Select for file system

Type	Windows	Linux	Description
			directories to be guarded manually.

Note

Manual Directory is guarded and unguarded (for example, mounted and unmounted) by running the `secfsd -guard` and `secfsd -unguard` commands. Do not run the `mount` and `umount` commands to swap GuardPoint nodes in a cluster configuration.

6. Specify the **Path** to be protected. This is a mandatory field. Options to specify the GuardPoint paths are:

- **Enter/Browse Path:** Select this option, and enter the GuardPoint paths by either typing or clicking the **Browse** button.

Note

A maximum of 200 GuardPaths can be specified using the **Enter/Browse Path** option.

Browse Method

- Click **Browse** to select a path by browsing the client file system. This method prevents typographical errors and verifies client availability. This is the recommended method to specify individual paths.

File system of a client that is not registered with the CipherTrust Manager cannot be browsed.

- In the **Search Local Path** field, specify a starting path and click **Refresh** or select from the on-screen file system browser.
- Click **Add**.

Note

If the paths are already guarded, you'll see an active GuardPoint icon before them.

Manual Method

Alternatively, if you know the path, manually enter full paths of one or more directories in the given text box. Enter one path per line.

- **Upload CSV:** Select this option and click **Browse** to upload the CSV file containing the list of one or more directories. This is the recommended method to specify a large number of paths in one step.

Note

- If a manually entered path does not yet exist, be sure to enter the path correctly. The CipherTrust Manager does not parse manually entered paths for correct syntax.
- See [Considerations Before Creating GuardPoints](#) for what to be aware of before creating a GuardPoint.
- If multiple paths are specified, they will all be protected by the same policy.
- A maximum of 1000 GuardPaths per CSV file can be uploaded.
- The following paths are restricted.

Linux: /proc, /usr/bin, /usr/sbin, /sbin, /bin, /opt/vormetric or install directory, /usr, /opt, /tmp, /var/log/vormetric, /lib64, /lib, /proc/*, /usr/bin/*, /usr/lib, /usr/lib/pam, /usr/lib/security, /usr/lib/security/*, /usr/sbin/*, /etc/, /sbin/*, /bin/*, /opt/vormetric/*, /etc/init.d/secfs, /etc/pam.d, /etc/pam.d/*, /etc/rc, /etc/security, /etc/security/*, /etc/ssh/sshd_config, /etc/ssh/sshr, /etc/systemd, /lib/systemd, and /usr/lib/systemd.

Windows: A few folders are restricted in the boot drive. If C:\ is the boot drive, the restricted folders are C:\Windows, C:\Program Files, C:\ProgramData, C:\User, C:\Users, C:\Program Files (x86), and C:\Documents And Settings.

7. Configure the **Preserve Sparse Region** toggle. The toggle is turned on by default.

Caution

If you turn off the **Preserve Sparse Region** toggle, you are prompted to confirm the action. This is an irreversible action.

If you plan not to enable the Secure Start now, you can do that later, as described in [Enabling Secure Start for GuardPoints](#).

9. (Optional, Windows only). Select **Multifactor Authentication** Refer to [Multifactor Authentication](#) for details.

10. Click **Create**.

Depending on the number of paths you add to a GuardPoint, a status information message may appear. Refer to [GuardPoint Status Information](#) for details.

The newly created GuardPoint appears on the GuardPoints tab. The status remains **Unknown** until the client sends the response after processing the GuardPoint request. Click the **Refresh GuardPoints** icon (🔄) to view the updated status.

Status of a GuardPoint can be checked at any time on the GuardPoints tab. Refer to [Viewing GuardPoint Status](#) for details.

An LDT GuardPoint is applied automatically according to the QoS settings configured in the linked profile. Refer

to [Creating a Profile and Setting Quality of Service Configuration](#).

Creating LDT GuardPoints on SMB/NFS Paths

You can apply LDT GuardPoints on:

- CIFS/SMB paths, for CTE Windows clients
- NFS paths, for Linux clients

Before applying LDT GuardPoints:

- Ensure that the LDT capability is enabled for the client. LDT capability can be enabled during the CTE Agent installation or later through the CipherTrust Manager console.
- Ensure that the File Header Support (FHS) capability is enabled on the Windows clients. By default, this capability is turned on when installing a compatible CTE Agent on a Windows client. Refer to the [CTE Agent Quick Start Guide](#) for details.

Note

- FHS on Windows paths and their browsing are supported CTE Agent 7.1.0.84 onward.
- A maximum of 200 GuardPaths can be specified using the **Enter/Browse Path** option.
- A maximum of 1000 GuardPaths per CSV file can be uploaded.

GuardPoint on a Client

To create an LDT over SMB/NFS GuardPoint on a client:

1. Open the **Transparent Encryption** application.
2. Click **Clients > Clients**.
3. Under **Client Name**, click the LDT client on which you want to create a GuardPoint.
4. In the **GuardPoints** tab, click **Create GuardPoint**.
5. Select a **Policy**. This is a mandatory field.
 - a. Click **Select**.
 - b. Select a *Live Data Transformation* policy. If no policy exists, create one, as described in [Creating Policies](#).

Name	Type	Version
☐ testcospic	Cloud Object Storage	0
☐ testpolicy	Standard	1
☒ idtpic	Live Data Transformation	0
☐ test-jdt-pic	In-place Data Transformation	0

c. Click **Select**.

6. Select **Auto Directory** as the **Type** of device to protect. This is a mandatory field.

7. Specify the **Path** to be protected. This is a mandatory field. Options to specify the GuardPoint paths are:

- **Enter/Browse Path:** Select this option, and enter GuardPoint paths (network paths) manually or click the **Browse** button.

Note

- Paths of only one type can be specified at once - either local or network, not a mix of both.

Browse Method

- a. In the text box, type the Windows SMB share (in the format, `\\nas-machine-hostname\share` or `\\nas-machine-ip\share`) or Linux NFS path (in the format, `/opt/nfs_shared_path1/`).

Note

Mount the Linux NFS path on the agent machine before applying guard point.

- b. Click **Browse** if you want to specify a lower-level network path. This method prevents typographical errors and verifies client availability. This is the recommended method to specify individual paths.

File system of a client that is not registered with the CipherTrust Manager cannot be browsed.

- c. (Applicable only for Client Groups) Click **Select Client** to select the Windows or Linux client.
- d. Select **Network Path** as the **Path Type**.
- e. Specify the **User Name** and **Password** to access the desired network path on the NAS machine.

- f. (Optional) Specify the **Domain** where the NAS machine exists.
- g. In the **Search Network Path** field, specify a starting path and click **Refresh** or select from the on-screen network path browser.
- h. Click **Add**. The selected paths appear on the right.

Manual Method

Alternatively, if you know the network path, manually enter full network paths in the given text box. Enter one path per line.

- **Upload CSV:** Select this option and click **Browse** to upload the CSV file containing the list of one or more directories. This is the recommended method to specify a large number of paths in one step.

Note

- If a manually entered path doesn't exist, be sure to enter the path correctly. The CipherTrust Manager doesn't parse manually entered paths for correct syntax.
- See [Considerations Before Creating GuardPoints](#) for what to be aware of before creating a GuardPoint.
- If multiple paths are specified, they will all be protected by the same policy.

8. (Windows only) Select the desired **SMB/CIFS Connection** if the GuardPaths are on an SMB/CIFS share.

This drop-down list is displayed when you specify a Windows SMB/CIFS share in the **Path** field.

Note

An SMB/CIFS connection must already exist on the CipherTrust Manager before you can apply GuardPoints to an SMB/CIFS share. Creating an SMB/CIFS connection requires credentials to access the share. Refer to [Connection Manager](#) for details.

9. (*Applicable only for Client Groups*) Select a **Designated Primary Set** from the dropdown options. See [Adding Designated Primary Set to a Client Group](#) for creating Designated Primary Set.
10. Configure the **Preserve Sparse Region** toggle. The toggle is turned on by default.

Caution

If you turn off the **Preserve Sparse Region** toggle, you are prompted to confirm the action. This is an irreversible action.

11. (Optional) Select **Secure Start** to enable the Secure Start feature. By default, the check box is clear.

If you plan not to enable the Secure Start now, you can do that later, as described in [Enabling Secure Start for GuardPoints](#).

12. (Optional, Windows only). Select **Multifactor Authentication** Refer to [Multifactor Authentication](#) for details.

13. Click **Create**.

Depending on the number of paths you add to a GuardPoint, a status information message may appear. Refer to [GuardPoint Status Information](#) for details.

The newly created GuardPoint appears on the GuardPoints tab. The status remains **Unknown** until the client sends the response after processing the GuardPoint request. Click the **Refresh GuardPoints** icon () to view the updated status.

Status of a GuardPoint can be checked at any time on the GuardPoints tab. Refer to [Viewing GuardPoint Status](#) for details.

An LDT GuardPoint is applied automatically according to the QoS settings configured in the linked profile. Refer to [Creating a Profile](#) and [Setting Quality of Service Configuration](#).

Refer to [Creating LDT GuardPoints on Local Paths](#) for information on creating LDT GuardPoints on local filesystem paths.

GuardPoint on a Client Group

Note

- All clients in the Client Group should be part of LDT Communication Group. See [Managing LDT Communication Groups](#) for more details.
- Clients within a Client Group should either be all Windows clients or all Linux clients.

To create an LDT over SMB/NFS GuardPoint on a client group:

1. Open the **Transparent Encryption** application.
2. Click **Clients > Client Groups**.
3. Click the LDT client group name on which you want to create a GuardPoint.

4. In the **GuardPoints** tab, click **Create GuardPoint**.
5. Select a **Policy**. This is a mandatory field.
 - a. Click **Select**.
 - b. Select a *Live Data Transformation* policy. If no policy exists, create one, as described in [Creating Policies](#).

	Name	Type	Version
☐	testcospic	Cloud Object Storage	0
☐	testpolicy	Standard	1
☒	ldtpic	Live Data Transformation	0
☐	test-ldt-pic	In-place Data Transformation	0

- c. Click **Select**.
6. Select **Auto Directory** as the **Type** of device to protect. This is a mandatory field.
7. Specify the **Path** to be protected. This is a mandatory field. Options to specify the GuardPoint paths are:
 - **Enter/Browse Path:** Select this option, and enter GuardPoint paths (network paths) manually or click the **Browse** button.

Note

- Paths of only one type can be specified at once - either local or network, not a mix of both.

Browse Method

- a. In the text box, type the Windows SMB share (in the format, `\\nas-machine-hostname\share` or `\\nas-machine-ip\share`) or Linux NFS path (in the format, `/opt/nfs_shared_path1/`).

Note

Mount the Linux NFS path on the agent machine before applying guard point.

- b. Click **Browse** if you want to specify a lower-level network path. This method prevents typographical errors and verifies client availability. This is the recommended method to specify individual paths.

File system of a client that is not registered with the CipherTrust Manager cannot be browsed.

- c. (Applicable only for Client Groups) Click **Select Client** to select the Windows or Linux client.
- d. Select **Network Path** as the **Path Type**.
- e. Specify the **User Name** and **Password** to access the desired network path on the NAS machine.
- f. (Optional) Specify the **Domain** where the NAS machine exists.
- g. In the **Search Network Path** field, specify a starting path and click **Refresh** or select from the on-screen network path browser.
- h. Click **Add**. The selected paths appear on the right.

Manual Method

Alternatively, if you know the network path, manually enter full network paths in the given text box. Enter one path per line.

- **Upload CSV:** Select this option and click **Browse** to upload the CSV file containing the list of one or more directories. This is the recommended method to specify a large number of paths in one step.

Note

- If a manually entered path doesn't exist, be sure to enter the path correctly. The CipherTrust Manager doesn't parse manually entered paths for correct syntax.
- See [Considerations Before Creating GuardPoints](#) for what to be aware of before creating a GuardPoint.
- If multiple paths are specified, they will all be protected by the same policy.

8. (Windows only) Select the desired **SMB/CIFS Connection** if the GuardPaths are on an SMB/CIFS share.

This drop-down list is displayed when you specify a Windows SMB/CIFS share in the **Path** field.

Note

An SMB/CIFS connection must already exist on the CipherTrust Manager before you can apply GuardPoints to an SMB/CIFS share. Creating an SMB/CIFS connection requires credentials to access the share. Refer to [Connection Manager](#) for details.

9. (Applicable only for Client Groups) Select a **Designated Primary Set** from the dropdown options. See [Adding Designated Primary Set to a Client Group](#) for creating Designated Primary Set.
10. Configure the **Preserve Sparse Region** toggle. The toggle is turned on by default.

Caution

If you turn off the **Preserve Sparse Region** toggle, you are prompted to confirm the action. This is an irreversible action.

11. (Optional) Select **Secure Start** to enable the Secure Start feature. By default, the check box is clear.

If you plan not to enable the Secure Start now, you can do that later, as described in [Enabling Secure Start for GuardPoints](#).

12. (Optional, Windows only). Select **Multifactor Authentication** Refer to [Multifactor Authentication](#) for details.
13. Click **Create**.

Depending on the number of paths you add to a GuardPoint, a status information message may appear. Refer to [GuardPoint Status Information](#) for details.

The newly created GuardPoint appears on the GuardPoints tab. The status remains **Unknown** until the client sends the response after processing the GuardPoint request. Click the **Refresh GuardPoints** icon () to view the updated status.

Status of a GuardPoint can be checked at any time on the GuardPoints tab. Refer to [Viewing GuardPoint Status](#) for details.

An LDT GuardPoint is applied automatically according to the QoS settings configured in the linked profile. Refer to [Creating a Profile and Setting Quality of Service Configuration](#).

Refer to [Creating LDT GuardPoints on Local Paths](#) for information on creating LDT GuardPoints on local filesystem paths.

Creating Cloud Object Storage GuardPoints

Steps to create GuardPoints on individual clients and client groups are similar. GuardPoints can be created on the GuardPoints tab of individual clients and client groups.

CTE supports protection of Amazon S3 and Wasabi cloud storages. Before proceeding, review the "CTE COS for Amazon S3" section of the [CTE Agent for Linux Advanced Configuration](#) document. Make sure to fulfill the COS requirements.

To create a Cloud Object Storage GuardPoint:

1. Open the **Transparent Encryption** application.
2. Select the client or client group on which you want to create a GuardPoint.

- Click a client under the **Client Name** column (**Clients > Clients**).
 - Click a client group under the **Client Group Name** column (**Clients > Client Groups**).
3. On the **GuardPoints** tab, click **Create GuardPoint**.
 4. Select a **Policy**. This is a mandatory field.
 - a. Click **Select** next to the Policy field.
 - b. Select a *Cloud Object Storage* policy. If no policy exists, create one, as described in [Creating Policies](#).

Name	Type	Version
☒ testcospic	Cloud Object Storage	0
☐ testpolicy	Standard	1
☐ idtpic	Live Data Transformation	0
☐ test-jdt-plc	In-place Data Transformation	0

- c. Click **Select**.
5. Select the **Type** of device to protect. This is a mandatory field. The options are:
 - **Auto Cloud Storage**: Select for Cloud Storage policies.
 - **Manual Cloud Storage**: Select for Cloud Storage policies to be guarded manually.

Note

Manual Cloud Storage are guarded and unguarded (for example, mounted and unmounted) by running the `secfsd -guard` and `secfsd -unguard` commands. Do not run the `mount` and `umount` commands to swap GuardPoint nodes in a cluster configuration.

6. Specify the **Cloud Object Storage URL** of the storage to be protected. The URL format must be valid. For example, the URL format for an S3 bucket is `https://s3.amazonaws.com/[bucket_name]`.

Options to specify the URLs are:

- **URL**: Select this option, and enter the URL in the box. Only one URL can be specified in the box.
- **Upload CSV**: Select this option and click **Browse** to upload the CSV file containing the list of one or more URLs. This is the recommended method to specify a large number of paths in one step.

Note

- When specifying the URLs using the Upload CSV option, be sure the URLs in the file are correct. The CipherTrust Manager does not parse manually specified URLs for correct syntax.
- See [Considerations Before Creating GuardPoints](#) for what to be aware of before creating a GuardPoint.
- If multiple URLs are specified, they will all be protected by the same policy.
- A maximum of 1000 URLs per CSV file can be uploaded.

Create GuardPoint **Policy:** *

testcosplc

Select**Type:** *

Auto Cloud Storage

Cloud Object Storage URL: *☒ URL ☐ Upload CSV

https://s3.amazonaws.com/testbucket

7. Click **Create**.

Depending on the number of paths you add to a GuardPoint, a status information message may appear. Refer to [GuardPoint Status Information](#) for details.

The newly created GuardPoint appears on the GuardPoints tab. The status remains **Unknown** until the client sends the response after processing the GuardPoint request. Click the **Refresh GuardPoints** icon () to view the updated status.

Status of a GuardPoint can be checked at any time on the GuardPoints tab. Refer to [Viewing GuardPoint Status](#) for details.

Creating IDT GuardPoints

Steps to create GuardPoints on individual clients and client groups are similar. GuardPoints can be created on the

GuardPoints tab of individual clients and client groups.

Before proceeding, review the "CipherTrust InPlace Data Transformation for Linux" section of the [CTE Agent for Linux Advanced Configuration](#) document. Make sure to fulfill the IDT requirements.

To create an IDT GuardPoint:

1. Open the **Transparent Encryption** application.
2. Select the client or client group on which you want to create a GuardPoint.
 - Click a client under the **Client Name** column (**Clients > Clients**).
 - Click a client group under the **Client Group Name** column (**Clients > Client Groups**).
3. On the **GuardPoints** tab, click **Create GuardPoint**.
4. Select a **Policy**. This is a mandatory field.
 - a. Click **Select** next to the Policy field.
 - b. Select an *In-place Data Transformation* policy. If no policy exists, create one, as described in [Creating Policies](#).

	Name	Type	Version
☐	testcospic	Cloud Object Storage	0
☐	testpolicy	Standard	1
☐	idtpic	Live Data Transformation	0
☒	test-idt-pic	In-place Data Transformation	0

- c. Click **Select**.

Note

When an IDT policy is selected, the read-only **In-place Data Transformation** toggle is displayed on the Create GuardPoint dialog box.

5. Select the **Type** of device to protect. This is a mandatory field. The options for a **In-place Data Transformation** policy are:

Type	Description
Auto Raw or Block Device	Select for IDT policies for raw (block) devices.
Manual Raw or Block Device	Select for IDT policies for raw (block) devices to be guarded manually.

Note

Manual Raw or Block Device are guarded and unguarded (for example, mounted and unmounted) by running the `secfsd -guard` and `secfsd -unguard` commands. Do not run the `mount` and `umount` commands to swap GuardPoint nodes in a cluster configuration.

6. Specify the **Path** to be protected. This is a mandatory field. Options to specify the GuardPoint paths are:

- **Enter/Browse Path:** Select this option, and enter the GuardPoint paths by either typing or clicking the **Browse** button.

Note

A maximum of 200 GuardPaths can be specified using the **Enter/Browse Path** option.

If the paths are already guarded, you'll see an active GuardPoint icon before them.

- Click **Browse** to select a path by browsing the client file system. This method prevents typographical errors and verifies client availability. This is the recommended method to specify individual paths.

File system of a client that is not registered with the CipherTrust Manager cannot be browsed.

- Alternatively, if you know the path, manually enter full paths of one or more directories in the given text box. Enter one path per line.
- **Upload CSV:** Select this option and click **Browse** to upload the CSV file containing the list of one or more directories. This is the recommended method to specify a large number of paths in one step.

Note

- If a manually entered path does not yet exist, be sure to enter the path correctly. The CipherTrust Manager does not parse manually entered paths for correct syntax.

- See [Considerations Before Creating GuardPoints](#) for what to be aware of before creating a GuardPoint.
- If multiple paths are specified, they will all be protected by the same policy.
- A maximum of 1000 GuardPaths per CSV file can be uploaded.
- If the paths are already guarded, you'll see an active GuardPoint icon before them.

/dev/sdb/

Browse

i To apply the same GuardPoint settings to multiple paths, type paths in the Path field or specify them using the Browse button. A maximum of 200 GuardPaths can be specified.

In-place Data Transformation: ☒

Efficient Storage: ☐

7. (Optional, Windows only). Select **Multifactor Authentication** Refer to [Multifactor Authentication](#) for details.

8. Click **Create**.

Depending on the number of paths you add to a GuardPoint, a status information message may appear. Refer to [GuardPoint Status Information](#) for details.

The newly created GuardPoint appears on the GuardPoints tab. The status remains **Unknown** until the client sends the response after processing the GuardPoint request. Click the **Refresh GuardPoints** icon () to view the updated status.

Status of a GuardPoint can be checked at any time on the GuardPoints tab. Refer to [Viewing GuardPoint Status](#) for details.

A use case of IDT GuardPoints is protection of Teradata appliances. Refer to [Protecting Teradata Appliances](#) for details.

Creating Ransomware Protection GuardPoints

Steps to create GuardPoints on individual clients and client groups are similar. GuardPoints can be created on the GuardPoints tab of individual clients and client groups.

Note

- Using Ransomware Protection GuardPoints to protect Network Shares in CTE for **Windows** is compatible with CipherTrust Manager v2.14 and subsequent versions.
- Using Ransomware Protection GuardPoints to protect Network Shares in CTE for Linux is compatible with CipherTrust Manager v2.17 and subsequent versions.

To create an RWP GuardPoint:

1. Open the **Transparent Encryption** application.
2. Select the client or client group on which you want to create a GuardPoint.
 - Click an RWP-enabled client under the **Client Name** column (**Clients > Clients**). These are the clients with RWP or CTE RWP as Protection Mode.
 - Click a client group under the **Client Group Name** column (**Clients > Client Groups**).
3. On the **GuardPoints** tab, click **Create GuardPoint**.

When creating an **RWP** GuardPoint, you do not need to specify a CTE policy when Guardpoint Type is "Ransomware Protection Only". For clients with the RWP protection mode, the **Policy** field is unavailable.

On clients with the **CTE RWP** protection mode, you can create RWP GuardPoints as well as other types of GuardPoints with policies. The **Policy** field is available for such clients. Although the field is available, do not select any policy when creating an RWP GuardPoint.

Refer to [Protection Modes](#) for information on CTE protection modes.

4. (For clients with the **CTE RWP** protection mode) Select **Ransomware Protection Only** as the **Type** of device to protect. This is a mandatory field.

For clients with the **RWP** protection mode, **Ransomware Protection Only** is the default **Type** and cannot be modified.

Note

A process set and the default operation that you want CTE to perform on Ransomware protected GuardPoint can be configured in the profile linked with the client. Refer to [Setting Ransomware Protection Configuration](#) for details.

5. Specify the **Path** (volume or network share) to be protected. This is a mandatory field. Options to specify the GuardPoint paths are:
 - **Enter/Browse Path:** Select this option, and enter the path (for example, C:\, D:\, shared volume, or network share) by either typing or clicking the **Browse** button.

Note

- For CTE for Windows, Ransomware Protection GuardPoints are applied at the volume level. Even if you specify the path of a folder or a file, the GuardPoint will be applied at the volume level.
- For CTE for Linux, Ransomware Protection is applied at GuardPoint level.
- If you specify a network share, *all the network shares to be mounted subsequently* will be protected.
- A CTE client administrator can configure protection of all existing volumes and mount points, and those to be added to the client subsequently. Refer to the [CTE Agent for Windows Advanced Configuration Guide](#) for details.

Note

A maximum of 200 GuardPaths can be specified using the **Enter/Browse Path** option.

Browse Method

- a. Click **Browse** to select the volume by browsing the client file system. This method prevents

typographical errors and verifies client availability. This is the recommended method to specify individual paths.

File system of a client that is not registered with the CipherTrust Manager cannot be browsed.

- b. In the **Enter Path** field, specify the volume path. Alternatively, in the **Select Path** field, select the path from the on-screen file system browser, and click **Select Path**.
- c. Click **Add**.

Note

If the paths are already guarded, you'll see an active GuardPoint icon before them.

Manual Method

Alternatively, if you know the volume, manually enter volume in the given text box. Enter one volume per line.

- **Upload CSV:** Select this option and click **Browse** to upload the CSV file containing the list of one or more paths. This is the recommended method to specify a large number of paths in one step.

Note

- If a manually entered path does not yet exist, be sure to enter the path correctly. The CipherTrust Manager does not parse manually entered paths for correct syntax.
- See [Considerations Before Creating GuardPoints](#) for what to be aware of before creating a GuardPoint.
- A maximum of 1000 paths per CSV file can be uploaded.
- The following paths are restricted on Linux: `/proc`, `/usr/bin`, `/usr/sbin`, `/sbin`, `/bin`, `/opt/vormetric` or `install` directory, `/usr`, `/opt`, `/tmp`, `/var/log/vormetric`, `/lib64`, `/lib`, `/proc/*`, `/usr/bin/*`, `/usr/lib`, `/usr/lib/pam`, `/usr/lib/security`, `/usr/lib/security/*`, `/usr/sbin/*`, `/etc/`, `/sbin/*`, `/bin/*`, `/opt/vormetric/*`, `/etc/init.d/secfs`, `/etc/pam.d`, `/etc/pam.d/*`, `/etc/rc`, `/etc/security`, `/etc/security/*`, `/etc/ssh/sshd_config`, `/etc/ssh/sshr`, `/etc/systemd`, `/lib/systemd`, and `/usr/lib/systemd`.

6. Click **Create**.

Depending on the number of paths you add to a GuardPoint, a status information message may appear. Refer to [GuardPoint Status Information](#) for details.

The newly created GuardPoint appears on the GuardPoints tab. The status remains **Unknown** until the client sends the response after processing the GuardPoint request. Click the **Refresh GuardPoints** icon () to view the updated status.

Status of a GuardPoint can be checked at any time on the GuardPoints tab. Refer to [Viewing GuardPoint Status](#) for details.

Enabling Secure Start for GuardPoints

Note

Information in this section is applicable to Windows clients.

Access to a Secure Start GuardPoint is permitted only during the boot sequence and for a short period. After the VMD is up and running, it performs normal agent initialization and communicates with the CipherTrust Manager to access files within a GuardPoint location.

A CipherTrust Manager administrator can enable Secure Start either when creating a GuardPoint or later by modifying the GuardPoint.

To enable Secure Start for a GuardPoint:

1. Open the **Transparent Encryption** application.
2. Click **Clients > Clients**.
3. Under **Client Name**, click the desired Windows client.
4. Click the **GuardPoints** tab.
5. Click the overflow icon () corresponding to the desired GuardPoint.
6. Click **View/Edit**. The Edit GuardPoint dialog box is displayed. In the edit mode, you can enable or disable the Secure Start and Preserve Sparse Region toggles.
7. Turn on the **Secure Start** toggle. By default, the toggle is off.

Preserve Sparse Region: 

Secure Start: 

8. Click **Save**.

Refer to the [CTE Agent for Windows Advanced Configuration and Integration Guide](#) for details about using the Secure Start feature.

Note

To disable Secure Start for a GuardPoint, turn off the **Secure Start** toggle in the Edit GuardPoint dialog box.

Protecting Teradata Appliances

Data on a Teradata appliance can be protected using IDT GuardPoints. In a Teradata appliance, the disks used by the database cannot be resized. So, when they are guarded as an IDT capable device, the metadata for those disks is stored externally in a directory on the local file system.

Fulfill the IDT requirements before proceeding. Refer to the CipherTrust InPlace Data Transformation for Linux section of the [CTE Agent for Linux Advanced Configuration](#) document.

To protect a Teradata appliance:

1. Register the Teradata node with the CipherTrust Manager. Refer to the [CTE Agent Quick Start Guide](#) for details.

After registration, you can apply GuardPoints to the data stored on the device, for example, `/dev/sdb`.

2. Make sure the path `/opt/vte/vte-metadata-dir` exists. Create, if it does not.
3. Apply a Standard GuardPoint to `/opt/vte/vte-metadata-dir`. Refer to [Creating Standard GuardPoints](#) for details.
4. Configure the device as IDT capable. Run the command:

```
voradmin idt config -external xform /dev/sdb
```

5. Apply an IDT GuardPoint to the device, as appropriate. Refer to [Creating IDT GuardPoints](#) for details.

Automatic and Manual GuardPoints

The following table lists the type of GuardPoints depending on the platform and type of the policy type:

Type	Windows	Linux	Description
Auto Directory	Yes	Yes	Select for file system directories.
Manual Directory	No	Yes	Select for file system directories to be guarded manually.
Auto Raw or Block Device	Yes	Yes	Select for standard policies for raw (block) devices.

Type	Windows	Linux	Description
Manual Raw or Block Device	No	Yes	Select for standard policies for raw (block) devices to be guarded manually.
Auto Cloud Storage	No	Yes	Select for Cloud Storage policies.
Manual Cloud Storage	No	Yes	Select for Cloud Storage policies to be guarded manually.

A GuardPoint is usually applied immediately after it is configured on the CipherTrust Manager GUI; however, it can be applied later on the client system.

When would you want to apply the GuardPoint later? Consider the case of a 2-node cluster configured as active/passive in a cluster environment, such as VCS, HACMP, or MSCS. There are two nodes, one which is currently active and the other that is currently inactive. Both nodes are locked.

Apply GuardPoint protection to active nodes only. You should never apply a GuardPoint to a passive node. If the active node develops a problem and tries to switch over to the inactive node, the cluster process fails to switch over because the mirror directory on the inactive node is currently mounted on the active node.

The solution is, for the cluster process to unmount (for example, unguard) the currently active node:

1. Place it in an inactive state.
2. Place the old inactive node in an active state.
3. Mount (for example, guard) the mirror directory on the newly active node.

Generally, when you get error messages, check that only active nodes are properly guarded.

When an auto GuardPoint is applied, regardless of whether it is a file system directory or a raw device, the change is pushed to the client system, and the GuardPoint is applied immediately.

Use the `df` command to display `secfs` mounts (for example, GuardPoints) or `secfsd` to display the GuardPoints themselves. The `secfsd` output shows a guard type of local for directories configured with Directory (Auto Guard).

Run:

```
df
```

Output:

```
Filesystem 1K-blocks  Used Available Use% Mounted on
/dev/mapper/VolGroup00-LogVol00
40123784  11352236  26733380   30% /
/dev/sda1  101086  14590   81277   16% /boot
none      254492    0   254492    0% /dev/shm
/opt/vormetric/DataSecurityExpert/agent/secfs/.sec
40123784  11352236  26733380   30%
/opt/vormetric/DataSecurityExpert/agent/secfs/.sec
```

```
/opt/apps/apps1/tmp 40123784 11352236 26733380 30% /opt/apps/apps1/tmp
/opt/apps/apps1/lib 40123784 11352236 26733380 30% /opt/apps/apps1/lib
/opt/apps/apps1/doc 40123784 11352236 26733380 30% /opt/apps/apps1/doc
```

Run:

```
secfsd -status guard
```

Output:

```
GuardPoint  Policy  Type    ConfigState  Status  Reason
-----
/opt/apps/apps1/tmp allowAllOps_fs local    guarded    guarded  N/A
/opt/apps/apps1/lib allowAllRootUsers_fs local    guarded    guarded  N/A
/opt/apps/apps1/doc allowAllOps-winusers1_fs local    guarded    guarded  N/A
```

When a manual GuardPoint is applied, regardless if it is a file system directory or a raw device, the change is pushed to the client system only. The client is aware of the GuardPoint but the client does not mount it. This is indicated in the **Type** column of the `secfsd -status guard` command output.

For example, the GuardPoint `/opt/apps/apps2/bin` has been configured with Manual Directory, so the guard type is set to `manual`.

```
secfsd -status guard
```

Output:

```
GuardPoint  Policy  Type    ConfigState  Status  Reason
-----
/opt/apps/apps1/tmp allowAllOps_fs local    guarded    guarded  N/A
/opt/apps/apps1/lib allowAllRootUsers_fs local    guarded    guarded  N/A
/opt/apps/apps1/doc allowAllOps-winusers1_fs local    guarded    guarded  N/A
/opt/apps/apps2/bin HR_policy01 manual    unguarded    not guarded  Inactive
```

Note the **Type** value. A **Type** of `manual` indicates a manual GuardPoint. A **Type** of `local` indicates an automatic GuardPoint.

A manually applied GuardPoint remains Inactive until the GuardPoint is applied on the client. After the GuardPoint is applied on the client, and the client communicates the change to the server, the status changes to Active. It returns to the Inactive state when the GuardPoint is manually unguarded.

Use the `secfsd` command to guard and unguard Manual GuardPoints. The `secfsd` command syntax is:

To guard, run:

```
secfsd -guard path
```

To unguard, run:

```
secfsd -unguard path
```

Example

To manually guard and unguard a file system directory:

1. As CipherTrust Manager administrator, configure a GuardPoint with the type Manual Directory.
2. Log on to the client as an administrator with root permissions.
3. Wait until the configuration change is downloaded to the Agent system.
4. Run the status command until the manual GuardPoint is displayed.

Run:

```
secfsd -status guard
```

Output:

GuardPoint	Policy	Type	ConfigState	Status	Reason
/opt/apps/etc	allowAllOps_fs	manual	unguarded	not guarded	N/A
/opt/apps/lib/dx3	allowAllOps_fs	local	guarded	guarded	N/A

5. Enable the GuardPoint.

Run:

```
secfsd -guard /opt/apps/apps2/bin
```

Output:

```
secfsd: Guard initiated
```

The manual GuardPoint is active and the policy is enforced.

6. Disable the GuardPoint.

Run:

```
secfsd -unguard /opt/apps/apps2/bin
```

Output:

```
secfsd: Unguard initiated
```

Viewing GuardPoints

The Status Bar on the GuardPoints tab of a client shows the total number of GuardPoints on the client, and inactive, disabled, active, and unknown GuardPoints. The Status Bar contains the following tabs:

- **Total GuardPoints:** Shows the total number of GuardPoints with all types of health status.
- **Inactive:** Shows the number of inactive GuardPoints. An inactive GuardPoint is enabled but not yet applied.
- **Disabled:** Shows the number of disabled GuardPoints. The CTE client does not enforce protection on disabled GuardPoints. However, references to the GuardPoints exist in the CipherTrust Manager configuration.
- **Active:** Shows the number of active GuardPoints. An active GuardPoint is deployed successfully and connection to the CTE Agent is healthy. The CTE client enforces protection on active GuardPoints.
- **Unknown:** Shows the number of GuardPoints whose status is unclear.

Click each tab to filter the GuardPoints. The GuardPoints list displays details of the GuardPoints on the client.

To view the GuardPoints created on a client:

1. Open the **Transparent Encryption** application.
2. Click **Clients > Clients**.
3. Under **Client Name**, click the desired client. The GuardPoints tab shows the GuardPoints configured on the client.

Status	Policy Name	Protected Path	Type	LGS Primary	SMB Connection	Efficient Storage	Client Group	Rekey Status	Enabled	LDT Progress	Native Domain
Active	Default	C:\ProgramData	directory_auto	N/A	N/A	No	-	Rekeyed	Yes	Rekeyed	root

The GuardPoints list shows the following details:

Column	Description
Status	Status of the GuardPoint. The status can be: • Inactive • Disabled • Active • Unknown A status Processing is displayed for a brief period until an operation on the GuardPoint completes.
Policy Name	Policy applied to the GuardPoint.
Protected Path	Path of the protected directory.
Type	Type of the GuardPoint. • Auto Directory

Column	Description
	• Manual Directory • Auto Raw or Block Device • Manual Raw or Block Device • Auto Cloud Storage • Manual Cloud Storage • Ransomware Protection Only
LDT Group Role	Whether the client is the primary or secondary node for this GuardPoint in the linked LDT communication group. The values can be: • Primary • Secondary • N/A: Displayed for clients that are not associated with an LDT communication group. N/A is also displayed for clients that do not share an NFS/CIFS path in an LDT communication group. When the primary node is down, another client is automatically assigned the primary role. Refer to Managing LDT Communication Groups for details on LDT communication groups.
SMB Connection	(Applicable to LDT over SMB GuardPoints, Windows clients) Name of the linked SMB connection.
Client Group	Origin of the GuardPoint. The origin can be the client itself or its client group. Filter the results by: • Client: GuardPoint is created on the client. A hyphen (-) indicates the GuardPoint is applied to the client itself. • Client Group: GuardPoint is applied through the client's client group. Name of the linked client group is displayed.
Rekey Status	Rekey status of the GuardPoint.
Enabled	Whether the GuardPoint is enabled.
LDT Progress	(Applicable to LDT GuardPoints) Progress of LDT. Rekeyed is displayed when LDT is complete. N/A is displayed for non-LDT GuardPoints.
Native Domain	Domain where the GuardPoint is created on the shared client.

Viewing GuardPoint Status

Status of GuardPoints can be seen on the CipherTrust Manager and on the client running the CTE Agent. The CipherTrust Manager GUI shows the GuardPoint status as it is configured on the CipherTrust Manager. It is not a real-time indication of the actual status.

Viewing GuardPoint Status on the Client

To view the actual status:

1. Log on to the CTE client as root/administrator.
2. Run the CTE Agent utilities.
3. Compare the GuardPoint status on the client with the status on the CipherTrust Manager GUI. If they do not match, go with the status on the CTE client.

Viewing GuardPoint Status on the GUI

The GuardPoints tab of the Clients page shows the total number of configured GuardPoints with their status. Similarly, status of GuardPoints on a client group can viewed on its GuardPoints tab.

To view the status on the GUI:

1. Open the **Transparent Encryption** application.
2. Click **Clients > Clients**.
3. Under **Client Name**, click the desired client.
4. Click the **GuardPoints** tab. This tab shows the list of configured GuardPoints.
5. View the **Status** of the GuardPoint. The status can be:
 - **Active:** GuardPoint is deployed successfully and connection to the CTE Agent is healthy. The CTE client enforces protection on active GuardPoints.
 - **Inactive:** GuardPoint is enabled but not yet applied. Possible reasons are:
 - The GuardPoint is manual and is not mounted on the client. To apply manual GuardPoints, the client administrator needs to run the `secfsd -guard` command on the client.
 - A communication error has occurred between the CipherTrust Manager and CTE client.
 - **Disabled:** GuardPoint is disabled. The CTE client does not enforce protection on disabled GuardPoints. However, references to the GuardPoints exist in the CipherTrust Manager configuration.
 - **Unknown:** GuardPoint is created. Awaiting response from the CTE Agent on the GuardPoint request.

To view more details about an **Active** or **Inactive** GuardPoint, click the corresponding status link.

A status **Processing** is displayed for a brief period until an operation on the GuardPoint completes.

Changing Designated Primary Set Connection

If a GuardPoint is associated with a Designated Primary Set, the Designated Primary Set can be modified after the GuardPoint is created.

To change the Designated Primary Set associated with a GuardPoint:

1. Open the **Transparent Encryption** application.
2. Click the client group under the **Client Group Name** column (**Clients > Client Groups**).
3. On the **GuardPoints** tab, click the overflow icon () corresponding to the desired GuardPoint.
4. Click **View/Edit**. The Edit GuardPoint dialog box is displayed.
5. Select the desired **Designated Primary Set** from the drop-down list.
6. Click **Save**.

The GuardPoint is updated successfully with the new Designated Primary Set.

Changing SMB Connection

If the GuardPaths are on an SMB share, the SMB connection can be modified after a GuardPoint is created.

To change the SMB connection:

1. Open the **Transparent Encryption** application.
2. Select the desired client or client group.
 - Click a client under the **Client Name** column (**Clients > Clients**).
 - Click a client group under the **Client Group Name** column (**Clients > Client Groups**).
3. On the **GuardPoints** tab, click the overflow icon () corresponding to the desired GuardPoint.
4. Click **View/Edit**. The Edit GuardPoint dialog box is displayed.
5. Select the desired **SMB Connection** from the drop-down list.
6. Click **Save**.

The GuardPoint is updated successfully with the new SMB connection.

Removing GuardPoints

GuardPoints can be unguarded (removed) from entire client groups or individual clients. When a GuardPoint is removed from a client group, the GuardPoint is automatically removed from all clients in the group.

When unguarded, all references to the GuardPoint are removed from the CipherTrust Manager, the mount point is removed from the client, and the client stops enforcing protection on the GuardPoint.

Before Removing GuardPoints

The following preliminary steps need to be taken before removing a GuardPoint:

- Encrypted data in a GuardPoint will still be encrypted when the GuardPoint is removed. If you are not going to reuse the GuardPoint for any reason, such as uninstalling the CTE Agent software from a client, do either of the following:
 - Copy the encrypted files out of the GuardPoint so that they are saved as unencrypted files. The GuardPoint must be enabled while copying encrypted files out. Also, ensure that the user or process copying files out of the GuardPoint is not restricted to ciphertext read access under any security rule in the policy applied to the GuardPoint.
 - Rekey the encrypted files while the GuardPoint is still applied under an offline transformation policy.

Note

For LDT GuardPoints, refer to [Migrating a GuardPoint Out of CTE-LDT](#) in the CTE-Live Data Transformation with CipherTrust Manager to ensure that the data in those GuardPoints remains available.

- Take the GuardPoint out of service so that no user or application is accessing the directories and files in the GuardPoint. A GuardPoint is a mounted file system. Removing a GuardPoint involves unmounting the file system. File systems cannot be unmounted when in use.
- Remove all the GuardPoints and disable the locks for a client before deleting the client from the CipherTrust Manager. This ensures that there are no residual GuardPoints in effect on the client.
- For LDT GuardPoints, refer to procedures described in the [CTE-Live Data Transformation](#) with CipherTrust Manager to ensure that the data in those GuardPoints remains available.

Removing a GuardPoint

To remove a GuardPoint:

1. Open the **Transparent Encryption** application.
2. Select the client or client group from which you want to remove the GuardPoint.
 - Click a client under the **Client Name** column (**Clients > Clients**).
 - Click a client group under the **Client Group Name** column (**Clients > Client Groups**).

3. On the **GuardPoints** tab, select the GuardPoint to be removed.

4. Click the delete icon ().

Alternatively, click the overflow icon () corresponding to the desired GuardPoint, and click **Unguard**.

A warning message appears stating that unguarding a GuardPoint is permanent and cannot be undone.

5. Click **Unguard** to confirm the action.

The GuardPoint status becomes **Processing**. While processing the GuardPoint removal:

- a. CipherTrust Manager notifies the CTE Agent that the GuardPoint is removed from the CipherTrust Manager.
- b. CTE Agent removes the mount point from the client.
- c. CTE Agent notifies the CipherTrust Manager about the GuardPoint removal.
- d. CipherTrust Manager removes the GuardPoint from the GuardPoints tab.

6. Click the **Refresh GuardPoints** icon () to update the tab.

7. Verify the mount points on the CTE client.

- On UNIX, run the command `df` or `secfsd -status guard`.
- On Windows, click the **Vormetric** icon and **View > File System > GuardPoints**.

Removing Multiple GuardPoints

The CipherTrust Manager provides an option to remove/unguard multiple GuardPoints. A maximum of 200 GuardPoints can be removed at once.

To remove multiple GuardPoints:

1. Open the **Transparent Encryption** application.
2. Select the client or client group from which you want to remove the GuardPoints.
 - Click a client under the **Client Name** column (**Clients > Clients**).
 - Click a client group under the **Client Group Name** column (**Clients > Client Groups**).
3. On the **GuardPoints** tab, select the GuardPoints to be removed.

To select all GuardPoints visible on the page, select the top check box to the left of the Status heading.

4. Click the delete icon ().

A warning message appears stating that unguarding GuardPoints is permanent and cannot be undone.

- Click **Unguard** to confirm the action.

The GuardPoint status becomes **Processing**. While processing the GuardPoint removal:

- CipherTrust Manager notifies the CTE Agent that the GuardPoint is removed from the CipherTrust Manager.
- CTE Agent removes the mount point from the client.
- CTE Agent notifies the CipherTrust Manager about the GuardPoint removal.
- CipherTrust Manager removes the GuardPoint from the GuardPoints tab.

- Click the **Refresh GuardPoints** icon () to update the tab.
- Verify the mount points on the CTE Agent client.
 - On UNIX, run the command `df` or `secfsd -status guard`.
 - On Windows, click the **Vormetric** icon and **View > File System > GuardPoints**.

Disabling GuardPoints

If you have protected a GuardPath with a GuardPoint, and you want to protect the path with a different policy, then you need to remove or disable the existing GuardPoint first.

When a GuardPoint is disabled, the client stops enforcing protection on the GuardPoint. However, references to the GuardPoint exist in the CipherTrust Manager configuration.

Disable individual GuardPoints

To disable a GuardPoint:

- Open the **Transparent Encryption** application.
- Select the client or client group from which you want to disable the GuardPoint.
 - Click a client under the **Client Name** column (**Clients > Clients**).
 - Click a client group under the **Client Group Name** column (**Clients > Client Groups**).
- On the **GuardPoints** tab, select the GuardPoint to be disabled.
- Click the overflow icon () corresponding to the desired GuardPoint, and click **Disable**.

The GuardPoint status becomes **Disabled**.

Disable multiple GuardPoints

To disable multiple GuardPoints at once:

1. Open the **Transparent Encryption** application.
2. Select the client or client group from which you want to enable the GuardPoints.
 - Click a client under the **Client Name** column (**Clients > Clients**).
 - Click a client group under the **Client Group Name** column (**Clients > Client Groups**).
3. In the the **GuardPoints** tab, select the checkboxes corresponding to the GuardPoints that you want to disable.
4. Select the **Disable** option from the top.

A confirmation dialog box with a message will appear.

5. Click **Disable**.

After the process is complete, a screen will be displayed showing the details of the successfully disabled GuardPoints. The status of these GuardPoints becomes **Disabled**.

This screen also provides information on any GuardPoints that could not be disabled, along with the corresponding troubleshooting error messages. After addressing the issues, you may attempt the disable operation again.

Enabling GuardPoints

A CTE client does not enforce protection on disabled GuardPoints. References to those GuardPoints exist in the CipherTrust Manager configuration. To resume protection of such GuardPoints, you need to enable them.

Enable individual GuardPoints

To enable a disabled GuardPoint:

1. Open the **Transparent Encryption** application.
2. Select the client or client group from which you want to enable the GuardPoint.
 - Click a client under the **Client Name** column (**Clients > Clients**).
 - Click a client group under the **Client Group Name** column (**Clients > Client Groups**).
3. On the **GuardPoints** tab, select the GuardPoint to be enabled.
4. Click the overflow icon () corresponding to the desired GuardPoint, and click **Enable**.

The GuardPoint status becomes **Active**. It might take some time to update the status. When the GuardPoint is enabled, the CTE client starts enforcing protection on the GuardPoint.

Enable multiple GuardPoints

To enable a disabled GuardPoints at once:

1. Open the **Transparent Encryption** application.
2. Select the client or client group from which you want to enable the GuardPoint.
 - Click a client under the **Client Name** column (**Clients > Clients**).
 - Click a client group under the **Client Group Name** column (**Clients > Client Groups**).
3. In the the **GuardPoints** tab, select the checkboxes corresponding to the GuardPoints that you want to enable.
4. Select the **Enable** option from the top.

A confirmation dialog box with a message will appear.

5. Click **Enable**.

After the process is complete, a screen will be displayed showing the details of the successfully enabled GuardPoints. The status of these GuardPoints becomes **Active**. This screen also provides information on any GuardPoints that could not be enabled, along with the corresponding troubleshooting error messages. After addressing the issues, you may attempt the enable operation again.

It might take some time to update the status. When the GuardPoints are enabled, the CTE client starts enforcing protection on the GuardPoint.

Enabling and Disabling MFA on GuardPoints

In Multifactor Authentication (MFA), access to the requested data is granted only after the requester satisfies two or more authentication criteria.

After you have configured MFA, you can enable it for individual clients and GuardPoints at the client and client group levels.

GuardPoint-level MFA can be enabled at the time of GuardPoint creation. Also, you can enable or disable it later.

- **GuardPoints on Clients**

When MFA is disabled at the client level, you can enable MFA for individual GuardPoints on clients. In this case, the CTE Agent processes the MFA configuration of individual GuardPoints. However, if client-level MFA is enabled, the MFA configuration of the client takes priority.

- **GuardPoints on Client Groups**

MFA cannot be enabled at the client group level. However, you can enable MFA for individual GuardPoints on client groups.

While propagating the MFA-enabled GuardPoints to the member clients, the CTE service on the CipherTrust Manager checks the MFA capability on the member clients. If a client is MFA-capable, the GuardPoints are added to the client. If a client is not MFA-capable, the GuardPoints are skipped.

Note

After GuardPoints are propagated to the member clients, the MFA configuration specified in the profiles associated with the member clients is used to send the security configuration to the CTE Agent.

Therefore, if the profiles of a client group and its member clients are different, the profiles of the member clients are used.

Enabling MFA on GuardPoints

MFA for individual GuardPoints can only be enabled when the client-level MFA is disabled.

To enable MFA on a GuardPoint:

1. Open the **Transparent Encryption** application.
2. Select the client or client group on which you want to enable the GuardPoint.
 - Click a client under the **Client Name** column (**Clients > Clients**).
 - Click a client group under the **Client Group Name** column (**Clients > Client Groups**).
3. On the **GuardPoints** tab, turn ON the **Multifactor Authentication** toggle corresponding to the desired GuardPoint.

MFA is enabled on the selected GuardPoint.

Disabling MFA on GuardPoints

MFA can't be disabled on individual GuardPoints of a *client* if MFA is enabled at the client level. Before proceeding with disabling MFA for individual GuardPoints, make sure that MFA is *disabled* on the client. Refer to [Enabling or Disabling MFA on Client Level](#) for details.

MFA enabled on the GuardPoints created on client groups can be disabled directly.

To disable MFA at GuardPoint:

1. Open the **Transparent Encryption** application.
2. Select the client or client group on which you want to disable the GuardPoint.
 - Click a client under the **Client Name** column (**Clients > Clients**).
 - Click a client group under the **Client Group Name** column (**Clients > Client Groups**).
3. On the **GuardPoints** tab, click the expand icon (▶) corresponding to the desired GuardPoint.
4. Clear **Multifactor Authentication**.

5. Click **Apply**.

MFA is disabled at the GuardPoint level.

Managing Kubernetes Storage Groups and Clients

This section describes how to manage Kubernetes (K8s) storage groups, manage K8s clients, apply GuardPolicies to storage groups, and protect K8s clients.

This section covers the following information:

- [Managing Kubernetes Storage Groups](#)
- [Managing Kubernetes Clients](#)
- [Protecting Kubernetes Clients](#)
- [Collecting Kubernetes Agent Information](#)

Managing Kubernetes Storage Groups

Create, view, edit, and delete Kubernetes (K8s) storage groups on the K8s Storage Groups page of the CipherTrust Manager GUI.

Note

The terms storage group, CSI storage group, Kubernetes storage group, and K8s storage group refer to the same resource and can be used interchangeably.

Creating Kubernetes Storage Groups

Note

All the K8s clients that you want to attach to a storage group must have the same K8s Namespace and K8s StorageClass.

To create a storage group:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Clients > K8s Storage Groups**. The K8s Storage Groups page is displayed.
3. Click **Create K8s Storage Group**. The General Info screen of the Create K8s Storage Group wizard is displayed.

4. Specify a unique **Name** for the group.
5. Enter the **K8s Namespace**.
6. Enter the **K8s StorageClass**.
7. (Optional) Select a **Client Profile** for the storage group. The default profile is **DefaultClientProfile**.
8. (Optional) Provide a **Description** for the storage group.
9. Click **Next**. The Review screen is displayed.
10. Review the provided details. The Review screen displays general information about the storage group you specified. If the details are incorrect or you want to modify them, click **Back** and update the details.
11. Click **Save**.

The newly created storage group appears in the K8s Storage Groups list.

You can change the client profile linked to the storage group later. Refer to [Changing the Client Profile](#) for details.

Viewing Details of Kubernetes Storage Groups

To view the details K8s storage groups:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Clients > K8s Storage Groups**. The list of K8s storage groups is displayed. The following details are displayed:

Column	Description
Name	Name of the K8s storage group.
StorageClass	K8s StorageClass linked to the storage group.
Namespace	K8s Namespace linked to the storage group.
Created At	Date and time when the storage group is created.
Updated At	Date and time when the storage group is updated the last.
Description	Description of the storage group.

The K8s Storage Groups page also provides options to view the client profile and K8s clients linked to the storage groups. To view these details, click the expand icon  corresponding to the desired storage group.

The K8s clients attached to a storage group are also visible on the Membership tab of the storage group. Refer to [Viewing Attached K8s Clients](#) for details.

Changing the Client Profile

To change the linked client profile:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Clients > K8s Storage Groups**.
3. Click the expand icon  corresponding to the desired storage group.

Alternatively, click the **Name** link corresponding to the desired storage group.

4. Next to **Client Profile**, click the profile link (for example, **DefaultClientProfile**). The Select Profile dialog box shows the current client profile and Rekey Option, Rekey Rate, and Schedule of the selected profile.
5. From the **Profile** drop-down list, select the desired profile.
6. Click **OK**. The selected profile is linked successfully.

Updating Description of a Kubernetes Storage Group

To add or edit the description of a K8s storage group:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Clients > K8s Storage Groups**. The list of K8s storage groups is displayed.
3. Click the overflow icon () corresponding to the desired K8s storage group.
4. Click **Edit**.
5. Add or update the **Description** field.
6. Click **Update**.

The storage group description is updated.

Viewing GuardPolicies Applied to a Storage Group

To view GuardPolicies applied to a storage group:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Clients > K8s Storage Groups**. The list of K8s storage groups is displayed.
3. Under **Name**, click the desired storage group. The **GuardPolicies** tab shows the following details:

Column	Description
Policy Name	Name of the applied policy.
Type	Type of the GuardPolicy - csi_manual.
Enabled	Whether the GuardPolicy is enabled - Yes or No.

To remove/disable a GuardPolicy, click the overflow icon () corresponding to the GuardPolicy and click **Remove/Disable**.

Note

If a GuardPolicy is **active** on a K8s client, the policy cannot be removed or disabled from the storage group associated with that client.

Viewing Attached Kubernetes Clients

The Membership tab of a storage group displays the attached K8s clients.

To view the K8s clients attached to a storage group:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Clients > K8s Storage Groups**. The list of K8s storage groups is displayed.
3. Under **Name**, click the desired storage group.
4. Click the **Membership** tab. The tab displays the K8s clients attached to the storage group. The following details are displayed:

Column	Description
Status	Health status of the K8s client.
Name	Name of the K8s client. The name is a combination of: • The node on which the K8s client is running • The linked StorageClass • The namespace where the K8s client pod runs • A random string
Description	Description of the K8s client.

Deleting a Kubernetes Storage Group

A storage group can only be deleted if no K8s clients are attached to it. As K8s clients are automatically attached

to a storage group, they cannot be detached explicitly. K8s clients are detached from the linked storage groups only when the clients crash.

When a storage group is deleted, any attached GuardPolicies are removed automatically.

To delete a K8s storage group:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Clients > K8s Storage Groups**. The list of K8s storage groups is displayed.
3. Click the overflow icon () corresponding to the K8s storage group you want to delete.
4. Click **Delete**. A dialog box appears prompting to confirm the action.
5. Click **Delete**.

The K8s storage group is deleted.

Managing Kubernetes Clients

Register and view Kubernetes (K8s) clients on the K8s Clients page of the CipherTrust Manager GUI.

Every node of a Kubernetes cluster consumes one CTE for Kubernetes license. The license applies to worker nodes where CSI is attached to the application pod. Refer to [CTE Licensing Model](#) for details.

Registering Kubernetes Clients

Registration is the process of configuring a Kubernetes (K8s) client with a CipherTrust Manager.

This process creates SSL certificates for further communication between the CipherTrust Manager and the K8s client. Refer to [Preparing a CTE for Kubernetes Volume for Deployment](#) for details.

After registration, the K8s client can communicate with the CipherTrust Manager. All the GuardPolicies applied to the K8s storage group are automatically added to the K8s client. The client configuration is then built for K8s client (exactly like a CTE client) and sent to the client.

After successful registration, the K8s client appears on the K8s Clients page of the CipherTrust Manager GUI. The client status becomes Healthy.

Note

- All the K8s clients that you want to attach to a storage group must have the same K8s Namespace and K8s StorageClass.
- To automatically delete a node from CipherTrust Manager, you must be running both CipherTrust Manager 2.20 or later and CTE Agent 1.6 or later. If either component is older than these versions, the node will not be automatically deleted.

Viewing Details of Kubernetes Clients

The K8s Clients page shows the total number of K8s clients, clients with errors, clients with warnings, and healthy clients. The Status Bar contains the following tabs:

- **Total Clients:** Shows the total number of registered clients with all types of health status.
- **Errors:** Shows the number of clients with errors.
- **Warnings:** Shows the number of clients with warnings.
- **Healthy:** Shows the number of healthy clients.

Refer to [Client States](#) for details.

Click each tab to filter the K8s clients. The clients list displays names of clients in the CipherTrust Manager database and details about their configuration.

To view the details of a K8s client:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Clients > K8s Clients**. The list of K8s clients registered with the CipherTrust Manager is displayed. The following details are displayed:

Column	Description
Status	Health status of the K8s client.
Client Name	Name of the K8s client registered with the CipherTrust Manager. The name is a combination of: • The node on which the K8s client is running • The linked StorageClass • The namespace where the K8s client pod runs • A random string
Agent Version	Version of the CTE for Kubernetes Agent installed on the K8s client.
Description	Description of the K8s client.

Reregistration and Reenrollment

Unlike a CTE client, when a K8s client crashes or stops, it does not persist any information about its previous interaction with the CipherTrust Manager.

If you try to reregister the K8s client with same name (`<node-name>_<csi-storage-class>_<csi-namespace>`), the client is registered as a new client (with a new random string `_<random-string>` appended to its name).

After registration:

1. K8s client sends the enrollment request to the CipherTrust Manager.
2. CipherTrust Manager checks the request for the node name, namespace, and StorageClass.
3. CipherTrust Manager removes the existing registration entry of the client (with the old random string).

Viewing GuardPolicies Applied to Kubernetes Clients

To view the GuardPolicies applied to a K8s client:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Clients > K8s Clients**. The list of K8s clients registered with the CipherTrust Manager is displayed.
3. Under **Client Name**, click the desired client link. The detail view of the K8s client is displayed. The **GuardPolicies** tab shows the list GuardPolicies applied to the K8s client.
4. Under **Policy**, click the expand icon () to the left of the desired policy. The following policy details are displayed:

Column	Description
Pod	Name of the K8s pod.
CTE PVC Name	Name of the CTE PVC.
K8s PVC Name	Name of the K8s PVC.
K8s PVC Phase	Name of the K8s PVC phase.
StorageClass	Name of the K8s StorageClass.
CTE Guard Name	Name of the CTE GuardPolicy.

Deleting Kubernetes Clients with Error Status

The Kubernetes clients with the Error status can be deleted from the CipherTrust Manager GUI. Kubernetes clients with other status cannot be deleted.

To delete such a Kubernetes client:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Clients > K8s Clients**. The list of K8s clients registered with the CipherTrust Manager is displayed.

3. Click the **Delete** button corresponding to the erroneous Kubernetes client (with the status "Error") that you want to delete. A dialog box appears prompting to confirm the action.

Deleting a client is permanent and cannot be undone.

4. Click **Delete**.

A request to delete the client is submitted successfully to the CTE Agent. After the CipherTrust Manager receives confirmation from the CTE Agent, the Kubernetes client is deleted and its entry is removed from the K8s Clients page.

Note

You can force delete the Kubernetes clients from the CipherTrust Manager. Run the delete API, and set `"force_del_client": true`.

Protecting Kubernetes Clients

This section describes how to protect Kubernetes (K8s) clients attached to storage groups.

To protect a K8s client:

1. [Create a Kubernetes Storage Group](#)
2. [Apply a GuardPolicy to the Storage Group](#)
3. [Register the Kubernetes Client](#)

These steps are described below.

Create a Kubernetes Storage Group

First of all, you need to create a K8s storage group on the CipherTrust Manager. A storage group refers to a combination of a K8s StorageClass and a K8s Namespace. It is used to group together different K8s pods running on different nodes with the same K8s StorageClass and K8s Namespace. Different storage groups can exist for the same combination of K8s StorageClass and K8s Namespace.

While creating a K8s storage group, the Namespace and StorageClass of the K8s cluster are required. Contact your K8s administrator for these details.

Refer to [Creating Kubernetes Storage Groups](#) for details.

Apply a GuardPolicy to the Storage Group

After you have created a K8s storage group, you need to apply a GuardPolicy to it. Until a GuardPolicy is applied, a K8s client attached to the storage group cannot be registered successfully with the CipherTrust Manager.

To add a GuardPolicy to the storage group:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Clients > K8s Storage Groups**. The list of K8s storage groups is displayed.
3. Under **Name**, click the storage group to which you want to apply a GuardPolicy. The detail view of the K8s storage group is displayed.
4. On the **GuardPolicies** tab, click **Create GuardPolicy**. The General Info tab of the Create GuardPolicy screen is displayed.

The Create GuardPolicy screen shows the list of available GuardPolicies. If no policies exist, you can create a new one. You can either select an available GuardPolicy or create a new one. This section describes how to create a new GuardPolicy to a storage group.

Step 1: General Info

- a. Click **Create Policy**. The Create Policy wizard is displayed.
- b. Specify a unique **Name** for the policy. For example, `csi-policy`.
 - The name must start with a character. The maximum length can be 64 characters.
 - The name can contain alphanumeric characters, underscores (`_`), and dashes (`-`).
 - The name cannot contain the following special characters:
`? : ; | ! @ # $ % ^ & * < = > + ( ) { } ~ , \ / [ ] ' "`
- c. Select **CTE for Kubernetes** as the **Policy Type**. This policy is required to protect K8s clients.
- d. (Optional) Turn on the **Learn Mode** toggle. A warning message is displayed indicating that the policy is in Learn Mode.

Learn Mode:

 **Warning: This Policy is in Learn Mode** [Click here for more details](#)

Refer to [Learn Mode](#) for details. By default, the toggle is turned off.

- e. (Optional) Turn on the **Restrict Update** toggle. This option is used to restrict or allow any changes to the policy. By default, the toggle is turned off. This setting can be changed any time after the policy is created. Refer to [Controlling Updates to Policies](#).
- f. Click **Next**. The Security Rules screen is displayed.

Step 2: Security Rules

- a. Click **Create Security Rule**. The Create Security Rule dialog box is displayed.

- b. Specify the following details:

Field	Description
User Set	User set for the rule.
Process Set	Process set for the rule.
Resource Set	Resource set for the rule.
Action	Actions for the rule. Refer to Actions for the complete list of supported actions.
Effect	Effect permission and options for the rule. This is a mandatory field. By default, deny , audit is added.

Refer to [Step 2: Add Security Rules](#) for details on the fields.

- c. Click **Add**. The newly created security rule appears in the list of security rules.
- d. Click **Next**. The Key Rules screen is displayed.

Step 3: Add Key Rules

If you added a security rule with the Effect **ApplyKey** on the Security Rules screen, then you must add at least one key rule.

To add a key rule:

- a. Click **Create Key Rule**. The Create Key Rule dialog box is displayed.
- b. Select a **Key Name**. This is a mandatory field.
 - a. Click **Select** next to the field. The Select Key dialog box shows the list of available keys.

Optionally, you can create a new CBC-CS1 key on this dialog box by clicking **Create a New Key**. Refer to [Step 3: Add Key Rules](#) for details on the fields.
 - b. Select the desired **CBC-CS1** key. CTE for Kubernetes policies do not support XTS keys.
 - c. Click **Select**. The selected key appears in the Key Name field.
- c. Click **Add**. The newly created key rule appears in the list of key rules.
- d. Click **Next**. The Signature Rules screen is displayed.

Step 4: Add Signature Rules

- a. Click **Add Signature Rules**. The Add Signature Rules dialog box is displayed.

- b. Select a **Signature Rule** from the list.

Note

Ensure that you have already created a [signature set for container images](#).

- c. Click **Add**. The newly added signature rule appears in the list of signature rules.
- d. Click **Next**. The Confirmation screen is displayed.

Step 5: Confirmation

- a. Verify the policy details. The Confirmation screen displays general information about the policy and details of the security and key rules added to the policy.

If the details are incorrect or you want to modify them, click **Back** and update the details.

- b. Click **Save**.

The newly created CTE for Kubernetes policy appears on the Create GuardPolicy dialog box. Similarly, add as many policies as required.

5. Select the desired policy.
6. Click **Save**.

The newly created GuardPolicy is displayed on the GuardPolicies tab.

Register the Kubernetes Client

Registration is the process of configuring a Kubernetes (K8s) client with a CipherTrust Manager.

This process creates SSL certificates for further communication between the CipherTrust Manager and the K8s client. Refer to [Preparing a CTE for Kubernetes Volume for Deployment](#) for details.

After registration, the K8s client can communicate with the CipherTrust Manager. All the GuardPolicies applied to the K8s storage group are automatically added to the K8s client. The client configuration is then built for K8s client (exactly like a CTE client) and sent to the client.

After successful registration, the K8s client appears on the K8s Clients page of the CipherTrust Manager GUI. The client status becomes Healthy.

Collecting Kubernetes Agent Information

A Kubernetes Agent provides the `agentinfo` utility to collect system and CTE configuration data. The `agentinfo` utility takes a configuration snapshot of the system that you can send to Thales Customer Support to debug an issue.

The latest information about individual Kubernetes Agents can also be collected and downloaded on the CipherTrust Manager GUI. The collected information about all the Kubernetes Agents is stored in a dedicated volume on the CipherTrust Manager. An option is provided to clean the Agent information about all the Kubernetes Agents from the volume.

Collecting the Kubernetes Agent Information

To collect the latest Kubernetes Agent information:

1. Open the **Transparent Encryption** application.
2. Click **Clients > K8s Clients**.
3. Under **Client Name**, click the desired client.

Alternatively, click the expand icon () to the left of the desired client in the clients list.

4. Next to the **Agent Information** label, click **Collect**. A request is sent to the Kubernetes Agent to send the latest Agent information to the CipherTrust Manager.

Fetching the latest Agent information from the Kubernetes Agent might take some time. You need to *refresh* the page to download the latest Agent information. As soon as the information is available, the **Collect** link is replaced with the **Recollect** and **Download** links.

Recollecting the Kubernetes Agent Information

After you have fetched the Kubernetes Agent information from the Kubernetes client, a CTE Client Administrator might make some confirmation changes. To get the updated Kubernetes Agent configuration on the CipherTrust Manager, use the Recollect option.

To recollect the updated Kubernetes Agent information:

1. Open the **Transparent Encryption** application.
2. Click **Clients > K8s Clients**.
3. Under **Client Name**, click the desired client.

Alternatively, click the expand icon () to the left of the desired client in the clients list.

4. Next to the **Agent Information** label, click **Recollect**. A request is sent to the Kubernetes Agent to send the updated Agent information to the CipherTrust Manager. The **Recollect** and **Download** links are replaced with **Collect**.

Fetching the latest Agent information from the Kubernetes Agent might take some time. You need to *refresh* the page to download the latest Agent information. As soon as the information is available, the **Collect** link is replaced with the **Recollect** and **Download** links.

Downloading the Kubernetes Agent Information

After you have fetched the Agent information from a Kubernetes client, you can download this information from the CipherTrust Manager GUI. The information is downloaded in a tar file.

After the download, the Agent information is removed from the CipherTrust Manager. In a CipherTrust Manager cluster, the information will be downloaded from the node where the Agent information is requested.

To download the Kubernetes Agent information:

1. Open the **Transparent Encryption** application.
2. Click **Clients > K8s Clients**.
3. Under **Client Name**, click the desired client.

Alternatively, click the expand icon () to the left of the desired client in the clients list.

4. Next to the **Agent Information** label, click **Download**.

The Kubernetes Agent information currently available on the CipherTrust Manager is downloaded in a tar file, and removed from the CipherTrust Manager.

Cleaning the Kubernetes Agent Information Volume

When you fetch the Agent information from a Kubernetes Agent, this information is stored in a file in a dedicated volume on the CipherTrust Manager. This volume contains information about all the Kubernetes Agents from which you have collected the information.

The CipherTrust Manager provides an option to [clean the Agent information volume any time](#) to remove all the files containing the Agent information from the CipherTrust Manager. Also, when the [volume is 80% full](#), you are prompted to clean it while collecting the latest Agent information from clients.

Clean the Volume Any Time

To clean the volume containing the Kubernetes Agent information:

1. Log on to the **CipherTrust Manager** GUI.
2. Open the **Transparent Encryption** application.
3. Navigate to **Settings > Client Information and Capabilities**.
4. Under **Empty CTE Agent Information Log Volume**, click **Remove Agent Information**. A warning message is displayed.

Warning

The Agent information currently available on the CipherTrust Manager will be removed. You will have to regenerate the Agent information.

5. Select **Yes, clean up the entire volume containing the Agent information**.
6. Click **Clean**.

Clean the Volume When 80% Full

When the volume containing the Agent information is 80% full, a warning message is displayed while collecting the Agent information from a client. You need to clean the volume to collect the latest information.

To clean the volume, click **Clear Volume**. All the files containing the Agent information are removed from the volume. You can now retry collecting the latest Agent information.

Sharing Resources Across Domains

CTE clients having sensitive data can be shared across multiple departments and teams. Every department manages their data security requirements through different domains on the CipherTrust Manager. So, such a machine having sensitive data at multiple locations needs to be protected by different security administrators with different kinds of policies.

CipherTrust Manager supports sharing of CTE clients and client groups across multiple domains. Different domain administrators can apply different GuardPoints on the same client from their domains. On the client, there will be a single security configuration with all types of protection policies applied to multiple paths irrespective of the domains they are created in.

Note

If multiple domains with the same name exist in the domain hierarchy, clients and client groups are shared with the first domain found with that name.

The GuardPoints created on the clients and client groups in one domain (called native domain) will also be visible in other (nonnative) domains but in read-only mode.

Sharing a Client Across Domains

A shared client will be visible in read-only mode in all the domains where it is shared. The GuardPoints can be created on the shared client from any of the linked domains. These GuardPoints will be visible in read-only mode in all the linked domains except their native domains (where the GuardPoints are created). All the valid operations on the GuardPoints will be allowed from the native domains.

This functionality is transparent to the CTE client, that is, the client will receive a single security configuration having GuardPoint details of all the domains.

The following diagram shows the client-sharing workflow:

To share a client across domains:

1. Open the **Transparent Encryption** application.
2. Click **Clients > Clients**. The list of available CTE clients is displayed.
3. click the **Name** link of the desired client. The details page of the client is displayed.
4. Click the **Settings** tab.
5. Expand **GENERAL SETTINGS**.
6. Enable **Domain Sharing**.
7. Click **Update**.

Removing Client Sharing from Domains

You can remove client sharing from individual domains or from multiple domains in one go.

1. Open the **Transparent Encryption** application. The Clients page is displayed.
2. Click **Clients > Clients**.
3. Under **Client Name**, click the desired client. The detail view of the Clients page is displayed.

4. Click the **Sharing** tab.
5. Click the desired tab to view the instructions.

From Individual Domains

- a. Under **Domain Name**, select the check box corresponding to the desired domain.
- b. Click **Remove**. A dialog box appears prompting to confirm the action. Deleting this domain is permanent and cannot be undone.

From Multiple Domains

- a. Under **Domain Name**, select the check box corresponding to the desired domains. To select all domains visible on the page, select the top check box to the left of the Domain Name heading.
- b. Click the delete icon (). A dialog box appears stating that deleting the selected domains is permanent and cannot be undone.

6. Click **Delete**.

The client is no longer shared with the selected domain(s).

Sharing a Client Group Across Domains

A shared client group will be visible in read-only mode in all the domains where it is shared. The GuardPoints can be created on the shared client group from any of the linked domains. These GuardPoints will be visible in read-only mode in all the linked domains except their native domains (where the GuardPoints are created). All the valid operations on the GuardPoints will be allowed from the native domains.

Clients can be added to the shared client group from all the linked domains (including the native domain). All the GuardPoints added to the client group (from all the domains) will be propagated to the clients in the group.

Propagation of client settings and other configuration (like LDT suspend/resume) is passed on to all the clients in the group irrespective of the domain.

To share a client group across domains:

1. Open the **Transparent Encryption** application. The Clients page is displayed. This page lists the clients added to this CipherTrust Manager appliance.
2. Click **Clients > Client Groups**.
3. Under **Client Group Name**, click the desired client group.
4. In the mini detail view, select **Domain Sharing**.

Alternatively, to enable domain sharing on a client group, click the expand icon () corresponding to the desired group, select **Domain Sharing** in the mini detail view, and click **Apply**.

5. Click **Apply**. Now, the **Sharing** tab is displayed.

6. On the **Sharing** tab, click **Share With Other Domains**. The Share With Other Domains dialog box is displayed.
7. Under **Domain Name**, select the domains with which you want to share the client group. The dialog box also provides an option to select all the domains, if required.
8. Click **Share**.

The client group is shared across selected domains of the CipherTrust Manager.

Note

If a client group is shared across domains, then deleting its native domain member clients returns the "resource not found" error.

Removing Group Sharing from Domains

Removing Individual Domains

To remove group sharing from a domain:

1. Open the **Transparent Encryption** application. The Clients page is displayed.
2. Click **Clients > Client Groups**.
3. Under **Client Group Name**, click the desired client group. The detail view of the Client Groups page is displayed.
4. Click the **Sharing** tab.
5. Under **Domain Name**, select the check box corresponding to the desired domain.
6. Click **Remove**. A dialog box appears stating that deleting the selected domain is permanent and cannot be undone.
7. Click **Delete**.

The client group is no longer shared with the selected domain.

Removing Multiple Domains

To remove group sharing from multiple domains:

1. Open the **Transparent Encryption** application. The Clients page is displayed.
2. Click **Clients > Client Groups**.
3. Under **Client Group Name**, click the desired client group. The detail view of the Client Groups page is

displayed.

4. Click the **Sharing** tab.
5. Under **Domain Name**, select the check box corresponding to the desired domains. To select all domains visible on the page, select the top check box to the left of the Domain Name heading.
6. Click the delete icon (). A dialog box appears stating that deleting the selected domains is permanent and cannot be undone.
7. Click **Delete**.

The client group is no longer shared with the selected domains.

Multifactor Authentication

In Multifactor Authentication (MFA), access to the requested data is granted only after the requester satisfies two or more authentication criteria.

CTE adds an extra layer of security before granting access to the protected GuardPoints. If MFA is enabled, the users performing specific tasks on the configured GuardPoints need to perform an additional OpenID Connect (OIDC) based authentication.

MFA can be helpful in scenarios such as when the credentials of a client machine are compromised. As an additional level of authentication is enforced, the data security cannot be breached.

Prerequisites

Before configuring MFA, make sure that:

- A valid OIDC connection exists on the CipherTrust Manager. Refer to [Connection Manager](#) for details. Use this connection to configure MFA in CTE profiles.
- MFA is configured in profiles, which can be associated with the clients and client groups. Refer to [Setting MFA Configuration](#) for details.

After you have configured MFA, you can enable it for individual clients and GuardPoints at the client and client group levels.

MFA at Client Level

You can enable or disable MFA for all of the GuardPoints on a client. When MFA is enabled at the client level, the CTE Agent enforces MFA configuration for all GuardPoints configured on the client. It overrides any MFA configuration set for individual GuardPoints.

Enabling or Disabling MFA on Client Level

To enable MFA at client level (that is, for all GuardPoints on a client):

1. Open the **Transparent Encryption** application.
-

2. Click **Clients > Clients**.
3. Under **Client Name**, click the desired client.
4. In the mini details view, select **Multifactor Authentication**.
5. Select **Apply**.

On the GuardPoints tab, the **Multifactor Authentication** toggles for all the GuardPoints will be turned ON.

The GUI may take some time to reflect the changes. You can click the Refresh GuardPoints icon () to refresh the status. At this point, you can't disable MFA for individual GuardPoints.

Note

To disable MFA for all GuardPoints on the client, clear the **Multifactor Authentication** check box in the mini details view and click **Apply**. On the GuardPoints tab, the **Multifactor Authentication** toggles for all the GuardPoints will be turned OFF. You can now enable MFA for individual GuardPoints.

MFA at GuardPoint Level

GuardPoint-level MFA can be enabled at the time of GuardPoint creation. Also, you can enable or disable it later.

▪ GuardPoints on Clients

When MFA is disabled at the client level, you can enable MFA for individual GuardPoints on clients. In this case, the CTE Agent processes the MFA configuration of individual GuardPoints. However, if client-level MFA is enabled, the MFA configuration of the client takes priority.

▪ GuardPoints on Client Groups

MFA cannot be enabled at the client group level. However, you can enable MFA for individual GuardPoints on client groups.

While propagating the MFA-enabled GuardPoints to the member clients, the CTE service on the CipherTrust Manager checks the MFA capability on the member clients. If a client is MFA-capable, the GuardPoints are added to the client. If a client is not MFA-capable, the GuardPoints are skipped.

Note

After GuardPoints are propagated to the member clients, the MFA configuration specified in the profiles associated with the member clients is used to send the security configuration to the CTE Agent.

Therefore, if the profiles of a client group and its member clients are different, the profiles of the member

clients are used.

Enabling MFA on GuardPoints

MFA for individual GuardPoints can only be enabled when the client-level MFA is disabled.

To enable MFA on a GuardPoint:

1. Open the **Transparent Encryption** application.
2. Select the client or client group on which you want to enable the GuardPoint.
 - Click a client under the **Client Name** column (**Clients > Clients**).
 - Click a client group under the **Client Group Name** column (**Clients > Client Groups**).
3. On the **GuardPoints** tab, turn ON the **Multifactor Authentication** toggle corresponding to the desired GuardPoint.

MFA is enabled on the selected GuardPoint.

Disabling MFA on GuardPoints

MFA can't be disabled on individual GuardPoints of a *client* if MFA is enabled at the client level. Before proceeding with disabling MFA for individual GuardPoints, make sure that MFA is *disabled* on the client. Refer to [Enabling or Disabling MFA on Client Level](#) for details.

MFA enabled on the GuardPoints created on client groups can be disabled directly.

To disable MFA at GuardPoint:

1. Open the **Transparent Encryption** application.
2. Select the client or client group on which you want to disable the GuardPoint.
 - Click a client under the **Client Name** column (**Clients > Clients**).
 - Click a client group under the **Client Group Name** column (**Clients > Client Groups**).
3. On the **GuardPoints** tab, click the expand icon (▸) corresponding to the desired GuardPoint.
4. Clear **Multifactor Authentication**.
5. Click **Apply**.

MFA is disabled at the GuardPoint level.

For steps, refer to [Enabling and Disabling MFA on GuardPoints](#).

Communication with CipherTrust Manager

A REST-based connection is created from a CTE client to the CipherTrust Manager. Although the connection is one-way, it imitates a two-way connection-like interaction between the CTE client and the CipherTrust Manager.

To understand communication between CTE and CipherTrust Manager when using a load balancer, refer to [Communication Workflow with CipherTrust Manager Behind a Load Balancer](#).

How the Communication Works

1. The CTE client registers with the CipherTrust Manager using a registration token and fingerprint of the server's "web" interface certificate.
2. When the CTE client registers, the CipherTrust Manager sends the security configuration to the CTE client. This configuration includes the list of nodes in the CipherTrust Manager cluster.
3. The CTE client sends the connection request to every node of the CipherTrust Manager cluster.
4. Every node holds the connection request until either of the following happens:
 - Any event that requests configuration push to the CTE client
 - A timeout of three minutes

For example, in a five-node CipherTrust Manager cluster, after registration with a particular node, the CTE client:

1. Receives security configuration from that CipherTrust Manager node.
2. Establishes a connection with all five nodes of the cluster.
3. If a directory browse operation is triggered on any of the cluster nodes, the node sends the browse request to the connection held by it.
4. The CTE client responds to the browse request and sends a new connection request.

When a CipherTrust Manager Node is Down

If a CipherTrust Manager node goes down:

1. If any other node pushes the security configuration to the CTE client due to some event (for example, policy change etc.), the security configuration does not include details of the failed node in it. With the new security configuration, the CTE client identifies the new node list and does not send the request to failed node.
2. Until the updated node list is pushed to the CTE client through the security configuration, the CTE client keeps on sending the connection requests to the failed node, which in turn, is going to fail.

When a New Node is Added to the Cluster

Whenever a new node is added to the CipherTrust Manager cluster:

1. The CipherTrust Manager sends the updated node list to the CTE client.
2. The CTE client establishes the connection with the new node and existing nodes in the list.

Communication Workflow with CipherTrust Manager Behind a Load Balancer

When a load balancer is configured in front of the CipherTrust Manager cluster nodes, the following workflow illustrates how requests and responses flow. Consider a 4-node CipherTrust Manager cluster, where a user browses an agent's filesystem via the CipherTrust Manager GUI. The request is routed to Node1 through the load balancer, while the agent is connected to Node2. Here's how the process unfolds:

1. **Initiating the Request:** The user selects the "Enter/Browse Path" option to browse a directory on the agent, and the request is directed to Node1.
2. **Notifying Other Cluster Nodes:** Node1 broadcasts the request to all nodes in the cluster, storing the details in the database. This ensures all nodes are aware of the request.
3. **Handling the Request:** Each node processes the notification. Only the node connected to the agent (Node2 in this case) takes action; the others disregard the request.
4. **Retrieving the Data:** Node2 fetches the requested data from the agent, records it in the database, and notifies all nodes that the request has been completed.
5. **Notifying the User:** Node1, which initially received the request, retrieves the data and delivers the results to the user's interface.

This system ensures that regardless of where a request originates, all nodes work together to fulfill the request. The process remains efficient and seamless with the load balancer directing traffic across the CipherTrust Manager cluster nodes.

Configuring Cluster Node Preference

A CTE administrator can configure preferred nodes of a CipherTrust Manager cluster for sending status updates from CTE clients. The administrator assigns a priority to every node of the cluster.

The cluster nodes can be categorized into tiers on the CipherTrust Manager GUI, with every tier assigned a priority. For example, Tier 1 is assigned higher priority than Tier 2. All tiers (for example, Tier 1 + Tier 2) can have a total of 20 nodes. This preference is configured through server settings in profiles. If not configured, the CipherTrust Manager continues working with the default settings. Refer to [Communication with CipherTrust Manager](#) for the default behavior.

After the server settings are configured, the CTE clients associated with the profile first try to send status updates to the top tier. If none of the nodes in the tier is reachable, the CTE clients try to send updates to the next tier.

This feature is applicable to the CipherTrust Manager clusters.

To configure the cluster node preference in a profile:

1. Open the **Transparent Encryption** application.

2. In the left pane, click **Settings > Profiles**.

3. Under **Name**, click the desired profile.

Alternatively, click the overflow icon () corresponding to the desired profile and click **Edit**.

4. Expand **SERVER SETTINGS**.

5. Modify the server settings, as appropriate. Refer to [Configuring Server Settings](#) for details.

6. Click **Update**.

Backup and Restore

CipherTrust Manager provides options to back up CTE policies and restore them to other CipherTrust Manager appliances. A CipherTrust Manager administrator with backup and restore permissions can fully or partially export CTE policies from one domain and import them into a different domain on the same CipherTrust Manager or a different CipherTrust Manager. The data under the backed up (exported) policies will remain encrypted.

This section covers the following topics:

- [Assumptions](#)
- [Backing up and Restoring Keys and CTE Policies](#)
- [Signing Files in Restored Signature Sets](#)

Perform the steps in the given order.

Assumptions

- Before restoring CTE policies into the same or a different CipherTrust Manager:
 - Restore all the keys associated with CTE policies.
 - Restore the backup keys.
- The policy backup file contains policies with the associated resources, including:
 - Security rules
 - Key rules
 - LDT rules
 - IDT rules
 - Policy elements (user sets, process sets, resource sets, and signature sets)
- The backed up policy data does not include:

- Keys that are associated with key rules. However, if the backup of keys and CTE policies is taken together, then the linked keys are included in the backup.
- Signatures associated with signature sets

Note

If the system, where the policies are being restored, contains any conflicting policy or policy elements:

- Policies with the same name are skipped.
- All policies using the conflicting policy elements are skipped.

Backing up and Restoring Keys and CTE Policies

Tip

CTE policies and keys used can be backed up *separately* (in different backup files) or *together* (in a single backup file.) If they are backed up separately, the key backup must be restored before the CTE policies.

Keys and CTE Policies are Backed up Together

When you want to back up the keys and CTE policies together:

1. Back up the keys and CTE policies.

- a. Create a domain scoped backup key. You can also use an existing backup key. This key is needed to encrypt the backup file.
- b. Download the domain scoped backup key. Ignore this step if you have already downloaded the key.
- c. Create a domain scoped backup of keys and CTE policies.
- d. Download the domain scoped backup of keys and CTE policies.

A backup file of keys and CTE policies will be downloaded. You need to restore this backup file to the destination CipherTrust Manager where you want to restore the backed up keys and CTE policies.

Now, transfer the downloaded backup key and the backup file to the destination CipherTrust Manager, as described below.

2. Restore the backup file.

- a. Transfer the backup key and files using Secure Copy Protocol (SCP) to the destination CipherTrust

Manager.

- b. [Inspect the backup key file.](#)
- c. [Upload the backup key file.](#)
- d. [Inspect the backup file.](#)
- e. [Upload the backup file.](#)
- f. [Restore the backup file.](#)
- g. [Verify that the backup file is restored successfully.](#)

Keys and CTE Policies are Backed up Separately

When you want to back up the keys and CTE policies separately:

1. Back up the CTE keys.

- a. [Create a domain scoped backup key.](#) You can also use an existing backup key. This key is needed to encrypt the exported backup file.
- b. [Download the domain scoped backup key.](#) Ignore this step if you have already downloaded the key.
- c. [Create a domain scoped key backup.](#)
- d. [Download the domain scoped key backup.](#)

A backup file of keys will be downloaded. You need to restore this backup file to the destination CipherTrust Manager where you want to restore the backed up keys.

Now, transfer the downloaded backup key and the backup file to the destination CipherTrust Manager, as described below.

2. Back up the CTE policies.

- a. [Create a domain scoped backup key.](#) You can also use an existing backup key. This key is needed to encrypt the exported backup file.
- b. [Download the domain scoped backup key.](#) Ignore this step if you have already downloaded the key.
- c. [Create a domain scoped CTE policy backup.](#)
- d. [Download the domain scoped CTE policy backup.](#)

A backup file of CTE policies will be downloaded. You need to restore this backup file to the destination CipherTrust Manager where you want to restore the backed up policies.

Now, transfer the downloaded backup key and the backup file to the destination CipherTrust Manager, as

described below.

3. Import the downloaded backup file.

- a. Transfer the backup key, key backup, CTE policy backup files using Secure Copy Protocol (SCP) to the destination CipherTrust Manager.
- b. Inspect the backup key file.
- c. Upload the backup key file.
- d. Inspect the key backup file.
- e. Upload the key backup file.
- f. Inspect the CTE policy backup file.
- g. Upload the CTE policy backup file.
- h. Restore the key backup file.
- i. Verify that the key backup file is restored successfully.
- j. Restore the CTE policy backup file.
- k. Verify that the CTE policy backup file is restored successfully.

Signing Files in Restored Signature Sets

The restored policy backup contains imported signature sets. As the signatures linked with the signature sets are not included in the backup, you need to sign the files in the signature sets. Refer to [Signing Files in a Signature Set](#) for details.

Integrating CTE Logging with Splunk

The Thales Security Intelligence app for Splunk is created and published to the Splunkbase repository. This app provides a number of security intelligence reports and enables search operations that can be used to extract information from the log streams produced by CTE agents and the CipherTrust Manager.

Read the subsequent sections for instructions to integrate the CTE audit logging with Splunk.

Prerequisites

Before proceeding, ensure that:

- CipherTrust Manager is up and running.
- CTE clients are registered with the CipherTrust Manager.
- You have a valid account on Splunkbase.

Integration Steps

To integrate CTE audit logs with Splunk:

1. [Install Splunk](#)
2. [Install Thales Security Intelligence App](#)
3. [Configure CipherTrust Manager to Forward Messages to Splunk](#)
4. [Configure Splunk Server](#)

After successful integration, the CTE agent logs will be forwarded to the configured Splunk server over the configured protocol.

Install Splunk

First of all, install the supported Splunk version on a target system. This release supports Splunk 7 and 8. Refer to the Splunk [Installation Manual](#) for details.

After you have installed Splunk successfully, install the Thales Security Intelligence app. Refer to [Install Thales Security Intelligence App](#) for details.

Install Thales Security Intelligence App

To install the Thales Security Intelligence app:

1. Log on to your Splunkbase account.
2. Search for the **Thales Security Intelligence** app.
3. Install the app.

Refer to the Splunk documentation for details.

The next step is to configure the CipherTrust Manager to forward CTE audit log messages to Splunk. Refer to [Configure CipherTrust Manager to Forward Messages to Splunk](#) for details.

Configure CipherTrust Manager to Forward Messages to Splunk

To configure the CipherTrust Manager for forwarding audit log messages to Splunk:

1. [Create Certificates for TLS Communication](#)
2. [Enable Syslog on CipherTrust Manager](#)
3. [Configure Syslog on CipherTrust Manager](#)

These steps are described below.

Create Certificates for TLS Communication

This step is required if you want to establish secure communication between the Splunk server and the CipherTrust Manager over the TLS protocol. For TCP and UDP protocols, this step is not required.

Create the CA certificate, client certificate, and a private key. These are required when configuring Syslog over TLS on the CipherTrust Manager. A server certificate is also required that you need to upload to the Splunk server.

The following steps provide examples to create the required certificates and the private key using OpenSSL.

On the Linux shell:

1. Set the subject of the certificate.

```
SUBJ=' /C=US/ST=Ca/L=SanJose/O=Testing/OU=QA/CN=Test '
```

2. Set the password.

```
PW='pass:password'
```

This password will be added to the `password` field of the `inputs.conf` file.

3. Generate a self-signed CA using OpenSSL.

```
openssl req -subj $SUBJ -new -days 365 -out ca.pem -passout $PW -batch -x509
```

The generated `ca.pem` file is the CA certificate. This certificate is stored at the current directory.

4. Generate the server certificate and sign it using the CA certificate created in step 3. Run the following commands:

```
openssl genrsa -out server.key 2048
openssl req -key server.key -new -out server.req -batch
echo 00 > file.srl
openssl x509 -req -in server.req -CA ca.pem -CAkey privkey.pem -CAserial file.srl -out server.pem -passin $PW
```

The generated `server.pem` file is the server certificate. This certificate will be uploaded to the Splunk server (refer to [Configure Splunk Server](#)).

5. Generate the client certificate and sign it using the CA certificate created in step 3. Run the following

commands:

```
openssl genrsa -out client.key 2048
openssl req -subj $SUBJ -key client.key -new -out client.req -days 365 -passout $PW -batch
openssl x509 -req -in client.req -CA ca.pem -CAkey privkey.pem -CAserial file.srl -out client.pem -passin $PW
```

The generated `client.pem` file is the client certificate. This certificate and the generated `client.key` file will be uploaded to the CipherTrust Manager.

Enable Syslog on CipherTrust Manager

To enable Syslog on the CipherTrust Manager:

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Profiles**.
3. Under **Name**, click the profile linked to your CTE client. The edit view of the profile is displayed.
4. Expand **CLIENT LOGGING CONFIGURATION**.
5. Select **Syslog Enabled**.
6. Click **Apply**.

The Syslog setting is now enabled on the CipherTrust Manager. Next, you need to configure the Syslog settings on the CipherTrust Manager.

Configure Syslog on CipherTrust Manager

To configure Syslog on the CipherTrust Manager:

1. Expand **CLIENT SYSLOG CONFIGURATION**.
2. Specify the **Hostname or IP** address of the Splunk server.
3. Enter the **Port** of the Splunk server.
4. Ensure the **Message Format** is **RFC5424**.
5. Select the **Protocol**. This protocol acts as the transport protocol for the Syslog connection.

TLS is the preferred communication protocol.

6. (Applicable to the TLS protocol) Specify the certificates and key created in [Create Certificates for TLS Communication](#):

- **CA Certificate:** Click **Browse** to select the CA certificate, for example, `ca.pem`.
- **Certificate:** Click **Browse** to select the signed client certificate, for example, `client.pem`.
- **Private Key:** Click **Browse** to select the private key, for example, `client.key`.

7. Click **Apply**.

The Syslog server settings are configured on the CipherTrust Manager. Finally, you need to configure the Splunk server, as described below.

Configure Splunk Server

To configure the Splunk server:

1. Log on to your Splunk server.
2. Open the `inputs.conf` file in any text editor. The file is located at:
 - **Windows:** `C:\Program Files\Splunk\etc\system\local\inputs.conf`
 - **Linux:** `/opt/splunk/etc/system/local/inputs.conf`
3. Add the following content to the file:

```
[default]
host = <Splunk Server IP Address>

[tcp-ssl:<Splunk server port>]
listenOnIPv6 = yes
acceptFrom = *
sourcetype = rfc5424_syslog

[tcp:514]
listenOnIPv6 = yes
acceptFrom = *
sourcetype = rfc5424_syslog

[SSL]
password = password
requireClientCert = false
serverCert = <location for the server certificate (a .pem file)>
```

For example, location for the server certificate is:

- **Windows:** `C:\Program Files\Splunk\certs\server.pem`
- **Linux:** `/opt/splunk/certs/server.pem`

Here, `server.pem` is a sample name for the server certificate. Replace it with the name of your server certificate.

Refer to the Splunk [Admin Manual](#) for possible settings you can use to configure inputs in the `inputs.conf` file.

4. Copy the server certificate (for example, `server.pem`) to the `serverCert` location on the Splunk server. This is the same location you specified in the `inputs.conf` file above.
5. Restart the Splunk service. Refer to the Splunk [Admin Manual](#) for details.

The communication between the Splunk server and the CipherTrust Transparent Encryption service has been established.

Now, the CTE audit logs are visible on the app dashboards. Refer to the documentation on the Main tab of the **Thales Security Intelligence** app on the *Splunk server* on using "drill down" in reports, VSI Data Model and Pivot, searches, and [Thales Data Security Message Catalog](#).

Migrating CTE Configuration from Data Security Manager

This section describes steps to migrate configuration of CTE resources from a Data Security Manager (DSM) to a CipherTrust Manager.

Before proceeding with migration:

- Note that the password generation method of all *client groups* will be set to Generate after migration. If required, you can change the password method after migration. However, every client (standalone or in a client group) will retain its password and the password generation method as it is on the DSM.
- Ensure that no nested GuardPoints exist on the DSM. CipherTrust Manager doesn't support nested GuardPoints with different policies. As a result, client groups' GuardPoints can't be created during migration.
- To avoid key version mismatch on GuardPoints concerning DSM and CipherTrust Manager:
 - It is recommended to complete the end-to-end migration process in one go. Also, it is advised to pause or suspend LDT key rotation during migration.
 - If you plan to complete the migration later, ensure to extend the expiration date of the existing keys on DSM appropriately.

Prerequisites

- A sufficient number of CipherTrust Transparent Encryption (CTE) licenses is available on the CipherTrust Manager for clients to register successfully. For example, if you want to migrate 100 clients from the Data Security Manager (DSM), then at least 100 CTE licenses must be free on the CipherTrust Manager. Refer to [CTE Licensing Model](#) for details.
- DSM is up and running at the [supported](#) version. Refer to [DSM documentation](#) for details.

- A supported CTE version is configured with a supported DSM version. Refer to the [CTE Agent Quick Start Guide](#) specific to your platform for details.

Note

If you are running an unsupported version, upgrade your environment to the [supported](#) version before proceeding. Refer to the corresponding product documentation for upgrade instructions.

Supported Versions

Current Setup

Product	Version
CTE	7.1 and higher
DSM	6.4.5 and higher

Note

For the migration of LDT GuardPoints, the LDT clients must be running CTE Agent 7.1.1.55 or higher.

Target Setup

Product	Version
CTE	7.1 and higher
CipherTrust Manager	2.8 and higher

Supported Resources

CipherTrust Manager supports migration of the following CTE resources from a DSM backup file:

- Clients and client GuardPoints
- Client groups and client group GuardPoints
- Clients and client group associations
- User sets, resource sets, process sets, signature sets, and signatures
- Standard, Cloud Object Storage (COS), In-place Data Transformation (IDT), and Live Data Transformation (LDT) policies

- Client logging, upload logging, and Syslog settings
- LDT Quality of Service (QoS) and QoS schedules

Tip

Clients on the CipherTrust Manager are equivalent to *hosts* on the DSM.

Steps

To migrate the CTE configuration from the DSM to the CipherTrust Manager:

1. [Export and Import the Backup File](#)
2. [Verify Details of Migrated CTE Resources](#)
3. [Register CTE Clients with the CipherTrust Manager](#)
4. [Verify Access to GuardPoints](#)

Export and Import the Backup File

Export and import the backup file. Refer to [Exporting and Importing the Backup File](#) for details.

Caution

To minimize interruption of CTE client access to CTE keys, include the optional parameter `auto-cte-groups` with the `ksctl migrations apply` import command. This parameter automatically detects CTE keys and grants permission to access these keys to members of the `CTE Clients` group on CipherTrust Manager.

After migration, verify that the DSM keys are successfully migrated into the CipherTrust Manager domain.

Verify Details of Migrated CTE Resources

On the CipherTrust Manager GUI, verify details of the migrated CTE [resources](#).

The migrated resources can also be verified using the CTE reports available on the DSM and the CipherTrust Manager. Reports provide a comprehensive view of the migrated resources.

- A number of reports are available for the combination of clients, policies, GuardPoints, and encryption keys. Use these reports to match and verify the number of resources and their types on the DSM and the CipherTrust Manager.
- Both the DSM and the CipherTrust Manager provide options to download reports in the CSV format. So, if

needed, you can automate resource verification to parse and compare the report content.

Here is a mapping of CTE reports on the DSM and CipherTrust Manager to help verify migrated resources.

Resource	DSM Report	CipherTrust Manager Report
Clients	Hosts	Clients Health Report
Policies	Policy Key	Policies Keys Report
	Policy Host	Clients Policies Report
GuardPoints	GuardPoints	GuardPoints Report
	Hosts with GuardPoint Status	Client GuardPoint Status Report
Keys	Keys	Clients Keys Report
	Keys-Policy	Policies Keys Report

Refer to [Reports](#) for details on CTE reports available on the CipherTrust Manager. Refer to the DSM online help for details on CTE reports available on the DSM.

Verifying GuardPoints Configuration

GuardPoints that are applied to a client using a client group are created in the background. The original request is returned after initial validation of request parameters and migration proceeds further for other operations.

In some cases, creation of certain GuardPoints might fail later in the background due to various reasons. Any errors observed in the background cannot be updated in the migration status. The status is updated in the audit records of the CipherTrust Manager. So it is recommended to verify migration of CTE resources using the [CTE reports](#).

Verifying Profiles Configuration

Every migrated client is linked with a profile (named `profile_<dsm-hostname>_<dsm-domain-id>`) on the CipherTrust Manager. The profile contains information related to client logs, Syslog settings, and QoS configuration. If multiple clients have the same configuration on the DSM, they are linked with a single profile on the CipherTrust Manager. The following mapping helps you verify migration of client logging, Syslog, and QoS configuration.

Resource	Location on DSM	Location on CipherTrust Manager
Message Type	Hosts > FS/VDE Agent Log	Not displayed on the CipherTrust Manager GUI. You can verify them using the <code>/v1/transparent-encryption/profiles</code> APIs.
File Logging Settings	Hosts > FS/VDE Agent Log	Profiles > CLIENT LOGGING CONFIGURATION. Refer to Setting Client Log Configuration for details.
Syslog Settings	Hosts > FS/VDE Agent Log	Profiles > SYSLOG LOGGING CONFIGURATION. Refer to Setting Client Syslog Configuration for details.

Resource	Location on DSM	Location on CipherTrust Manager
Upload Logging Settings	Hosts > FS/VDE Agent Log	Profiles > CLIENT LOGGING CONFIGURATION. Refer to Setting Client Log Configuration for details.
Duplicate Message Suppression Settings	Hosts > FS/VDE Agent Log	Profiles > CLIENT LOGGING CONFIGURATION. Concise Logging settings are also displayed here. Refer to Setting Client Log Configuration for details.
LDT Quality of Service	Hosts > GuardPoints	Profiles > QUALITY OF SERVICE CONFIGURATION. Refer to Setting Quality of Service Configuration for details.
QoS Schedules	Hosts > GuardPoints	Profiles > QUALITY OF SERVICE CONFIGURATION > QoS Settings. Refer to Setting Quality of Service Configuration for details.

After you have successfully verified the CTE resources, proceed to the next step.

Register CTE Clients with the CipherTrust Manager

1. Ensure that the LDT GuardPoints, if any, are unguarded before re-registration of the migrated CTE clients.
2. Register your CTE clients with the CipherTrust Manager. Refer to [CTE Agent Quick Start Guide](#) specific to your platform for details.

Caution

- When registering a CTE client with the CipherTrust Manager, you must provide exactly the same client name with which that client was registered with the DSM before migration.
- Client names are case-sensitive, make sure that case-sensitivity is retained.
- If a different name is provided, the CipherTrust Manager considers it as a new client. The configurations migrated from the DSM are not propagated to this new client on the CipherTrust Manager.

After the CTE clients are successfully registered with the CipherTrust Manager, the migrated configuration is propagated to the CTE clients.

Verify Access to GuardPoints

When the initialization of the CTE clients is successful and the configuration is pushed to them, verify whether the GuardPoints are accessible according to the enforced policies.

Limitations

CTE resources of Container policies on the DSM cannot be migrated to the CipherTrust Manager using the backup/restore method. The Container policies are supported only on the DSM.

Migration Summary

This section provides a summary of the CTE resources migrated from the DSM to CipherTrust Manager, mapping of the resources that are handled differently between the two key managers. Also, the section provides any constraints applicable to the migrated resources and describes how to interpret the migration status.

Resource Mapping

This table describes how the DSM resources are mapped with resources on the CipherTrust Manager after migration.

DSM Resource	CipherTrust Manager Resource
Host	Client
Host Group	Client Group
Host Group - Host Association	Client Group - Client Association
User Sets	User Sets
Resource Sets	Resource Sets
Process Sets	Process Sets
Signature Sets	Signature Sets
Policy	Policy
Logging, QoS, and Syslog configuration	Profile
GuardPoints	GuardPoints

Migration Workflow and Exceptions/Deviations

Host | Client

Migration Workflow

- All related parameters configured on the DSM will be migrated as is to the CipherTrust Manager.
- Only the FS type hosts will be migrated to the CipherTrust Manager. Other host types, for example, VDE and Key, will NOT be migrated.
- After migration, every client needs to be registered with the CipherTrust Manager to receive its configuration.

Exceptions/Deviations

- Hosts marked for deletion on the DSM will NOT be migrated to the CipherTrust Manager.

Host Group | Client Group

Migration Workflow

- All related parameters (**except** the *client group password*) configured on the DSM will be migrated as is to the CipherTrust Manager.
- Host groups of only HDFS and NON-CLUSTER types will be migrated.

Exceptions/Deviations

- All host groups will be migrated with an auto-generated password (required for Challenge Response). Hosts with manual passwords configured on the DSM will also be migrated, but with a new auto generated password on the CipherTrust Manager. Manual password migration will be supported in a future CipherTrust Manager release.

If required, auto generated password could be changed to manual mode on the CipherTrust Manager interfaces after migration.

- Host groups' HDFS configurations for browsing HDFS nodes will NOT be migrated. The CipherTrust Manager does not support browsing of resource sets.

Host Group Association | Client Group - Client Association

Migration Workflow

All successfully migrated host will be migrated as members to the successfully migrated host groups according to the DSM configuration.

Exceptions/Deviations

- Configurations of hosts or host groups that could not be migrated due to any reason will NOT be migrated.
- GuardPoints of host groups will NOT be migrated as part of the migration activity. All GuardPoints of a host group will be automatically propagated in the background after successful association.

User Sets | User Sets

Migration Workflow

- All related parameters configured on the DSM will be migrated as is to the CipherTrust Manager.

Exceptions/Deviations

- Not applicable

Resource Sets | Resource Sets

Migration Workflow

- All related parameters configured on the DSM will be migrated as is to the CipherTrust Manager.

Exceptions/Deviations

- Not applicable

Process Sets | Process Sets

Migration Workflow

- All related parameters configured on the DSM will be migrated as is to the CipherTrust Manager.

Exceptions/Deviations

- Not applicable

Signature Sets | Signature Sets

Migration Workflow

- All related parameters configured on the DSM will be migrated as is to the CipherTrust Manager.
- All the associated signatures under each signature set will be migrated to the CipherTrust Manager.
- Signature sets will retain their last signing state on the DSM on the CipherTrust Manager after migration.

Exceptions/Deviations

- Not applicable

Policy | Policy

Migration Workflow

- All related parameters configured on the DSM will be migrated as is to the CipherTrust Manager.
- All policy elements, that is, security rules, key rules, data transformation rules, LDT rules, and IDT rules will be migrated as is to the CipherTrust Manager.

Exceptions/Deviations

- Policies will be migrated with version 0 to the CipherTrust Manager irrespective of their versions on the DSM.
- Policy audit records on the DSM will NOT be migrated to the CipherTrust Manager.

Logging, QoS, and Syslog configuration | Profile

Migration Workflow

- Logging, QoS, and Syslog configuration on the DSM will be migrated as a joint resource under profiles on the CipherTrust Manager. Profiles will be associated with the clients and client groups based on the DSM configuration. Every client or client group will have the same configuration for these resources/parameters. However, they will be controlled through a single resource called profile on the CipherTrust Manager.

-
- All the host/host groups having the same configuration on the DSM will be associated with the **same profile** on the CipherTrust Manager.
 - After migration, clients and client groups can be associated with different profiles or the existing profile can be modified appropriately.
 - After migration, any modifications in profiles will affect all the clients and client groups linked with the profile.

Exceptions/Deviations

- Syslog configuration used only for the CTE agents will be migrated. Syslog configuration used by the DSM for its log upload will NOT be migrated.
- If migration of these configurations fails due to any reason (for example, invalid TLS configuration on the DSM), the default profile will be associated with the migrated hosts and host groups.

GuardPoints | GuardPoints

Migration Workflow

- *Client GuardPoints*
 - All related parameters configured on the DSM will be migrated as is to the CipherTrust Manager.
- *ClientGroup GuardPoints*
 - All valid GuardPoints under a host group will be migrated as is to the CipherTrust Manager.

Exceptions/Deviations

- Efficient Storage GuardPoints (ESG) will NOT be migrated.
- *ClientGroup GuardPoints*

GuardPoints having invalid configuration that might be created due to limited restrictions on the DSM will either be modified before migration or dropped from the migration, as described below.

- GuardPoints with Secure Start enabled on non-Windows paths will NOT be migrated.
 - GuardPoints with Transform Sparse Region enabled with a non-LDT policy will be modified by disabling Sparse Region and then migrated with rest of the configuration intact.
 - GuardPoints with Automount enabled on Windows path will be modified by disabling Automount and then migrated with rest of the configuration intact.
 - *ClientGroup - Client Association GuardPoints*
 - Client group GuardPoints that are propagated to all member clients will NOT be migrated. They will be created in background after the association between the client groups and clients is successfully migrated.
 - Any modifications made to such GuardPoints on the DSM after their propagation on the client, will NOT be
-

available after migration. GuardPoints with the configuration available under the client group will be propagated as is on the CipherTrust Manager.

Important Notes on Migration

- Hosts marked for deletion on the DSM will NOT be migrated to the CipherTrust Manager.
- All host groups will be migrated with an auto-generated password.
- GuardPoints of host groups will NOT be migrated as part of the migration activity. All GuardPoints of a host group will be automatically propagated in the background after successful association.

Any modifications made to host group GuardPoints on the DSM on the client level after their propagation on the client, will NOT be available after migration. GuardPoints with the configuration available under the client group will be propagated as is on the CipherTrust Manager.

For example, a host group GuardPoint **HG_GP1** is enabled under a host group and propagated to the host. Later this GuardPoint is disabled on the host on the DSM. After that, if such data is migrated to the CipherTrust Manager, the corresponding GuardPoint will be created as an enabled GuardPoint on the client group and client on the CipherTrust Manager. The GuardPoint is enabled at the client group level, so the GuardPoint is propagated accordingly.

- Policies will be migrated with version **0**. Policy audit records will NOT be migrated.
- Time Sets will NOT be migrated. They are not supported on the CipherTrust Manager.
- Syslog configuration used only for the CTE agents will be migrated. Syslog configuration used by the DSM for its log upload will NOT be migrated.
- Efficient Storage and CIFS GuardPoints will NOT be migrated.
- GuardPoints with Secure Start enabled on non-Windows paths will NOT be migrated.

Interpreting Migration Status

After you have triggered the migration, you can track its progress by running the `ksctl migration status` command. This command returns the overview of all the migrated resources classified in multiple categories, for example, Number of Processed, Number of Ignored, and Number of Failed (Error) with the high-level reasons why a particular resource is ignored or failed during the migration process.

```
./ksctl migrations status
```

```
{
  "id": "06d3efbe-590b-4e55-ace5-96e9ba486246",
  "overall_status": "Failed",
  "source": "DSM",
```

```

"keys_status": {
  "status": "Completed",
  "num_processed": 0,
  "num_failed": 0,
  "num_ignored": 2,
  "error_details": [
    "Key uniquetohost exists for version 0, ignoring it",
    "Key uniquetohost_auto exists for version 0, ignoring it",
  ]
},
"keys_links_status": {
  "status": "",
  "num_processed": 0,
  "num_failed": 0,
  "num_ignored": 0
},
"domains_status": {
  "status": "Completed",
  "num_processed": 0,
  "num_failed": 0,
  "num_ignored": 1,
  "error_details": [
    "Domain dom1 already exists, not recreating it",
  ]
},
"cte_client_status": {
  "status": "Completed",
  "num_processed": 10,
  "num_failed": 0,
  "num_ignored": 2,
  "ignore_details": [
    "CTE Client keyagent-one migration Skipped. Reason: Only FS agent Hos
ts to be migrated. Skipping Host: keyagent-one",
    "CTE Client 10.164.15.216 already exists, not recreating it",
  ]
},
...
...
...
"cte_guard_point_status": {
  "status": "Failed",
  "num_processed": 34,
  "num_failed": 1,
  "num_ignored": 2,
  "error_details": [
    "failed to create CTE GuardPoint /test-1/ Err: Server error [16/NCERR
ResourceNotFound: Resource not found]: . HTTP code:404: 404 Not Found",
  ],
  "ignore_details": [
    "CTE GuardPoint https://s3.amazonaws.com/amithenrytestbucket6;http
s://s3.amazonaws.com/amithenrytestbucket777 already exists, not recreating it",
    "CTE GuardPoint E:\\my_test_1\\ already exists, not recreating it",
  ]
},
"cte_client_domain_sharing_status":{
  "status": "Completed",
  "num_processed": 1,
  "num_failed": 0,
  "num_ignored": 0
}

```

```

    },
    "cte_client_group_domain_sharing_status": {
      "status": "Completed",
      "num_processed": 1,
      "num_failed": 0,
      "num_ignored": 0
    }
  }
}

```

Important Notes on Migration Status

- The **error_details** and **ignore_details** parameters provide the high-level information about the reason of failure or skipping the resource from migration. For detailed information, review the CipherTrust Manager logs and audit records (for each domain).
- For resources such as GuardPoint, the number shown in the status will NOT include the client group-client association GuardPoints available in the backup. They are created in the background after successful association of clients and client groups.
- Status shown as **Failed** indicates an error with the resources shown under **num_failed**. Other resources with no issues under the same category are successfully processed and are not affected with overall status as failed.

For example, GuardPoints of hosts marked for deletion are not migrated and end up in the error section, as the linked host is not migrated itself. It leads to the overall status as failed for the GuardPoint migration, but all other GuardPoints under **num_processed** are successfully migrated.

- CTE reports offer a better alternative to verify the resources migrated from the DSM.

Permissions

This section provides the complete list of permissions required by a CipherTrust Manager user to perform create, read, update, delete, upload, and download operations on CTE resources.

Create Operations

Operation	Required Permissions
Create a CTE client	• CreateClientCTE • ReadClientCTE • ReadProfileCTE
Create a standard policy with existing policy elements and an existing key	• ReadPolicyCTE • ReadSignatureSetCTE • ReadUserSetCTE • ReadProcessSetCTE • ReadResourceSetCTE • ReadSecurityRuleCTE • ReadClientAndResourceMappingReadCTE • CreatePolicyCTE

Operation	Required Permissions
	• CreateKeyRuleCTE • ReadKeyMetaCTE • CreateKeyMetaCTE • UpdateKeyMetaCTE • CreateSecurityRuleCTE • ReadKeyRuleCTE • ReadKey
Create an LDT policy with existing policy elements and an existing key	• ReadPolicyCTE • ReadSignatureSetCTE • ReadUserSetCTE • ReadProcessSetCTE • ReadResourceSetCTE • ReadSecurityRuleCTE • ReadClientAndResourceMappingReadCTE • CreatePolicyCTE • CreateKeyRuleCTE • ReadKeyMetaCTE • CreateKeyMetaCTE • UpdateKeyMetaCTE • CreateLDTRuleCTE • CreateSecurityRuleCTE • ReadKeyRuleCTE • ReadLDTRuleCTE • ReadKey
Create an IDT policy with existing policy elements and an existing key	• ReadPolicyCTE • ReadSignatureSetCTE • ReadUserSetCTE • ReadProcessSetCTE • ReadResourceSetCTE • ReadSecurityRuleCTE • ReadClientAndResourceMappingReadCTE • CreatePolicyCTE • CreateKeyRuleCTE • ReadKeyMetaCTE • CreateKeyMetaCTE • UpdateKeyMetaCTE • CreateLDTRuleCTE • CreateSecurityRuleCTE • ReadKeyRuleCTE • ReadLDTRuleCTE • ReadKey • CreateIDTRuleCTE • ReadIDTRuleCTE
Create a COS policy with existing policy elements and an existing key	• ReadPolicyCTE • ReadSignatureSetCTE • ReadUserSetCTE • ReadProcessSetCTE • ReadResourceSetCTE • ReadSecurityRuleCTE • ReadClientAndResourceMappingReadCTE • CreatePolicyCTE • CreateKeyRuleCTE • ReadKeyMetaCTE • CreateKeyMetaCTE

Operation	Required Permissions
	• UpdateKeyMetaCTE • CreateSecurityRuleCTE • ReadKeyRuleCTE • ReadKey
Create a standard policy with permission to create policy elements and using an existing key	• ReadPolicyCTE • ReadSignatureSetCTE • ReadUserSetCTE • ReadProcessSetCTE • ReadResourceSetCTE • ReadSecurityRuleCTE • ReadClientAndResourceMappingReadCTE • CreatePolicyCTE • CreateKeyRuleCTE • ReadKeyMetaCTE • CreateKeyMetaCTE • UpdateKeyMetaCTE • CreateSecurityRuleCTE • ReadKeyRuleCTE • ReadKey • CreateSignatureSetCTE • CreateUserSetCTE • CreateProcessSetCTE • CreateResourceSetCTE
Create an LDT policy with permission to create policy elements and using an existing key	• ReadPolicyCTE • ReadSignatureSetCTE • ReadUserSetCTE • ReadProcessSetCTE • ReadResourceSetCTE • ReadSecurityRuleCTE • ReadClientAndResourceMappingReadCTE • CreatePolicyCTE • CreateKeyRuleCTE • ReadKeyMetaCTE • CreateKeyMetaCTE • UpdateKeyMetaCTE • CreateLDTRuleCTE • CreateSecurityRuleCTE • ReadKeyRuleCTE • ReadLDTRuleCTE • ReadKey • CreateSignatureSetCTE • CreateUserSetCTE • CreateProcessSetCTE • CreateResourceSetCTE
Create an IDT policy with permission to create policy elements and using an existing key	• ReadPolicyCTE • ReadSignatureSetCTE • ReadUserSetCTE • ReadProcessSetCTE • ReadResourceSetCTE • ReadSecurityRuleCTE • ReadClientAndResourceMappingReadCTE • CreatePolicyCTE • CreateKeyRuleCTE • ReadKeyMetaCTE

Operation	Required Permissions
	• CreateKeyMetaCTE • UpdateKeyMetaCTE • CreateSecurityRuleCTE • ReadKeyRuleCTE • ReadKey • CreateIDTRuleCTE • ReadIDTRuleCTE • CreateSignatureSetCTE • CreateUserSetCTE • CreateProcessSetCTE • CreateResourceSetCTE
Create a COS policy with permission to create policy elements and using an existing key	• ReadPolicyCTE • ReadSignatureSetCTE • ReadUserSetCTE • ReadProcessSetCTE • ReadResourceSetCTE • ReadSecurityRuleCTE • ReadClientAndResourceMappingReadCTE • CreatePolicyCTE • CreateKeyRuleCTE • ReadKeyMetaCTE • CreateKeyMetaCTE • UpdateKeyMetaCTE • CreateSecurityRuleCTE • ReadKeyRuleCTE • ReadKey • CreateSignatureSetCTE • CreateUserSetCTE • CreateProcessSetCTE • CreateResourceSetCTE
Create a client group	• CreateProfileCTE • ReadProfileCTE • CreateClientGroupCTE • ReadClientGroupCTE
Create a signature set superset	• CreateSignatureSetCTE • ReadSignatureSetCTE • ReadClientCTE • CreateSignatureCTE • ReadSignatureCTE
Create a user set superset	• CreateUserSetCTE • ReadUserSetCTE • ReadClientCTE
Create a process set superset	• CreateProcessSetCTE • ReadProcessSetCTE • CreateProcessSetSignatureSetAssociationCTE • CreateSignatureSetCTE • ReadSignatureSetCTE • ReadClientCTE • CreateSignatureCTE • ReadSignatureCTE • ReadProcessSetSignatureSetAssociationCTE • ReadProcessSetResourceSetAssociationCTE • CreateProcessSetResourceSetAssociationCTE

Operation	Required Permissions
Create a resource set	• CreateResourceSetCTE • ReadResourceSetCTE • ReadClientCTE
Create a CTE Profile	• CreateProfileCTE • ReadProfileCTE
Create an LDT Communication Group	• CreateLDTGroupCommServiceCTE • ReadLDTGroupCommServiceCTE • CreateLDTGroupCommServiceClientAssociationCTE • ReadLDTGroupCommServiceClientAssociationCTE • ReadClientsCTE
Create client group - client association	• CreateClientCTE • ReadClientCTE • UpdateClientCTE • CreateClientGroupCTE • ReadClientGroupCTE • UpdateClientGroupCTE • CreateClientGroupClientAssociationCTE • ReadClientGroupClientAssociationCTE • UpdateClientGroupClientAssociationCTE
Create a Storage Group	• CreateProfileCTE • ReadProfileCTE • CreateCSISStorageGroupCTE • ReadCSISStorageGroupCTE
Create Storage Group - client association	• CreateClientCTE • ReadClientCTE • UpdateClientCTE • CreateCSISStorageGroupCTE • ReadCSISStorageGroupCTE • UpdateCSISStorageGroupCTE • CreateCSISStorageGroupClientAssnCTE • ReadCSISStorageGroupClientAssnCTE
Add a GuardPolicy to a Storage Group	• CreateCSISStorageGroupCTE • ReadCSISStorageGroupCTE • UpdateCSISStorageGroupCTE • ReadPolicyCTE • UpdatePolicyCTE • ReadGuardPointCTE • UpdateGuardPointCTE • CreateGuardPointCTE
Create signatures in a signature set	• UpdatePolicyElementsCTE • ReadSignatureSetCTE • UpdateSignatureSetCTE • ReadSignatureCTE • CreateSignatureCTE • UpdateSignatureCTE • ReadSecurityRuleCTE • ReadProcessSetCTE • ReadSignatureRuleCTE • ReadGuardPointCTE • ReadClientCTE
Create a client group / client GuardPoint /	• ReadPolicyCTE

Operation	Required Permissions
Create GuardPoints using a CSV file	• ReadSecurityRuleCTE • ReadKeyRuleCTE • ReadLDTRuleCTE • CreatePolicyCTE • ReadClientGroupCTE • CreateGuardPointCTE • ReadClientCTE
Create a new security rule for a policy	• ReadKeyRuleCTE • ReadPolicyCTE • ReadResourceSetCTE • ReadGuardPointCTE • CreateSecurityRuleCTE • ReadSecurityRuleCTE • ReadUserSetCTE • ReadProcessSetCTE • UpdatePolicyCTE
Create a new key rule/ LDT rule / transformation rule for a policy	• UpdatePolicyCTE • ReadPolicyCTE • ReadSecurityRuleCTE • ReadKeyRuleCTE • ReadLDTRuleCTE • ReadResourceSetCTE • ReadGuardPointCTE • CreateKeyRuleCTE • ReadUserSetCTE • ReadProcessSetCTE • ReadResourceSetCTE • ReadClientAndResourceMappingReadCTE
Create a new signature rule	• UpdatePolicyCTE • ReadPolicyCTE • ReadSignatureSetCTE • CreateSignatureRuleCTE • UpdatePolicyCTE • ReadUserSetCTE • ReadProcessSetCTE • ReadResourceSetCTE

Update Operations

Operation	Required Permissions
Update an unregistered client / Enable capabilities/ Reset CTE client password	• ReadClientCTE • UpdateClientCTE
Update a client profile	• CreateProfileCTE • ReadProfileCTE • UpdateProfileCTE
Update authentication binaries for a client and a client group	• ReadClientCTE • UpdateClientCTE • ReadClientGroupCTE • UpdateClientGroupCTE • ReadClientGroupClientAssociationCTE

Operation	Required Permissions
Update a CTE policy	• ReadPolicyCTE • ReadSignatureSetCTE • ReadUserSetCTE • ReadProcessSetCTE • ReadResourceSetCTE • ReadSecurityRuleCTE • ReadClientAndResourceMappingReadCTE • CreatePolicyCTE • CreateKeyRuleCTE • ReadKeyMetaCTE • CreateKeyMetaCTE • UpdateKeyMetaCTE • CreateLDTRuleCTE • CreateSecurityRuleCTE • ReadKeyRuleCTE • ReadLDTRuleCTE • ReadKey • UpdatePolicyCTE • UpdateKeyRuleCTE • UpdateLDTRuleCTE • UpdateSecurityRuleCTE • UpdateIDTRuleCTE
Update a CTE client group	• ReadClientCTE • UpdateClientCTE • ReadClientGroupCTE • UpdateClientGroupCTE • CreateClientGroupClientAssociationCTE • ReadClientGroupClientAssociationCTE • UpdateClientGroupClientAssociationCTE
Update a signature set	• ReadSignatureSetCTE • ReadClientCTE • CreateSignatureCTE • ReadSignatureCTE • UpdateSignatureSetCTE • UpdateSignatureCTE • ReadClientAndResourceMappingReadCTE • UpdatePolicyElementsCTE • ReadPolicyCTE • ReadProcessSetSignatureSetAssociationCTE • ReadSignatureRuleCTE • ReadProcessSetCTE
Update a user set	• ReadUserSetCTE • UpdateUserSetCTE • ReadClientCTE • ReadClientAndResourceMappingReadCTE • UpdatePolicyElementsCTE
Update a process set	• UpdatePolicyElementsCTE • ReadProcessSetCTE • UpdateProcessSetCTE • ReadSignatureSetCTE • ReadProcessSetSignatureSetAssociationCTE • CreateProcessSetSignatureSetAssociationCTE • ReadProcessSetResourceSetAssociationCTE • CreateProcessSetResourceSetAssociationCTE

Operation	Required Permissions
Update a resource set	• ReadResourceSetCTE • UpdateResourceSetCTE • ReadClientCTE • ReadCTEClientAndResourceMappingRead • UpdatePolicyElementsCTE
Update a CTE profile	• ReadProfileCTE • UpdateProfileCTE • ReadUserSetCTE • ReadProcessSetCTE
Update an LDT Communication Group	• ReadLDTGroupCommServiceCTE • UpdateLDTGroupCommServiceCTE • ReadLDTGroupCommServiceClientAssociationCTE • ReadClientCTE
Update a CSI Storage Group	• ReadClientCTE • UpdateClientCTE • ReadCSIStorageGroupCTE • UpdateCSIStorageGroupCTE • ReadCSIStorageGroupClientAssnCTE • CreateCSIStorageGroupClientAssnCTE
Update a GuardPolicy in a Storage Group	• ReadClientCTE • UpdateClientCTE • ReadCSIStorageGroupCTE • UpdateCSIStorageGroupCTE • ReadPolicyCTE • UpdatePolicyCTE • ReadGuardPointCTE • UpdateGuardPointCTE
Modify existing Designated Primary Set parameters	• ReadClientGroupCTE • UpdateClientGroupCTE
Send an LDT suspend / resume request to a CTE client	• ReadClientCTE
Send an LDT suspend / resume request to a CTE client group	• ReadClientGroupCTE • ReadClientGroupClientAssociationCTE • UpdateClientGroupCTE
Turn off Preserve Sparse Region	• ReadGuardPointCTE • ReadPolicyCTE • ReadSecurityRuleCTE • ReadKeyRuleCTE • ReadLDTRuleCTE • ReadClientGroupCTE • UpdateGuardPointCTE • ReadClientCTE
Update Early Access on a client group GuardPoint	• ReadClientGroupCTE • ReadGuardPointCTE • UpdateGuardPointCTE
Update Early Access on a client GuardPoint	• ReadClientCTE • ReadGuardPointCTE • UpdateGuardPointCTE
Unguard single / bulk GuardPoint(s) from a client	• ReadClientGroupCTE

Operation	Required Permissions
group	• ReadGuardPointCTE • DeleteGuardPointCTE
Unguard a client GuardPoint	• ReadClientCTE • ReadGuardPointCTE • DeleteGuardPointCTE
Update a client group GuardPoint parameters	• ReadClientGroupCTE • ReadGuardPointCTE • DeleteGuardPointCTE
Update a client GuardPoint	• UpdateGuardPointCTE • ReadClientCTE • ReadGuardPointCTE • DeleteGuardPointCTE • UpdateClientCTE • ReadProfileCTE • ReadGuardPointCTE • ReadClientGroupClientAssociationCTE • ReadClientGroupCTE • ReadPolicyCTE • CreateGuardPointCTE • ReadKernelVersionCTE
Add a new Designated Primary Set (DPS) to a client group	• CreateClientGroupCTE • ReadClientGroupCTE
Add client(s) to client group	• ReadClientGroupCTE • UpdateClientCTE • ReadGuardPointCTE • ReadClientCTE • CreateClientGroupClientAssociationCTE • ReadSignatureSetCTE
Reset password for a CTE client group	• ReadClientGroupCTE • UpdateClientGroupCTE • ReadClientGroupClientAssociationCTE • ReadClientCTE • UpdateClientCTE
Update client settings for a client group	• ReadClientGroupCTE • UpdateClientGroupCTE • ReadSignatureSetCTE • ReadClientGroupClientAssociationCTE • ReadClientCTE
Update client group password	• PermissionCTEClientPasswordRead • PermissionCTEClientPasswordUpdate
Update a CTE client	• ReadClientCTE • UpdateClientCTE • ReadProfileCTE • ReadGuardPointCTE • ReadClientGroupClientAssociationCTE • ReadClientGroupCTE • ReadPolicyCTE • CreateGuardPointCTE • ReadKernelVersionCTE

Operation	Required Permissions
Update client password	• ReadClientPasswordCTE • UpdateClientPasswordCTE
Update the list of signatures to be added to the signature set	• UpdatePolicyElementsCTE • ReadSignatureSetCTE • UpdateSignatureSetCTE • ReadSignatureCTE • CreateSignatureCTE • UpdateSignatureCTE • ReadSecurityRuleCTE • ReadProcessSetCTE • ReadSignatureRuleCTE • ReadGuardPointCTE • ReadClientCTE
Update a user in a user set	• UpdatePolicyElementsCTE • ReadUserSetCTE • UpdateUserSetCTE
Update a security rule	• UpdatePolicyCTE • ReadPolicyCTE • ReadGuardPointCTE • UpdateSecurityRuleCTE • ReadSecurityRuleCTE • UpdateSecurityRuleCTE • ReadUserSetCTE • ReadProcessSetCTE • ReadResourceSetCTE • UpdatePolicyCTE
Update a Key rule	• UpdatePolicyCTE • ReadPolicyCTE • ReadGuardPointCTE • ReadResourceSetCTE • ReadKeyRuleCTE • UpdateKeyRuleCTE
Update a signature rule	• UpdatePolicyCTE • ReadPolicyCTE • ReadGuardPointCTE • ReadSignatureRuleCTE • UpdateSignatureRuleCTE • ReadSignatureSetCTE • ReadUserSetCTE • ReadProcessSetCTE • ReadResourceSetCTE
Update an LDT key rule / Transformation rule	• UpdatePolicyCTE • ReadPolicyCTE • ReadResourceSetCTE • ReadLDTRuleCTE • UpdateLDTRuleCTE • ReadGuardPointCTE • UpdateKeyRuleCTE • ReadClientAndResourceMappingReadCTE • ReadUserSetCTE • ReadProcessSetCTE

Operation	Required Permissions
Add a client to an LDT Communication Group	• ReadLDTGroupCommServiceCTE • ReadClientCTE • CreateLDTGroupCommServiceClientAssociationCTE • UpdateClientCTE

Read Operations

Operation	Required Permissions
Read a CTE client / all operations for agent information	• ReadClientCTE
Read a CTE client and its profile	• ReadClientCTE • ReadProfileCTE
Read a CTE policy	• ReadPolicyCTE • ReadCTEClientAndResourceMappingRead • ReadUserSetCTE • ReadProcessSetCTE • ReadResourceSet • ReadSecurityRuleCTE • ReadKeyRuleCTE • ReadLDTRuleCTE • ReadIDTRuleCTE
Read a CTE client group	• ReadClientGroupCTE
Read a CTE client group and its profile	• ReadClientGroupCTE • ReadProfileCTE
Get client group - client association	• ReadClientCTE • ReadClientGroupCTE • ReadClientGroupClientAssociationCTE
Read a signature set	• ReadSignatureSetCTE
Read a user set	• ReadUserSetCTE
Read a process set	• ReadProcessSetCTE • ReadProcessSetSignatureSetAssociationCTE
Read a resource set	• ReadResourceSetCTE
Read signatures	• ReadSignatureCTE
Read a CTE profile	• ReadProfileCTE
Read an LDT Communication Group	• ReadLDTGroupCommServiceCTE

Quorum Control

CTE supports the quorum feature of the CipherTrust Manager. A CipherTrust Manager administrator can configure a quorum policy to have multiple approvers for supported operations. After the quorum policy is configured for an operation, all the approvers need to approve the operation before it can be successfully executed.

Refer to [Quorums](#) for details on the quorum feature of the CipherTrust Manager.

Supported Operations

Operation	Authorized Group for Approval
DeleteClientCTE	CTE Admins

Operation	Authorized Group for Approval
DeleteClientGroupCTE	CTE Admins
DeleteCSIStorageGroupCTE	CTE Admins
DeleteGuardPointCTE	CTE Admins
DeletePolicyCTE	CTE Admins
DeletePolicyElementsCTE	CTE Admins
DeleteProfileCTE	CTE Admins
UpdateClientGroupCTE	CTE Admins
UpdateCSIStorageGroupCTE	CTE Admins
UpdateGuardPointCTE	CTE Admins
UpdatePolicyCTE	CTE Admins
UpdatePolicyElementsCTE	CTE Admins
UpdateProfileCTE	CTE Admins
UpdateClientPasswordCTE	CTE Admins
UpdateClientGroupPasswordCTE	CTE Admins

Note

CTE for Kubernetes clients with healthy status cannot be deleted by the CipherTrust Manager Administrator. Only the CTE Agent can trigger their deletion. So, quorum is not supported for CTE for Kubernetes clients.

Supported APIs and Resources

Operation	APIs	Applicable to	Remarks
Delete clients (DeleteClientCTE)	- Single client deletion - Bulk client deletion	- FS (CTE and RWP) clients - CTE-U (CTE UserSpace) clients	Bulk client deletion behavior: Quorums are created for all resources. The administrators (approvers) need to approve quorum for all resources. Do not modify/delete the requested clients after a quorum request is created for bulk deletion. To make any changes, ensure that the quorum request is deleted.
Delete client groups (DeleteClientGroupCTE)	Delete client groups	- NON-CLUSTER groups - HDFS groups	-

Operation	APIs	Applicable to	Remarks
Update client groups (UpdateClientGroupCTE)	- Update client groups - Send LDT suspend/resume request to the CTE client groups	- NON- CLUSTER groups - HDFS groups	-
Delete client GuardPoints (DeleteGuardPointCTE)	- Single GuardPoint deletion - Bulk GuardPoint deletion	- FS (CTE and RWP) GuardPoints - CTE-U (CTE UserSpace) GuardPoints	Bulk GuardPoint deletion behavior: Quorums are created for all resources. The administrators (approvers) need to approve quorum for all resources. Do not modify/delete the requested GuardPoints after a quorum request is created for bulk deletion. To make any changes, ensure that the quorum request is deleted.
Delete client group GuardPoints (DeleteGuardPointCTE)	- Single GuardPoint deletion - Bulk GuardPoint deletion	- NON- CLUSTER groups - HDFS groups	Bulk client group GuardPoint deletion behavior: Quorums are created for all resources. The administrators (approvers) need to approve quorum for all resources. Do not modify/delete the requested GuardPoints after a quorum request is created for bulk deletion. To make any changes, ensure that the quorum request is deleted.
Update client GuardPoints (UpdateGuardPointCTE)	Single GuardPoint update	- FS (CTE and RWP) GuardPoints - CTE-U (CTE UserSpace) GuardPoints	Bulk update is not supported.
Update client group GuardPoints (UpdateGuardPointCTE)	Single GuardPoint update	- NON- CLUSTER groups - HDFS groups	Bulk update is not supported.
Delete Kubernetes storage group GuardPolicies (DeleteGuardPointCTE)	Delete GuardPolicies from Kubernetes storage groups	Kubernetes clients	-
Update Kubernetes storage group GuardPolicies (UpdateGuardPointCTE)	Single Kubernetes storage group GuardPolicy update	Kubernetes clients	-
Delete Kubernetes storage groups (DeleteCSISStorageGroup)	Single Kubernetes storage group deletion from Kubernetes clients	Kubernetes clients	-

Operation	APIs	Applicable to	Remarks
CTE)			
Update policy (UpdatePolicyCTE)	• Update a policy • Add, update, delete key rules • Add, update, delete security rules • Add, update, delete data transformation rules • Add, update, delete LDT rules • Update IDT rules • Add, update, and delete signature rules	• LDT policies • IDT policies • COS policies • CTE for Kubernetes policies • STANDARD policies	-
Delete policy elements (DeletePolicyElementsCTE)	Delete policy elements • Delete a resource set • Delete a user set • Delete a process set • Delete a signature set	Delete an element	Bulk deletion is not supported.
Update policy elements (UpdatePolicyElementsCTE)	Update policy elements • Update a resource set • Update a user set • Update a process set • Update a signature set • Add or remove a resource from a resource set • Add or remove a user from a user set • Add or remove a process from a process set • Add or remove a signature from a signature set	Single element update	Bulk update is not supported.
Delete profiles (DeleteProfileCTE)	Delete a profile	-	Bulk deletion is not supported.
Update profiles (UpdateProfileCTE)	Update a profile	-	Bulk update is not supported.

Workflow

This section provides the basic flow of the quorum process for the *DeleteClientCTE* operation. The process is similar for all the supported operations. This section assumes that a quorum policy, which requires two approvals for the DeleteClientCTE operation, is activated on the CipherTrust Manager.

1. Attempt to delete a client:
 - a. Open the **Transparent Encryption** application.
 - b. Click **Clients > Clients**.

- c. Under **Client Name**, click the overflow icon () corresponding to the client you want to delete.
- d. Click **Delete**. A dialog box appears prompting to confirm the action.
- e. Click **Delete**.

A dialog box appears stating that a quorum request has been made, and you need to get approval for this action.

The Quorum ID is displayed on the dialog box.

2. View details of the quorum.

- a. On the Requesting dialog box, click the **Go to Quorums Screen** link.

Alternatively, click **OK** on the Requesting dialog box and navigate to the Quorums page of the CipherTrust Manager GUI.

The Quorums page contains the Active Quorums and Inactive Quorums tabs. These tabs show quorum details such as the operation name, the requester who initiated the quorum, status and state of the quorum, and the quorum actions.

- b. Under the **Operation** column, expand **DeleteClientCTE: <client-name>**.

Information about the client to be deleted and the quorum approvers is displayed on the Quorum Client Info and Quorum Approvers tabs respectively.

- c. Click the **Quorum Approvers** tab to view details about the quorum approvers.

3. Approve the quorum. You, another CTE administrator, or a CipherTrust Manager Administrator can approve the quorum.

To approve the quorum:

- a. Under **Actions**, click the **Approve Quorum** icon () next to the desired **DeleteClientCTE: <client-name>** operation. The Approve Quorum dialog box is displayed.

If you are the last approver, the dialog box displays the message, *"This is the final approval. If you approve the quorum, the operation will be executed automatically."*

- b. (Optional) Specify a **Reason** for the approval.
- c. Click **Confirm** to approve the quorum. A message stating that the quorum is successfully approved is displayed.

Similarly, all the approvers need to approve the quorum for successful execution of the operation. The number of approvers is configured under **Approvals Needed** on the **Admin Settings > Quorum Policy** page.

When the last approver approves the quorum, the operation is removed from the Active Quorums tab and the client is deleted from the Clients page. The executed operation is displayed on the Inactive Quorums tab of

the Quorums page with the **executed** state.

The logs of the operation are available on the **Records > Server Records** page.

4. Verify the client deletion.
 - a. Open the **Transparent Encryption** application.
 - b. Click **Clients > Clients**.

Notice that the client is no longer listed on the Clients page. This indicates successful deletion of the client.

Confidential Computing

Confidential Computing is a cloud computing technology that can isolate and protect data on Confidential Virtual Machines (CVMs) or Trusted Domains (TDs) to protect them from a broad range of software attacks. Confidential Computing ensures that all data operations are executed within a Trusted Execution Environment.

Confidential Computing provisioning requires an attestation authority, such as Intel Trust Authority, to attest the CVMs or TDs and create a Trusted Execution Environment around them.

CTE makes Confidential Computing provisioning seamless, without the need to install or configure any additional tools on CTE clients. CTE together with CipherTrust Manager takes care of the attestation process to provision Confidential Computing on VMs running on CTE agents. If attestation fails, any access to the encrypted data guarded by CTE is prohibited.

Requirements & Specifications

Refer to [Requirements & Specifications](#) for details.

Prerequisite

Ensure that **Confidential Computing** is enabled for the CTE client to register it with the CipherTrust Manager. Refer to [prerequisites](#) for details.

Note

Ensure that the clocks on the CipherTrust Manager, client, and Intel server are synchronized. If they are not, [configure a Network Time Protocol Server](#).

Activate Confidential Computing on CTE Clients

To activate Confidential Computing on a CTE client, complete the following steps:

1. Create **Attestation Authority** connections in the CipherTrust Manager.

Note

To provision Confidential Computing on CTE clients, you require one **admin connection** (connection with administrator privileges) and one **non-admin connection** (connection without administrator privileges). The admin connection is necessary to retrieve the policies from the Attestation Authority, while the details of the non-admin connection are shared with the CTE agents.

- a. Log on to CipherTrust Manager.
- b. Go to **Access Management > Connections**.
- c. Select **+ Add Connection**.
- d. In the **Select Connection Type** section, select **More** and then select **Attestation Authority** from the **Select Connection** dropdown.
- e. Click **Next**.
- f. In the **General Info** section, enter the **Name** and **Description** for the connection.
- g. Click **Next**.
- h. In **Configure Connection** section, enter the following details:

Field Name	Description
URL	Provide the URL for connecting to the Attestation Authority.
Base URL	Provide base URL for the Attestation Authority.
API Key	Provide the allocated API key to establish connection with Attestation Authority.
Meta	Provide meta information in the JSON format.

Select the **Admin User** checkbox to create a connection with administrator privileges. By default, a connection without administrator privileges will be created.

- i. Click **Next**.
- j. In **Add Products** section, select the **CTE** checkbox.
- k. Click **Add Connection**.

To edit or delete the created connection, see [Attestation Authority Connection](#).

2. Create a Client Profile associated with above connection.
 - a. In CipherTrust Manager, click **Access Management > Add Client Profile**.
 - b. Enter **Profile Name** and **Description**.
 - c. Select **CA Type**: Local or External.
 - d. Select the respective Local or External CA in **Select <Local or External> CA**.
 - e. Enter the **Certificate Duration** for which the CA certificate will remain active.
 - f. Expand the **CONFIDENTIAL COMPUTING** section and add the following details:
 - a. Select **Attestation Authority Identifier**. Currently, only Intel Trust Authority (ITA) is supported.
 - b. Select **Cloud Provider**. The options are Azure and Google Cloud.
 - c. Select a non-admin connection in the **Attestation Connection** field.
 - d. Select an admin connection in the **Admin Connection** field. By default, this field remains blank. Selecting a value in this field allows you to select policies in the **Policy Names** field.

Note

Admin and non-admin type connections should belong to the same Attestation Authority.

- e. Select the policies in the **Policy Names** field. These policies are fetched from the Attestation Authority server. You can select multiple policies.
- f. Keep the default values for the remaining fields.
- g. (Optional) Click **Reset confidential computing form** to reset all the fields to the default values and input the information again.
- g. Click **Add Client Profile**.

To update or delete the created client profile, see [Managing Client Profiles](#).

3. [Create a registration token](#) associated to the above Client Profile. Retain this registration token.
4. Use the registration token during [installation and registration of CTE agents](#).

Ransomware Protection

Ransomware is a type of malicious software that is designed to block access to a computer system until a sum of money is paid. CTE Agent supports detection of Ransomware and protection of sensitive data from Ransomware.

Ransomware Protection is applied at GuardPoint, that is, at volume level for Windows and directory level for Linux. CTE Agent monitors the GuardPoints, analyzes the data, and looks for processes that might perform suspicious activities on the sensitive data. Examples of such processes are processes that try to encrypt files, open thousands of files, or change permissions on files. If a process displays suspicious behavior, then it is either blocked or audited (that is, flagged in a log file). The action taken is preconfigured by the CTE administrator in the [profile](#) linked to the client.

Licensing

Ransomware Protection is supported with RWP-enabled CTE clients. A CTE for Ransomware Protection license must be activated on the CipherTrust Manager to register an RWP-enabled CTE client. Refer to [CTE Licensing Model](#) for details.

Protection Modes

Based on the capabilities enabled during CTE registration, CTE clients can support the following protection modes:

- **Filesystem Protection (CTE):** Allows you to protect and encrypt files with policies.
- **Ransomware Protection (RWP) Only:** CTE is deployed to monitor GuardPoints for suspicious behavior from processes, and supports auditing or blocking of the processes.
- **Both filesystem and Ransomware Protection (CTE RWP):** Protects GuardPoints from Ransomware and allows you to protect and encrypt files with policies.

Ransomware Protection is available for *all* types of GuardPoints in the **RWP** and **CTE RWP** protection modes.

- The **RWP** protection mode doesn't support CTE file *encryption* and *protection*. Therefore, only Ransomware Protection Guardpoints are available in this mode, and these GuardPoints don't require any protection policies.
- The **CTE RWP** protection mode supports both Ransomware Protection and CTE file encryption. Therefore, all types of GuardPoints are available in the **CTE RWP** protection mode.

Use the [Ransomware Protection GuardPoints](#) to monitor or block Ransomware access attempts to the sensitive data stored on the CTE clients.

Protecting Non-Sensitive Data

Use the Ransomware Protection mode to protect systems that don't contain sensitive data, but have access to your network.

A use case of this scenario is when you have users with laptops who frequently use your network and access servers on it, but they do not have any sensitive data locally on their laptops. A system like this might belong to a salesperson who travels and frequently uses other networks to access the internet. When such users log on to your network, they access the sales network server and upload data to it. They could easily pick up a Ransomware from another network and accidentally upload it to your company's network.

Using the Ransomware Protection mode would protect the data on the GuardPoints from being infected with Ransomware.

Protecting Sensitive Data

The Ransomware Protection mode protects data on servers and endpoints from Ransomware attacks by auditing and blocking malicious IPs. Users can strengthen the security posture with CTE access and encryption policies and Ransomware protection for complete control on their data.

To protect sensitive data against Ransomware:

1. Ensure that the CTE Ransomware Protection license is activated and available on the CipherTrust Manager. Refer to [CTE Licensing Model](#) for details.
2. Install the CTE Agent with the Ransomware Protection capability enabled. The Ransomware Protection support uses the same registration process as CTE clients. Refer to [CTE Agent Linux and Windows Quick Start Guide](#) for information on installing and configuring CTE Agents.
3. Configure the Ransomware Protection settings in the linked client profile. Refer to [Setting Ransomware Protection Configuration](#) for details.
4. Create a Ransomware Protection GuardPoint on the volume for Windows and on the directory for Linux. Refer to the [Creating Ransomware GuardPoints](#) for details.

Disabling Ransomware Protection

To disable Ransomware Protection for all GuardPoints on the clients linked with a profile.

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Settings > Profiles**.
3. Under **Name**, click the desired profile.
4. Expand **RANSOMWARE PROTECTION CONFIGURATION**.
5. Select the **Operation** to **Disable**.

Note

- When you change the operation to **Disable** in a profile, Ransomware Protection for all GuardPoints on the linked clients is disabled.
- When you change the *profile* of a client to another profile with the operation set to **Disable**, Ransomware Protection for all GuardPoints on the client is disabled.

6. Click **Update**.

File Activity Monitoring (FAM)

File Activity Monitoring (FAM) catalogs, monitors, and secures unstructured data (files). It provides insights into data location, ownership, access history, permissions, protection, sharing, and sensitivity, enabling informed decisions about data protection.

A FAM Destination is where audit logs are sent. This can be a single Data Security Fabric (DSF) gateway (IP or hostname) or a group of DSF gateways (hostname suffix), such as `dsf-gateways.dsf.abcyz.com`. When using a group, each client sends logs to a unique hostname combining a client identifier and the FQDN suffix (for example, `clientid.dsf-gateways.dsf.abcyz.com`).

Viewing FAM Destination

To view the FAM destinations added to the CipherTrust Manager:

1. Open the **Transparent Encryption** application.
2. Click **Settings > FAM Destination**. The FAM destination page shows the list of FAM destinations added to the CipherTrust Manager. The page displays the following details:

Column	Description
Name	Name of the FAM destination.
Type	The type of the FAM destination.
Mode	The mode of the FAM destination. The supported modes are TCP and TLS.
Destination Address	The address of the FAM destination.
FQDN Suffix	A fully qualified domain name (FQDN) for the FAM destination.
Port	The port for the FAM destination.
Description	Description of the FAM destination.
TLS Verify	Whether TLS Verify is enabled. The value can be Yes or No. Applicable only when TLS mode is enabled.
Compress	Whether the data is compressed. Value can be Yes or No.

Unique to Client Keys

CTE on the CipherTrust Manager supports *Unique to Client* keys.

On the Data Security Manager (DSM), this feature is known as the Unique to Host keys.

A key is made unique to a client by using a token stored with the client record on the CipherTrust Manager. Unique to client keys provide greater security because a key compromised on one client does not compromise the keys on other clients.

Properties

- Unique to client keys are stored on the client for offline use. These keys are downloaded to the client and stored and encrypted using the client password.
- When the key is needed, it is decrypted and cached. If the client goes offline and is disconnected from the CipherTrust Manager, the current policy remains in effect because the encryption key is locally available in the system cache.
- If the CTE Agent cannot connect to the CipherTrust Manager after a reboot, any attempt to access the contents of an encrypted file on an unconnected client will not complete. The application will hang until the CTE Agent client password is entered in another terminal window. The application resumes execution after the password is provided.
- The key can also be re-established after a reboot without access to the CipherTrust Manager using the client password. You can specify the client password using the "vmsec passwd" utility, or, you can display the challenge string in challenge-response client deployments using the "vmsec challenge" utility.
- These keys are used for locally attached devices, as files encrypted by them can be read by only one client. Therefore, do not use "Unique to Client" keys in situations where data may be shared by multiple clients, such as in clustered environment or any environment that uses client mirroring.

Creating Unique to Client Keys

A unique to client key can be created when [adding key rules](#) during policy creation or on the Keys page of the CipherTrust Manager GUI, as described below.

To create a unique to client key:

1. Log on to the CipherTrust Manager with a user having permissions to manage CTE keys.
2. In the left pane, click **Keys**.
3. Create a key for use with **CTE**.

Tip

- When creating the key, make sure to select the **Unique to Client** check box under the CTE Property section.
- For a unique to client key, the **Persistent on Client** check box is selected automatically, and is non-editable. The key will be downloaded and stored (in an encrypted form) in persistent memory on the

client. This can be used in the event that a connection to the CipherTrust Manager is unreliable.

Refer to [Creating a New Key](#) for detailed instructions on creating a CTE key.

Limitation

A unique to client key will have different key values on different clients. If the key is used in a file system shared by different clients, it will cause data corruption.

So, it is recommended to not use a unique to client key to protect network shares. For example, when securing a CIFS path using an LDT communication group, the CIFS path should not be guarded with a policy having a Unique to Client key.

Load Balancer

This document describes the configuration steps to allow CTE agents communicate with a CipherTrust Manager cluster behind a network load balancer.

Prerequisites

Make sure a passthrough network load balancer is configured with the nodes of the CipherTrust Manager cluster. Refer to [Clusters and Nodes](#) for details on creating a CipherTrust Manager cluster.

Note

Only network load balancers with passthrough authentication are supported.

Configure the Load Balancer on CipherTrust Manager

After completing the prerequisites, you can configure the load balancer. Click the desired tab to view the instructions.

Using the UI

1. Login to the root domain as an Application Administrator.
2. Navigate to **Admin Settings > Properties**.
3. In **Load Balancer Address**, add an IP address or hostname for the load balancer to the **Value** field.
4. Click **Update** to update it.

Using the API

1. Authenticate to the REST API.
2. Go to the **Properties** section.
3. Update the name of the load balancer address.

Run the API

```
patch /v1/configs/properties/{name}
```

Example

```
/v1/configs/properties/LOAD_BALANCER_ADDRESS
```

Sample Output

```
{
  "name": "LOAD_BALANCER_ADDRESS" ,
  "value": "cte-cm-d91617b26a55d596.elb.us-east-1.amazonaws.com",
  "description": "Add IP/URL/Hostname of load balancer configured with CM. D
efault value is empty for CM."
}
```

Limitations

- If the nodes are configured with the load balancer, the configured Server Settings for the CTE Profiles on the CipherTrust Manager will not be applicable.

Refer to [Configuring Server Settings](#) for details.

- The Agent Information on the CipherTrust Manager will be unavailable for the CTE clients registered with the load balancer.
- If the load balancer configuration is deactivated and the CipherTrust Manager cluster is also removed, the agents registered with the load balancer need to be reregistered with the desired CipherTrust manager.
- When the load balancing setup changes to the non-load balancing mode, that is, when the load balancing configuration is removed, any configuration changes take time to reflect on the registered clients. If a client is down/unavailable, the configuration changes would not be updated for that client.

Workaround: To update the client with the configuration changes, reregister the client after it is up and running!

Operations

This section provides information on operations that the CTE Server Administrator performs on the CipherTrust Manager. These operations include registering CTE clients with the CipherTrust Manager, and protecting file system on a CTE client.

Registering Clients

Registration is the process of configuring a CTE client with a CipherTrust Manager. This process creates SSL certificates for further communication between the CipherTrust Manager and the CTE client.

Warning

If you use a registration token created with a newly created Local CA, you must restart the CipherTrust Manager services before registering a CTE client. This step is required to ensure the new CA is loaded correctly by all services.

Registering a CTE client with the CipherTrust Manager requires a [registration token](#). Single registration token can be used to register any number of CTE clients. Refer to the [CTE Agent Quick Start Guide](#) specific to your platform for details.

The following diagram shows the process of registering CTE clients with the CipherTrust Manager:

By default, CipherTrust Manager issues a Local CA with Common Name "KeySecure Root CA" which is used by CTE for signing client certificates. This Local CA is, by default, marked as trusted by the "web" interface which is also used by CTE for client authentication. Make sure that the CA whose signature is used for registering CTE clients is trusted by the "web" interface. Refer to [Authentication Settings for NAE, KMIP, and Web Interfaces](#) for details.

Third party (external) CA certificates can also be used for securing communication between the CipherTrust Manager and CTE clients. Refer to [Using External CA Certificates](#) for details.

Using External CA Certificates

All local and external CAs that participate in securing communication between the CipherTrust Manager and CTE clients must be added to the list of trusted CAs for the "web" interface on the CipherTrust Manager. Refer to [Certificate Authority](#) for details.

To use an external CA certificate:

1. Create a registration token using the ID of the Local CA signed by the external CA. Refer to [Creating a Registration Token](#) for details.
2. Register the CTE clients using this registration token. The registration process will automatically use the Local CA signed by the external CA. Refer to the [CTE Agent Quick Start Guide](#) specific to your platform for details.

CA Certificates Renewal Notification

When the CA that signed a client certificate or the web interface certificate is modified, a compatible CTE client is notified of the change. The client can then generate or install a new certificate and update its truststore to ensure uninterrupted communication with CipherTrust Manager.

Note

Auto-Renewal Compatibility

Automatic CA certificate renewal notification is supported on CipherTrust Manager version 2.14 and later, when used with CTE version 7.5 and higher and CTE UserSpace version 10.2 and higher.

- This feature is enabled by the `CA_RENEWAL` capability, which can be set during agent installation.
- This feature is not available for CTE for Kubernetes clients.
- When you upgrade CipherTrust Manager to version 2.14 or higher, it uses client management profiles for registration tokens. The CA that was linked to a token used for an older client's registration will be linked to a client management profile.

Scenarios Requiring Manual Intervention

Manual intervention is required in the following scenarios where automatic renewal is not supported:

- **Unsupported Agent/CipherTrust Manager Versions:** If you are using CTE 7.4, CTE UserSpace 10.1, or any lower version, or your agent is registered with CipherTrust Manager 2.13 or lower, automatic notifications are not sent. If the certificate expires or is modified, you must reregister the client. Refer to [Reregistering CTE Clients](#) for instructions.
- **Upgrading CipherTrust Manager with Existing Agents:** If a compatible CTE Agent — such as CTE 7.5, CTE UserSpace 10.2, or later — was registered with CipherTrust Manager 2.13 or lower, the CipherTrust Manager is unaware of the agent's `CA_RENEWAL` capability after an upgrade to CipherTrust Manager 2.14+.

To resolve this, you must make the CipherTrust Manager aware of the agent's capabilities. You can do this in one of two ways:

- **Fetch Capabilities from CipherTrust Manager (Recommended):** In the CipherTrust Manager GUI, navigate to **Transparent Encryption > Settings > Client Information and Capabilities**, then click **Get Capability**. This action fetches the latest capabilities from all active clients without requiring a restart.
- **Reboot the CTE Agent:** Rebooting the CTE client causes it to reinitialize and send its capabilities to CipherTrust Manager, enabling future auto-renewal notifications.

Reregistering CTE Clients

In some cases, you need to change the CA certificate that was used to register a client with the CipherTrust Manager. If the CA used to generate the client certificate is about to expire or is modified, the CTE clients are notified of the CA certificate auto renewal.

Warning

If the client certificate is not renewed timely, it results in a connection failure. You need to reregister the client with the CipherTrust Manager.

While reregistering a client, you can enable capabilities even if they were disabled earlier.

To reregister a client with the CipherTrust Manager:

1. Create a new registration token. Use the ID of the trusted CA that will be used to sign the client certificate. By default, a local CA will be used to issue certificates. Refer to [Creating a Registration Token](#) for details.
2. Register the client again using the new registration token created in step 1. The client administrator reregisters the client with the CipherTrust Manager. Steps are similar to registering a new client with the CipherTrust Manager.

Protecting Data on Clients

After registration, the client can communicate with the CipherTrust Manager, and is ready for data protection using CTE. This section describes how CTE GuardPoints, policies, and policy elements work together to encrypt file systems.

Refer to [Common Scenarios](#) for prerequisites and procedures to encrypt data in the most common scenarios.

GuardPoints

A GuardPoint specifies the path on the client that is to be protected with different access and encryption policies. GuardPoint is configured by specifying the guard path, policy, and other policy/path specific configuration parameters.

A sample configuration of a GuardPoint is shown below:

Refer to [Managing GuardPoints](#) for details.

Policies

A policy is the resource where all the access privileges and key configuration is done to achieve the required use cases. Policies are categorized as:

- Standard Policies
- LDT Policies
- COS Policies
- IDT Policies

Refer to [Creating Policies](#) for details.

Standard Policies

Depending on the availability of data in GuardPoints, standard policies can be applied in two different scenarios.

- The GuardPoint **does not contain** any data. The data would be created after the GuardPoint is applied. These policies are also called production policies.

A sample production policy is shown below:

1 General Info

Name: ProductionPolicy

Policy Type: Standard

Description:

2 Security Rules

Resource Set	User Set	Process Set	Action	Effect	Browsing
*	User1		all_ops	permit,applykey	Yes

3 Key Rules

Resource Set	Key Name
	Key1

- The GuardPoint already **contains** data. The existing data is migrated to encrypted form by using the data transformation policy.

A sample data transformation policy is shown below:

1 General Info

Name: dataformplc

Policy Type: Standard

Description:

2 Security Rules

Resource Set	User Set	Process Set	Action	Effect	Browsing
			key_op	permit,applykey	Yes

3 Key Rules

Resource Set	Current Key Name
	clear_key

4 Data Transformation Rules

Resource Set	Transformation Key Name
	Key1

After the data is migrated, unguard the data transformation policy, apply the standard policy with same key (as used by the data transformation policy). A sample standard policy applied after unguarding a data transformation policy is shown below:

1 General Info

Name: UCT-Standard

Policy Type: Standard

Description:

2 Security Rules

Resource Set	User Set	Process Set	Action	Effect	Browsing
*	User1		all_ops	permit,applykey	Yes
*	User2		all_ops	permit	Yes
				deny	Yes

3 Key Rules

Resource Set	Key Name
	Key1

Data transformation policies are created by turning on the Data Transformation toggle when creating a Standard policy. These policies require downtime, so they are referred to as offline policies. If you do not want downtime, you can deploy LDT policies.

LDT Policies

As their name implies, LDT policies perform live transformation of data. They do not require any time downtime, so they are referred to as online policies. You can continue to work while the transformation of your data in GuardPoints is in progress. To benefit from LDT, you need to purchase an Add-On LDT license with the CTE Base license.

LDT policies can handle both these cases:

- The GuardPoint **does not contain** any data. No data is migrated. A production policy is applied to encrypt/decrypt the future data.
- The GuardPoint already **contains** data. The existing data is automatically migrated. After the data is migrated, the data is encrypted/decrypted like a production policy.

A sample LDT policy is shown below:

Name: UC1-LDT

Policy Type: ldt

Description:

2 Security Rules

Resource Set	User Set	Process Set	Action	Effect	Browsing
*			key_up	permit,applykey	No
*	User1		all_ops	permit,applykey	Yes
*	User2		all_ops	permit	Yes
				dany	Yes

3 Key Rules

Resource Set	Current Key Name	Transformation Key Name	Exclusion Rule
	clear_key	testldt	No

COS Policies

These policies are used to encrypt data and apply access rules on the GuardPoints on cloud. CTE supports Amazon S3 buckets.

A sample COS policy is shown below:

Name: RS3-COSPolicy

Policy Type: cloud_object_storage

Description:

2 Security Rules

User Set	Process Set	Action	Effect	Browsing
		all_ops	permit,applykey	No

3 Key Rules

Key Name
Key2

IDT Policies

These policies are used to create GuardPoints for Teradata clusters. Access to data is blocked during encryption or rekeying of data.

A sample IDT policy is shown below:

Name: IDT-Policy

Policy Type: in-place Data Transformation

Description:

1 Security Rules

Resource Set	User Set	Process Set	Action	Effect	Browsing
*				deny,audit	Yes

2 Key Rules

Current Key: clear_key

Transformation Key: testb1t6

Refer to [Protecting Teradata Appliances](#) for details on protecting Teradata appliances.

Policy Elements

To achieve different access privileges based on users, processes, and different resources (sub-directory/specific file formats), create these policy elements:

- User Sets
- Process Sets
- Resource Sets

Refer to [Creating Policy Elements](#) for details.

User Sets

Groups of single or multiple users that can be used as individual entities in policies to grant user specific privileges. A sample user set is shown below:

1 General Info

Name: UserSet1

Description:

2 Users / Groups

uname	UID	gname	GID	OS domain	
user1	1000	group1	1000		 Remove

Process Sets

Groups of single or multiple processes that can be used as individual entities in policies to grant process specific privileges.

1 General Info

Name: ProcessSet

Description:

2 Processes

Directory	File	Signature
/usr/bin	vi	

Resource Sets

Groups of single or multiple resources (sub-directory or specific file formats) that can be used as individual entities in policies to grant resource specific privileges.

1 General Info

Name: ResourceSet1

Description:

2 Resources

Directory	File	Include Sub Folders	File System Type
/	*.txt	Yes	Local File System

Certificate Renewal

If the CA that signed the client certificate or the web interface certificate is modified, the CTE client is notified about this change. The CTE client can now generate or install a new certificate and update the truststore for uninterrupted connections.

Refer to [CA Certificates Renewal Notification](#) for compatibility information.

Client Certificate Renewal

CTE Agents with the `CA_RENEWAL` capability support the CA renewal feature. When the CA (local or external) is updated in a client management profile, the `Client Profile updated` message is logged on the CipherTrust Manager. Also, all the clients linked with the updated client management profile are notified of the CA update. A message `RenewCerts - Renewal has been scheduled - OK` is generated in the VMD logs (client logs) on the linked clients.

Note

Client certificate renewal is applicable to all the **CA_RENEWAL** capable CTE clients in *all the domains* of the CipherTrust Manager.

Possible Scenarios

- Client with the **CA_RENEWAL** Capability is Active
- Client with the **CA_RENEWAL** Capability is Inactive
- Client with the **CA_RENEWAL** Capability is Registered with an Unsupported CipherTrust Manager Version
- Client Doesn't have the **CA_RENEWAL** Capability

Client with the **CA_RENEWAL** Capability is Active

A CTE client with the **CA_RENEWAL** capability is active. After the CA is updated in a client management profile:

1. The active client with the **CA_RENEWAL** capability linked with the updated profile receive the certificate renewal notification.
2. The CTE Agent generates a log of CA renewal, **RenewCerts: Renewal has been scheduled - OK**, in the client logs. The client continues to work properly after the CA renewal.

All the active and **CA_RENEWAL** capable CTE clients linked with the updated client management profile reflect the same behavior.

Client with the **CA_RENEWAL** Capability is Inactive

A CTE client with the **CA_RENEWAL** capability is inactive, that is, unable to communicate with the CipherTrust Manager it is registered with. In this case, if the CipherTrust Manager administrator updates the CA in the linked client management profile, the following message is generated in the CipherTrust Manager logs. This shows that the client can't be notified of the CA update.

```
Client cert updated. LONGPOLL connection is not available for client
```

The CA Renewal Notification ERROR message is also logged in the audit records on the CipherTrust Manager (**Records > Loki Audit Records > Server Records**).

Now, if the connection between the client and the CipherTrust Manager is restored:

- The CipherTrust Manager log shows that a **LONGPOLL** command of **RenewCertificates** is sent to the clients. This indicates that the communication between the CipherTrust Manager and the client is enabled. The client is notified of the CA update.
- The client log shows **RenewCerts: OK - Renewal has been scheduled**.

Note

If a client with the `CA_RENEWAL` capability is *inactive* (disabled or unreachable), the CipherTrust Manager can't notify the client of the certificate update. The CipherTrust Manager will retry notifying the client when it is *active* again.

Client with the `CA_RENEWAL` Capability is Registered with an Unsupported CipherTrust Manager Version

A CTE client with the `CA_RENEWAL` capability is registered with a CipherTrust Manager version that does not support certificate renewal notification. In this case, if the CA is updated in the linked client management profile, the CipherTrust Manager can't notify the linked clients of any CA updates.

Client Doesn't have the `CA_RENEWAL` Capability

A CTE Agent doesn't have the `CA_RENEWAL` capability. In this case, if the CA is updated in the linked client management profile, the CipherTrust Manager doesn't send CA update notifications to the client. An audit record is logged on the CipherTrust Manager.

When the CA in the linked client management profile is updated:

- A message `Client Profile updated` is displayed on the CipherTrust Manager GUI.
- A message `Client Cert updated. Cert renewal notification are not supported for the CTE Client` is logged on the CipherTrust Manager. The CA Renewal Notification ERROR message is also logged in the audit records on the CipherTrust Manager (**Records > Loki Audit Records > Server Records**).

Web Interface Certificate Renewal

When the CipherTrust Manager's web interface certificate is updated (or renewed), all the `CA_RENEWAL` capable CTE clients from *all the domains* of the CipherTrust Manager are notified of the changes in the web interface certificate.

Click the desired tab to view instructions to update the web interface certificate through the API or GUI.

API

To update the web interface certificate:

1. Add the new certificate to the list of upcoming interface certificates.

```
put /v1/configs/interfaces/web/renewal-certificate
```

In the `certificate` parameter, specify the certificate chain having the primary certificate, the CA, and its private key. Also, specify the `format` parameter.

After the upcoming certificate is updated successfully

- a. The active **CA_RENEWAL** capable clients receive notification of this update.
 - The CipherTrust Manager logs show that a **LONGPOLL** command of **RenewCertificates** is sent to the *active* clients. The clients are notified of the web interface certificate update.
 - The client log shows **RenewCerts: OK - CA trust store updated**.
- b. The CTE Agent updates the truststore with the new certificate chain. Both the old and the updated certificates are stored on the client at: **/opt/vormetric/DataSecurityExpert/agent/secfs/.sec/pem**

2. Fetch the upcoming renewal certificate.

```
get /v1/configs/interfaces/web/renewal-certificate
```

The command returns the public portion (only public key and CA chain) of the upcoming renewal certificate in the PEM format.

3. When the current interface certificate is about to expire, apply the new certificate.

```
post /v1/configs/interfaces/{interface}/renewal-certificate/apply
```

Note

If the new certificate is not applied before the current certificate expires, the new certificate will be automatically applied when the current certificate expires.

GUI

To renew the web certificate:

Upload the updated web certificate

1. Go to **Admin Settings > Interfaces**.
 2. Click the Overflow Icon () next to the web interface.
 3. Click **Renewal Certificate Options...** The Interface Renewal Certificate Options on 'web' dialog box is displayed.
 4. Click **Upload/Generate** to upload a new server certificate.
 5. Click **OK**. The Upload/Generate Upcoming Certificate dialog box is displayed.
-

6. Select a certificate upload option. You can either upload the certificate using the **File Upload** option or paste the signed certificate and its private key content in the **Text** field.
7. Select **PEM** as **Format**.
8. Click **Upload Certificate**. The certificate is uploaded successfully.

Apply the new certificate

When the current interface certificate is about to expire, you need to apply the newly uploaded certificate.

1. Click the Overflow Icon () next to the web interface.
2. Click **Renewal Certificate Options...** The Interface Renewal Certificate Options on 'web' dialog box is displayed.
3. Click **Apply** to apply the upcoming renewal server certificate. The existing server certificate is replaced with the newly generated server certificate.

Note

If the new certificate is not applied before the current certificate expires, the new certificate will be automatically applied when the current certificate expires.

Refer to [managing upcoming server certificate](#) for details on upcoming server certificates.

Web Service Restart Required

When renewing the CipherTrust Manager web interface SSL certificate—including when using the "Automatically Renew the Upcoming Certificate" feature—a restart of the CipherTrust Manager web service is required to activate the new certificate.

- **Action Required:** Restart the web service through **Admin Settings > Services**.
- **Impact:** Until the web service is restarted, the new certificate will not be active, and "Failed to notify the CTE client" errors may appear in system logs.
- **After Upgrade:** This restart remains necessary even after upgrading the CipherTrust Manager to version 2.14 or higher.

After the CTE Agent has successfully updated the truststore and the updated web interface certificate is *applied* successfully, the **CA_RENEWAL** capable clients start communicating with the CipherTrust Manager over the renewed certificate.

Important Notes

- The CipherTrust Manager doesn't notify the clients that don't have the `CA_RENEWAL` capability. The following message is displayed in the CipherTrust Manager logs for such clients.

```
Web interface CA is updated but Auto-CA Renewal is not supported for the CTE Client
```

The CA Renewal Notification ERROR message is also logged in the audit records on the CipherTrust Manager (**Records > Loki Audit Records > Server Records**).

- When renewing a web interface SSL certificate that was signed by an external CA, re-registering older CTE Agents is not required if the certificate is renewed using the **same external CA signer**. This exception applies even to agents on versions 7.4.0 and lower.
- If the CA signer for the web interface certificate changes, or if you are using CTE or CipherTrust Manager versions that do not support automatic renewal notifications, manual re-registration of the CTE Agents is required.
- If the web interface SSL certificate was signed by an external CA and is renewed using the same external CA signer, then reregistering the CTE Agents is not required, even if they are on a version lower than 7.5.0.
- The CipherTrust Manager retries notifying all the `CA_RENEWAL` capable clients whether they are *active* or *inactive*.

If a client with the `CA_RENEWAL` capability is *inactive* (disabled or unreachable), the CipherTrust Manager can't notify the client of the certificate update (until it is active). The following message is displayed in the CipherTrust Manager logs.

```
Failed to notify the CTE client
```

The CA Renewal Notification ERROR message is also logged in the audit records on the CipherTrust Manager (**Records > Loki Audit Records > Server Records**).

The CipherTrust Manager retries notifying the client of the update when the client is active again (the connection is re-established). A `LONGPOLL` message `Sending pending event to CTE client` is displayed in the CipherTrust Manager logs.

After the client is notified of the update, the Agent updates the truststore. A message `RenewCerts: OK - CA trust store updated` is logged in the client logs.

Caution

- Restore the connectivity of inactive clients with the **CA_RENEWAL** capability before **applying** the updated web interface certificate. If the certificate is applied when a client is inactive, the client needs to be reregistered.
- In a clustered environment, all the CipherTrust Manager nodes must have the same certificate active. If the web interface certificate is renewed (updated and applied) at one node, the same certificate chain must be renewed on all nodes of the CipherTrust Manager cluster. Failure to do so can break the connectivity and the CTE clients need to be reregistered.

Common Scenarios

This section describes the common encryption scenarios in which paths can be encrypted using the CTE solution. Similarly, you can configure different types of policies with different combinations of policy elements to suit your requirements.

This section describes encryption using:

- User-based Access Privileges
- Process-based Access Privileges
- Signature-based Access Privileges for Processes
- Different Access Privileges for Subdirectory or Different File Formats
- Different Access Privileges for Combination of Users, Processes, and Resources

Prerequisites

- The CipherTrust Manager is up and running. Refer to the [CipherTrust Manager Deployment Guide](#) for details.
- A CTE base license is activated and installed. Refer to [Licensing](#) for details.
- (Optional) Add-on LDT license is activated and installed. This license is needed only if you want to deploy LDT policies. A CTE base license must be activated on the CipherTrust Manager. Refer to [Licensing](#) for details.
- The CTE Agent is installed on client machines where data is to be protected. The client machines are running a supported platform. Refer to the [CTE Agent Quick Start Guide](#) specific to your platform for details.

Note

Policy elements can be created either in advance or when creating the policy. Refer to [Creating Policy Elements](#) for details.

User-based Access Privileges

Encrypt a local path with the following access privileges:

- User set UserSet1 can encrypt/decrypt data in the GuardPoint.
- User set UserSet2 can access the ciphertext data but cannot encrypt or decrypt.
- All other user sets are denied access to the GuardPoint data.

Depending on the data availability (or downtime) and storage requirements in your setup, you can apply any of these policies:

- [Standard Production Policies](#)
- [Standard Data Transformation Policies](#)
- [LDT Policies](#)

Refer to [Data Transformation Techniques](#) for advantages and limitations of data transformation techniques. LDT policies require an add-on license to use them.

Standard Production Policies

If the GuardPoint does not contain any existing data, and the data would be created after the GuardPoint is applied:

1. Create a standard policy. Refer to [Creating Policies](#) for details.

1 General Info

Name: ProductionPolicy

Policy Type: Standard

Description:

2 Security Rules

Resource Set	User Set	Process Set	Action	Effect	Browsing
+	User1		all_ops	permit,applykey	Yes

3 Key Rules

Resource Set	Key Name
	Key1

2. Apply a GuardPoint using the standard policy. Refer to [Creating Standard GuardPoints](#) for details.

Standard Data Transformation Policies

If the GuardPoint already contains data, and the existing data needs to be migrated to encrypted form by using the `dataxform` utility:

1. Create a data transformation policy. Refer to [Creating Policies](#) for details.

1 General Info

Name: dataxformplc

Policy Type: Standard

Description:

2 Security Rules

Resource Set	User Set	Process Set	Action	Effect	Browsing
			key_op	permit,applykey	Yes

3 Key Rules

Resource Set	Current Key Name
	clear_key

4 Data Transformation Rules

Resource Set	Transformation Key Name
	Key1

2. Apply a GuardPoint using the data transformation policy. Refer to [Creating Standard GuardPoints](#) for details.
3. After the existing data is migrated, unguard the data transformation policy from the GuardPoint. Refer to [Removing GuardPoints](#) for details.
4. Create a standard policy with same key (as used by the data transformation policy in the first step). Refer to

Creating Policies for details.

1 General Info

Name: UCI-Standard

Policy Type: Standard

Description:

2 Security Rules

Resource Set	User Set	Process Set	Action	Effect	Browsing
*	User1		all_ops	permit,applykey	Yes
*	User2		all_ops	permit	Yes
				deny	Yes

3 Key Rules

Resource Set	Key Name
	Key1

Now, you must run the `dataxform --rekey --gp <GuardPath>` command on the CTE Agent. Refer to the [CTE Data Transformation Guide](#) specific to your platform for details.

5. Apply the GuardPoint using the standard policy created in the previous step. Refer to [Creating Standard GuardPoints](#) for details.

LDT Policies

If you have an add-on LDT license, you can achieve the combined effects of the standard production and standard data transformation policies by applying the LDT policies.

- If the GuardPoint already contains data, the policy migrates the existing data automatically. No need to run the `dataxform` utility manually. Later, the policy automatically encrypts/decrypts the data similar to a standard policy.
- If the GuardPoint does not contain any existing data, migration is not required. A standard (production) policy of encryption/decryption is applied automatically.

To apply an LDT policy:

1. Create an LDT policy. Refer to [Creating Policies](#) for details.

Name: UC1-LDT

Policy Type: ldt

Description:

2 Security Rules

Resource Set	User Set	Process Set	Action	Effect	Browsing
*			key_up	permit,applykey	No
*	User1		all_ops	permit,applykey	Yes
*	User2		all_ops	permit	Yes
				deny	Yes

3 Key Rules

Resource Set	Current Key Name	Transformation Key Name	Exclusion Rule
	clear_key	testldt	No

2. Apply the GuardPoint using the LDT policy. Refer to [Creating LDT GuardPoints](#) for details.

Process-based Access Privileges

Encrypt a local path with the following access privileges:

- Process set ProcessSet1 can encrypt/decrypt data in the GuardPoint.
- Process set ProcessSet2 can access the ciphertext data but cannot encrypt or decrypt.
- All other process sets are denied access to the GuardPoint data.

Process-based policies are configured in exactly the same way the user-based policies are configured, as described in [User-based Access Privileges](#). The only difference is that instead of adding user sets add process sets to the Security Rules tab of the policy.

Depending on the data availability (or downtime) and storage requirements in your setup, you can apply any of these policies:

- [Standard Production Policies](#)
- [Standard Data Transformation Policies](#)
- [LDT Policies](#)

Refer to [Data Transformation Techniques](#) for advantages and limitations of data transformation techniques. LDT policies require an add-on license to use them.

Signature-based Access Privileges for Processes

Encrypt a local path with the following access privileges:

- Process Process1 with a particular signature can encrypt/decrypt data in the GuardPoint.
- All other processes are denied access to the GuardPoint data.

To apply a signature-based access policy for a process:

1. Create a signature set. When creating the set, add the source path of Process1. This process will be signed. Refer to [Creating Signature Sets](#).

1 General Info

Name: SignSet1

Description:

2 Sources

Source Directory

/usr/bin/vi

2. Sign the signature set. Use a CTE client having the desired process to sign the process. Refer to [Signing Files in a Signature Set](#) for details.

3. Create a process set. When creating the set, add the newly created signature set. Refer to [Creating Process Sets](#) for details.

1 General Info

Name: UC-3-ProcessSet

Description:

2 Processes

Directory	File	Signature	
/usr/bin/	vi	SignSet1	***

4. Configure process-based access policies. Refer to [Process-based Access Privileges](#) for details.

Different Access Privileges for Subdirectory or Different File Formats

Encrypt a local path with the following access privileges:

- Encrypt/decrypt only a subdirectory, subdir1, under the GuardPath.
- Deny access to all other files and directories under the GuardPoint.

To achieve this use case, you need to add a resource set to the policy. In a resource set, you can provide details about the subdirectories or specific file formats that need to be handled differently under a GuardPoint.

To achieve this use case:

1. Create a resource set. Specify the details of the subdirectory (subdir1) in the resources. Refer to [Creating Resource Sets](#) for details.

1 General Info

Name: UC4_ResourceSet_SubDir1

Description:

2 Resources

Directory	File	Include Sub Folders	File System Type
/subdir1/	*	Yes	Local File System

Note

Paths specified in a resource set should be relative to the GuardPath. Do not provide absolute path for the resources.

2. Create the desired policy type. Make sure to add the resource set created in the previous step. This is done to enforce the desired access policy. Refer to [Creating Policies](#) for details.

1 General Info

Name: UC4-Policy

Policy Type: Standard

Description:

2 Security Rules

Resource Set	User Set	Process Set	Action	Effect	Browsing
+ UC4_ResourceSet_SubDir1			all_ops	permit_applykey	Yes
				deny	Yes

3 Key Rules

Resource Set	Key Name
UC4_ResourceSet_SubDir1	Key1

3. Apply the GuardPoint using the policy created in the previous step. Refer to [Managing GuardPoints](#) for details.

Different Access Privileges for Combination of Users, Processes, and Resources

Encrypt a local path with the following access privileges:

- Allow only the process usrbn.exe being run by User1 to encrypt/decrypt text files (*.txt) present under the GuardPath.
- Deny access to all other users and processes.

To achieve this use case:

1. Created the required resource set. Refer to [Creating Resource Sets](#) for details.
2. Create the required user set. Refer to [Creating User Sets](#) for details.
3. Create the required process set. Refer to [Creating Process Sets](#) for details.
4. Create the desired policy type using the resource set, the user set, and the process set created above. Refer

to [Creating Policies](#) for details.

1 General Info

Name: UCS-Combination-Policy
Policy Type: Standard
Description:

2 Security Rules

Resource Set	User Set	Process Set	Action	Effect	Browsing
Text_ResourceSet	User1	UsrBin_ProcessSet	all_ops	permit,applykey	Yes
				deny	Yes

3 Key Rules

Resource Set	Key Name
Text_ResourceSet	Key1

5. Apply the GuardPoint using the policy created in the previous step. Refer to [Managing GuardPoints](#) for details.

Reports

Reports provide an easy and quick method to answer queries such as:

- How many clients are registered with the CipherTrust Manager?
- What is the health status of clients?
- How many keys are used for protecting data?
- What keys and policies are linked?
- How many GuardPoints are applied on a client?
- What key is used to protect a specific GuardPoint?
- What CTE resources belong to a specific CipherTrust Manager domain?

Use the **Domain Sharing Data** toggle button to include/exclude information about CTE resources shared across domains.

Dashboard

The dashboard on the Reports page shows the following information:

- **TOTAL CLIENTS:** Shows the total count of registered and unregistered clients on the CipherTrust Manager.
- **CTE LICENSES USED:** Shows the count of consumed *CipherTrust Transparent Encryption* licenses out of

available licenses.

- **CTE-U LICENSES USED:** Shows the count of consumed *CipherTrust Transparent Encryption for UserSpace* licenses out of available licenses.
- **K8S LICENSES USED:** Shows the count of consumed *CipherTrust Transparent Encryption for Kubernetes* licenses out of available licenses.
- **TOTAL GUARDPOINTS:** Shows the total count of GuardPoints configured on the registered and unregistered clients on the CipherTrust Manager.
- **ACTIVE GUARDPOINTS:** Shows the count of active GuardPoints on the CipherTrust Manager.
- **INACTIVE GUARDPOINTS:** Shows the count of inactive GuardPoints on the CipherTrust Manager.

Download Formats

View the latest CTE reports and download them as PDF and CSV documents on your local machines. The PDF and CSV formats present reports in easy-to-understand tabular forms.

Important Note on CSV Reports

If the names of CTE resources include special characters like equals (=), plus (+), minus (-), at (@), tab (0x09), and carriage return (0x0D), the resources are renamed in the downloaded CSV reports by applying the following rules:

- Every cell is wrapped in double quotes
- Every cell is prepended with a single quote
- Every double quote is escaped using an additional double quote

For example, a resource named `=A+B " ; , =C+D` is renamed as `" '=A+B ' "' ; , =C+D"` in the downloaded CSV report.

Report Types

The Reports page shows different types of CTE reports on the following tabs:

Tab	Description
Clients	Shows the health status of the CTE clients available on the CipherTrust Manager. Refer to Clients Health Report .
Clients Keys	Shows the keys used for protecting GuardPoints on the CTE clients available on the CipherTrust Manager. Refer to Clients Keys Report .
Clients Profiles	Shows the mapping of clients with the profiles they are linked to on the CipherTrust Manager. Refer to Clients Profiles Report .
Clients Policies	Shows the mapping of clients with the policies applied

Tab	Description
	to them on the CipherTrust Manager. Refer to Clients Policies Report .
Policies Keys	Shows the list of keys used by the CTE policies. A key can be used by multiple policies, similarly, a policy can have multiple keys. Refer to Policies Keys Report .
GuardPoints	Shows the GuardPoints applied to the CTE clients available on the CipherTrust Manager. Refer to GuardPoints Report .
Clients GuardPoints Status	Shows the status of GuardPoints applied to the CTE clients available on the CipherTrust Manager. Refer to Clients GuardPoint Status Report .

Filtering Reports

Use the "Search by" box to search for records in the reports by different resources or CipherTrust Manager domains.

When searching for records by domain names, specify the complete and exact domain name including case-sensitivity. For example, searching for "test", "test-domain", and "Test-Domain" will return different search results.

However, search by other resources support regular expressions and case-insensitivity. For example, when searching the Clients reports by Name, if you type the letter "t", the search results will display all the reports that have the letter "t" in their names, regardless of the order, complete name, and case-sensitivity.

The records can also be filtered using the on-screen filters. To filter the records, click the Filter icon (), selected/clear the desired option, and click **OK**. When a filter is applied, the icon changes to ().

To hide/show desired columns in the report, click the Custom View icon (), select/clear the check box against the desired column, and click **OK**.

Clients Health Report

The Clients Health Report shows the health status of the CTE clients available on the CipherTrust Manager. You can download the report as a PDF or CSV document, as required. Refer to [Downloading the Report](#).

Use the "Search by" box to search for records in the report by Client Name or Domain. When searching for records by domain names, specify the complete and exact domain name including case-sensitivity. For example, searching for "test", "test-domain", and "Test-Domain" will return different search results.

Viewing the Report

To view the Clients Health Report:

1. Open the Transparent Encryption application.
2. In the left pane, click **Reports**. The Reports page is displayed.
3. Click the **Clients** tab.

The report shows all or some of the following columns:

Column	Description
Domain	Name of the CipherTrust Manager domain to which the record belongs. If the Domain Sharing Data toggle is turned ON, the report displays all the domains where the resource is shared.
Client Name	Name of the client on the CipherTrust Manager.
Status	Status of the client. The status can be: • Unregistered • Error • Warning • Healthy • Expunged Refer to Client States for details.
Client Type	Type of the client: • FS: CTE client • CSI: CTE for Kubernetes client • CTE-U: CTE UserSpace client
OS Type	Operating system running on the client - AIX, LINUX, WINDOWS, UNKNOWN, FREEBSD. UNKNOWN is displayed for unregistered or manually added clients. FREEBSD is supported by CTE UserSpace.
Details	Versions of the platform and kernel installed on the client, for example, RHEL7.8 - 3.10.0-1127.el7.x86_64. For Windows clients and unregistered or manually added clients, the field is empty. The Details column shows hyphen-separated (-) combination of these fields: • Details-OS Sub Type: Variant of the operating system running on the client, for example, RHEL7.8. • Details-OS Kernel: Version of the kernel running on the client, for example, 3.10.0-1127.el7.x86_64. To view/hide their values, click the custom view icon (⚙️), select/clear the desired column, and click OK .
Client Version	Version of the CTE Agent installed on the client, for example, 7.2.0.xxxx. For unregistered or manually added clients, the field is empty.
Client Description	Description of the client.
Client Group Name	Name of the client group associated with the client.
Total GuardPoints	Total number of GuardPoints applied on the client.
Enabled GuardPoints	Number of enabled/active GuardPoints on the client.

Downloading the Report

Download the report as a PDF or CSV document. Based on the displayed columns and applied filters, the downloaded report shows all or some of the columns listed in [Viewing the Report](#).

Reports provide an easy and quick method to answer queries such as:

- How many clients are registered with the CipherTrust Manager?
- What is the health status of clients?
- How many keys are used for protecting data?
- What keys and policies are linked?
- How many GuardPoints are applied on a client?
- What key is used to protect a specific GuardPoint?
- What CTE resources belong to a specific CipherTrust Manager domain?

Use the **Domain Sharing Data** toggle button to include/exclude information about CTE resources shared across domains.

Dashboard

The dashboard on the Reports page shows the following information:

- **TOTAL CLIENTS:** Shows the total count of registered and unregistered clients on the CipherTrust Manager.
- **CTE LICENSES USED:** Shows the count of consumed *CipherTrust Transparent Encryption* licenses out of available licenses.
- **CTE-U LICENSES USED:** Shows the count of consumed *CipherTrust Transparent Encryption for UserSpace* licenses out of available licenses.
- **K8S LICENSES USED:** Shows the count of consumed *CipherTrust Transparent Encryption for Kubernetes* licenses out of available licenses.
- **TOTAL GUARDPOINTS:** Shows the total count of GuardPoints configured on the registered and unregistered clients on the CipherTrust Manager.
- **ACTIVE GUARDPOINTS:** Shows the count of active GuardPoints on the CipherTrust Manager.
- **INACTIVE GUARDPOINTS:** Shows the count of inactive GuardPoints on the CipherTrust Manager.

Download Formats

View the latest CTE reports and download them as PDF and CSV documents on your local machines. The PDF and CSV formats present reports in easy-to-understand tabular forms.

Important Note on CSV Reports

If the names of CTE resources include special characters like equals (=), plus (+), minus (-), at (@), tab (0x09), and carriage return (0x0D), the resources are renamed in the downloaded CSV reports by applying the following rules:

- Every cell is wrapped in double quotes
- Every cell is prepended with a single quote
- Every double quote is escaped using an additional double quote

For example, a resource named `=A+B' " ; , =C+D` is renamed as `" '=A+B' " " ; , =C+D` in the downloaded CSV report.

To download the report:

1. Open the Transparent Encryption application.
2. In the left pane, click **Reports**. The Reports page is displayed.
3. Click the **Clients** tab.
4. Download the report:
 - Click **Download CSV** to download the report as a CSV file. The file is named `<DOMAIN>_cte_client_health_<TIMESTAMP>.csv`, for example, `root_cte_client_health_2021-01-12T06_52_51Z.csv`.
 - Click **Download PDF** to download the report as a PDF file. The file is named `<DOMAIN>_cte_client_health_<TIMESTAMP>.pdf`, for example, `root_cte_client_health_2021-01-12T06_55_09Z.pdf`.

Note

If the CipherTrust Manager is part of a cluster environment, the filename of the downloaded report (CSV and PDF) will also include the cluster ID.

If the downloaded report is a CSV file, the file will be named `<CLUSTER ID><DOMAIN>_cte_client_health_<TIMESTAMP>.csv`, for example, `51.26.30.11_root_cte_client_health_2021-01-12T06_52_51Z.csv`. The PDF file will also be named in the same way.

The downloaded PDF document shows the **Report Name** as *Clients Health Report* and time the report is **Generated At**.

Clients Keys Report

The Clients Keys Report shows the keys used for protecting GuardPoints on the CTE clients available on the CipherTrust Manager. You can download the report as a PDF or CSV document, as required. Refer to [Downloading the Report](#).

Use the "Search by" box to search for records in the report by Client Name, Key Name, or Domain. When searching for records by domain names, specify the complete and exact domain name including case-sensitivity.

For example, searching for "test", "test-domain", and "Test-Domain" will return different search results.

Viewing the Report

To view the Clients Keys Report:

1. Open the Transparent Encryption application.
2. In the left pane, click **Reports**. The Reports page is displayed.
3. Click the **Clients Keys** tab.

The report shows all or some of the following columns:

Column	Description
Domain	Name of the CipherTrust Manager domain to which the record belongs. If the Domain Sharing Data toggle is turned ON, the report displays all the domains where the resource is shared.
Client Name	Name of the client on the CipherTrust Manager.
Description	Description of the client.
Key Name	Name of the key.

Downloading the Report

Download the report as a PDF or CSV document. Based on the displayed columns and applied filters, the downloaded report shows all or some of the columns listed in [Viewing the Report](#).

Reports provide an easy and quick method to answer queries such as:

- How many clients are registered with the CipherTrust Manager?
- What is the health status of clients?
- How many keys are used for protecting data?
- What keys and policies are linked?
- How many GuardPoints are applied on a client?
- What key is used to protect a specific GuardPoint?
- What CTE resources belong to a specific CipherTrust Manager domain?

Use the **Domain Sharing Data** toggle button to include/exclude information about CTE resources shared across domains.

Dashboard

The dashboard on the Reports page shows the following information:

- **TOTAL CLIENTS:** Shows the total count of registered and unregistered clients on the CipherTrust Manager.
- **CTE LICENSES USED:** Shows the count of consumed *CipherTrust Transparent Encryption* licenses out of available licenses.
- **CTE-U LICENSES USED:** Shows the count of consumed *CipherTrust Transparent Encryption for UserSpace* licenses out of available licenses.
- **K8S LICENSES USED:** Shows the count of consumed *CipherTrust Transparent Encryption for Kubernetes* licenses out of available licenses.
- **TOTAL GUARDPOINTS:** Shows the total count of GuardPoints configured on the registered and unregistered clients on the CipherTrust Manager.
- **ACTIVE GUARDPOINTS:** Shows the count of active GuardPoints on the CipherTrust Manager.
- **INACTIVE GUARDPOINTS:** Shows the count of inactive GuardPoints on the CipherTrust Manager.

Download Formats

View the latest CTE reports and download them as PDF and CSV documents on your local machines. The PDF and CSV formats present reports in easy-to-understand tabular forms.

Important Note on CSV Reports

If the names of CTE resources include special characters like equals (=), plus (+), minus (-), at (@), tab (0x09), and carriage return (0x0D), the resources are renamed in the downloaded CSV reports by applying the following rules:

- Every cell is wrapped in double quotes
- Every cell is prepended with a single quote
- Every double quote is escaped using an additional double quote

For example, a resource named `=A+B' " ; , =C+D` is renamed as `"' =A+B' " " " ; , =C+D"` in the downloaded CSV report.

To download the report:

1. Open the Transparent Encryption application.
2. In the left pane, click **Reports**. The Reports page is displayed.
3. Click the **Clients Keys** tab.
4. Download the report:

- Click **Download CSV** to download the report as a CSV file. The file is named `<DOMAIN>_cte_client_keys_<TIMESTAMP>.csv`, for example, `root_cte_client_keys_2021-01-12T06_56_30Z.csv`.
- Click **Download PDF** to download the report as a PDF file. The file is named `<DOMAIN>_cte_client_keys_<TIMESTAMP>.pdf`, for example, `root_cte_client_keys_2021-01-12T06_56_30Z.pdf`.

Note

If the CipherTrust Manager is part of a cluster environment, the filename of the downloaded report (CSV and PDF) will also include the cluster ID.

If the downloaded report is a CSV file, the file will be named `<CLUSTER ID><DOMAIN>_cte_client_health_<TIMESTAMP>.csv`, for example, `51.26.30.11_root_cte_client_health_2021-01-12T06_52_51Z.csv`. The PDF file will also be named in the same way.

The downloaded PDF document shows the **Report Name** as *Clients Keys Report* and time the report is **Generated At**.

Clients Profiles Report

The Clients Profile Report shows the mapping of clients with the profiles they are linked to on the CipherTrust Manager. A client can be linked to a single profile at once. However, multiple clients can be linked to a single profile. You can download the report as a PDF or CSV document, as required. Refer to [Downloading the Report](#).

Use the "Search by" box to search for records in the report by Client Name, Profile Name, or Domain. When searching for records by domain names, specify the complete and exact domain name including case-sensitivity. For example, searching for "test", "test-domain", and "Test-Domain" will return different search results.

Viewing the Report

To view the Clients Profiles Report:

- Open the Transparent Encryption application.
- In the left pane, click **Reports**. The Reports page is displayed.
- Click the **Clients Profiles** tab.

The report shows all or some of the following columns:

Column	Description
Domain	Name of the CipherTrust Manager domain to which the record belongs. If the Domain Sharing Data toggle is

Column	Description
	turned ON, the report displays all the domains where the resource is shared.
Client Name	Name of the client on the CipherTrust Manager.
Profile Name	Name of the profile the client is linked to.
Description	Description of the linked profile.

Downloading the Report

Download the report as a PDF or CSV document. Based on the displayed columns and applied filters, the downloaded report shows all or some of the columns listed in [Viewing the Report](#).

Reports provide an easy and quick method to answer queries such as:

- How many clients are registered with the CipherTrust Manager?
- What is the health status of clients?
- How many keys are used for protecting data?
- What keys and policies are linked?
- How many GuardPoints are applied on a client?
- What key is used to protect a specific GuardPoint?
- What CTE resources belong to a specific CipherTrust Manager domain?

Use the **Domain Sharing Data** toggle button to include/exclude information about CTE resources shared across domains.

Dashboard

The dashboard on the Reports page shows the following information:

- **TOTAL CLIENTS:** Shows the total count of registered and unregistered clients on the CipherTrust Manager.
- **CTE LICENSES USED:** Shows the count of consumed *CipherTrust Transparent Encryption* licenses out of available licenses.
- **CTE-U LICENSES USED:** Shows the count of consumed *CipherTrust Transparent Encryption for UserSpace* licenses out of available licenses.
- **K8S LICENSES USED:** Shows the count of consumed *CipherTrust Transparent Encryption for Kubernetes* licenses out of available licenses.
- **TOTAL GUARDPOINTS:** Shows the total count of GuardPoints configured on the registered and unregistered clients on the CipherTrust Manager.

- **ACTIVE GUARDPOINTS:** Shows the count of active GuardPoints on the CipherTrust Manager.
- **INACTIVE GUARDPOINTS:** Shows the count of inactive GuardPoints on the CipherTrust Manager.

Download Formats

View the latest CTE reports and download them as PDF and CSV documents on your local machines. The PDF and CSV formats present reports in easy-to-understand tabular forms.

Important Note on CSV Reports

If the names of CTE resources include special characters like equals (=), plus (+), minus (-), at (@), tab (0x09), and carriage return (0x0D), the resources are renamed in the downloaded CSV reports by applying the following rules:

- Every cell is wrapped in double quotes
- Every cell is prepended with a single quote
- Every double quote is escaped using an additional double quote

For example, a resource named `=A+B " ; , =C+D` is renamed as `" '=A+B ' "' ; , =C+D"` in the downloaded CSV report.

To download the report:

1. Open the Transparent Encryption application.
2. In the left pane, click **Reports**. The Reports page is displayed.
3. Click the **Clients Profiles** tab.
4. Download the report:
 - Click **Download CSV** to download the report as a CSV file. The file is named `<DOMAIN>_cte_client_profile_<TIMESTAMP>.csv`, for example, `root_cte_client_profile_2021-01-12T07_05_03Z.csv`.
 - Click **Download PDF** to download the report as a PDF file. The file is named `<DOMAIN>_cte_client_profile_<TIMESTAMP>.pdf`, for example, `root_cte_client_profile_2021-01-12T07_07_10Z.pdf`.

Note

If the CipherTrust Manager is part of a cluster environment, the filename of the downloaded report (CSV and PDF) will also include the cluster ID.

If the downloaded report is a CSV file, the file will be named `<CLUSTER`

ID><DOMAIN>_cte_client_health_<TIMESTAMP>.csv, for example, **51.26.30.11_root_cte_client_health_2021-01-12T06_52_51Z.csv**. The PDF file will also be named in the same way.

The downloaded PDF document shows the **Report Name** as *Clients Profile Report* and time the report is **Generated At**.

Clients Policies Report

The Clients Policies Report shows the mapping of clients with the policies applied to them on the CipherTrust Manager. You can download the report as a PDF or CSV document, as required. Refer to [Downloading the Report](#).

Use the "Search by" box to search for records in the report by Client Name, Policy Name, or Domain. When searching for records by domain names, specify the complete and exact domain name including case-sensitivity. For example, searching for "test", "test-domain", and "Test-Domain" will return different search results.

Viewing the Report

To view the Clients Policies Report:

1. Open the Transparent Encryption application.
2. In the left pane, click **Reports**. The Reports page is displayed.
3. Click the **Clients Policies** tab.

The report shows all or some of the following columns:

Column	Description
Domain	Name of the CipherTrust Manager domain to which the record belongs. If the Domain Sharing Data toggle is turned ON, the report displays all the domains where the resource is shared.
Client Name	Name of the client on the CipherTrust Manager. Click the up/down arrow icon to sort the report list by client name.
Policy Name	Name of the applied policy. Click the up/down arrow icon to sort the report list by policy name.
Policy Description	Description of the applied policy.
Transformation Policy	Displays whether the listed policy is a transformation policy or not.
Client Type	Type of the client: • FS: CTE client • CSI: CTE for Kubernetes client • CTE-U: CTE UserSpace client

Column	Description
OS Type	Operating system running on the client - AIX, LINUX, WINDOWS, UNKNOWN, FREEBSD. UNKNOWN is displayed for unregistered or manually added clients. FREEBSD is supported by CTE UserSpace.
Policy Type	Type of the policy. The type can be: • Standard • Live Data Transformation • Cloud Object Storage • In-place Data Transformation • CSI
Guard Enabled	Whether a GuardPoint is enabled.
Learn Mode	Whether Learn Mode is enabled on the policy.
Last Update	Displays the most recent time of policy update. Click the up/down arrow icon to sort the report list based on the time of last update.

Downloading the Report

Download the report as a PDF or CSV document. Based on the displayed columns and applied filters, the downloaded report shows all or some of the columns listed in [Viewing the Report](#).

Reports provide an easy and quick method to answer queries such as:

- How many clients are registered with the CipherTrust Manager?
- What is the health status of clients?
- How many keys are used for protecting data?
- What keys and policies are linked?
- How many GuardPoints are applied on a client?
- What key is used to protect a specific GuardPoint?
- What CTE resources belong to a specific CipherTrust Manager domain?

Use the **Domain Sharing Data** toggle button to include/exclude information about CTE resources shared across domains.

Dashboard

The dashboard on the Reports page shows the following information:

- **TOTAL CLIENTS:** Shows the total count of registered and unregistered clients on the CipherTrust Manager.
- **CTE LICENSES USED:** Shows the count of consumed *CipherTrust Transparent Encryption* licenses out of available licenses.

-
- **CTE-U LICENSES USED:** Shows the count of consumed *CipherTrust Transparent Encryption for UserSpace* licenses out of available licenses.
 - **K8S LICENSES USED:** Shows the count of consumed *CipherTrust Transparent Encryption for Kubernetes* licenses out of available licenses.
 - **TOTAL GUARDPOINTS:** Shows the total count of GuardPoints configured on the registered and unregistered clients on the CipherTrust Manager.
 - **ACTIVE GUARDPOINTS:** Shows the count of active GuardPoints on the CipherTrust Manager.
 - **INACTIVE GUARDPOINTS:** Shows the count of inactive GuardPoints on the CipherTrust Manager.

Download Formats

View the latest CTE reports and download them as PDF and CSV documents on your local machines. The PDF and CSV formats present reports in easy-to-understand tabular forms.

Important Note on CSV Reports

If the names of CTE resources include special characters like equals (=), plus (+), minus (-), at (@), tab (0x09), and carriage return (0x0D), the resources are renamed in the downloaded CSV reports by applying the following rules:

- Every cell is wrapped in double quotes
- Every cell is prepended with a single quote
- Every double quote is escaped using an additional double quote

For example, a resource named `=A+B' " ; , =C+D` is renamed as `" '=A+B' '" " ; , =C+D"` in the downloaded CSV report.

To download the Clients Policies Report:

1. Open the Transparent Encryption application.
2. In the left pane, click **Reports**. The Reports page is displayed.
3. Click the **Clients Profiles** tab.
4. Download the report:
 - Click **Download CSV** to download the report as a CSV file. The file is named `<DOMAIN>_cte_clients_policies_<TIMESTAMP>.csv`, for example, `root_cte_clients_policies_2021-01-12T07_08_43Z.csv`.
 - Click **Download PDF** to download the report as a PDF file. The file is named `<DOMAIN>_cte_clients_policies_<TIMESTAMP>.pdf`, for example, `root_cte_clients_policies_2021-01-12T07_08_50Z.pdf`.

Note

- If the CipherTrust Manager is part of a cluster environment, the filename of the downloaded report (CSV and PDF) will also include the cluster ID.

If the downloaded report is a CSV file, the file will be named <CLUSTER ID><DOMAIN>_cte_client_health_<TIMESTAMP>.csv, for example, **51.26.30.11_root_cte_client_health_2021-01-12T06_52_51Z.csv**. The PDF file will also be named in the same way.

- Exclude at least two columns to download the report in the PDF format. Use the gear icon (⚙️) to select which fields should appear in the report.

The downloaded PDF document shows the **Report Name** as *Clients Policies Report* and time the report is **Generated At**.

Policies Keys Report

The Policies Keys Report shows the list of keys used by the CTE policies. A key can be used by multiple policies, similarly, a policy can have multiple keys. You can download the report as a PDF or CSV document, as required. Refer to [Downloading the Report](#).

Use the "Search by" box to search for records in the report by Policy Name, Key Name, or Domain. When searching for records by domain names, specify the complete and exact domain name including case-sensitivity. For example, searching for "test", "test-domain", and "Test-Domain" will return different search results.

Viewing the Report

To view the Policies Keys Report:

1. Open the Transparent Encryption application.
2. In the left pane, click **Reports**. The Reports page is displayed.
3. Click the **Clients Policies** tab.

The report shows all or some of the following columns:

Column	Description
Domain	Name of the CipherTrust Manager domain to which the record belongs. The Domain Sharing Data toggle does not affect the Policies Keys report.
Policy Name	Name of the policy.
Description	Description of the policy.
Policy Type	Type of the policy. The type can be:

Column	Description
	• Standard • Live Data Transformation • Cloud Object Storage • In-place Data Transformation • CSI
Key Name	Key used by the policy.

Downloading the Report

Download the report as a PDF or CSV document. Based on the displayed columns and applied filters, the downloaded report shows all or some of the columns listed in [Viewing the Report](#).

Reports provide an easy and quick method to answer queries such as:

- How many clients are registered with the CipherTrust Manager?
- What is the health status of clients?
- How many keys are used for protecting data?
- What keys and policies are linked?
- How many GuardPoints are applied on a client?
- What key is used to protect a specific GuardPoint?
- What CTE resources belong to a specific CipherTrust Manager domain?

Use the **Domain Sharing Data** toggle button to include/exclude information about CTE resources shared across domains.

Dashboard

The dashboard on the Reports page shows the following information:

- **TOTAL CLIENTS:** Shows the total count of registered and unregistered clients on the CipherTrust Manager.
- **CTE LICENSES USED:** Shows the count of consumed *CipherTrust Transparent Encryption* licenses out of available licenses.
- **CTE-U LICENSES USED:** Shows the count of consumed *CipherTrust Transparent Encryption for UserSpace* licenses out of available licenses.
- **K8S LICENSES USED:** Shows the count of consumed *CipherTrust Transparent Encryption for Kubernetes* licenses out of available licenses.
- **TOTAL GUARDPOINTS:** Shows the total count of GuardPoints configured on the registered and unregistered clients on the CipherTrust Manager.

- **ACTIVE GUARDPOINTS:** Shows the count of active GuardPoints on the CipherTrust Manager.
- **INACTIVE GUARDPOINTS:** Shows the count of inactive GuardPoints on the CipherTrust Manager.

Download Formats

View the latest CTE reports and download them as PDF and CSV documents on your local machines. The PDF and CSV formats present reports in easy-to-understand tabular forms.

Important Note on CSV Reports

If the names of CTE resources include special characters like equals (=), plus (+), minus (-), at (@), tab (0x09), and carriage return (0x0D), the resources are renamed in the downloaded CSV reports by applying the following rules:

- Every cell is wrapped in double quotes
- Every cell is prepended with a single quote
- Every double quote is escaped using an additional double quote

For example, a resource named `=A+B " ; , =C+D` is renamed as `" '=A+B ' "' ; , =C+D"` in the downloaded CSV report.

To download the Policies Keys Report:

1. Open the Transparent Encryption application.
2. In the left pane, click **Reports**. The Reports page is displayed.
3. Click the **Clients Profiles** tab.
4. Download the report:
 - Click **Download CSV** to download the report as a CSV file. The file is named `<DOMAIN>_cte_policies_keys_<TIMESTAMP>.csv`, for example, `root_cte_policies_keys_2021-01-12T07_11_57Z.csv`.
 - Click **Download PDF** to download the report as a PDF file. The file is named `<DOMAIN>_cte_policies_keys_<TIMESTAMP>.pdf`, for example, `root_cte_policies_keys_2021-01-12T07_13_23Z.pdf`.

Note

If the CipherTrust Manager is part of a cluster environment, the filename of the downloaded report (CSV and PDF) will also include the cluster ID.

If the downloaded report is a CSV file, the file will be named `<CLUSTER`

ID><DOMAIN>_cte_client_health_<TIMESTAMP>.csv, for example, **51.26.30.11_root_cte_client_health_2021-01-12T06_52_51Z.csv**. The PDF file will also be named in the same way.

The downloaded PDF document shows the **Report Name** as *Policies Keys Report* and time the report is **Generated At**.

GuardPoints Report

The GuardPoints Report shows the GuardPoints applied to the CTE clients available on the CipherTrust Manager. A client can have multiple GuardPoints. Similarly, a GuardPoint can be applied to multiple clients. You can download the report as a PDF or CSV document, as required. Refer to [Downloading the Report](#).

Use the "Search by" box to search for records in the report by Client Name, Policy Name, or Domain. When searching for records by domain names, specify the complete and exact domain name including case-sensitivity. For example, searching for "test", "test-domain", and "Test-Domain" will return different search results.

Viewing the Report

To view the GuardPoints Report:

1. Open the Transparent Encryption application.
2. In the left pane, click **Reports**. The Reports page is displayed.
3. Click the **GuardPoints** tab.

The report shows all or some of the following columns:

Column	Description
Domain	Name of the CipherTrust Manager domain to which the record belongs. If the Domain Sharing Data toggle is turned ON, the report displays all the domains where the resource is shared.
Client Name	Name of the client on the CipherTrust Manager.
Policy Name	Name of the applied policy.
Guard Path	Path where the GuardPoint is applied.
Guard Type	Type of the GuardPoint. The type can be: • Auto Directory • Manual Directory • Auto Raw Device • Manual Raw Device • Auto Cloud Storage • Manual Cloud Storage • Ransomware Protection Only
Guard Enabled	Whether a GuardPoint is enabled. Value can be Yes or

Column	Description
	No.

Downloading the Report

Download the report as a PDF or CSV document. Based on the displayed columns and applied filters, the downloaded report shows all or some of the columns listed in [Viewing the Report](#).

Reports provide an easy and quick method to answer queries such as:

- How many clients are registered with the CipherTrust Manager?
- What is the health status of clients?
- How many keys are used for protecting data?
- What keys and policies are linked?
- How many GuardPoints are applied on a client?
- What key is used to protect a specific GuardPoint?
- What CTE resources belong to a specific CipherTrust Manager domain?

Use the **Domain Sharing Data** toggle button to include/exclude information about CTE resources shared across domains.

Dashboard

The dashboard on the Reports page shows the following information:

- **TOTAL CLIENTS:** Shows the total count of registered and unregistered clients on the CipherTrust Manager.
- **CTE LICENSES USED:** Shows the count of consumed *CipherTrust Transparent Encryption* licenses out of available licenses.
- **CTE-U LICENSES USED:** Shows the count of consumed *CipherTrust Transparent Encryption for UserSpace* licenses out of available licenses.
- **K8S LICENSES USED:** Shows the count of consumed *CipherTrust Transparent Encryption for Kubernetes* licenses out of available licenses.
- **TOTAL GUARDPOINTS:** Shows the total count of GuardPoints configured on the registered and unregistered clients on the CipherTrust Manager.
- **ACTIVE GUARDPOINTS:** Shows the count of active GuardPoints on the CipherTrust Manager.
- **INACTIVE GUARDPOINTS:** Shows the count of inactive GuardPoints on the CipherTrust Manager.

Download Formats

View the latest CTE reports and download them as PDF and CSV documents on your local machines. The PDF and CSV formats present reports in easy-to-understand tabular forms.

Important Note on CSV Reports

If the names of CTE resources include special characters like equals (=), plus (+), minus (-), at (@), tab (0x09), and carriage return (0x0D), the resources are renamed in the downloaded CSV reports by applying the following rules:

- Every cell is wrapped in double quotes
- Every cell is prepended with a single quote
- Every double quote is escaped using an additional double quote

For example, a resource named `=A+B ' " ; , =C+D` is renamed as `" ' =A+B ' " " ; , =C+D "` in the downloaded CSV report.

To download the GuardPoints Report:

1. Open the Transparent Encryption application.
2. In the left pane, click **Reports**. The Reports page is displayed.
3. Click the **GuardPoints** tab.
4. Download the report:
 - Click **Download CSV** to download the report as a CSV file. The file is named `<DOMAIN>_cte_guardpoints_<TIMESTAMP>.csv`, for example, `root_cte_guardpoints_2021-01-12T07_15_38Z.csv`.
 - Click **Download PDF** to download the report as a PDF file. The file is named `<DOMAIN>_cte_guardpoints_<TIMESTAMP>.pdf`, for example, `root_cte_guardpoints_2021-01-12T07_17_21Z.pdf`.

Note

If the CipherTrust Manager is part of a cluster environment, the filename of the downloaded report (CSV and PDF) will also include the cluster ID.

If the downloaded report is a CSV file, the file will be named `<CLUSTER ID><DOMAIN>_cte_client_health_<TIMESTAMP>.csv`, for example, `51.26.30.11_root_cte_client_health_2021-01-12T06_52_51Z.csv`. The PDF file will also be named in the same way.

The downloaded PDF document shows the **Report Name** as *GuardPoints Report* and time the report is **Generated At**.

Clients GuardPoint Status Report

The Clients GuardPoint Status Report shows the status of GuardPoints applied to the CTE clients available on the CipherTrust Manager. The report also shows the states of the GuardPoints and whether they are enabled or not. You can download the report as a PDF or CSV document, as required. Refer to [Downloading the Report](#).

Use the "Search by" box to search for records in the report by Client Name, Policy Name, or Domain. When searching for records by domain names, specify the complete and exact domain name including case-sensitivity. For example, searching for "test", "test-domain", and "Test-Domain" will return different search results.

Viewing the Report

To view the Clients GuardPoint Status Report:

1. Open the Transparent Encryption application.
2. In the left pane, click **Reports**. The Reports page is displayed.
3. Click the **Clients Guard Status** tab.

The report shows all or some of the following columns:

Column	Description
Domain	Name of the CipherTrust Manager domain to which the record belongs. If the Domain Sharing Data toggle is turned ON, the report displays all the domains where the resource is shared.
Client Name	Name of the client on the CipherTrust Manager.
Policy Name	Name of the applied policy.
Key Name	Name of the key used to protect the GuardPoint.
Guard Path	Path where the GuardPoint is applied.
Guard State	State of the GuardPoint. The state can be: • Active • Inactive • Unknown • Disabled
Guard Enabled	Whether a GuardPoint is enabled. Value can be Yes or No.

Downloading the Report

Download the report as a PDF or CSV document. Based on the displayed columns and applied filters, the downloaded report shows all or some of the columns listed in [Viewing the Report](#).

Reports provide an easy and quick method to answer queries such as:

-
- How many clients are registered with the CipherTrust Manager?
 - What is the health status of clients?
 - How many keys are used for protecting data?
 - What keys and policies are linked?
 - How many GuardPoints are applied on a client?
 - What key is used to protect a specific GuardPoint?
 - What CTE resources belong to a specific CipherTrust Manager domain?

Use the **Domain Sharing Data** toggle button to include/exclude information about CTE resources shared across domains.

Dashboard

The dashboard on the Reports page shows the following information:

- **TOTAL CLIENTS:** Shows the total count of registered and unregistered clients on the CipherTrust Manager.
- **CTE LICENSES USED:** Shows the count of consumed *CipherTrust Transparent Encryption* licenses out of available licenses.
- **CTE-U LICENSES USED:** Shows the count of consumed *CipherTrust Transparent Encryption for UserSpace* licenses out of available licenses.
- **K8S LICENSES USED:** Shows the count of consumed *CipherTrust Transparent Encryption for Kubernetes* licenses out of available licenses.
- **TOTAL GUARDPOINTS:** Shows the total count of GuardPoints configured on the registered and unregistered clients on the CipherTrust Manager.
- **ACTIVE GUARDPOINTS:** Shows the count of active GuardPoints on the CipherTrust Manager.
- **INACTIVE GUARDPOINTS:** Shows the count of inactive GuardPoints on the CipherTrust Manager.

Download Formats

View the latest CTE reports and download them as PDF and CSV documents on your local machines. The PDF and CSV formats present reports in easy-to-understand tabular forms.

Important Note on CSV Reports

If the names of CTE resources include special characters like equals (=), plus (+), minus (-), at (@), tab (0x09), and carriage return (0x0D), the resources are renamed in the downloaded CSV reports by applying the following rules:

- Every cell is wrapped in double quotes

- Every cell is prepended with a single quote
- Every double quote is escaped using an additional double quote

For example, a resource named `=A+B' " ; , =C+D` is renamed as `"' =A+B' '" " ; , =C+D"` in the downloaded CSV report.

To download the Clients GuardPoint Status Report:

1. Open the Transparent Encryption application.
2. In the left pane, click **Reports**. The Reports page is displayed.
3. Click the **Clients Guard Status** tab.
4. Download the report:
 - Click **Download CSV** to download the report as a CSV file. The file is named `<DOMAIN>_cte_clients_gp_status_<TIMESTAMP>.csv`, for example, `root_cte_clients_gp_status_2020-11-30T13_29_25Z.csv`.
 - Click **Download PDF** to download the report as a PDF file. The file is named `<DOMAIN>_cte_clients_gp_status_<TIMESTAMP>.pdf`, for example, `root_cte_clients_gp_status2021-01-12T07_18_55Z.pdf`.

Note

If the CipherTrust Manager is part of a cluster environment, the filename of the downloaded report (CSV and PDF) will also include the cluster ID.

If the downloaded report is a CSV file, the file will be named `<CLUSTER ID><DOMAIN>_cte_client_health_<TIMESTAMP>.csv`, for example, `51.26.30.11_root_cte_client_health_2021-01-12T06_52_51Z.csv`. The PDF file will also be named in the same way.

The downloaded PDF document shows the **Report Name** as *Clients GuardPoint Status Report* and time the report is **Generated At**.

Troubleshooting

This section describes how to handle the issues that you might face when using CTE with the CipherTrust Manager.

Connection Issues

Symptoms	Possible Cause and Remediation
- Client status is Error - Configuration changes are not pushed to the client - Requests like Browse file system are failing	Analyze the CTE logs, identify connection failure reasons, and rectify them: - Look for the issues in the <code>/var/log/vormetric/server_comms.log</code> file on the CTE agent. This file contains information about the CipherTrust Manager's communication with the client. - Identify the cause of the issue. - Restart <code>vmd</code> to get the latest <code>init</code>.
Client status is Error This can occur for CTE clients running version 7.4.0 or lower when a CipherTrust Manager node in a cluster goes down.	With CTE Agent versions 7.4.0 and lower, this issue occurs because they lack the functionality for the default server health check setting (<code>server_response_rate</code> set to 0). This capability was introduced in a later version. Workaround: In the client's profile, change <code>server_response_rate</code> from the default of 0 to a value between 1 and 100 using the <code>/v1/transparent-encryption/profiles/</code> API. This parameter sets a health threshold. For example, a value of 75 means the server is considered healthy if 75% or more of its API calls succeed. If the success rate drops below this threshold, the agent marks the server as unhealthy.

Registration Issues

Symptoms	Possible Cause and Remediation
Registration fails with conflict errors	Conflict errors occur when a client with the given name already exists on the CipherTrust Manager. To fix these issues: - Delete the existing client entry from the CipherTrust Manager. - Unenroll the existing client if you want to register it with another CipherTrust Manager. NOTE: A conflict error might occur even if no CTE client with the given name exists on the CipherTrust Manager. This happens because the client's entry, which was added during registration, is no longer associated with the CTE client due to any failure in enrollment. To resolve this issue: - Run the API <code>/v1/transparent-encryption/clients/delete</code> with the flag <code>delete_stale_clients</code> set to <code>true</code>. DON'T specify any other parameters when running the API. Alternatively, run the command <code>ksctl cte clients bulk-delete --delete-stale-clients true</code> on the CLI. This cleans up the stale client entries. - Retry registration with the same name.

Symptoms	Possible Cause and Remediation
Reregistration fails with capabilities related errors	Capabilities cannot be disabled during reregistration with the CipherTrust Manager. To disable the CTE Agent capabilities, delete the client from the CipherTrust Manager and register again with these capabilities disabled.

Backup and Restore Issues

Symptoms	Possible Cause and Remediation
Reregistration issues after CipherTrust Manager is restored on a new CipherTrust Manager appliance	After the backup of a CipherTrust Manager is restored to another CipherTrust Manager, CTE client reregistration does not work as expected. To work around this issue: 1. Before taking the backup, disable or stop the LDT GuardPoints on the current CipherTrust Manager. 2. Back up the CipherTrust Manager. 3. Restore the backup to another CipherTrust Manager. 4. Unenroll the client using the UnEnroll option on the details view of the Clients page. 5. Reregister the CTE client with the restored CipherTrust Manager.

Licensing Issues

Symptoms	Possible Cause and Remediation
• Registration fails with licensing errors • LDT feature cannot be used • CTE configurations are read-only	Registration can fail if the number of purchased licenses are consumed or the validity of a license is expired. This is applicable for all types of licenses: the base license (CTE - TransparentEncryption), the CTE for Kubernetes license (CTE - KubernetesProtection), and the add-on license (CTE - LiveDataTransformation). • To enable LDT at the time of registration (or later), make sure that you have a valid base license and a valid add-on LDT license. • After a license is expired: – A new client cannot be registered. – Existing operations on registered clients remain in tact. Their existing security configurations are pushed as and when required.

Configuration Issues

Symptoms	Possible Cause and Remediation
Mismatched log levels between the CipherTrust Manager configuration and client logs	Try these: • Check the configuration in the linked profile on the CipherTrust Manager. • Validate the vmd configuration on the CTE client by running: <pre>vmsec vmdconfig</pre>

API Examples

This section provides examples to use different CTE APIs to perform the following tasks:

- [Creating Keys](#)
- [Creating Policy Elements](#)
- [Creating Policies](#)
- [Creating GuardPoints](#)
- [LDT Use Cases](#)

For description of different response codes returned when running CTE APIs, refer to [API Response Codes](#).

Creating Keys

This section describes steps to create an encryption key using the CTE API.

Overview

Keys in a CTE policy must fulfill the following conditions. The keys should:

- Have the **CTE Clients** group permissions
- Be exportable
- Be non-versioned/versioned
- Be of the type "CBC" / "CBC_CS1" or "XTS"

Note

The XTS keys are required for creating GuardPoints with In-place Data Transformation (IDT) policies.

- Have metadata with the following details:

```
{
  "cte": {
    "is_used": <true/false>,
    "cte_versioned": <true/false>,
    "encryption_mode": <"CBC"/"CBC_CS1"/"XTS">,
    "persistent_on_client": <true/false>
  },
  "ownerId": "string",
  "permissions": {
    "ReadKey": [
      "CTE Clients"
    ],
    "ExportKey": [
      "CTE Clients"
    ]
  }
}
```

CTE supports standard, LDT, COS, and IDT policies. Click the following tabs for policy-specific key requirements.

Standard

Keys for Standard Policies

- Standard policies support only non-versioned keys.
- Keys should have the CTE Clients group access.
- CTE Clients group should have the Read Key and Export Key permissions.
- Standard policies support "CBC" / "CBC_CS1" keys.

API

```
/v1/vault/keys2/
```

Sample

```
{
  "name": "Standard_pol_key",
  "algorithm": "aes",
  "size": 256,
  "undeletable": true,
```

```

"unexportable": false,
"meta": {
  "ownerId": "local|f02d8ec9-34dd-42fd-99e7-85cb7f18180c",
  "permissions": {
    "DecryptWithKey": [
      "CTE Clients"
    ],
    "EncryptWithKey": [
      "CTE Clients"
    ],
    "ExportKey": [
      "CTE Clients"
    ],
    "MACVerifyWithKey": [
      "CTE Clients"
    ],
    "MACWithKey": [
      "CTE Clients"
    ],
    "ReadKey": [
      "CTE Clients"
    ],
    "SignVerifyWithKey": [
      "CTE Clients"
    ],
    "SignWithKey": [
      "CTE Clients"
    ],
    "UseKey": [
      "CTE Clients"
    ]
  },
  "cte": {
    "persistent_on_client": true,
    "encryption_mode": "CBC",
    "cte_versioned": false
  }
},
"xts": false
}

```

LDT

Keys for LDT Policies

- LDT policies support only "CBC" and "CBC_CS1" keys.
- Keys should have the CTE Clients group access.
- CTE Clients group should have the Read Key and Export Key permissions.
- LDT policies support only non-versioned keys in the "current_key" field.
- LDT policies support only versioned keys in the "transformation_key" field.

API

```
/v1/vault/keys2/
```

Sample

Click the tabs to view the samples for the current key and transformation key.

Current Key

Sample for the Current Key

```
{
  "name": "LDT_Current_Key",
  "algorithm": "aes",
  "size": 256,
  "undeletable": true,
  "unexportable": false,
  "meta": {
    "ownerId": "local|f02d8ec9-34dd-42fd-99e7-85cb7f18180c",
    "permissions": {
      "DecryptWithKey": [
        "CTE Clients"
      ],
      "EncryptWithKey": [
        "CTE Clients"
      ],
      "ExportKey": [
        "CTE Clients"
      ],
      "MACVerifyWithKey": [
        "CTE Clients"
      ],
      "MACWithKey": [
        "CTE Clients"
      ],
      "ReadKey": [
        "CTE Clients"
      ],
      "SignVerifyWithKey": [
        "CTE Clients"
      ],
      "SignWithKey": [
        "CTE Clients"
      ],
      "UseKey": [
        "CTE Clients"
      ]
    },
    "cte": {
      "persistent_on_client": true,
      "encryption_mode": "CBC",
      "cte_versioned": false
    }
  },
}
```

```
"xts": false
}
```

Transformation Key

Sample for the Transformation Key

```
{
  "name": "LDT_transformation_key",
  "algorithm": "aes",
  "size": 256,
  "undeletable": true,
  "unexportable": false,
  "meta": {
    "ownerId": "local|f02d8ec9-34dd-42fd-99e7-85cb7f18180c",
    "permissions": {
      "DecryptWithKey": [
        "CTE Clients"
      ],
      "EncryptWithKey": [
        "CTE Clients"
      ],
      "ExportKey": [
        "CTE Clients"
      ],
      "MACVerifyWithKey": [
        "CTE Clients"
      ],
      "MACWithKey": [
        "CTE Clients"
      ],
      "ReadKey": [
        "CTE Clients"
      ],
      "SignVerifyWithKey": [
        "CTE Clients"
      ],
      "SignWithKey": [
        "CTE Clients"
      ],
      "UseKey": [
        "CTE Clients"
      ]
    },
    "cte": {
      "persistent_on_client": true,
      "encryption_mode": "CBC",
      "cte_versioned": true
    }
  },
  "xts": false
}
```

COS

Keys for COS Policies

- Keys should have the CTE Clients group access.
- CTE Clients group should have the Read Key and Export Key permissions.
- COS policies support only non-versioned keys.
- COS policies support only "CBC_CS1" keys.

API

```
/v1/vault/keys2/
```

Sample

```
{
  "name": "COS_Key",
  "algorithm": "aes",
  "size": 256,
  "undeletable": true,
  "unexportable": false,
  "meta": {
    "ownerId": "local|f02d8ec9-34dd-42fd-99e7-85cb7f18180c",
    "permissions": {
      "DecryptWithKey": [
        "CTE Clients"
      ],
      "EncryptWithKey": [
        "CTE Clients"
      ],
      "ExportKey": [
        "CTE Clients"
      ],
      "MACVerifyWithKey": [
        "CTE Clients"
      ],
      "MACWithKey": [
        "CTE Clients"
      ],
      "ReadKey": [
        "CTE Clients"
      ],
      "SignVerifyWithKey": [
        "CTE Clients"
      ],
      "SignWithKey": [
        "CTE Clients"
      ],
      "UseKey": [
```

```

    "CTE Clients"
  ]
},
"cte": {
  "persistent_on_client": true,
  "encryption_mode": "CBC_CS1",
  "cte_versioned": false
}
},
"xts": true
}

```

IDT

Keys for IDT Policies

- Keys should have the CTE Clients group access.
- CTE Clients group should have the Read Key and Export Key permissions.
- IDT policies support only the "XTS" encryption mode.
- IDT policies support only non-versioned keys in the "current_key" and "transformation_key" fields.
- IDT policies are used for IDT-capable devices.

API

```
/v1/vault/keys2/
```

Sample

Click the tabs to view the samples for the current key and transformation key.

Current Key

Sample for the Current Key

```

{
  "name": "IDT_Policy_Current_key",
  "algorithm": "aes",
  "size": 256,
  "undeletable": true,
  "unexportable": false,
  "meta": {
    "ownerId": "local|f02d8ec9-34dd-42fd-99e7-85cb7f18180c",
    "permissions": {
      "DecryptWithKey": [
        "CTE Clients"
      ]
    }
  }
}

```

```

    "EncryptWithKey": [
      "CTE Clients"
    ],
    "ExportKey": [
      "CTE Clients"
    ],
    "MACVerifyWithKey": [
      "CTE Clients"
    ],
    "MACWithKey": [
      "CTE Clients"
    ],

      "CTE Clients"
    ],
    "SignWithKey": [
      "CTE Clients"
    ],
    "UseKey": [
      "CTE Clients"
    ]
  },
  "cte": {
    "persistent_on_client": true,
    "encryption_mode": "XTS",
    "cte_versioned": false
  }
},
"xts": true,
"id": "694bf52e-d0c2-4416-b615-feab9ce27940"
}

```

Transformation Key

Sample for the Transformation Key

```

{
  "name": "IDT_Policy_Transformation_Key",
  "algorithm": "aes",
  "size": 256,
  "undeletable": true,
  "unexportable": false,
  "meta": {
    "ownerId": "local|f02d8ec9-34dd-42fd-99e7-85cb7f18180c",
    "permissions": {
      "DecryptWithKey": [
        "CTE Clients"
      ],
      "EncryptWithKey": [
        "CTE Clients"
      ],
      "ExportKey": [
        "CTE Clients"
      ],
    ]
  }
}

```

```

    "MACVerifyWithKey": [
      "CTE Clients"
    ],
    "MACWithKey": [
      "CTE Clients"
    ],
    "ReadKey": [
      "CTE Clients"
    ],
    "SignVerifyWithKey": [
      "CTE Clients"
    ],
    "SignWithKey": [
      "CTE Clients"
    ],
    "UseKey": [
      "CTE Clients"
    ]
  },
  "cte": {
    "persistent_on_client": true,
    "encryption_mode": "XTS",
    "cte_versioned": false
  }
},
"xts": true,
"id": "d32d1b65-5a09-403e-921d-8d1c8db39a75"
}

```

Deleting CTE Keys

- A CTE key cannot be deleted if it is being used in a policy.
- The CTE Admins and Key Admins group permissions are required to delete a CTE key.

API

```
/v1/vault/keys2/{id} [DELETE]
```

Creating Policy Elements

Policy rule criteria consist of resource sets, user sets, signature sets, process sets, action, and effect, and are called policy elements. These elements should exist on the CipherTrust Manager before you can use them in security policies. This section describes steps to create policy elements using the CTE API.

Click the following tabs for details on policy elements.

User Sets

Creating User Sets

- The `name` field is mandatory for creating a user set.
- Any number of users can be added to a single user set.
- Add users by specifying `uname`, `gname`, `uid`, or `gid`.

The following sample creates a user set, `UserSet1` having two users, `user1` and `user2`.

API

```
/v1/transparent-encryption/usersets
```

Sample

```
{
  "name": UserSet1,
  "users": [
    {
      "gid": 1001,
      "gname": "user1",
      "os_domain": "Linux",
      "uid": 1001,
      "uname": "user1"
    },
    {
      "gid": 1002,
      "gname": "user2",
      "os_domain": "Linux",
      "uid": 1002,
      "uname": "user2"
    }
  ]
}
```

Resource Sets

Creating Resource Sets

- The `name` field is mandatory for creating a resource set.
- The `type` field determines the type of the resource set. The type can be `Directory` or `Classification`. The default type is `Directory`.
- Any number of resources can be added to a single resource set.

- Add resources by specifying paths using `directory` and/or `file` fields. For `Directory` type resource sets, you can specify whether to include subdirectories by using `include_subfolders`. Set to `true` to include subdirectories, set to `false` to exclude.
- Set `hdfs` to `true` for an HDFS path.

The following samples create two resource sets, `ResourceSet1` and `ResourceSetHDFS1` of the type `Directory` having two resources.

API

```
/v1/transparent-encryption/resourcesets
```

Sample

```
{
  "name": "ResourceSet1",
  "resources": [
    {
      "directory": "/home/test-user/dir1/",
      "file": "*.txt",
      "include_subfolders": true
    },
    {
      "directory": "/home/test-user/dir2/",
      "file": "*.bin",
      "include_subfolders": true
    }
  ],
  "type": "Directory"
}
```

Sample (HDFS)

```
{
  "name": "ResourceSetHDFS1",
  "resources": [
    {
      "directory": "/home/test-user/dir3/",
      "file": "*.txt",
      "include_subfolders": true,
      "hdfs": true
    },
    {
      "directory": "/home/test-user/dir4/",
      "file": "*.bin",
      "include_subfolders": true,
      "hdfs": true
    }
  ],
  "type": "Directory"
}
```

Signature Sets

Creating Signature Sets

- The **name** field is mandatory for creating a signature set.
- Any number of sources can be added to a single signature set.

The following sample creates a signature set, **SignatureSet1** having a **source_list** of two processes, **/usr/bin** and **/usr/sbin**.

API

```
/v1/transparent-encryption/signaturesets
```

Sample

```
{
  "name": "SignatureSet1",
  "source_list": [
    "/usr/bin",
    "/usr/sbin"
  ]
}
```

Process Sets

Creating Process Sets

- The **name** field is mandatory for creating a process set.
- Any number of processes can be added to a single process set.
- Add processes by specifying their details using **signature**, **directory**, and/or **file**.

The following sample creates a process set, **ProcessSet1** having two processes with their **signature**, **directory**, and process **file** name.

API

```
/v1/transparent-encryption/processsets
```

Sample

```
{
  "name": "ProcessSet1",
```

```

"processes": [
  {
    "signature": "SignatureSet1",
    "directory": "/home/testUser",
    "file": "*"
  },
  {
    "signature": "SignatureSet2",
    "directory": "/home/kyloTest",
    "file": "kylo.bin"
  }
]
}

```

Creating Policies

This section describes steps to create policies using the CTE API. CTE supports Standard, LDT, COS, and IDT policies. Different types of policies can have different types of security and key rule requirements, as described in the sections below. Also, key uses can be different based on the types of policies they are used with. Refer to [Creating Keys](#) for details.

Click the following tabs for policy-specific details, requirements, and samples.

Standard

Creating Standard Policies

A STANDARD policy should contain security rules and/or key rules. At least one of these rules must be added to the standard policy.

The security rules define the access permissions based on the policy elements (user sets, resource set, and process sets). The key rules define what key is used for encryption and decryption of data.

In the following sample, in the security rule:

- All users in the user set "Sample_User_Set1" have read/write access on the processes in the process set "Sample_Process_Set1" and resources in the resource set "Sample_Resource_Set1".
- When a user of "Sample_User_Set1" performs any operation, the policy with the key "Sample_StandardPolicyKey" is applied.

API

```
/v1/transparent-encryption/policies/
```

Sample

```

{
  "never_deny": false,
  "security_rules": [

```

```

    {
      "process_set_id": "Sample_Process_Set1",
      "resource_set_id": "Sample_Resource_Set1",
      "user_set_id": "Sample_User_Set1",
      "exclude_user_set": false,
      "exclude_resource_set": false,
      "exclude_process_set": false,
      "partial_match": true,
      "action": "read,write",
      "effect": "permit,audit,applykey"
    },
    {
      "process_set_id": "",
      "resource_set_id": "",
      "user_set_id": "",
      "exclude_user_set": false,
      "exclude_resource_set": false,
      "exclude_process_set": false,
      "partial_match": true,
      "action": "all_ops",
      "effect": "deny,audit"
    }
  ],
  "policy_type": "Standard",
  "key_rules": [
    {
      "key_id": "Sample_StandardPolicyKey"
    }
  ],
  "name": "Sample_Standard_Policy",
  "description": "This is a sample for a Standard policy."
}

```

LDT

Creating LDT Policies

An LDT policy should contain at least one non-exclusion key rule. The security rules define the access permissions based on the policy elements (user sets, resource set, and process sets).

An LDT policy has two sets of keys, one is the current key and the other is transformation key.

- **Current key:** The key with which the data is encrypted before any transformation. If the data is in plaintext, then the current key should be set as "clear_key".
- **Transformation key:** The key with which the data is to be encrypted. This key must be VERSIONED so that multiple key versions can be created as and when required.

In the following sample, in the security rule:

- All users in the user set "Sample_User_Set1" have "all_ops" access on the processes in the process set "Sample_Process_Set1" and resources in the resource set "Sample_Resource_Set1".
- The key rule indicates that the data on which encryption will be performed is plaintext (the current key as

"clear_key"). The data will be encrypted with the transformation key "Sample_LDTPolicyKey".

API

```
/v1/transparent-encryption/policies/
```

Sample

```
{
  "never_deny": false,
  "security_rules": [
    {
      "action": "key_op",
      "effect": "permit,applykey",
      "type": "default"
    },
    {
      "process_set_id": "Sample_Process_Set1",
      "resource_set_id": "Sample_Resource_Set1",
      "user_set_id": "Sample_User_Set1",
      "exclude_user_set": false,
      "exclude_resource_set": false,
      "exclude_process_set": false,
      "partial_match": true,
      "action": "all_ops",
      "effect": "permit,audit,applykey"
    }
  ],
  "policy_type": "LDT",
  "ldt_key_rules": [
    {
      "is_exclusion_rule": false,
      "current_key": {
        "key_id": "clear_key"
      },
      "transformation_key": {
        "key_id": "Sample_LDTPolicyKey"
      }
    }
  ],
  "name": "Sample_LDT_Policy",
  "description": "This is a sample for an LDT policy."
}
```

COS

Creating COS Policies

A COS policy should contain security rules and/or key rules. At least one of these rules must be added to the COS policy.

The security rules define the access permissions based on the policy elements (user sets, resource set, and process sets). The key rules define what key is used for encryption and decryption of data.

Note

COS policies support the "CBC_CS1" keys only.

In the following sample, in the security rule:

- All users in the user set "Sample_User_Set1" have read/write access on the processes in the process set "Sample_Process_Set1" and resources in the resource set "Sample_Resource_Set1".
- When a user of "Sample_User_Set1" performs any operation, the policy with the key "Sample_COSPolicyKey" is applied.

API

```
/v1/transparent-encryption/policies/
```

Sample

```
{
  "never_deny": false,
  "security_rules": [
    {
      "process_set_id": "Sample_Process_Set1",
      "resource_set_id": "Sample_Resource_Set1",
      "user_set_id": "Sample_User_Set1",
      "exclude_user_set": false,
      "exclude_resource_set": false,
      "exclude_process_set": false,
      "action": "all_ops",
      "effect": "permit,audit,applykey"
    }
  ],
  "policy_type": "Cloud_Object_Storage",
  "key_rules": [
    {
      "key_id": "Sample_COSPolicyKey"
    }
  ],
  "name": "Sample_COS_Policy",
  "description": "This is a sample for a COS policy."
}
```

IDT**Creating IDT Policies**

An IDT policy should contain security rules and/or key rules. At least one of these rules must be added to the standard policy.

The security rules define the access permissions based on the policy elements (user sets, resource set, and process sets). The key rules define what key is used for encryption and decryption of data.

Note

IDT policies support the "XTS" keys only.

In the following sample, in the security rule:

- All users in the user set "Sample_User_Set1" have read/write access on the processes in the process set "Sample_Process_Set1" and resources in the resource set "Sample_Resource_Set1".
- When a user of "Sample_User_Set1" performs any operation, the policy linked with the key "Sample_IDTPolicyKey" is applied.

API

```
/v1/transparent-encryption/policies/
```

Sample

```
{
  "never_deny": false,
  "security_rules": [
    {
      "process_set_id": "Sample_Process_Set1",
      "resource_set_id": "Sample_Resource_Set1",
      "user_set_id": "Sample_User_Set1",
      "exclude_user_set": false,
      "exclude_resource_set": false,
      "exclude_process_set": false,
      "partial_match": true,
      "action": "all_ops",
      "effect": "permit,audit,applykey"
    }
  ],
  "policy_type": "IDT",
  "idt_key_rules": [
    {
      "current_key": "clear_key",
      "transformation_key": "Sample_IDTPolicyKey"
    }
  ],
  "name": "Sample_IDT_Policy",
  "description": "This is a sample for an IDT policy."
}
```

LDT Use Cases

This section describes various LDT scenarios using the CTE APIs.

Suspend/Resume Rekey

The LDT rekey operation can be paused and resumed on the protected LDT clients. Run the `ldtpause` API with `"paused": true` to pause, and `"paused": false` to resume the operation.

API

```
/v1/transparent-encryption/clients/{id}/ldtpause
```

Sample

```
{  
  "paused": <true/false>  
}
```

Key Rotation

On a path guarded using an LDT policy, you can create a new version of the key used for encryption. This triggers the rekey operation on the client for the GuardPath using the rotated key.

API

```
/v1/vault/keys2/{id}/versions
```

Decrypting LDT-protected GuardPoints

This section describes steps to decrypt an LDT-protected GuardPoint using the CTE APIs.

Note

- Reverse migration/decryption is **not** supported for network shares.

To decrypt an LDT-protected GuardPoint:

1. Get the LDT policy currently being used by the GuardPoint.

Run the API

```
get /v1/transparent-encryption/clients/<client-name>/guardpoints
```

Example

```
get /v1/transparent-encryption/clients/ldt-client-name/guardpoints
```

This API returns the list of GuardPoints applied to the client. Copy the value of LDT `"policy_name"` (for example, `ldt-policy`) applied to the desired LDT GuardPoint.

2. Get the key linked to the LDT policy.

Run the API

```
get /v1/transparent-encryption/policies/<ldt-policy-name>/ldtkeyrules
```

Example

```
get /v1/transparent-encryption/policies/ldt-policy/ldtkeyrules
```

This API returns the LDT key rules of the LDT policy. Copy the value of `"key_id"` (for example, `current-key`). This key is used to encrypt the LDT GuardPoint.

3. Clone the current (latest) version of the key to a non-versioned CTE key.

Run the API

```
post /v1/vault/keys2/<current-key-name>/clone
```

Request Parameters

```
{
  "newKeyName": "<clone-key-name>",
  "meta": {
    "cte": {
      "persistent_on_client": true,
      "cte_versioned": false,
      "encryption_mode": "<enc-mode>"
    }
  }
}
```

Note

Make sure that "cte_versioned" is set to false.

Example

```
post /v1/vault/keys2/current-key/clone
{
  "newKeyName": "cloned-key",
  "meta":
  {
    "cte":
    {
      "persistent_on_client":true,
      "cte_versioned":false,
      "encryption_mode":"CBC"
    }
  }
}
```

A new key with the specified name (for example, `cloned-key`) is created with version 0.

4. Create a new LDT policy (for example, `new-ldt-policy`). In "ldt_key_rules", set:
 - The cloned key (`cloned-key`) as the "key_id" for "current_key".
 - `clear_key` as the "key_id" for "transformation_key".

Run the API

```
post /v1/transparent-encryption/policies
```

Request Parameters

```
{
  "name":"<new-ldt-policy-name>",
  "policy_type":"LDT",
  "never_deny":false,
  "security_rules":[
    {
      "effect":"permit,applykey",
      "action":"key_op"
    },
  ],
}
```

```

    {
      "effect": "permit, applykey, audit",
      "action": "all_ops",
      "partial_match": true
    }
  ],
  "ldt_key_rules": [
    {
      "resource_set_id": "<resource-set>",
      "current_key": {
        "key_id": "<clone-key-name>"
      },
      "transformation_key": {
        "key_id": "clear_key"
      }
    }
  ]
}

```

Example

```

post /v1/transparent-encryption/policies
{
  "name": "new-ldt-policy",
  "policy_type": "LDT",
  "never_deny": false,
  "security_rules": [
    {
      "effect": "permit, applykey",
      "action": "key_op"
    },
    {
      "effect": "permit, applykey, audit",
      "action": "all_ops",
      "partial_match": true
    }
  ],
  "ldt_key_rules": [
    {
      "resource_set_id": "",
      "current_key": {
        "key_id": "cloned-key"
      },
      "transformation_key": {

```

```

        "key_id": "clear_key"
      }
    }
  ]
}

```

A new LDT policy with the name `new-ldt-policy` is created.

5. Remove the LDT GuardPoint.

Run the API

```

patch /v1/transparent-encryption/clients/<client-name>/guardpoints/<GuardPoint-resource-id>/unguard/

```

Example

```

patch /v1/transparent-encryption/clients/ldt-client-name/guardpoints/a724ed5d-b5c5-45f3-8b8f-77ec3ec976d1/unguard

```

6. On the CTE client, remove the existing CTE-LDT attributes on the GuardPoint.

Run the Command

```

voradmin ldt attr delete <GuardPoint>

```

Example

```

voradmin ldt attr delete /ldt_path

```

The LDT metadata has been removed from all files in the GuardPoint `/ldt_path`.

7. Create a new GuardPoint for the directory using the new policy.

Run the API

```

post /v1/transparent-encryption/clients/<client-name>/guardpoints

```

Request Parameters

```

{
  "guard_paths": ["/<GuardPath>"],

```

```

    "guard_point_params":
    {
        "is_idt_capable_device":false,
        "guard_point_type":"directory_auto",
        "policy_id":"<new-ldt-policy-name>",
        "preserve_sparse_regions":true
    }
}

```

Example

```

post /v1/transparent-encryption/clients/ldt-client-name/guardpoints
{
    "guard_paths":["/ldt_path"],
    "guard_point_params":
    {
        "is_idt_capable_device":false,
        "guard_point_type":"directory_auto",
        "policy_id":"new-ldt-policy",
        "preserve_sparse_regions":true
    }
}

```

- Wait for the rekey to complete. You can check the rekey status, as described below.

Run the API

```
get /v1/transparent-encryption/clients/<client-name>/guardpoints
```

Example

```
get /v1/transparent-encryption/clients/ldt-client-name/guardpoints
```

When the **"rstatus"** status becomes **"Rekeyed"**, the rekey (decryption) is complete.

Note

- If you have selected **directory_auto**, data transformation begins as soon as the client gets the new policy information from the key manager.
- If you have selected **directory_manual**, use the **secfsd -guard <GuardPoint>** command

on the client to begin data transformation.

9. Remove the GuardPoint. This ensures rekey is no longer triggered for any new data added to the specified GuardPath.

Run the API

```
patch /v1/transparent-encryption/clients/<client-name>/guardpoints/<GuardPoint-resource-id>/unguard/
```

Example

```
patch /v1/transparent-encryption/clients/ldt-client-name/guardpoints/77ec9ec67d3-c5b5-435f-7b8f-a275de45e/unguard
```

Creating GuardPoints

This section describes steps to protect create GuardPoints using the CTE APIs.

To create a GuardPoint:

1. Create keys (non-versioned and/or versioned keys) required for your policy. Standard and COS policies require one key while LDT and IDT policies require two keys. Refer to [Creating Keys](#) for details.
2. Create a policy with the keys created in the previous step. Refer to [Creating Policies](#) for details.
3. Create a GuardPoint using the policy.

Refer to the following sections for the API and sample for creating a GuardPoint. Also, for creating GuardPoints for supported CTE capabilities, refer to [GuardPoint Features](#).

API

```
/v1/transparent-encryption/clients/{clientId}/guardpoints
```

Sample

```
{
  "guard_paths": [
    <GuardPath_Name>
  ],
  "guard_point_params": {
```

```

    "guard_point_type": "directory_auto"/"directory_manual",
    "policy_id": <policy_name>
  }
}

```

Refer to [Creating Policies](#) for information on creating GuardPoints for different policy types.

GuardPoint Features

Depending on the capabilities enabled on the LDT client, you can use Preserve Sparse Region, Secure Start, and LDT over CIFS when creating GuardPoints. The following table lists the platforms and policies they are supported with.

Feature	Supported Platform	Supported Policies
Preserve Sparse Region	Windows, Linux	LDT
Secure Start	Windows	Standard, LDT
LDT over CIFS	Windows	LDT

Click the following tabs for samples to create GuardPoints with these features.

Preserve Sparse Region

The default value is `True`.

Note

The value cannot be changed to `True` if you have set it `False` for a GuardPoint.

```

{
  "guard_paths": [
    <GuardPath_Name>
  ],
  "guard_point_params": {
    "guard_point_type": "directory_auto"/"directory_manual",
    "policy_id": <policy_name>,
    "preserve_sparse_regions": True/False
  }
}

```

Secure Start

```

{
  "guard_paths": [
    <GuardPath_Name>
  ],
  "guard_point_params": {
    "guard_point_type": "directory_auto"/"rawdevice_auto",

```

```

    "policy_id": <policy_name>,
    "early_access": True/False
  }
}

```

LDT over CIFS

```

{
  "guard_paths": [
    <GuardPath_Name>
  ],
  "guard_point_params": {
    "guard_point_type": "directory_auto",
    "policy_id": <policy_name>,
    "cifs_enabled": True/False,
    "network_share_credentials_id":<CIFS connection manager name> (Applicable
if 'cifs_enabled' parameter is TRUE)
  }
}

```

API Response Codes

This section lists the response codes returned by the CTE APIs. The section describes the response codes, corresponding messages, and possible corrective actions to be taken for them.

Clients API

patch /v1/transparent-encryption/clients/{id}/resetpassword

Resets a client's password.

Response Code	Messages	Corrective Actions
400 Bad Request	Client is marked for deletion. Cannot modify CTE Client	Specify a client that is not marked for deletion. The clients marked for deletion cannot be modified.
401 Unauthorised	Unauthorised: Bearer token malformed: Token is expired by 50s	Refresh the authentication token. The current token has expired.
404 Not Found	Resource not found	Specify a valid client ID. A client with the specified ID does not exist.
422 Unprocessable Entity	Client has MANUAL password_creation_method. Cannot generate automatic password	Change the password creation method to MANUAL , and then reset the password.

Client Groups APIs

post /v1/transparent-encryption/clientgroups

Creates a client group.

Response Code	Messages	Corrective Actions
400 Bad Request	Invalid name supplied. The name must consist of alpha-numeric characters; it must start with an alpha character; and the only non-alpha-numeric characters allowed are underscore (_) and dash (-).	Specify a valid client group name.
401 Unauthorized	Unauthorized: Bearer token malformed: Token is expired by 50s	Refresh the authentication token. The current token has expired.
404 Not Found	ClientGroup Profile set Failed: Failed to get CTE profile for ProfileID: <profile-id>. Err: record not found	Specify a valid profile ID.
409 Conflict	Could not create clientgroup as it already exists	Specify a different name for the group. A client group with the specified name already exists.
422 Unprocessable Entity	Validation errors:\ncluster_type: cluster_type is a required field	Specify the cluster type.
422 Unprocessable Entity	Validation errors:\ncluster_type: Key: 'CreateClientGroupParams.cluster_type' Error:Field validation for 'cluster_type' failed on the 'eq=NON-CLUSTER eq=HDFS' tag.	Specify a valid cluster type, NON-CLUSTER or HDFS . The specified cluster type is invalid.

post /v1/transparent-encryption/clientgroups/{id}/clients

Adds a client to a client group.

Response Code	Messages	Corrective Actions
400 Bad Request	Client <client-name> is marked for deletion. Cannot add client to clientgroup. Rejecting complete request	Specify a client that is not marked for deletion. The clients marked for deletion cannot be added to a client group.
401 Unauthorized	Unauthorized: Bearer token malformed: Token is expired by 50s	Refresh the authentication token. The current token has expired.
409 Conflict	Failed to create Client-ClientGroup Association. Error:could not create clientgroupclientassn as it already exists	Ensure that the association of the specified client and the group does not exist. The specified client is already part of the client group.
422 Unprocessable Entity	Failed to get CTE ClientGroup:	Specify a valid client group ID.

Response Code	Messages	Corrective Actions
	record not found	
422 Unprocessable Entity	Failed to get CTE Client: record not found	Specify a valid <code>client_id</code> list.
422 Unprocessable Entity	Validation errors:\nclient_list: client_list must contain at least 1 item	Specify at least one client ID in the <code>client_id</code> list.

How to Configure the External CA for CTE

CipherTrust Transparent Encryption can now use an external certificate, available at a user-defined path, to communicate with CipherTrust Manager.

Prerequisites

- The external certificate must be on the file system and in the PEM format.
- A key pair must already exist for the client and:
 - Must have encryption type of either `sha256WithRSAEncryption` or `ecdsa-with-SHA384`
 - Must be encrypted with a passphrase

Initial Setup

1. Obtain your external CA certificate.
2. Create a certificate using the external CA certificate and key.

CipherTrust Manager Setup

To setup CipherTrust Manager to communicate through an external certificate:

1. Import the CA certificate into the CipherTrust Manager:
 - Navigate to **CA > External > Add External CA**.
 - In the dialog, paste the content of `<ca_certificate_name>.pem` and provide a user-friendly name.

See [Using an Externally Generated Server Certificate for an Interface](#) for more information.
2. Add the CA certificate to trusted sources for the web interface. Go to **Admin Settings > Interfaces > web > Edit > External Trusted CAs**.
3. Restart the web server. Navigate to **Admin Settings > Services > web > Restart**.
4. [Create a Registration Token](#) for the CTE agent.

CTE Agent Setup

1. Create a directory on the system to hold required files, for example:

- Linux/AIX: /root/cert_files
- Windows: c:\temp\cert_files

2. Copy or create the following files in the directory:

- client_cert.pem
- client_key.pem
- passphrase (plain text)

3. (Linux/AIX) Set the environment variable:

```
export EXTERNAL_CERT_DIR=/root/cert_files
```

Registering the Client

- If the agent is installed but registration is pending:
 - Linux/AIX: Run `register_host`
 - Windows: Run `c:\> register_host.exe -extcertdir=c:\temp\cert_files`
- If the agent is not yet installed, and you want to install it and register the client:
 - Linux/AIX: Run `./vee-fs-<release>-<build>-<system>.bin`
 - Windows: Run `c:\> installer.exe -extcertdir=c:\temp\cert_files`

Post Registration

During registration:

1. The certificate file is uploaded to the CipherTrust Manager.
2. The certificate and key files are imported into the CTE PEM store.
3. The key is decoded using the passphrase and re-encoded securely.

After successful registration, the input files should be removed.

Certificate Renewal

- The certificate directory path is stored in `agent.conf` (via `EXTERNAL_CERT_DIR` or `-extcertdir`).
- ~60 days before expiration, CTE agent checks for updated certificate files in this directory.
 - If present, the new certificate is pushed to CipherTrust Manager and applied.
 - If not, a **WARNING** is logged (and/or uploaded to CipherTrust Manager per the logging settings) and retry occurs every 24 hours.

To manually update the certificate set, run the following command. Note that this command does not update the saved path in `agent.conf` for future automatic renewals.

```
vmutil -a vmd -d <ext_cert_Dir> updatecerts
```

If you wish to permanently change the directory path for new certificates, you must update the `EXTERNAL_CERT_DIR` entry in the `agent.conf` file and then restart the `vmd` service.

Note

- If certificate is not updated before expiry, communication may fail and re-registration will be required.
- The renewed certificate must have **exactly the same common name** as the original, or CipherTrust Manager will reject it.

Reference: [Using external certificates for communication between CTE Agent and CipherTrust Manager](#)

How to Change Local CA or External CA for CTE

How to Change Local CA

The CipherTrust Manager allows you to renew the local CA certificates in the certificate chain when they are about to expire.

When a local CA in the certificate chain expires, the entire certificate chain validation fails.

In such scenarios, the user has to create a new CA and renew the client/server certificates or both using the new CA.

When to Renew

To avoid any service downtime, it is recommended to prepare the new Local CA certificate chain in advance before the CA expiration. During the overlapping period, the new server certificate chain as described in the below section should be downloaded and added to the trust store in the client's setup.

How to Renew on the Web Console UI

The CA certificate chain renewal process contains the following steps:

1. Create a new local CA using the same attributes as an existing CA.
2. Renew server certificates issued by the original local CA.

Create a New Local CA Using the Same Attributes as Existing CA

1. Log on to CipherTrust Manager as a user in the Admins group, such as **admin**.
2. Navigate to **CA > Local**.
3. In the **Local Certificate Authorities** table, find the local CA to copy attributes from. Click the corresponding overflow icon (ellipsis) and select **Renew**.

A CSR with the same attributes as the local CA is present in the **Pending CAs** table.

Sign the CSR to Make the New Local CA Active

- **Self-sign:**
 - a. Find the desired CSR in the Pending CAs table.
 - b. Click the overflow icon and select **Self-sign**.
 - c. Set a **Duration (days)**. Default is 365.

Caution

When a CA expires, all the certificates it has issued also expire. If you use a Local CA for client and server certificates that access CipherTrust Manager, you must replace the certificate chain across multiple interfaces and clients before the Local CA expires to maintain communication. When setting the CA duration, consider how often your organization is prepared to perform this maintenance.

- d. Click **Save**. The new Local CA appears in the table.

- **Sign with an Existing Local CA:**
 - a. Find the desired CSR in the Pending CAs table.
 - b. Copy or download the CSR.
 - a. Click the overflow icon.

-
- b. Select either of the following:
 - **Copy CSR** to copy the CSR contents to the clipboard.
 - **Download CSR** to download the CSR as a file.
 - c. In the Local Certificate Authorities table, find the signing CA and click its name.
 - d. Click **Upload CSR** and:
 - a. Specify the **Display name** for the new CA.
 - b. In the **CSR** field, paste CSR text.
 - c. Choose **CA** as Certificate Purpose.
 - e. Set the **Duration in days** before the new CA will expire.

Caution

When a CA expires, all the certificates it has issued also expire. If you use a Local CA for client and server certificates that access CipherTrust Manager, you must replace the certificate chain across multiple interfaces and clients before the Local CA expires to maintain communication. When setting the CA duration, consider how often your organization is prepared to perform this maintenance.

- f. Click **Issue Certificate**.
- g. Copy or download the new CA certificate.
 - a. Find the new CA certificate in the **Certificates issued by** table.
 - b. Click the corresponding overflow icon.
 - c. Select either **Copy** to copy the CA certificate contents to the clipboard, or **Download** to download the CA certificate as a file.
- h. Return to **CA > Local**, locate the CSR in the **Pending CAs** table, click the corresponding overflow icon, and select **Install**.
- i. Choose **Local CA** as Parent CA Type.
- j. From the **Select Local Parent CA** drop-down, select the local CA that signed the CA certificate.
- k. Paste certificate text in the **Certificate** field.
- l. Click **Save**.

▪ Sign with an External CA:

- a. Make sure the external CA is added via **CA > External**. An external CA must exist on this page. If no external CA exists, add one.
- b. Navigate to **CA > Local**.
- c. Find the desired CSR in the Pending CAs table.
- d. Copy or download the CSR.
 - a. Click the overflow icon.
 - b. Select either of the following:
 - **Copy CSR** to copy the CSR contents to the clipboard.
 - **Download CSR** to download the CSR as a file.
- e. Sign the CSR *externally*, then retain the signed certificate.

Caution

When a CA expires, all the certificates it has issued also expire. If you use a Local CA for client and server certificates that access CipherTrust Manager, you must replace the certificate chain across multiple interfaces and clients before the Local CA expires to maintain communication. When setting the CA duration, consider how often your organization is prepared to perform this maintenance.

- f. Return to **CA > Local**, find the CSR in the Pending CAs table, click the corresponding overflow icon, and select **Install**.
- g. Choose **External CA** as Parent CA Type.
- h. From the **Select External Parent CA** drop-down, select the external CA that signed the CA certificate.
- i. Paste certificate text in the **Certificate** field.
- j. Click **Save**.

The new local CA is now created and visible in the Local Certificate Authorities table. Note down the CA's name for renewing certificates.

Renew Server Certificate Using New Local CA

1. Issue a new server certificate from the new CA. See [Issuing Certificate Signed by Local CA](#) for details.
 2. Create a certificate chain in PEM or PKCS12 format with the following in the given order:
-

-
- a. Server certificate
 - b. Intermediate CAs (in hierarchy order). Start with the intermediate CA that issued the server certificate. Next, add the issuer of the intermediate CA, if any. Continue adding any intermediate CAs higher up the hierarchy, each time adding the issuer of the last certificate you uploaded.
 - c. Intermediate CAs, ordered from the one that signed the server certificate up to the one signed by the root CA.
 - d. Root CA

Note

In PEM format, include the server certificate's private key first. In PKCS#12 format, include it last.

3. Upload the chain on CipherTrust Manager's [interface](#) associated with the clients.
 - a. Log on to CipherTrust Manager as a user in the Admins group, such as [admin](#).
 - b. Go to **Admin Settings > Interfaces**.
 - c. In the table, find the interface associated with the clients.
 - Most clients authenticate to the web interface.
 - NAE clients authenticate to the original nae interface, or additional NAE interfaces created later.
 - KMIP clients authenticate to the original kmip interface, or additional KMIP interfaces created later.
 - d. Upload the renewal certificate. See [Upload renewal server certificate](#) for details.

For clients, the uploaded certificate chain is available for [download](#).

4. Add the downloaded certificate to the client trust store.

Now, the clients can use this new chain to set up their environment.

5. (Optional) After the clients have been updated with the new certificate chain, [apply](#) the new certificate chain on CipherTrust Manager. This immediately replaces the existing server certificates with the newly generated server certificates.

If not applied manually, the new certificate chain will auto-apply when the CA expires.

See [Renewing Local CA certificate](#) for details.

How to Change External CA

To use an external CA as a trusted entity:

1. Log on to CipherTrust Manager as a user in the Admins group, such as **admin**.
2. Navigate to **CA > External**.
3. Click **+ Add External CA**.
4. Specify a Display Name.
5. Specify a certificate (upload or paste).
 - Upload: Select **File Upload > Upload Certificate** to upload the certificate file.
 - Paste: Select **Text** and paste the certificate content in the text field.
6. Click **Add External CA**.

See [Adding an External CA](#) for details.

How to Renew the Client Certificates

Renewing the Local CA

Client certificates are automatically renewed starting 60 days before expiration. The agent retries daily until successful.

You can also renew the client certificates manually:

- **Linux:** `./vmutil -a vmd renewcerts`
- **Windows:** `vmutil -a vmd renewcerts` (`vmutil` is located at `C:\Program Files\Vormetric\DataSecurityExpert\agent\vmd\bin`)

Renewing the External CA

Client certificates from an external CA are not automatically renewed. To renew:

1. Place the new certificate and key files in the designated folder on the client.
2. Run the following command:
 - **Linux:** `./vmutil -a vmd updatecerts`
 - **Windows:** `vmutil -a vmd updatecerts` (`C:\Program Files\Vormetric\DataSecurityExpert\agent\vmd\bin`)

CipherTrust Batch Data Transformation

Secure Static Data Masking

Static Data Masking

Static Data Masking refers to the process of transforming selected data in various data stores to unreadable or unusable forms, typically order to utilize data sets while preventing misuse of sensitive data.

CipherTrust Batch Data Transformation offers high-performance static data masking with centralized encryption key management as part of the [CipherTrust Data Security Platform](#). It leverages the power of [CipherTrust Application Data Protection](#) and [CipherTrust Tokenization](#) to protect vast quantities of data quickly. It also can be used as a high-performance encryption or tokenization solution for compliance.

The breadth of use cases for static data masking is surprisingly large. These first four begin with “masking sensitive data”:

1. Prior to third-party data sharing
2. In databases shared with development, QA, R&D, or data science/analytics teams
3. Before adding a data set to a data lake or big data environment
4. In advance of starting big data extract, transform and load (ETL) operations

Batch Data Transformation has many other use cases beyond Static Data Masking. Here are a couple of examples:

- Preparing a database for tokenization or encryption deployment
- Rekeying data in a database following a new key version or key rotation

Key Advantages

Secure, cost-effective static data masking

Not every static data masking solution is secure. With Batch Data Transformation, you can depend on the security of centralized key management provided by [CipherTrust Manager](#), which can provide up to FIPS 140-2 Level 3 key security. Meanwhile, every investment in the Data Security Platform makes it more valuable to you.

Accelerate Transformation of Existing Sensitive Data

Following deployment and execution of [CipherTrust Data Discovery and Classification](#), you can protect sensitive information in database columns quickly and efficiently using either encryption or tokenization with minimal disruption, effort and cost.

Enable database sharing with reduced risk

Static data masking enables you to remove sensitive information before sharing with third-party developers and big data environments while maintaining data integrity and still supporting mission-critical testing and analytical activities.

Static Data Masking where you need it

Batch Data Transformation and its data protection tools are all software and completely cloud friendly. You can mask data on premises and use it in the cloud, mask data in the cloud and use it there, or secure data in one cloud and use it in another.

The CipherTrust Data Security Platform provides a wide range of data protection capabilities from on-premises to cloud, enabling secure digital transformations.

Batch Data Transformation Key Features

Efficient and Flexible Encryption

Large volumes of data are encrypted quickly with Batch Data Transformation in conjunction with CipherTrust Application Data Protection installed on the same server. Policy files define encryption options including standard AES encryption or format preserving encryption, while identifying the database columns to be protected and the number of records in each batch. Data filtering enables creation of customized destination record subsets.

Batch Data Transformation offers a choice in encryption “operating modes”:

- Encryption keys provided by CipherTrust Manager are cached on the Batch Data Transformation server where encryption occurs
- Encryption operations can occur on CipherTrust Manager. This mode is available for the highest security transformation environments where there is a requirement to retain the key in the key source

Flexible Tokenization

An alternative to encryption in Batch Data Transformation is tokenization. Batch Data Transformation can utilize the CipherTrust Tokenization Server to tokenize select database columns. Detokenization is supported so that applications can access the clear data again when required, or, irreversible tokenization can ensure that third parties never gain access to original sensitive data.

Flexible Conversion Between Data Stores

CipherTrust Batch Data Transformation can protect data while it is moving, for example, from a database to various flat file formats or in reverse. CipherTrust Batch Data Transformation supports:

- Flat-file (CSV) to flat-file
- Flat-file to Database
- Database to flat-file
- Database to Database

Supported databases include

- Oracle
- Microsoft SQL Server
- Oracle MySQL
- IBM DB2
- SAP HANA

Transformation from a source database is read-only, so production databases may be used transparently.

CipherTrust Data Security Platform

CipherTrust Tokenization is part of the CipherTrust Data Security Platform, which unifies data discovery, classification, data protection, and unprecedented granular access controls, all with centralized key management. This simplifies data security operations, accelerates time to compliance, secures cloud migrations and reduces risk across your business. You can rely on Thales CipherTrust Data Security Platform to help you discover, protect and control your organization's sensitive data

About Thales

The people you rely on to protect your privacy rely on Thales to protect their data. When it comes to data security, organizations are faced with an increasing number of decisive moments. Whether the moment is building an encryption strategy, moving to the cloud, or meeting compliance mandates, you can rely on Thales to secure your digital transformation.

Decisive technology for decisive moments.

CipherTrust Batch Data Transformation (BDT)

Version: v3.0.0 (latest)

30 January 2026

Administration

CipherTrust Batch Data Transformation (BDT) is a high-performance, scalable, and containerized data security solution designed to securely process large volumes of sensitive data in bulk. It leverages advanced protection mechanisms, such as encryption, tokenization, and data masking, ensuring that sensitive information is protected across various files and databases.

BDT integrates seamlessly with [Application Data Protection](#) on CipherTrust Manager, enabling organizations to centrally configure, manage, and enforce data-centric cryptographic policies and job configurations in a reusable, human-readable format, providing flexibility and ease of management. Jobs can be initiated directly from CipherTrust Manager, where users can also monitor the intermediate status of the data transformation process.

BDT offers flexibility in how data is processed, allowing transformations either in place (within the same location) or by generating transformed data in a separate file or database. This adaptability makes it an ideal solution for organizations looking to securely manage and transform large-scale sensitive data, ensuring both scalability and efficiency.

Specifications

Supported Transformations

BDT supports the following transformations:

Database to database (DB-to-DB)

Protects, reveals, or reprotects the data of a database table and move it to another database. Multiple tables can be transformed in a single execution. You can choose table columns and specify what action needs to be performed on a particular column.

Database to file (DB-to-File)

Protects, reveals, or reprotects the data of a database table and move it to another file. You can choose table columns and specify what action needs to be performed on a particular column.

File to database (File-to-DB)

Protects, reveals, or reprotects the data of a file and move it to another database. You can choose file columns and specify what action needs to be performed on a particular column.

File to file (File-to-File)

Protects, reveals, or reprotects the data of a file and move it to another file. You can choose file columns and specify what action needs to be performed on a particular column.

In-Place Transformation

BDT also supports **In-Place Transformation**, where the *source and destination tables are same and transformation takes place within the same table of the database*. This transformation is only applicable to database. For In-Place transformation to work, a **Primary Key column** must be available in the table.

For SQL Server, primary key should be a non-clustered index key.

Supported File Formats

BDT accepts the input and output files in the following formats:

- CSV
- Fixed-length format

Supported Databases

- MySQL
- Oracle
- IBM Db2
- SAP HANA
- Microsoft SQL Server
- PostgreSQL

For supported database versions, refer to [Release Notes](#).

Supported Algorithms

- FPE/AES
- FPE/FF1v2
- FPE/FF3
- FPE/FF3-1
- AES/CBC/NoPadding
- AES/CBC/PKCS5Padding
- AES/ECB/NoPadding
- AES/ECB/PKCS5Padding
- AES/GCM (Support available in CipherTrust Manager 2.22 and higher versions)

Supported Operations

- Protect

-
- Reveal
 - Reprotect

Licensing

BDT is licensed per deployed instance. Licenses for BDT are part of the Flex Connector Premium. Refer to [Batch Data Transformation Licensing Model](#) for details.

Quick Start

This section describes how to get BDT up and running in less than 10 minutes using a Helm Chart. Refer to [Alternative Deployment Methods](#) for instructions on deployment as a standalone container or deployment without a Helm Chart.

Prerequisites

- Kubernetes environment is up and running and kubectl is installed.
- Helm is installed. Refer to <https://helm.sh/docs/intro/install/> for details.
- CipherTrust Manager 2.19 or higher is up and running. Refer to [CipherTrust Manager Deployment](#) for details.
- Docker hub must be accessible.
- BDT image repository, [thalesciphertrust/ciphertrust-batch-data-transformation](#), is accessible. This repository contains images for BDT. The image path with the **latest** tag always points to the latest release.

Note

- The instructions provided in this section are for deploying BDT in the default namespace.
- The user is responsible for maintaining the **security of their deployment environment**.
- This sample values are enclosed within `< >`, for example, `<target_directory>`. Replace these values with the actual values per your environment.

Following section provides instructions for deploying BDT within the Kubernetes Pod for both **File-to-File** and **DB-to-DB** transformations. Click the tab of your choice.

DB-to-DB

Steps for DB-to-DB

1. Create a BDT application from the **Application Data Protection** tile on CipherTrust Manager. Click the desired tab to view the instructions.
-

GUI

To create an application from CipherTrust Manager's UI, follow this [link](#).

The application is created on the CipherTrust Manager and a registration token is returned in response. This token is passed in the deployment scripts to register BDT client on the CipherTrust Manager as shown in the below steps.

API

API: `/v1/data-protection/client-profiles`

Request

```
{
  "name": "client_profile_bdt",
  "app_connector_type": "BDT",
  "heartbeat_threshold": 5,
  "configurations":

  {

    "log_level": "WARN",

    "thread_count": 1,
    "batch_size": 1000,
  }
}
```

```

    "enable_performance_metrics": true,
    "tls_to_appserver": {
      "tls_skip_verify": true,
      "tls_enabled": false
    },
    "auth_method_used": {
      "scheme_name": "Basic"
    },
    "symmetric_key_cache_enabled": true,
    "symmetric_key_cache_expiry": 43200,
    "size_of_connection_pool": 300,
    "load_balancing_algorithm": "round-robin",
    "connection_timeout": 30000,
    "connection_read_timeout": 7000,
    "connection_idle_timeout": 600000,
    "connection_retry_interval": 600000,
    "maximum_idle_connection": 10000,
    "maximum_idle_connection_per_host": 10000,
    "dial_timeout": 10,
    "dial_keep_alive": 60,
    "log_level": "WARN",
    "log_rotation": "Daily",
    "log_size_limit": "100K",
    "log_max_backup_index": -1,
    "log_type": "Console",
    "log_gmt": false,
    "heartbeat_interval": 300,
    "heartbeat_timeout_count": 5
  },
  "csr_parameters": {
    "csr_cn": "Application Data Protection"
  },
  "ca_id": "04d7f146-684b-47a2-a2c2-e8690be50e18",
  "enable_client_autorenewal": false,
  "client_management_profile_id": "0a3b495c-26c2-4a1a-a722-f46bec47e
689",
  "registration_token_id": "0850f54a-dc42-4f3e-a2d3-0b49e19c5ece",
  "meta": {
    "has_active_clients": false,
    "status": "Healthy"
  }
}

```

In response, a *registration token* is returned. The registration token is passed in the deployment script to

register BDT client on the CipherTrust Manager as shown in the below steps.

2. Download and copy the following files:

- `deployment.yaml` to `<target_directory>/templates`.

Warning

The `deployment.yaml` file should not be modified.

- `values.yaml` to `<target_directory>`.
- `Chart.yaml` to `<target_directory>`.

3. Navigate to the `<target_directory>`.

Before proceeding to the next step, we recommend reviewing the concept of [environment variables](#). While the variable names may differ, their purpose and usage remain consistent.

4. In the `values.yaml` file, update the following values:

- `kmsHost`: IP address of your CipherTrust Manager instance.
- `regToken`: Registration token generated on the CipherTrust Manager.
- `dbCertValue`: **(Optional)** Certificate value required for SSL connection with databases.
- `jdbcDriverDownloadUrl`: **(Optional)** URL or location from where BDT will download/load the driver jars required for JDBC connection.

5. Deploy the BDT application in your Kubernetes environment. This section uses `bdt` as the release name.

- When you are in the `<target_directory>`, run the below command:

```
helm install bdt .
```

- When you are in some other directory, run the below command:

```
helm install bdt <target_directory>
```

Note

Here, `<target_directory>` is the location where you have kept all the configuration files.

The status `DEPLOYED` indicates a successful deployment.

Verify the deployment

1. List the deployed BDT pods.

```
kubectl get pods
```

The output should list the deployed BDT pod.

2. Test your deployment.

```
curl -X GET http://<node ip>:32082/liveness
```

Replace `<node ip>` with the actual IP address of your Kubernetes node where the BDT pod is deployed.

Additional commands

- To get the IP address of your Kubernetes node, you can run the following command.

```
kubectl get nodes -o wide
```

- To fetch BDT logs, run the following command.

```
kubectl logs -f <bdp pod name>
```

Sample Transformation

This section explains how to perform a **db-to-db** transformation, demonstrated using an Oracle database. The high-level steps include:

- Creating data source
- Creating access policy
- Creating protection policy
- Creating job configuration

- Running job
- Viewing job status

Tip

The transformation steps provided in this example can be performed using the CipherTrust Manager UI or API playground.

Create data source

Here, we are using the option where the source and destination data-sources are same.

GUI

To create a data source from CipherTrust Manager's UI, follow this [link](#).

API

API: `post /v1/data-protection/data-sources`

Create source data-source

Request

```
{
  "name": "Oracle_ds1",
  "description": "",
  "type": "Oracle",
  "database_properties": {
    "password": "asdf1234",
    "username": "USER5",
    "connection_url": "jdbc:oracle:thin:@<db_host_ip>:orcl",
  }
}
```

Response

```
{
  "id": "17a6f8d0-5db4-4435-984f-fc2a5dbac72e",
  "uri": "kylo:kylo:adp-management:data-sources:oracle_ds1-17a6f8d0-5db4-4435-984f-fc2a5dbac72e",
  "account": "kylo:kylo:admin:accounts:kylo",
  "createdAt": "2025-07-08T03:27:35.049159948Z",
  "updatedAt": "0001-01-01T00:00:00Z",
  "name": "Oracle_ds1",
  "description": "",
  "type": "Oracle",
}
```

```
"database_properties": {
  "connection_url": "jdbc:oracle:thin:@<db_host_ip>:orcl",
}
```

In response, ID of *source data-source* (17a6f8d0-5db4-4435-984f-fc2a5dbac72e) is returned.

Create access policy

GUI

To create access policy from CipherTrust Manager's UI, follow this [link](#).

API

API: `post /v1/data-protection/access-policies`

API Request

```
{
  "name": "ap",
  "description": "access policy description",
  "default_reveal_type": "Plaintext",
  "default_error_replacement_value": "",
  "user_set_policy": [
    {
      "user_set_id": "39738cd0-c7f9-4450-99ea-96b5257d0700",
      "reveal_type": "Plaintext"
    }
  ]
}
```

API Response

```
{
  "id": "396eb554-d167-46f4-a8a5-8a2c9a99648d",
  "uri": "kylo:kylo:adp-management:access-policies:ap-396eb554-d167-46f4-a8a5-8a2c9a99648d",
  "account": "kylo:kylo:admin:accounts:kylo",
  "createdAt": "2025-07-08T04:28:18.702065393Z",
  "updatedAt": "2025-07-08T04:28:18.706185882Z",
  "created_by": "local|5bb48a34-b391-4886-8f7c-31f7ac6f2fd9",
  "name": "ap1",
  "description": "access policy description",
  "default_reveal_type": "Plaintext",
  "default_error_replacement_value": "",
  "default_masking_format_id": null,
  "user_set_policy": [
    {
      "user_set_id": "39738cd0-c7f9-4450-99ea-96b5257d0700",
```

```

        "reveal_type": "Plaintext",
        "error_replacement_value": null,
        "masking_format_id": null
    },
    ],
    "version": 1
}

```

In response, ID of *access policy* (396eb554-d167-46f4-a8a5-8a2c9a99648d) is returned.

Create protection policy

When creating protection policy, the key should exist on the CipherTrust Manager, if it does not exist, create one following the instructions mentioned [here](#).

Note

Ensure the key used in protection policy has correct permissions. For more details on key permissions, refer to [Supported key types](#).

The protection policy will be created with the following specifications:

- **Algorithm:** AES/CBC/PKCS5Padding
- **Versioning:** Internal

GUI

To create protection policy from CipherTrust Manager's UI, follow this [link](#).

API

API: `post /v1/data-protection/protection-policies`

API Request

```

{
  "name": "ppinternal1",
  "key": "bdtkey",
  "algorithm": "AES/CBC/PKCS5Padding",
  "use_external_versioning": false,
  "access_policy_name": "ap"
}

```

API Response

```

{

```

```

    "id": "9b2237ea-315f-4e20-96e6-38e6be76cb8c",
    "uri": "kylo:kylo:adp-management:protection-policies:ppinternal1-9b2237ea-315f-4e20-96e6-38e6be76cb8c",
    "account": "kylo:kylo:admin:accounts:kylo",
    "createdAt": "2025-07-08T03:37:39.934151665Z",
    "updatedAt": "2025-07-08T03:37:39.920679472Z",
    "name": "ppinternal1",
    "version": 1,
    "latest_version": true,
    "key": "bdtkey",
    "algorithm": "AES/CBC/PKCS5Padding",
    "use_external_versioning": false,
    "disable_versioning": false,
    "access_policy_name": "ap"
  }

```

In response, ID of *protection policy* (9b2237ea-315f-4e20-96e6-38e6be76cb8c) is returned.

Create job configuration

Here, we are creating a job configuration to protect *latitude* using the protection policy *ppinternal1*. Similarly, you can also reveal and reprotect any columns by changing the operation type as required.

GUI

To create job configuration from CipherTrust Manager's UI, follow this [link](#).

API

API: `post /v1/data-protection/bdt/job-configurations`

API Request

```

{
  "name": "ora-ora-pr",
  "source_id": "17a6f8d0-5db4-4435-984f-fc2a5dbac72e",

        "order_by": "",
        "order": "ASC",
        "filters": null
      },
      "columns": [
        {
          "id": "0ce7ebf9-e6ac-44d9-bd96-29838fa632a9",
          "uri": "kylo:kylo:adp-management:bdp-job-configurations-tables-columns:0ce7ebf9-e6ac-44d9-bd96-29838fa632a9",
          "account": "kylo:kylo:admin:accounts:kylo",
          "createdAt": "2025-07-08T03:40:23.803205011Z",
          "updatedAt": "2025-07-08T03:40:23.801725918Z",
          "source_column_name": "latitude",
          "operation": "protect",
          "protection_policy": "ppinternal1"
        }
      ]
    }
  ],
  "meta": {
    "job_running": false
  }
}
```

In response, ID of the job configuration (f448f111-adeb-46e1-ad56-d9d67e723e27) is returned.

Run job

Here, we will run the job by passing the job configuration ID (generated in [Create job configuration](#)) and client profile ID (generated in step 1) in the API request. To run a job, at least **one healthy BDT client** must be registered with the application.

GUI

To run a job from CipherTrust Manager's UI, follow this [link](#).

API

There is slight difference in the Run Job API call depending on the CipherTrust Manager version you are using. Choose the preferred tab to view the details.

API call in CM 2.19

API: `post /v1/data-protection/run-job`

API Request

```
{
  "job_configuration_id": "f448f111-adeb-46e1-ad56-d9d67e723e27",
  "client_profile_id": "9f3edcb1-38e8-4bc7-8c41-99e897560328"
}
```

API Response

```
{
  "job_status_id": "29994ae1-acd0-415b-bf92-a23cf68a3fb8"
}
```

In response, a job status ID (29994ae1-acd0-415b-bf92-a23cf68a3fb8) is returned, use this ID to check the intermediate status of the job.

API call in CM 2.20 and higher versions

API: `post /v1/data-protection/bdt/job-configurations/{id}/run`

API Request

```
post /v1/data-protection/bdt/job-configurations/{f448f111-adeb-46e1-ad56-d9d67e723e27}/run
{ "client_profile_id": "9f3edcb1-38e8-4bc7-8c41-99e897560328" }
```

API Response

```
{
  "job_status_id": "29994ae1-acd0-415b-bf92-a23cf68a3fb8"
}
```

In response, a job status ID (29994ae1-acd0-415b-bf92-a23cf68a3fb8) is returned, use this ID to check the intermediate status of the job.

Check job status

Here, you will check the status of the job by passing the job status ID generated in [above step](#) in the API request.

GUI

To run a job from CipherTrust Manager's UI, follow this [link](#).

API

There is slight difference in the Job Status API call depending on the CipherTrust Manager version you are using. Choose the preferred tab to view the details.

API call in CM 2.19

API: `get /v1/data-protection/job-status/{id}`

API Request

```
{
  /v1/data-protection/job-status/{29994ae1-acd0-415b-bf92-a23cf68a3fb8}
}
```

In response, information about the job in various stages, total number of records processed, error messages are returned.

API call in CM 2.20 and higher versions

API: `get /v1/data-protection/jobs/{id}`

API Request

```
/v1/data-protection/jobs/29994ae1-acd0-415b-bf92-a23cf68a3fb8
```

In response, information about the job in various stages, total number of records processed, error messages are returned.

Verify results

After the job status gets completed, Check the destination table, *EXPORT20* for transformed data. The column

named *latitude* will contain the protected data as shown here:

Input Data	Protected Data
latitude	latitude
38.631913	1002008eb.QbvK1B
38.478902	1002008bX.lyin02
38.618305	1002008Oq.238Xpk
38.616835	10020088g.ZnhFEO
38.51947	1002008zQ.9RjXy
38.662595	1002008qg.xrjv8K
38.681659	1002008Ns.Sz5Hc6
38.535092	1002008kl.Elfmor
38.621188	1002008Qq.elSZHs
38.700909	1002008NT.QXs6S8
38.637663	1002008IG.f1U4xg
38.470746	1002008j4.qQLRIV

In the output, you can see that the version header is prepended to the ciphertext (1002008eb.QbvK1B).

File-to-File

Steps for File-to-File

1. Create a BDT application from the **Application Data Protection** tile on CipherTrust Manager. Click the desired tab to view the instructions.

GUI

To create an application from CipherTrust Manager's UI, follow this [link](#).

The application is created on the CipherTrust Manager and a registration token is returned in response. This token is passed in the deployment scripts to register BDT client on the CipherTrust Manager as shown in the below steps.

API

API: `/v1/data-protection/client-profiles`

Request

```
{
  "name": "client_profile_bdt",
  "app_connector_type": "BDT",
  "heartbeat_threshold": 5,
  "configurations":
```

```
{
  "log_level": "WARN",
  "heartbeat_interval": 300,
  "heartbeat_timeout_count": 5,
  "thread_count": 1,
  "batch_size": 1000
}
```

Response

```
{
  "id": "9f3edcb1-38e8-4bc7-8c41-99e897560328",
  "uri": "kylo:kylo:adp-management:client-profiles:client-profile-bd

  "updatedAt": "2025-03-24T03:26:15.949341161Z",
  "name": "client_profile_bdt",
  "app_connector_type": "BDT",
  "configurations": {
    "thread_count": 1,
    "batch_size": 1000,
    "enable_performance_metrics": true,
    "tls_to_appserver": {
      "tls_skip_verify": true,
      "tls_enabled": false
    },
    "auth_method_used": {
      "scheme_name": "Basic"
    },
    "symmetric_key_cache_enabled": true,
    "symmetric_key_cache_expiry": 43200,
    "size_of_connection_pool": 300,
    "load_balancing_algorithm": "round-robin",
    "connection_timeout": 30000,
    "connection_read_timeout": 7000,
    "connection_idle_timeout": 600000,
    "connection_retry_interval": 600000,
    "maximum_idle_connection": 10000,
    "maximum_idle_connection_per_host": 10000,
  }
}
```

```

        "dial_timeout": 10,
        "dial_keep_alive": 60,
        "log_level": "WARN",
        "log_rotation": "Daily",
        "log_size_limit": "100K",
        "log_max_backup_index": -1,
        "log_type": "Console",
        "log_gmt": false,
        "heartbeat_interval": 300,
        "heartbeat_timeout_count": 5
    },
    "csr_parameters": {
        "csr_cn": "Application Data Protection"
    },
    "ca_id": "04d7f146-684b-47a2-a2c2-e8690be50e18",
    "enable_client_autorenewal": false,
    "client_management_profile_id": "0a3b495c-26c2-4a1a-a722-f46bec47e
689",
    "registration_token_id": "0850f54a-dc42-4f3e-a2d3-0b49e19c5ece",
    "meta": {
        "has_active_clients": false,
        "status": "Healthy"
    }
}

```

In response, a *registration token* is returned. The registration token is passed in the deployment script to register BDT client on the CipherTrust Manager as shown in the below steps.

2. Download and copy the following files:

- `deployment.yaml` to `<target_directory>/templates`.

Warning

The `deployment.yaml` file should not be modified.

- `values.yaml` to `<target_directory>`.
- `Chart.yaml` to `<target_directory>`.

3. Navigate to the `<target_directory>`.

Before proceeding to the next step, we recommend reviewing the concept of *environment variables*.

While the variable names may differ, their purpose and usage remain consistent.

4. In the `values.yaml` file, update the following values:

- `kmsHost` is the IP address of your CipherTrust Manager instance.
- `regToken` is the registration token generated on the CipherTrust Manager.
- `volumeHostPath` is the location of the directory on the host machine where input file exists. In this sample we are using the same path for generating output file. If required, you can mount different paths.
- `volumeMountPath` is the path of directory inside the BDT container to be mounted to the `volumeHostPath`.

Caution

Volume mounting is mandatory in the following cases during deployment to allow BDT to read or create a file.

- When using file as source/destination
- When configuring unprocessed record file path
- When loading the JDBC driver from the host machine

Use `/opt/app/tmp/` to map the external volume with container. Ensure the BDT container has permission to read, write, and execute on the mounted volume else, **the deployment will fail**.

5. Deploy the BDT application in your Kubernetes environment. This section uses `bdt` as the release name.

- When you are in the `<target_directory>`, run the below command:

```
helm install bdt .
```

- When you are in some other directory, run the below command:

```
helm install bdt <target_directory>
```

Note

Here, `<target_directory>` is the location where you have kept all the configuration files.

The status `DEPLOYED` indicates a successful deployment.

Verify the deployment

1. List the deployed BDT pods.

```
kubectl get pods
```

The output should list the deployed BDT pod.

2. Test your deployment.

```
curl -X GET http://<node ip>:32082/liveness
```

Replace `<node ip>` with the actual IP address of your Kubernetes node where the BDT pod is deployed.

Additional commands

- To get the IP address of your Kubernetes node, you can run the following command.

```
kubectl get nodes -o wide
```

- To fetch BDT logs, run the following command.

```
kubectl logs -f <bdp pod name>
```

Sample Transformation

This section explains how to perform a File-to-File transformation, demonstrated using a CSV file. The high-level steps include:

- Creating data source
- Creating access policy
- Creating protection policy
- Creating job configuration
- Running job
- Viewing job status

Tip

The transformation steps provided in this example can be performed using the CipherTrust Manager UI or API playground.

Important Points

- We have provided the following sample files with this example.
 - **Input.csv:** Contains the data to be processed. Download and save this file on the host machine specified during volume mapping when deploying BDT.
 - **Output.csv:** Contains the processed data. This file will get created on the host machine specified during volume mapping when deploying BDT.
- Column of the `input.csv` file that to be protected: *latitude*.

Create data source**GUI**

To create a data source from CipherTrust Manager's UI, follow this [link](#).

API

API: `post /v1/data-protection/data-sources`

Create source data-source**Request**

```
{
  "name": "sourcefile",
  "description": "source details",
  "type": "CSV File",
  "file_properties":
    {"file_path": "/opt/app/tmp/input/inputProtect.csv", "delimiter": ",", "column_count": 12, "has_header_row": true}
}
```

Response

```
{
  "id": "5c22a447-f8dd-4c4c-af7d-149123ecf974",
  "uri": "kylo:kylo:adp-management:data-sources:sourcefile-5c22a447-f8dd-4c"
```

```

4c-af7d-149123ecf974",
  "account": "kylo:kylo:admin:accounts:kylo",
  "createdAt": "2025-03-20T11:08:05.940999Z",
  "updatedAt": "0001-01-01T00:00:00Z",
  "name": "sourcefile",
  "description": "source details",
  "type": "CSV File",
  "file_properties": {
    "file_path": "/opt/app/tmp/input/input.csv",
    "delimiter": ",",
    "qualifier": "\"",
    "column_count": 12,
    "has_header_row": true,
    "encoding": null,
    "record_length": null,
    "line_separator": null
  }
}

```

In response, ID of *sourcefile* (5c22a447-f8dd-4c4c-af7d-149123ecf974) is returned.

Create destination data-source

Request

```

{
  "name": "destinationfile",
  "description": "destination details",
  "type": "CSV File",
  "file_properties": {
    "file_path": "/opt/app/tmp/output/outputProtect-2025-03-26.10.35.15.348.csv",
    "delimiter": ",",
    "column_count": 12,
    "has_header_row": true
  }
}

```

Response

```

{
  "id": "9b9520e2-2d86-46bd-a615-375b689ee03b",
  "uri": "kylo:kylo:adp-management:data-sources:destinationfile-9b9520e2-2d86-46bd-a615-375b689ee03b",
  "account": "kylo:kylo:admin:accounts:kylo",
  "createdAt": "2025-03-20T10:56:19.706092Z",
  "updatedAt": "0001-01-01T00:00:00Z",
  "name": "destinationfile",
  "description": "destination details",
  "type": "CSV File",
  "file_properties": {
    "file_path": "/opt/app/tmp/output/output.csv",
    "delimiter": ",",
    "qualifier": "\"",
    "column_count": 12,
    "has_header_row": true,
    "encoding": null,

```

```

    "record_length": null,
    "line_separator": null
  }
}

```

In response, ID of *destinationfile* (9b9520e2-2d86-46bd-a615-375b689ee03b) is returned.

Create access policy

GUI

To create access policy from CipherTrust Manager's UI, follow this [link](#).

API

API: `/v1/data-protection/access-policies`

Request

```

{
  "name": "access_policy",
  "description": "access policy ",
  "default_reveal_type": "Plaintext"
}

```

Response

```

{
  "id": "24e1f7eb-63a8-4b9f-abc3-0295098ad98f",
  "uri": "kylo:kylo:adp-management:access-policies:access-policy-24e1f7eb-63a8-4b9f-abc3-0295098ad98f",
  "account": "kylo:kylo:admin:accounts:kylo",
  "createdAt": "2025-03-18T11:30:54.511291Z",
  "updatedAt": "2025-03-18T11:30:54.513016Z",
  "created_by": "local|238dfbe5-dff4-4c56-8474-480fb3c51701",
  "name": "access_policy",
  "description": "",
  "default_reveal_type": "Plaintext",
  "default_error_replacement_value": "",
  "default_masking_format_id": null,
  "user_set_policy": [],
  "version": 1
}

```

In response, ID of the access policy (24e1f7eb-63a8-4b9f-abc3-0295098ad98f) is returned.

Create protection policy

When creating protection policy, the key should exist on the CipherTrust Manager, if it does not exist, create one following the instructions mentioned [here](#).

Note

Ensure the key used in protection policy has correct permissions. For more details on key permissions, refer to [Supported key types](#).

The protection policy will be created with the following specifications:

- **Algorithm:** FPE/FF1v2
- **Versioning:** Internal version
- **Character set:** Alphanumeric

GUI

To create protection policy from CipherTrust Manager's UI, follow this [link](#).

API

API: `post /v1/data-protection/protection-policies`

API Request

```
{
  "name": "fpeProtectionPolicy",
  "description": "FPE protection policy",
  "key": "aakey",
  "algorithm": "FPE/FF1v2/UNICODE",
  "tweak": "121212121212",
  "tweak_algorithm": "SHA1",
  "character_set_id": "2d00cfdb-c422-46ac-8a05-6152806a5715",
  "access_policy_name": "access_policy"
}
```

API Response

```
{
  "id": "ed2efc0b-bf78-4b0f-bb0a-2077475fe5ba",

    "prefix": "",
    "data_format": "",
    "nonce": "",
    "tag_length": 0,
    "allow_small_input": true
  }
}

```

In response, ID of protection policy (ed2efc0b-bf78-4b0f-bb0a-2077475fe5ba) is returned.

Create job configuration

Here, we are creating a job configuration to protect column *latitude* using the protection policy *fpeProtectionPolicy*. Similarly, you can also reveal and reprotect any columns by changing the operation type as required.

GUI

To create job configuration from CipherTrust Manager's UI, follow this [link](#).

API

API: `post /v1/data-protection/bdt/job-configurations`

API Request

```

{
  "name": "job configuration for file",
  "in_place_update": false,
  "source_id": "5c22a447-f8dd-4c4c-af7d-149123ecf974",

    ]
  },
  "meta": {
    "job_running": false
  }
}

```

In response, ID of the job configuration (142b84d8-22ba-4b66-8fec-16076911ec7a) is returned.

Tip

Multiple columns can be configured in a single job configuration, and each column can be associated with different protection policies.

Run job

Here, we will run the job by passing the job configuration ID (generated in above step) and client profile ID (generated in step 1) in the API request. To run a job, at least **one healthy BDT client** must be registered with the application.

GUI

To run a job from CipherTrust Manager's UI, follow this [link](#).

API

There is slight difference in the Run Job API call depending on the CipherTrust Manager version you are using. Choose the preferred tab to view the details.

API call in CM 2.19

API: `post /v1/data-protection/run-job`

API Request

```

{
  "job_configuration_id": "142b84d8-22ba-4b66-8fec-16076911ec7a",
  "client_profile_id": "9f3edcb1-38e8-4bc7-8c41-99e897560328"
}

```

API Response

```

{ "job_status_id": "a960a20c-4852-4fee-a18b-302710f67170" }

```

In response, a job status ID (a960a20c-4852-4fee-a18b-302710f67170) is returned, use this ID to check the intermediate status of the job.

API call in CM 2.20 and higher versions

API: `post /v1/data-protection/bdt/job-configurations/{id}/run`

API Request

```
post /v1/data-protection/bdt/job-configurations/{142b84d8-22ba-4b66-8fec-16076911ec7a}/run
{ "client_profile_id": "9f3edcb1-38e8-4bc7-8c41-99e897560328" }
```

API Response

```
{ "job_status_id": "a960a20c-4852-4fee-a18b-302710f67170" }
```

In response, a *job_status_id* (a960a20c-4852-4fee-a18b-302710f67170) is returned. Use this ID to check the status of the job.

Check job status

Here, you will check the status of the job by passing the job status ID (generated in above step) in the API request.

GUI

To run a job from CipherTrust Manager's UI, follow this [link](#).

API

There is slight difference in the Job Status API call depending on the CipherTrust Manager version you are using. Choose the preferred tab to view the details.

API call in CM 2.19

API: `get /v1/data-protection/job-status/{id}`

Pass the *job_status_id* (generated in step 5) in the API request.

API Request

```
{
/v1/data-protection/job-status/{a960a20c-4852-4fee-a18b-302710f67170}
}
```

In response, information about the job in various stages, total number of records processed, error messages are returned.

API call in CM 2.20

API: `get /v1/data-protection/jobs/{id}`

Pass the `job_status_id` (generated in step 5) in the API request.

API Request

```
/v1/data-protection/jobs/a960a20c-4852-4fee-a18b-302710f67170
```

In response, information about the jobs in various stages, total number of records processed, error messages are returned.

Verify results

After the job status gets completed, Check the [Output.csv](#) for transformed data.

Note

For transformations, where destination is file, the output file name (provided on UI) will also contain a timestamp appended to it. For example, `<output-name-as-per-ui>-2025-04-01.17.57.01.521.csv`

- For CSV file, the output file will be formatted as: `<file-name>-<timestamp>.csv`
- For fixed length file, the output file will be formatted as: `<file-name>-<timestamp>.txt`

In the **Input.csv** file, the *latitude* column was in plaintext, after transformation, the data is in ciphertext.

Before Transformation	After Transformation
latitude	latitude
38.631913	1002008eb.QbvK1B
38.478902	1002008bX.lyin02
38.618305	1002008Oq.238Xpk
38.616835	10020088g.ZnhFEO
38.51947	1002008zQ.9RjXy
38.662595	1002008qg.xrjv8K
38.681659	1002008Ns.Sz5Hc6
38.535092	1002008kl.Elfmor
38.621188	1002008Qq.elSZHs
38.700909	1002008NT.QXs6S8
38.637663	1002008IG.f1U4xg
38.470746	1002008j4.qQLRIV

In the output, you can see that the version header is prepended to the ciphertext (1002008eb.QbvK1B).

Alternative Deployment Methods

This section offers the following alternative deployment methods for BDT:

- [Deploy BDT in Kubernetes Environment \(without Helm Chart\)](#)
- [Deploy BDT as a Standalone Container](#)

Deploy BDT in Kubernetes Environment (without Helm Chart)

This section describes steps to deploy BDT in a Kubernetes pod without using a Helm Chart.

Tip

You can use any orchestration tool for deployment.

Prerequisites

- Kubernetes environment is up and running and kubectl is installed.
- CipherTrust Manager 2.19 or higher is up and running. Refer to [CipherTrust Manager Deployment](#) for details.
- BDT image repository, [thalesciphertrust/ciphertrust-batch-data-transformation](#), is accessible. This repository contains images for BDT. The image path with the **latest** tag always points to the latest release.

Note

The user is responsible for maintaining the **security of their production environment**.

Steps to Deploy BDT within your Kubernetes Pod

1. Create an BDT application on CipherTrust Manager. Click the desired tab to view the instructions.

GUI

To create an application from CipherTrust Manager's UI, follow this [link](#).

The application is created on the CipherTrust Manager and a registration token is returned in response. This token is passed in the deployment scripts to register BDT client on the CipherTrust Manager as shown in the below steps.

API

API: `/v1/data-protection/client-profiles`

Request

```
{
  "name": "client_profile_bdt",
  "app_connector_type": "BDT",
  "heartbeat_threshold": 5,
  "configurations":
  {
    "log_level": "INFO",
    "heartbeat_interval": 30,
    "heartbeat_timeout_count": 3,
    "thread_count": 2,
    "batch_size": 10
  }
}
```

Response

```
{
  "id": "9f3edcb1-38e8-4bc7-8c41-99e897560328",
  "uri": "kylo:kylo:adp-management:client-profiles:client-profile-bd

    "connection_timeout": 30000,
    "connection_read_timeout": 7000,
    "connection_idle_timeout": 600000,
    "connection_retry_interval": 600000,
    "maximum_idle_connection": 10000,
    "maximum_idle_connection_per_host": 10000,
    "dial_timeout": 10,
    "dial_keep_alive": 60,
    "log_level": "INFO",
    "log_rotation": "Daily",
    "log_size_limit": "100K",
    "log_max_backup_index": -1,
    "log_type": "Console",
    "log_gmt": false,
    "heartbeat_interval": 30,
    "heartbeat_timeout_count": 3
},
"csr_parameters": {
    "csr_cn": "Application Data Protection"
},
"ca_id": "04d7f146-684b-47a2-a2c2-e8690be50e18",
"enable_client_autorenewal": false,
"client_management_profile_id": "0a3b495c-26c2-4a1a-a722-f46bec47e
689",
"registration_token_id": "0850f54a-dc42-4f3e-a2d3-0b49e19c5ece",
"meta": {
    "has_active_clients": false,
    "status": "Healthy"
}
}

```

In response, a *registration token* is returned. The registration token is passed in the deployment script to register BDT client on the CipherTrust Manager as shown in the below steps.

2. Create the secret using the following command.

```
kubectl create secret generic <bdt secret name> --from-literal=regtoken=<registration token>
```

3. Create a deployment file, for example, `<bdt-deployment.yaml>` with the following content.

```
apiVersion: apps/v1
kind: Deployment
metadata:
  name: bdt-deployment
  labels:
    app: bdt
spec:
  replicas: 1
  selector:
    matchLabels:
      app: bdt
  template:
    metadata:
      labels:
        app: bdt
    spec:
      containers:
        - name: bdt-container
          image: <bdt-image-name>
          imagePullPolicy: IfNotPresent
          env:
            - name: KMS_HOST
              value: "<key manager ip>"
            - name: REG_TOKEN
              valueFrom:
                secretKeyRef:
                  name: <bdt secret name>
                  key: regtoken
          volumeMounts:
            - mountPath: <container mount path>
              name: bdt-volume
      volumes:
        - name: bdt-volume
          hostPath:
            path: <host path to mount>
            type: Directory
```

Note

- The <container mount path> should exist inside the container's home directory (/opt/app/tmp/). For example, <container mount path> can be /opt/app/tmp/input/ for input files. Similarly, volumes for output and unprocessed record files can also be mapped.
- To run database-related transformations, you might need to configure more environment variables, click [here](#) for details.

Caution

Volume mounting is mandatory in the following cases during deployment to allow BDT to read or create a file.

- When using file as source/destination
- When configuring unprocessed record file path
- When loading the JDBC driver from the host machine

Use /opt/app/tmp/ to map the external volume with container. Ensure the BDT container has permission to read, write, and execute on the mounted volume else, **the deployment will fail**.

4. Apply the deployment configuration.

```
kubectl apply -f <bdtd-deployment.yaml>
```

5. Create a service to expose the BDT pod, for example, <bdtd-service.yaml> with the following content.

```
apiVersion: v1
kind: Service
metadata:
  name: bdt-service
  labels:
    app: bdt
spec:
  selector:
    app: bdt
  type: NodePort
  ports:
```

```
- port: 8080
  nodePort: 32085
```

6. Apply the service configuration.

```
kubectl apply -f <bdt-service.yaml>
```

7. Check whether your deployment is ready.

```
kubectl get deployments
```

8. Verify the deployment.

```
curl -X GET http://<node ip>:32085/liveness
```

The following response indicates a successful deployment.

```
{
  "status": "OK"
}
```

BDT is now deployed successfully and is ready to protect, reveal, and reprotect data. Refer to [Tasks](#) for details.

Deploy BDT as a Standalone Container

This article covers the steps involved in deploying BDT as a standalone container in Docker. Refer to [Alternative Deployment Methods](#) for other methods of deploying BDT.

Prerequisites

- Docker Container Runtime Environment (CRE) is ready.
- Docker version 24.0.1 or higher is installed.
- CipherTrust Manager 2.19 or higher is up and running. Refer to [CipherTrust Manager Deployment](#) for details.
- BDT image repository, [thalesciphertrust/ciphertrust-batch-data-transformation](#), is accessible. This repository contains images of BDT. The image path with the **latest** tag always points to the latest release.

Note

The user is responsible for maintaining the **security of their production environment**.

Steps to Deploy BDT as Standalone Container

1. Create an BDT application on CipherTrust Manager. Click the desired tab to view the instructions.

GUI

To create an application from CipherTrust Manager's UI, follow this [link](#).

The application is created on the CipherTrust Manager and a registration token is returned in response. This token is passed in the deployment scripts to register BDT client on the CipherTrust Manager as shown in the below steps.

API

API: `/v1/data-protection/client-profiles`

Request

```
{
  "name": "client_profile_bdt",
  "app_connector_type": "BDT",
  "heartbeat_threshold": 5,
  "configurations":
  {
    "log_level": "INFO",
    "heartbeat_interval": 30,
    "heartbeat_timeout_count":3,
    "thread_count": 2,
    "batch_size": 10
  }
}
```

Response

```
{
```

```

    "id": "9f3edcb1-38e8-4bc7-8c41-99e897560328",
    "uri": "kylo:kylo:adp-management:client-profiles:client-profile-bd
t-9f3edcb1-38e8-4bc7-8c41-99e897560328",
    "account": "kylo:kylo:admin:accounts:kylo",
    "createdAt": "2025-03-24T03:26:15.949341161Z",
    "updatedAt": "2025-03-24T03:26:15.949341161Z",
    "name": "client_profile_bdt",
    "app_connector_type": "BDT",
    "configurations": {
      "thread_count": 2,
      "batch_size": 10,
      "enable_performance_metrics": true,
      "tls_to_appserver": {
        "tls_skip_verify": true,
        "tls_enabled": false
      },
      "auth_method_used": {
        "scheme_name": "Basic"
      },
      "symmetric_key_cache_enabled": true,
      "symmetric_key_cache_expiry": 43200,
      "size_of_connection_pool": 300,
      "load_balancing_algorithm": "round-robin",
      "connection_timeout": 30000,
      "connection_read_timeout": 7000,
      "connection_idle_timeout": 600000,
      "connection_retry_interval": 600000,
      "maximum_idle_connection": 10000,
      "maximum_idle_connection_per_host": 10000,
      "dial_timeout": 10,
      "dial_keep_alive": 60,
      "log_level": "INFO",
      "log_rotation": "Daily",
      "log_size_limit": "100K",
      "log_max_backup_index": -1,
      "log_type": "Console",
      "log_gmt": false,
      "heartbeat_interval": 30,
      "heartbeat_timeout_count": 3
    },
    "csr_parameters": {
      "csr_cn": "Application Data Protection"
    },
    "ca_id": "04d7f146-684b-47a2-a2c2-e8690be50e18",

```

```

        "enable_client_autorenewal": false,
        "client_management_profile_id": "0a3b495c-26c2-4a1a-a722-f46bec47e
689",
        "registration_token_id": "0850f54a-dc42-4f3e-a2d3-0b49e19c5ece",
        "meta": {
            "has_active_clients": false,
            "status": "Healthy"
        }
    }
}

```

In response, a *registration token* is returned. The registration token is passed in the deployment script to register BDT client on the CipherTrust Manager as shown in the below steps.

2. Pull the BDT image to the container environment as shown below:

```
docker pull thalesciphertrust/ciphertrust-batch-data-transformation:latest
```

3. Create a **docker-compose.yml** file by copying the following content. You can modify the parameters as needed:

```

services:

  bdt:
    container_name: bdt
    volumes:
      - <host_location_for_input>:/opt/app/tmp/<subdirectory_for_input>
      - <host_location_for_output>:/opt/app/tmp/<subdirectory_for_output>
    image: <bdt_image_name>
    ports:
      - "<host_port>:8080"
    environment:
      KMS_HOST: "<kms_host>"
      KMS_PORT: "443"
      REG_TOKEN: "<registration_token>"

```

Note

The BDT container listens for healthz and liveness probes on port 8080.

You can also download the [docker-compose.yml](#) file modify according to your needs.

Here,

- `<host_port>`: Any available port on the host machine.
- `<kms_host>`: The IP address or host name of the key manager.
- `<bdtd_image_name>`: Name of the BDT image pulled.
- `<registration_token>`: Registration token generated [here](#).
- `<host_location_for_input>`: Location of the directory on the host machine where input file exists.
- `<host_location_for_output>`: Location of the directory on the host machine where output file exists.

Note

Similarly, you can also map the location of the directory for unprocessed record file.

- `<subdirectory_for_input>`: Directory location inside the container where `<host_location_for_input>` will be mounted. This location must reside inside the `/opt/app/tmp` path of the **container**. Use this location in the **File Path** field with input file name when [creating data source](#).
- `<subdirectory_for_output>`: Directory location inside the container where `<host_location_for_output>` will be mounted. This location must reside inside the `/opt/app/tmp` path of the **container**. Use this location in the **File Path** field with output file name when [creating data source](#).

To run database-related transformations, you will need to configure different environment variables in your deployment files, click [here](#) for details.

Caution

Volume mounting is mandatory in the following cases during deployment to allow BDT to read or create a file.

- When using file as source/destination
- When configuring unprocessed record file path
- When loading the JDBC driver from the host machine

Use `/opt/app/tmp/` to map the external volume with container. Ensure the BDT container has permission to read, write, and execute on the mounted volume else, **the deployment will fail**.

4. Run the below command from the location where you have downloaded the `docker-compose.yml` file to bring the BDT container up and running.

```
docker compose up
```

5. Run the following command to stop the BDT container.

```
docker compose down
```

Verify your deployment

Run the following command to verify your deployment:

```
curl <BDT instanceip>:<host_port>/healthz
```

Replace `<BDT instanceip>` and `<host_port>` with the actual values from your BDT deployment.

BDT is now deployed successfully and is ready to protect, reveal, and reprotect data. Refer to [Tasks](#) for details.

Transformation Process

This section outlines the complete transformation process for data source types — Files and Databases. The transformation can include protect, reveal, or reprotect operation.

- The protect operation protects the plaintext data and returns the ciphertext based on the protection policy selected in the job configuration.
- The reveal operation returns the output based on the default reveal format configured in access policy.
- The reprotect operation protects the plaintext data with the latest version of the protection policy and returns the ciphertext based on the protection policy selected in the job configuration.

Prerequisites

- BDT application must be registered on the CipherTrust Manager. Refer to [Quick Start](#) for details.
- BDT must be deployed. Refer to [Quick Start](#) for details.
- A compatible CipherTrust Manager must be up and running. Refer to [CipherTrust Manager Deployment](#) for

details.

Steps

Tip

The transformation steps provided in this example can be performed using the CipherTrust Manager UI or API playground.

1. Create source and destination data-sources. A data source is required to specify the details of input and output data sources that are part of the transformation process. The data source can be database or file.

GUI

To create a data source from CipherTrust Manager's UI, follow this [link](#).

API

`/data-protection/data-sources`

- a. Access the API playground.
- b. In the left pane of the API playground, click **Data Protection**.
- c. Under **Data Sources**, click **Create**. The Create section of the API playground is displayed in the right pane.
- d. In the body field, specify required parameters with their values.

Expand schema under the body field for names and types of fields. Hover your mouse over each field to view its description. The parameter names and casing in the body field must match with those shown in the schema. Also, ensure that parameters and their values are specified in double quotes.

- e. Click **POST**.
2. Create access policy. The access policies contain set of rules that govern how the protected data will be revealed to users.

GUI

To create access policy from CipherTrust Manager's UI, follow this [link](#).

API

`/data-protection/access-policies`

- a. Access the API playground.

-
- b. In the left pane of the API playground, click **Data Protection**.
 - c. Under **Access Policies**, click **Create**. The Create section of the API playground is displayed in the right pane.
 - d. In the body field, specify required parameters with their values.

Expand schema under the body field for names and types of fields. Hover your mouse over each field to view its description. The parameter names and casing in the body field must match with those shown in the schema. Also, ensure that parameters and their values are specified in double quotes.

- e. Click **POST**.
3. Create protection policy. A protection policy defines a set of rules that govern the cryptographic operations. The protection policy includes entities such as algorithm, key, IV, access policy name, and character set.

GUI

To create protection policy from CipherTrust Manager's UI, follow this [link](#).

API

`data-protection/protection-policies`

- a. Access the API playground.
- b. In the left pane of the API playground, click **Data Protection**.
- c. Under **Protection Policies**, click **Create**. The Create section of the API playground is displayed in the right pane.
- d. In the body field, specify required parameters with their values.

Expand schema under the body field for names and types of fields. Hover your mouse over each field to view its description. The parameter names and casing in the body field must match with those shown in the schema. Also, ensure that parameters and their values are specified in double quotes.

- e. Click **POST**.
4. Create job configuration. A job configuration is required to specify details about the data to be transformed and the destination where the transformed data will be stored.

GUI

To create job configuration from CipherTrust Manager's UI, follow this [link](#).

API

`/data-protection/bdt/job-configurations`

- a. Access the API playground.
- b. In the left pane of the API playground, click **Data Protection**.
- c. Under **BDT Job Configurations**, click **Create**. The Create section of the API playground is displayed in the right pane.
- d. In the body field, specify required parameters with their values.
 - To protect, select **operation** type as **protect**.
 - To reveal, select **operation** type as **reveal**.
 - To reprotect, select **operation** type as **reprotect**.

Tip

Multiple columns can be configured in a single job configuration, and each column can be associated with different protection policies.

Expand schema under the body field for names and types of fields. Hover your mouse over each field to view its description. The parameter names and casing in the body field must match with those shown in the schema. Also, ensure that parameters and their values are specified in double quotes.

- e. Click **POST**.
5. Run job. To run a job, at least one **active client must be registered with the application**.

GUI

To run a job from CipherTrust Manager's UI, follow this [link](#).

API

```
data-protection/bdt/job-configurations/{id}/run
```

- a. Access the API playground.
- b. In the left pane of the API playground, click **Data Protection**.
- c. Under **BDT Job Configurations**, click **Run Job**. The Create section of the API playground is displayed in the right pane.
- d. In the body field, specify required parameters with their values.

Expand schema under the body field for names and types of fields. Hover your mouse over each field to view its description. The parameter names and casing in the body field must match with those shown in

the schema. Also, ensure that parameters and their values are specified in double quotes.

- e. Click **POST**.
6. Check status of the job. The job status provides the information about the various stages of jobs, total number of records processed, error messages, and so on.

GUI

To run a job from CipherTrust Manager's UI, follow this [link](#).

API

```
/data-protection/jobs/{id}
```

- a. Access the API playground.
- b. In the left pane of the API playground, click **Data Protection**.
- c. Under **Jobs**, click **get**. Enter the query parameters with which you want to filter the jobs.
- d. Click **GET**.

Verify Results

After the job status gets completed, Check the destination data data-source for transformed data.

Note

- For transformations, where *destination is file*, the output file name (provided on UI) will also contain a timestamp appended to it. For example, <output-name-as-per-ui>-2025-04-01.17.57.01.521.csv
 - For CSV file, the output file will be formatted as: <file-name>-<timestamp>.csv
 - For fixed length file, the output file will be formatted as: <file-name>-<timestamp>.txt
- For *database and file related transformation*, if you have configured **Unprocessed Record File Path**, the *unprocessed record file* will be created with the following formats:
 - Database: <job_id>-<source_table>-<timestamp>.txt
 - File: <job_id>-<timestamp>.txt

Tasks

This section describes BDT tasks:

- [How to protect data](#)
- [How to reveal data](#)
- [How to reprotect data](#)
- [Change key manager](#)
- [Change application](#)
- [View logs in Kubernetes environment](#)
- [Monitor BDT health](#)
- [Renew client certificate](#)

How to protect data

This section outlines the complete File-to-File transformation process for CSV files. The example provided here demonstrates how to protect data of a CSV file. The protect operation protects the plaintext data and returns the ciphertext based on the protection policy selected in the job configuration. The protection policy provides different functionalities as described [here](#); the output will change according to these functionalities.

Important Points

- We have provided the following sample files with this example.
 - [Input.csv](#): Contains the data to be processed. Download and save this file on the host machine specified during volume mapping when deploying BDT.
 - [Output.csv](#): Contains the processed data. This file will get created on the host machine specified during volume mapping when deploying BDT.
- Column of the `input.csv` file that to be protected: *latitude*.
- Type of protection policy used: Internal version.
- Algorithm: FPE/FF1v2.
- Character set: Alphanumeric.

Prerequisites

- BDT application must be registered on the CipherTrust Manager. Refer to [Quick Start](#) for details.

- BDT must be deployed. Refer to [Quick Start](#) for details.
- A compatible CipherTrust Manager must be up and running. Refer to [CipherTrust Manager Deployment](#) for details.

Steps

The transformation steps provided in this example can be performed using the [CipherTrust Manager UI](#) or [API playground](#).

1. Create source and destination data-sources. The source data-source contains the data to be processed while the destination data-source will store the processed data.

API

API: `post /v1/data-protection/data-sources`

Create source data-source

Request

```
{
  "name": "sourcefile",
  "description": "source details",
  "type": "CSV File",
  "file_properties":
    {
      "file_path": "/opt/app/tmp/input/inputProtect.csv", "delimiter": ",",
      "column_count": 12, "has_header_row": true
    }
}
```

Response

```
{
  "id": "5c22a447-f8dd-4c4c-af7d-149123ecf974",
  "uri": "kylo:kylo:adp-management:data-sources:sourcefile-5c22a447-f8dd-4c4c-af7d-149123ecf974",
  "account": "kylo:kylo:admin:accounts:kylo",
  "createdAt": "2025-03-20T11:08:05.940999Z",
  "updatedAt": "0001-01-01T00:00:00Z",
  "name": "sourcefile",
  "description": "source details",
  "type": "CSV File",
  "file_properties": {
```

```

        "file_path": "/opt/app/tmp/input/input.csv",
        "delimiter": ",",
        "qualifier": "\"",
        "column_count": 12,
        "has_header_row": true,
        "encoding": null,
        "record_length": null,
        "line_separator": null
    }
}

```

In response, ID of *sourcefile* (5c22a447-f8dd-4c4c-af7d-149123ecf974) is returned.

Create destination data-source

Request

```

{
  "name": "destinationfile",
  "description": "destination details",
  "type": "CSV File",
  "file_properties":
    {
      "file_path": "/opt/app/tmp/output/outputProtect-2025-03-26.10.35.15.348.csv",
      "delimiter": ",",
      "column_count": 12,
      "has_header_row": true
    }
}

```

Response

```

{
  "id": "9b9520e2-2d86-46bd-a615-375b689ee03b",
  "uri": "kylo:kylo:adp-management:data-sources:destinationfile-9b9520e2-2d86-46bd-a615-375b689ee03b",
  "account": "kylo:kylo:admin:accounts:kylo",
  "createdAt": "2025-03-20T10:56:19.706092Z",
  "updatedAt": "0001-01-01T00:00:00Z",
  "name": "destinationfile",
  "description": "destination details",
  "type": "CSV File",
  "file_properties": {
    "file_path": "/opt/app/tmp/output/output.csv",
    "delimiter": ",",

```

```

        "qualifier": "\"",
        "column_count": 12,
        "has_header_row": true,
        "encoding": null,
        "record_length": null,
        "line_separator": null
    }
}

```

In response, ID of *destinationfile* (9b9520e2-2d86-46bd-a615-375b689ee03b) is returned.

GUI

To create a data source from CipherTrust Manager's UI, follow this [link](#).

Similarly, you can also create data sources for fixed length file and databases. For fixed length file follow the [link](#). For databases, refer to [Managing Data Sources](#).

2. Create access policy

API

API: /v1/data-protection/access-policies

Request

```

{
  "name": "access_policy",
  "description": "access policy ",
  "default_reveal_type": "Plaintext"
}

```

Response

```

{
  "id": "24e1f7eb-63a8-4b9f-abc3-0295098ad98f",
  "uri": "kylo:kylo:adp-management:access-policies:access-policy-24e1f7eb-63a8-4b9f-abc3-0295098ad98f",
  "account": "kylo:kylo:admin:accounts:kylo",
  "createdAt": "2025-03-18T11:30:54.511291Z",
  "updatedAt": "2025-03-18T11:30:54.513016Z",
  "created_by": "local|238dfbe5-dff4-4c56-8474-480fb3c51701",
  "name": "access_policy",
}

```

```

    "description": "",
    "default_reveal_type": "Plaintext",
    "default_error_replacement_value": "",
    "default_masking_format_id": null,
    "user_set_policy": [],
    "version": 1
  }

```

In response, ID of the access policy (24e1f7eb-63a8-4b9f-abc3-0295098ad98f) is returned.

GUI

To create access policy from CipherTrust Manager's UI, follow this [link](#).

3. Create protection policy.

API

API: `post /v1/data-protection/protection-policies`

API Request

```

{
  "name": "fpeProtectionPolicy",
  "description": "FPE protection policy",
  "key": "aakey",
  "algorithm": "FPE/FF1v2/UNICODE",
  "tweak": "121212121212",
  "tweak_algorithm": "SHA1",
  "character_set_id": "2d00cfdb-c422-46ac-8a05-6152806a5715",
  "access_policy_name": "access_policy"
}

```

API Response

```

{
  "id": "ed2efc0b-bf78-4b0f-bb0a-2077475fe5ba",
  "uri": "kylo:kylo:adp-management:protection-policies:fpeprotectionpolicy-v10-ed2efc0b-bf78-4b0f-bb0a-2077475fe5ba",
  "account": "kylo:kylo:admin:accounts:kylo",
  "createdAt": "2025-04-02T06:29:16.772448Z",
  "updatedAt": "2025-04-02T06:29:16.771811Z",
  "name": "fpeProtectionPolicy",

```

```

    "version": 10,
    "latest_version": true,
    "description": "",
    "key": "aakey",
    "iv": "",
    "tweak": "121212121212",
    "tweak_algorithm": "SHA1",
    "character_set_id": "2d00cfdb-c422-46ac-8a05-6152806a5715",
    "character_set": {
      "id": "2d00cfdb-c422-46ac-8a05-6152806a5715",
      "uri": "kylo:kylo:adp-management:character-sets:alphanumeric-2d00cfdb-c422-46ac-8a05-6152806a5715",
      "account": "kylo:kylo:admin:accounts:kylo",
      "createdAt": "2025-01-31T07:15:53.167752Z",
      "updatedAt": "2025-01-31T07:15:53.167752Z",
      "name": "Alphanumeric",
      "description": "",
      "range": "0030-0039,0041-005A,0061-007A",
      "encoding": "UTF-8",
      "predefined": true
    },
    "masking_format_id": "",
    "algorithm": "FPE/FF1v2/UNICODE",
    "use_external_versioning": false,
    "disable_versioning": false,
    "access_policy_name": "access_policy",
    "prefix": "",
    "data_format": "",
    "nonce": "",
    "tag_length": 0,
    "allow_small_input": true
  }

```

GUI

To create protection policy from CipherTrust Manager's UI, follow this [link](#).

A protection policy, named `fpeProtectionPolicy` is created and this policy will be used to protect data as shown the in next step.

Note

Ensure the key used in protection policy has correct permissions. For more details on key permissions, refer to [Supported key types](#).

4. Create job configuration.

API

API: `post /v1/data-protection/bdt/job-configurations`

API Request

```
{
  "name": "job configuration for file",
  "in_place_update": false,
  "source_id": "5c22a447-f8dd-4c4c-af7d-149123ecf974",
  "destination_id": "9b9520e2-2d86-46bd-a615-375b689ee03b",
  "tables": [
    {
      "columns": [
        {
          "source_column_name": "latitude", "operation": "protect", "protectio
n_policy": "fpeProtectionPolicy"
        }
      ]
    }
  ]
}
```

API Response

```
{
  "id": "142b84d8-22ba-4b66-8fec-16076911ec7a",
  "uri": "kylo:kylo:adp-management:bdt-job-configurations:job-configurat
ion-for-file-142b84d8-22ba-4b66-8fec-16076911ec7a",
  "account": "kylo:kylo:admin:accounts:kylo",
  "createdAt": "2025-03-18T11:43:40.577668Z",
  "updatedAt": "2025-04-04T09:14:59.905281Z",
  "version": 26,
  "name": "job configuration for file",
  "description": "",
}
```

```

"case_sensitive": false,
"source_id": "5c22a447-f8dd-4c4c-af7d-149123ecf974",
"destination_id": "9b9520e2-2d86-46bd-a615-375b689ee03b",
"in_place_update": false,
"unprocessed_record_file": "/opt/app/tmp/unProcessedRecordFiles/",
"tables": [
  {
    "id": "2eefe155-7bee-41a9-aacf-546c52f75880",

    "source_table": "",
    "source_schema": "",
    "destination_table": "",
    "destination_schema": "",
    "create_destination_table": false,
    "subset": {
      "limit": 0,
      "offset": 0,
      "recurrency": 1,
      "order_by": "",
      "order": "ASC",
      "filters": []
    },
    "columns": [
      {
        "id": "dfd71200-1c83-40c5-921d-e941496a72b2",
        "uri": "kylo:kylo:adp-management:bdt-job-configuration
s-tables-columns:dfd71200-1c83-40c5-921d-e941496a72b2",
        "account": "kylo:kylo:admin:accounts:kylo",
        "createdAt": "2025-04-04T08:11:39.332823Z",
        "updatedAt": "2025-04-04T08:11:39.332262Z",
        "source_column_name": "latitude",
        "operation": "protect",
        "protection_policy": "fpeProtectionPolicy"
      }
    ]
  }
],
"meta": {
  "job_running": false
}

```

```
}
```

In response, ID of the job configuration (142b84d8-22ba-4b66-8fec-16076911ec7a) is returned.

GUI

To create job configuration from CipherTrust Manager's UI, follow this [link](#).

To protect, select **operation** type as **protect**.

Tip

Multiple columns can be configured in a single job configuration, and each column can be associated with different protection policies.

5. Run job.

To run a job, at least one **active client must be registered with the application**.

API

There is slight difference in the Run Job API call depending on the CipherTrust Manager version you are using. Choose the preferred tab to view the details.

API call in CM 2.19

API: `post /v1/data-protection/run-job`

API Request

```
{
  "job_configuration_id": "142b84d8-22ba-4b66-8fec-16076911ec7a",
  "client_profile_id": "9f3edcb1-38e8-4bc7-8c41-99e897560328"
}
```

API Response

```
{ "job_status_id": "a960a20c-4852-4fee-a18b-302710f67170" }
```

In response, a job status ID (a960a20c-4852-4fee-a18b-302710f67170) is returned, use this ID to check the intermediate status of the job.

API call in CM 2.20 and higher versions

API: `post /v1/data-protection/bdt/job-configurations/{id}/run`

API Request

```
post /v1/data-protection/bdt/job-configurations/{142b84d8-22ba-4b66-8fec-16076
911ec7a}/run
{ "client_profile_id": "9f3edcb1-38e8-4bc7-8c41-99e897560328" }
```

API Response

```
{ "job_status_id": "a960a20c-4852-4fee-a18b-302710f67170" }
```

In response, a *job_status_id* (a960a20c-4852-4fee-a18b-302710f67170) is returned. Use this ID to check the status of the job.

GUI

To run a job from CipherTrust Manager's UI, follow this [link](#).

6. Check status of the job.

API

There is slight difference in the `Job Status` API call depending on the CipherTrust Manager version you are using. Choose the preferred tab to view the details.

API call in CM 2.19

API: `get /v1/data-protection/job-status/{id}`

Pass the *job_status_id* (generated in step 5) in the API request.

API Request

```
{
  /v1/data-protection/job-status/{a960a20c-4852-4fee-a18b-302710f67170}
}
```

API call in CM 2.20 and higher version

API: `get /v1/data-protection/jobs/{id}`

Pass the `job_status_id` (generated in step 5) in the API request.

API Request

```
/v1/data-protection/jobs/a960a20c-4852-4fee-a18b-302710f67170
```

GUI

To run a job from CipherTrust Manager's UI, follow this [link](#).

In response, information about the jobs in various stages, total number of records processed, error messages are returned.

Verify Results

After the job status gets completed, check the [Output.csv](#) for transformed data.

Note

For transformations, where destination is file, the output file name (provided on UI) will also contain a timestamp appended to it. For example, `<output-name-as-per-ui>-2025-04-01.17.57.01.521.csv`

- For CSV file, the output file will be formatted as: `<file-name>-<timestamp>.csv`
- For fixed length file, the output file will be formatted as: `<file-name>-<timestamp>.txt`

In the **Input.csv** file, the *latitude* column was in plaintext, after transformation, the data is in ciphertext.

Before Transformation	After Transformation
latitude	latitude
38.631913	1002008eb.QbvK1B
38.478902	1002008bX.lyin02
38.618305	1002008Oq.238Xpk
38.616835	10020088g.ZnhFEO
38.51947	1002008zQ.9RjXy
38.662595	1002008qg.xrjv8K
38.681659	1002008Ns.Sz5Hc6
38.535092	1002008kl.Elfmor
38.621188	1002008Qq.elSZHs
38.700909	1002008NT.QXs6S8
38.637663	1002008IG.f1U4xg
38.470746	1002008j4.qQLRIV

In the output, you can see that the version header is prepended to the ciphertext (1002008eb.QbvK1B).

Protect Use cases

Protect with Prefix

To configure prefix, enter a user friendly name in the **Prefix** text-box when configuring [protection policy](#).

Example

Protection Policy Type: Internal version

Prefix: geo-

Character Set: Alphanumeric

Input data: 38.689999

Ciphertext: 1002008geo-eb.QbvK1B

Protect Luhn compliant data

To protect luhn compliant data, the **Luhn toggle** must be turned on when configuring [protection policy](#). To use, this functionality, following points must be considered:

- It is only compatible with **All digits character set (0-9)** and **FPE algorithms**.
- The luhn check requires **minimum3 characters** to perform crypto operations.

Example

Protection Policy Type: Internal version

Character Set: All digits (0030-0039)

Input data: 1234567812345670

Ciphertext: 9262746894652355

Note

The generated ciphertext is also luhn complaint. To check if a number is valid luhn, starting from the rightmost digit, double every other digit, and if the doubled value is greater than 9, add its digits. Then, sum all the digits (including the original and doubled ones) and check if the sum is divisible by 10.

Protect with static masking format

The static masking format allows you to preserve starting and ending characters of the input data. It is only applicable with FPE algorithms.

To configure static masking format, select the desired format when configuring [protection policy](#).

Example

Protection Policy Type: Internal version

Static masking format: Preserve LAST_FOUR characters

Character Set: Alphanumeric (0030-0039, 0041-005A, 0061-007A)

Note

Any character outside the given character set range will be preserved in the output.

Input Data: 3526 HIGH ST

Ciphertext: 10020080j37 PaGH ST (last 4 characters are preserved.)

How to reveal data

This section outlines the complete File-to-File transformation process for CSV files. The example provided here demonstrates how to reveal data of a CSV file. The reveal operation returns the data based on the default reveal format defined in the [access policy](#).

Note

Currently, the default reveal format supported by BDT is only *plaintext*.

Important Points

- We have provided the following sample files with this example.
 - **Input.csv:** Contains the data to be processed. Download and save this file on the host machine specified during volume mapping when deploying BDT.
 - **Output.csv:** Contains the processed data. This file will get created on the host machine specified during volume mapping when deploying BDT.
- Column of the `input.csv` file that will be revealed in this demo is: *latitude*.
- We will use the same protection policy for reveal that was used during protect (**fpeProtectionPolicy**) else, data can't be revealed.

Prerequisites

- BDT application must be registered on the CipherTrust Manager. Refer to [Quick Start](#) for details.

- BDT must be deployed. Refer to [Quick Start](#) for details.
- A compatible CipherTrust Manager must be up and running. Refer to [CipherTrust Manager Deployment](#) for details.

Steps

The transformation steps provided in this example can be performed using the [CipherTrust Manager UI](#) or [API playground](#).

1. Create source and destination data-sources. The source data-source contains the data to be processed while the destination data-source will store the processed data. The output of protect operation will act as input for the reveal operation.

API

API: `post /v1/data-protection/data-sources`

Create source data-source

Request

```
{
  "name": "sourcefileforreveal",
  "description": "source details",
  "type": "CSV File",
  "file_properties": {
    "file_path": "/opt/app/tmp/input/inputReveal.csv", "delimiter":
    ",", "column_count": 12, "has_header_row": true}
}
```

Response

```
{
  "id": "24fad7da-d288-47cb-b93b-815760cad19f",
  "uri": "kylo:kylo:adp-management:data-sources:sourcefileforreveal-24fa
d7da-d288-47cb-b93b-815760cad19f",
  "account": "kylo:kylo:admin:accounts:kylo",
  "createdAt": "2025-04-10T10:30:54.678120212Z",
  "updatedAt": "0001-01-01T00:00:00Z",
  "name": "sourcefileforreveal",
  "description": "source details",
  "type": "CSV File",
  "file_properties": {
```

```

        "file_path": "/opt/app/tmp/input/inputReveal.csv",
        "delimiter": ",",
        "qualifier": "\"",
        "column_count": 12,
        "has_header_row": true,
        "encoding": null,
        "record_length": null,
        "line_separator": null
    }
}

```

In response, ID of *sourcefile* (24fad7da-d288-47cb-b93b-815760cad19f) is returned.

Create destination data-source

Request

```

{
  "name": "destinationfileforreveal",
  "description": "destination details",
  "type": "CSV File",
  "file_properties":
    {
      "file_path": "/opt/app/tmp/output/outputReveal-2025-03-26.11.01.5
5.639.csv", "delimiter": ",", "column_count": 12, "has_header_row": true
    }
}

```

Response

```

{
  "id": "c1e06436-2ae9-48a3-b3c7-79f6c909b3ef",
  "uri": "kylo:kylo:adp-management:data-sources:destinationfileforreveal-c1e06436-2ae9-48a3-b3c7-79f6c909b3ef",
  "account": "kylo:kylo:admin:accounts:kylo",
  "createdAt": "2025-04-10T10:33:47.6178149Z",
  "updatedAt": "0001-01-01T00:00:00Z",
  "name": "destinationfileforreveal",
  "description": "destination details",
  "type": "CSV File",
  "file_properties": {
    "file_path": "/opt/app/tmp/output/outputReveal-2025-03-26.11.01.5

```

```
5.639.csv",
    "delimiter": ",",
    "qualifier": "\"",
    "column_count": 12,
    "has_header_row": true,
    "encoding": null,
    "record_length": null,
    "line_separator": null
  }
}
```

In response, ID of *destinationfile* (c1e06436-2ae9-48a3-b3c7-79f6c909b3ef) is returned.

GUI

To create a data source from CipherTrust Manager's UI, follow this [link](#).

Similarly, you can also create data sources for fixed length file and databases. For fixed length file follow the [link](#). For databases, refer to [Managing Data Sources](#).

2. Create job configuration.

API

API: `post /v1/data-protection/bdt/job-configurations`

API Request

```
{
  "name": "job configuration for reveal",
  "in_place_update": false,
  "source_id": "24fad7da-d288-47cb-b93b-815760cad19f",
  "destination_id": "c1e06436-2ae9-48a3-b3c7-79f6c909b3ef",
  "tables": [
    {
      "columns": [
        {
          "source_column_name": "latitude", "operation": "reveal", "protection_policy": "fpeProtectionPolicy"
        }
      ]
    }
  ]
}
```

API Response

```
{
  "id": "210cfdec-37d5-44f3-b9e0-fa4663030f74",
  "uri": "kylo:kylo:adp-management:bdt-job-configurations:job-configuration-

        "offset": 0,
        "recurrency": 1,
        "order_by": "",
        "order": "ASC",
        "filters": null
      },
      "columns": [
        {
          "id": "67074d83-cd41-4481-bdb7-0d798736fb52",
          "uri": "kylo:kylo:adp-management:bdt-job-configurations-ta
bles-columns:67074d83-cd41-4481-bdb7-0d798736fb52",
          "account": "kylo:kylo:admin:accounts:kylo",
```

```

        "createdAt": "2025-04-10T10:40:08.630819232Z",
        "updatedAt": "2025-04-10T10:40:08.628260173Z",
        "source_column_name": "latitude",
        "operation": "reveal",
        "protection_policy": "fpeProtectionPolicy"
      }
    ]
  },
  "meta": {
    "job_running": false
  }
}

```

In response, ID of the job configuration (210cfdec-37d5-44f3-b9e0-fa4663030f74) is returned.

GUI

To create job configuration from CipherTrust Manager's UI, follow this [link](#).

To reveal, select **operation** type as **reveal**.

Tip

Multiple columns can be configured in a single job configuration, and each column can be associated with different protection policies.

3. Run job.

To run a job, at least one **active client must be registered with the application**.

API

There is slight difference in the Run Job API call depending on the CipherTrust Manager version you are using. Choose the preferred tab to view the details.

API call in CM 2.19

API: `post /v1/data-protection/run-job`

API Request

```
{
```

```
"job_configuration_id": "210cfdec-37d5-44f3-b9e0-fa4663030f74",
"client_profile_id": "ab2e3f89-b277-4821-9939-4e5ee6e82352"
}
```

API Response

```
{ "job_status_id": "a960a20c-4852-4fee-a18b-302710f67170" }
```

In response, a job status ID (a960a20c-4852-4fee-a18b-302710f67170) is returned, use this ID to check the intermediate status of the job.

API call in CM 2.20 and higher versions

API: `post /v1/data-protection/bdt/job-configurations/{id}/run`

Pass the job configuration ID (generated in step 2) and client profile ID (generated in deployment steps) in the API request.

API Request

```
post /v1/data-protection/bdt/job-configurations/{210cfdec-37d5-44f3-b9e0-fa4663030f74}/run
{"client_profile_id": "ab2e3f89-b277-4821-9939-4e5ee6e82352"}
```

API Response

```
{ "job_status_id": "bf2a71d7-8c7f-438a-8a87-35c0bb351383" }
```

In response, a *job_status_id* (bf2a71d7-8c7f-438a-8a87-35c0bb351383) is returned. Use this ID to check the status of the job.

GUI

To run a job from CipherTrust Manager's UI, follow this [link](#).

4. Check status of the job.

API

There is slight difference in the `Job Status` API call depending on the CipherTrust Manager version you are using. Choose the preferred tab to view the details.

API call in CM 2.19

API: `get /v1/data-protection/job-status/{id}`

API Request

```
{
  /v1/data-protection/job-status/{bf2a71d7-8c7f-438a-8a87-35c0bb351383}
}
```

In response, information about the job in various stages, total number of records processed, error messages are returned.

API call in CM 2.20 and higher versions

API: `get /v1/data-protection/jobs/{id}`

Pass the `job_status_id` (generated in step 3) in the API request.

API Request

```
/v1/data-protection/jobs/bf2a71d7-8c7f-438a-8a87-35c0bb351383
```

In response, information about the job in various stages, total number of records processed, error messages are returned.

GUI

To run a job from CipherTrust Manager's UI, follow this [link](#).

In response, information about the jobs in various stages, total number of records processed, error messages are returned.

Verify Results

After the job status gets completed, check the [Output.csv](#) for transformed data.

Note

For transformations, where destination is file, the output file name (provided on UI) will also contain a timestamp appended to it. For example, `<output-name-as-per-ui>-2025-04-01.17.57.01.521.csv`

- For CSV file, the output file will be formatted as: `<file-name>-<timestamp>.csv`

- For fixed length file, the output file will be formatted as: <file-name>-<timestamp>.txt

In the **Input.csv** file, the *latitude* column was in ciphertext, after transformation, the data is in plaintext.

Before Transformation	After Transformation
latitude	latitude
1002008eb.QbvK1B	38.631913
1002008bX.lyin02	38.478902
1002008Oq.238Xpk	38.618305

1002008kl.Elfmor	38.535092
1002008Qq.eISZHs	38.621188
1002008NT.QXs6S8	38.700909
1002008lG.f1U4xg	38.637663
1002008j4.qQLRIV	38.470746

How to reprotect data

This section outlines the complete File-to-File transformation process for CSV files. The example provided here demonstrates how to reprotect data of a CSV file. The reprotect operation protects the plaintext data with the **latest version of the protection policy** and returns the ciphertext based on the protection policy selected in the job configuration.

Important Points

- We have provided the following sample files with this example.
 - Input.csv:** Contains the data to be processed. Download and save this file on the host machine specified during volume mapping when deploying BDT.
 - Output.csv:** Contains the processed data. This file will get created on the host machine specified during volume mapping when deploying BDT.
- Column of the `input.csv` file that will be reprotected in this example is: *latitude*.
- We will modify some of the attributes of the protection policy that was used during protect (**fpeProtectionPolicy**). Doing this will increment the version of the protection policy.
- BDT application must be registered on the CipherTrust Manager. Refer to [Quick Start](#) for details.

- BDT must be deployed. Refer to [Quick Start](#) for details.
- A compatible CipherTrust Manager must be up and running. Refer to [CipherTrust Manager Deployment](#) for details.

Steps

The transformation steps provided in this example can be performed using the [CipherTrust Manager UI](#) or [API playground](#).

1. Create source and destination data-sources. The source data-source contains the data to be processed while the destination data-source will store the processed data.

API

API: `post /v1/data-protection/data-sources`

Request

```
{
  "name": "sourcefileforreprotect",
  "description": "source details",
  "type": "CSV File",

  "file_properties":
    {
      "file_path": "/opt/app/tmp/input/inputReprotect", "delimiter": ",", "column_count": 12, "has_header_row": true
    }
}
```

Response

```
{
  "id": "060f5f02-0020-4391-8622-986a17a67242",
  "uri": "kylo:kylo:adp-management:data-sources:sourcefilefor-reprotect-060f5f02-0020-4391-8622-986a17a67242",
  "account": "kylo:kylo:admin:accounts:kylo",
  "createdAt": "2025-04-10T11:45:11.181451365Z",
  "updatedAt": "0001-01-01T00:00:00Z",
  "name": "sourcefileforreprotect",
  "description": "source details",
  "type": "CSV File",
  "file_properties": {
    "file_path": "/opt/app/tmp/input/inputReprotect",
```

```

        "delimiter": ",",
        "qualifier": "\"",
        "column_count": 12,
        "has_header_row": true,
        "encoding": null,
        "record_length": null,
        "line_separator": null
    }
}

```

In response, ID of *sourcefileforreprotect* (060f5f02-0020-4391-8622-986a17a67242) is returned.

Request

```

{
  "name": "destinationfileforreprotect",
  "description": "destination details",
  "type": "CSV File",
  "file_properties":
    {
      "file_path": "/opt/app/tmp/output/outputReprotect-2025-03-26.10.54.05.32
6.csv", "delimiter": ",", "column_count": 12, "has_header_row": true
    }
}

```

Response

```

{
  "id": "f1092d62-c64d-4dd5-ba21-0a30a1b7d17f",
  "uri": "kylo:kylo:adp-management:data-sources:destinationfileforreprotect-f1092d62-c64d-4dd5-ba21-0a30a1b7d17f",
  "account": "kylo:kylo:admin:accounts:kylo",
  "createdAt": "2025-04-10T11:46:54.504532806Z",
  "updatedAt": "0001-01-01T00:00:00Z",
  "name": "destinationfileforreprotect",
  "description": "destination details",
  "type": "CSV File",
  "file_properties": {
    "file_path": "/opt/app/tmp/output/outputReprotect-2025-03-26.10.54.05.326.csv",
    "delimiter": ",",
    "qualifier": "\"",

```

```

        "column_count": 12,
        "has_header_row": true,
        "encoding": null,
        "record_length": null,
        "line_separator": null
    }
}

```

In response, ID of *destinationfileforreprotect* (f1092d62-c64d-4dd5-ba21-0a30a1b7d17f) is returned.

GUI

To create a data source from CipherTrust Manager's UI, follow this [link](#).

Similarly, you can also create data sources for fixed length file and databases. For fixed length file follow the [link](#). For databases, refer to [Managing Data Sources](#).

2. Update protection policy. The updated protection policy will be used to reprotect data.
3. Create job configuration.

API

API: `post /v1/data-protection/bdt/job-configurations`

API Request

```

{
  "name": "job configuration for reprotect",
  "in_place_update": false,
  "source_id": "060f5f02-0020-4391-8622-986a17a67242",
  "destination_id": "f1092d62-c64d-4dd5-ba21-0a30a1b7d17f",
  "tables": [
    {
      "columns": [
        {

    ]
  },
  "meta": {
    "job_running": false
  }
}

```

In response, ID of the job configuration (7e5a96f6-d8ff-4e07-8017-62329e52c22f) is returned.

GUI

To create job configuration from CipherTrust Manager's UI, follow this [link](#).

To reprotect, select **operation** type as **reprotect**.

Tip

Multiple columns can be configured in a single job configuration, and each column can be associated with different protection policies.

4. Run job.

To run a job, at least one **active client must be registered with the application**.

API

There is slight difference in the Run Job API call depending on the CipherTrust Manager version you are using. Choose the preferred tab to view the details.

API call in CM 2.19

API: `post /v1/data-protection/run-job`

Pass the job configuration ID (generated in step 4) and client profile ID (generated in deployment steps) in the API request.

API Request

```
{
  "job_configuration_id": "7e5a96f6-d8ff-4e07-8017-62329e52c22f",
  "client_profile_id": "ab2e3f89-b277-4821-9939-4e5ee6e82352"
}
```

API Response

```
{ "job_status_id": "b960a20c-4852-4fee-a18b-302710f67170" }
```

In response, a job status ID (b960a20c-4852-4fee-a18b-302710f67170) is returned, use this ID to check the intermediate status of the job.

API call in CM 2.20 and higher versions

API: `post /v1/data-protection/bdt/job-configurations/{id}/run`

Pass the job configuration ID (generated in step 4) and client profile ID (generated in deployment steps) in the API request.

API Request

```
post /v1/data-protection/bdt/job-configurations/{7e5a96f6-d8ff-4e07-8017-6
2329e52c22f}/run
{ "client_profile_id": "ab2e3f89-b277-4821-9939-4e5ee6e82352" }
```

API Response

```
{ "job_status_id": "b960a20c-4852-4fee-a18b-302710f67170" }
```

In response, a *job_status_id* (b960a20c-4852-4fee-a18b-302710f67170) is returned. Use this ID to check the status of the job.

GUI

To run a job from CipherTrust Manager's UI, follow this [link](#).

5. Check status of the job.

API

There is slight difference in the `Job Status` API call depending on the CipherTrust Manager version you are

using. Choose the preferred tab to view the details.

API call in CM 2.19

API: `get /v1/data-protection/job-status/{id}`

Pass the `job_status_id` (generated in step 5) in the API request.

API Request

```
{  
  /v1/data-protection/job-status/{b960a20c-4852-4fee-a18b-302710f67170}  
}
```

API call in CM 2.20 and higher versions

API: `get /v1/data-protection/jobs/{id}`

Pass the `job_status_id` (generated in step 5) in the API request.

API Request

```
/v1/data-protection/jobs/b960a20c-4852-4fee-a18b-302710f67170
```

GUI

To run a job from CipherTrust Manager's UI, follow this [link](#).

In response, information about the jobs in various stages, total number of records processed, error messages are returned.

Verify Results

After the job status gets completed, Check the [Output.csv](#) for transformed data.

Note

For transformations, where destination is file, the output file name (provided on UI) will also contain a timestamp appended to it. For example, `<output-name-as-per-ui>-2025-04-01.17.57.01.521.csv`

- For CSV file, the output file will be formatted as: `<file-name><timestamp>.csv`
- For fixed length file, the output file will be formatted as: `<file-name><timestamp>.txt`

In the **Input.csv** file, the *latitude* column was protected with older version of protection policy (1002008), after transformation, the data is reprotected with the latest version of protection policy (1003008).

Before Transformation	After Transformation
latitude <pre>1002008eb.QbvK1B 1002008bX.lyin02 1002008Oq.238Xpk 10020088g.ZnhFEO 1002008zQ.9RjXy 1002008qg.xrjv8K 1002008Ns.Sz5Hc6 1002008kl.Elfmor 1002008Qq.eISZHs 1002008NT.QXs6S8 1002008lG.f1U4xg 1002008j4.qQLRIV</pre>	latitude <pre>1003008eb.QbvK1B 1003008bX.lyin02 1003008Oq.238Xpk 10030088g.ZnhFEO 1003008zQ.9RjXy 1003009qg.xrjv8K 1003008Ns.Sz5Hc6 1003008kl.Elfmor 1003008Qq.eISZHs 1003008NT.QXs6S8 1003008lG.f1U4xg 1003008j4.qQLRIV</pre>

In the output, you can see that the incremented version header is prepended to the ciphertext (1003008eb.QbvK1B).

Change key manager

This article describes how to change a key manager. BDT uses the CipherTrust Manager as a trusted key manager.

For Kubernetes deployment with Helm

1. In the `values.yaml` file, under the `env` section, update the value of `kmsHost` with a valid IP address or hostname of the CipherTrust Manager.
2. Update your BDT deployment.

```
helm upgrade <helm chart name> <path of helm chart>
```

For Kubernetes deployment without Helm

1. In the BDT deployment file (for example, `<bdtd-deployment.yaml>`), update the value of `KMS_HOST` with a valid IP address or hostname of the CipherTrust Manager.
2. Update your BDT deployment.

```
kubect1 replace -f <bdtd-deployment.yaml>
```

For Standalone deployment

1. Stop the existing container.
2. In the environment variable, update the `KMS_HOST` field with a valid IP address or hostname of the CipherTrust Manager
3. Start the container.

```
docker run -e KMS_HOST=<new-IP address or host name of kms> -e REG_TOKEN=<registration_token> -p <host-port>:<bdp-port> <bdp_image_name>
```

Change application

This section provides instructions to change the application you want to redeploy BDT with.

1. Define the new application on the CipherTrust Manager and generate a new registration token. Refer to [Defining applications](#) for details.
2. Redeploy BDT to use the new application. Refer to the following sections for instructions on deploying BDT based on your deployment.
 - [With helm deployment](#)
 - [Without helm chart deployment](#)
 - [Standalone deployment](#)

Note

If you are making changes in the existing application BDT is configured with, no need to redeploy BDT. The configuration will be reflected based on the [heartbeat configuration](#).

View logs in Kubernetes environment

A log serves as the record that captures every minute details of what your application did.

To fetch BDT specific logs in *Kubernetes* (with and without helm) deployment from *sysout*, you can use the following command:

```
kubectl logs <pod_name> -c <bdp_container_name>
```

To fetch BDT specific logs in *standalone* deployment, use the following command:

```
docker logs <container_id>
```

Monitoring BDT health

BDT provides `healthz` and `liveness` probes to monitor BDT health.

`healthz` Probe

Checks the current health status of the BDT container and reports whether BDT is serving the requests.

- If the status code `200` (`status is OK`) is returned, BDT is running fine. You can proceed with your operations.
- If the status code `503` (`Container is not healthy`), BDT can't process any requests but it is recoverable. Check the issue in the BDT logs and fix it to recover from the error state.

Example

```
GET https://<BDT instanceip>:<port>/healthz
```

Output

```
{  
  "status": "OK"  
}
```

In the above API call, replace `<BDT instanceip>` and `<port>` with the actual values from your BDT deployment.

`liveness` Probe

Checks the liveness of the BDT container whether BDT is running healthy.

- If the status code `200` (`status is OK`) is returned, BDT is running fine. You can proceed with your operations.
- If the status code `503` is returned, BDT can't process any requests and isn't recoverable. In this case, you need to restart or redeploy the BDT container.

Example

```
GET https://<BDT instanceip>:<port>/liveness
```

Output

```
{  
  "status": "OK"  
}
```

In the above API call, replace `<BDT_instanceip>` and `<port>` with the actual values from your BDT deployment.

Renewing client certificate

While creating the application on CipherTrust Manager, the Application Data Protection admin configures the Certificate Duration (in days). When the certificate expiry duration ranges from 90-60 days, the client logs the `Client certificate will expire in <number> Days` notification message daily. To renew the client certificate, use either of the ways:

Auto renew

When the [Certificate Auto Renewal](#) toggle is enabled and the client certificate is between 60 and 1 day before expiration, it is auto-renewed, and the message `Client certificate renewed successfully` is returned.

Manual renew

When the [Certificate Auto Renewal](#) toggle is not enabled and the client certificate is between 60 and 1 day before expiration, the certificate will expire. To renew it manually, restart your container.

Advanced Topics

This section describes advanced BDT topics.

- [Environment Variables](#)
- [Concepts](#)
- [Protection Policy](#)
- [BDT Logging](#)
- [Using Fixed-Length Record Format](#)
- [Supported Encoding](#)
- [Behavior of BDT on Container Shutdown](#)
- [Unprocessed Record File](#)
- [Using JDBC Driver URLs](#)
- [Thread Count and Batch Sizes](#)

Environment Variables

Variable	Description	Optional/Mandatory
KMS_HOST	IP address or hostname of the	Mandatory

Variable	Description	Optional/Mandatory
	CipherTrust Manager.	
KMS_PORT	Port on which BDT communicates with the CipherTrust Manager. The default port is 443.	Optional
REG_TOKEN	Registration token used to register a BDT client on the CipherTrust Manager.	Mandatory
DB_CERT_VALUE	Comma separated certificate values in <i>.pem</i> format required to make a secure JDBC connection with databases.	Optional
JDBC_DRIVER_DOWNLOAD_URL	The URL or location from where BDT will download/load the driver jars required to make a JDBC connection with the database. Click here for more details.	Optional

Concepts

Application

An application, configured on the CipherTrust Manager, contains the necessary settings that are required to protect/reveal/reprotect data. Refer to [Managing Application](#) for details.

Access policy

Access policies contain set of rules that govern how the protected data will be revealed to users. Since there is no concept of users in BDT, the data will be revealed based on the default reveal format configured in the access policy.

Note

For BDT, it is recommended to configure the default reveal format as plaintext.

Refer to [Managing Access Policy](#) for details.

Dynamic Masking

Creates masking format for the reveal operation. Dynamic masking format determines how the output of the reveal operation is displayed to the application users. Refer to [Masking Format](#) for details.

Heartbeat

Heartbeat is a lightweight mechanism that allows BDT to poll the CipherTrust Manager for any change in configurations. Refer to [Heartbeat Configuration](#)

Note

- Every transformation will run with the latest configurations.
- For BDT, only protection policy configurations get reflected with heartbeat in a running transformation. Modifications done in all other configurations can not get reflected in a running transformation.
- The time on both the client and server machines must be synchronized. To achieve this, NTP (Network Time Protocol) should be configured. Follow [instructions](#) to set up NTP.

Behavior of BDT when heartbeat timeout count is reached

If the count of the continuous skipped heartbeat becomes equivalent to the value of `Heartbeat Timeout Count` parameter, the BDT client enters a revoked state after a maximum of 5 minutes. At this point, its liveness and health probes become false. In this scenario, BDT does not transform data. This safeguard ensures the crypto operations are not performed when the container's state is unhealthy and unrecoverable.

Note

If a client is processing a job and in-between its heartbeat timeout count has reached due to any issue on the Key Manager, the client enters a revoked state. The CipherTrust Manager will stop running the job linked to that client. The job status page may not reflect the actual progress of that stopped job.

Behavior of BDT when client gets deleted, revoked, or expired

If a client gets deleted, revoked or expired on Key Manager, the liveness and health probes become false. In this scenario, BDT does not transform data. This safeguard ensures the crypto operations are not performed when the container's state is unhealthy and unrecoverable.

Note

- When a client gets deleted on Key Manager, the status of its running job will no longer get updated on the [Job Status](#) page. As a result, the associated job configuration can't be reused to run a new job.
- The deleted, revoked, or expired client will be in healthy state for maximum 5 minutes.

Key Caching

The key caching feature allows BDT to securely cache a copy of the in-use key that it received from the CipherTrust Manager using the REST protocol. Key caching is limited for the value set in the `Key Cache Expiry` parameter while creating an application to perform cryptographic operations locally.

See the `Key Cache Expiry` parameter under the BDT tab [here](#) for details.

Key States

A key state determines which operations can be performed using that key. Refer to [Key States](#) for details. Based on the key states, BDT will throw error for the following key states.

Compromised Key State: Cannot Protect with Compromised Key Version

Deactivated Key State: Cannot perform operation with Deactivated Key Version

Protection Policy

Protection policy defines a set of rules that govern the cryptographic operations. The protection policy includes entities such as algorithm, key, IV, access policy name, and character set. Refer to [Managing Protection Policy](#) for details.

Protection policy specifications

Internal versioning protection policy

It is a type of protection policy where the version header is prepended with the ciphertext. For example, 1001000B1E06A7C20585E0F5A13233953B4971D. The protected text reserves 7 digits for version header. The permissible version header range is 1001000 - 1999999.

- The first digit is reserved for type
- The next 3 digits are reserved for protection policy version
- The last 3 digits are reserved for key version.

Important Notes

- The length of the ciphertext will increase after prepending the 7-digit version header to it. So, the *length of the column* receiving the ciphertext will increase by 7.
- In case of protect operation for Fixed Length File, the white spaces at the end of the plaintext will be removed to ensure the version header is prepended to the ciphertext.

External versioning protection policy

It is a type of protection policy where the version header is not part of the ciphertext and it is stored in a different column. Specify the column name (where you want to insert the version header value) in the *Version header column*. Refer to [Managing Job Configuration](#) for details.

Important Notes

Protect operation

- For transformations where destination is database, the version header column should exist in the destination table. Else, the following error will be thrown:

```
Version header column <version header name> not present in destination table.
```

Note

If **Create Destination** check-box is selected, BDT will create the column with the name specified in the version header column parameter (if it is not already in source) with datatype as VARCHAR (7). For Oracle, the datatype will be VARCHAR2 (7).

- If the destination table already contains the column with the same name as the version header column value, BDT will use that column to add the version header value.
- For transformations where destination is file, if the version header column is already present in the source, the column data will be overwritten with version header value. If version header column doesn't exist, BDT will create column in the output file.
- For Fixed length file transformation, following points will be taken into consideration:
 - If the version header column value length is greater than 7, BDT will add spaces in the version header value.
 - If the version header column value length is less than 7, BDT will add spaces in the version header column name.
 - If the version header column already present in destination, the column length of the original column will be used.

Reveal Operation

If the version header column is not null or does not exist in the source table or input file, BDT throws the following error:

```
Version header column is not present in source.
```

Disable versioning protection policy

It is a type of policy where information about version header is not returned with the ciphertext. In this scenario, only *Version 0* of a key can be used to protect data.

Luhn check

A luhn check is a method to validate identification of numbers. Protection policy is configured to protect or reveal luhn complaint data. This check is only compatible with All digits character set (0-9) and FPE algorithms. The luhn

check requires minimum 3 characters to perform crypto operations. For configuring luhn data format, refer to [Creating Protection Policy](#).

Prefix

It is a user friendly name that helps user identify the type of data being protected. This value is specified while creating a protection policy. For configuring prefix, refer to [Creating Protection Policy](#).

Note

In case of protect operation for Fixed Length File, the white spaces at the end of the plaintext will be removed to ensure the prefix is prepended to the ciphertext.

Static masking format

Allows you to preserve starting and ending characters of the input data. The remaining characters will be protected based on the selected algorithm. It is only applicable for FPE algorithms. Refer to [Masking Format](#) for details.

Allow Small Input Value

Support available in CipherTrust Manager future releases

Support to handle small character input will be available in CipherTrust Manager 2.22 and higher versions.

Format-preserving algorithms require a character set during cryptographic operations. When the effective input length does not meet the minimum length criteria supported by the underlying algorithm, an error is thrown. To handle this scenario, use the **Allow Small Input** parameter. This parameter allows BDT to process small input.

Conversely, if the Allow Small Input parameter is disabled and user attempts to protect a small input value, BDT doesn't process it and returns the `Input buffer is too short (len=1), it has to be at least 2 bytes long` error.

This parameter is only supported with FPE and Random2 algorithms.

Random nonce

Support for Random Nonce in AES algorithms will be available in CipherTrust Manager 2.22 and higher versions.

A random nonce is a randomly generated nonce (IV) that can be used only once in cryptographic operations. It can be internal, external, or disabled.

Internal random nonce: The nonce generated during protect is returned with the ciphertext. The structure of ciphertext is as follows: `versionheader + prefix + nonce + ciphertext`. Internal random nonce works with internal and disabled protection policies.

External random nonce: The nonce generated during protect is not part of the ciphertext and it is stored in a different column. Specify the column name (where you want to insert the random nonce value) when creating job configuration. External random nonce works with external and disabled protection policies.

Disable random nonce: In this case, nonce is not returned with the ciphertext. Disable nonce can be used with internal, external, or disabled protection policy.

Important Notes

Protect Operation

- For transformations where destination is database, the random nonce column should exist in the destination table. Else, the following error will be thrown:

```
Random nonce column <random nonce column name> not present in destination table.
```

Note

If **Create Destination** check-box is selected, BDT will create the column with the name specified in the random nonce column parameter (if it is not already in source) with datatype as VARCHAR (32). For Oracle, the datatype will be VARCHAR2 (32).

- If the destination table already contains the column with the same name as the random nonce column value, BDT will use that column to add the random nonce value.
- For transformations where destination is file, if the random nonce column is already present in the source, the column data will be overwritten with random nonce value. If random nonce column doesn't exist, BDT will create column in the output file.
- For Fixed length file transformation, following points will be taken into consideration:
 - If the random nonce column value length is greater than 32, BDT will add spaces in the random nonce value.
 - If the random nonce column value length is less than 32, BDT will add spaces in the random nonce column name.
 - If the random nonce column already present in destination, the column length of the original column will be used.

Reveal Operation

If the random nonce column is not null or does not exist in the source table or input file, BDT throws the following error:

```
Random nonce column is not present in source.
```

BDT Logging

Logs contain information about the events happening inside your application. Logs can be very helpful when trying to troubleshoot a problem. The BDT logging framework is designed in such a way that it can be integrated with most of the third-party external loggers such as Splunk and Datadog. The BDT logs are captured on the console. Users are free to choose any logging agent that works with the containerized solutions. A logging agent fetches the logs from the BDT console and pushes them to the user configured environment.

Application logs: Capture implementation level details required by the developer to understand what happened or how the application responded during a specific event. The application logs are printed in text format. Click [here](#) to know more.

Log level specifies the level of logging to be performed by the application. Following table describes the supported log levels with their description.

Log Level	Description
INFO	Records error messages, warnings, and informational messages.
WARN	Records error messages and warnings.
ERROR	Records only error messages.
DEBUG	Records diagnostic information.

These log levels are configurable and can be changed from the [CipherTrust Manager UI](#).

Format of Application Log

The log format determines how the contents of a log should be interpreted. Below is the sample of an application log:

```
bdt | 2025-01-15 08:53:30:577 INFO [main] - BDT is registered successfully on ke  
y manager  
bdt | 2025-01-15 08:53:30:578 WARN [main] - Connection not secure  
bdt | 2025-01-15 08:53:30:598 INFO [main] - Started HTTP server on port 80
```

Fixed-length Format File

Some systems may require fixed-length record formats. As described by IBM:

"In fixed-length or fixed-format records, each field starts and ends at the same place in every record. A data file that contains data records of equal and constant length might be organized as follows.

```
aaabbbbccccdddgghhhh
```

The data illustrated above has three records. Each record has a field of three characters followed by a field of four characters, so the total record length is seven characters. The file does not contain any separation between records; delimiters are unnecessary because all fields have the same length."

Reference: [IBM® Informix® 12.10](#)

In the above example, the records are not separated with a newline character (↵). For such types of file, line separator should not be enabled in the data source. Refer to [Managing Data Source](#) for details.

Fixed-length file only works with FPE algorithms.

References

We have provided samples of fixed length file where records are separated with a newline character (↵) followed by its data source configuration.

- [Fixed length file where records are separated with a newline character](#)
- [Fixed length data source configuration sample](#)

Supported Encoding

The following table lists the standard encoding supported by Oracle Java. BDT uses these encodings to read input files.

Encoding Set

Encoding	Description
Cp858	Variant of Cp850 with Euro character
Cp437	MS-DOS United States, Australia, New Zealand, South Africa
Cp775	PC Baltic
Cp850	MS-DOS Latin-1
Cp852	MS-DOS Latin-2
Cp855	IBM Cyrillic
Cp857	IBM Turkish
Cp862	PC Hebrew
Cp866	MS-DOS Russian
ISO8859_1	ISO-8859-1, Latin Alphabet No. 1
ISO8859_2	Latin Alphabet No. 2
ISO8859_4	Latin Alphabet No. 4
ISO8859_5	Latin/Cyrillic Alphabet
ISO8859_7	Latin/Greek Alphabet (ISO-8859-7:2003)
ISO8859_9	Latin Alphabet No. 5
ISO8859_13	Latin Alphabet No. 7
ISO8859_15	Latin Alphabet No. 9
KOI8_R	KOI8-R, Russian

Encoding	Description
KOI8_U	KOI8-U, Ukrainian
ASCII	American Standard Code for Information Interchange
UTF8	Eight-bit Unicode (or UCS) Transformation Format
UTF-16	Sixteen-bit Unicode (or UCS) Transformation Format, byte order identified by an optional byte-order mark
UnicodeBigUnmarked	Sixteen-bit Unicode (or UCS) Transformation Format, big-endian byte order
UnicodeLittleUnmarked	Sixteen-bit Unicode (or UCS) Transformation Format, little-endian byte order
UTF_32	32-bit Unicode (or UCS) Transformation Format, byte order identified by an optional byte-order mark
UTF_32BE	32-bit Unicode (or UCS) Transformation Format, big-endian byte order
UTF_32LE	32-bit Unicode (or UCS) Transformation Format, little-endian byte order
UTF_32BE_BOM	32-bit Unicode (or UCS) Transformation Format, big-endian byte order, with byte-order mark
UTF_32LE_BOM	32-bit Unicode (or UCS) Transformation Format, little-endian byte order, with byte-order mark
Cp1250	Windows Eastern European
Cp1251	Windows Cyrillic
Cp1252	Windows Latin-1
Cp1253	Windows Greek
Cp1254	Windows Turkish
Cp1257	Windows Baltic
UnicodeBig	Sixteen-bit Unicode (or UCS) Transformation Format, big-endian byte order, with byte-order mark
Cp737	PC Greek
Cp874	IBM Thai
UnicodeLittle	Sixteen-bit Unicode (or UCS) Transformation Format, little-endian byte order, with byte-order mark
Big5	Big5, Traditional Chinese
Big5_HKSCS	Big5 with Hong Kong extensions, Traditional Chinese (incorporating 2001 revision)
EUC_JP	JISX 0201, 0208 and 0212, EUC encoding Japanese
EUC_KR	KS C 5601, EUC encoding, Korean
GB18030	Simplified Chinese, PRC standard
EUC_CN	GB2312, EUC encoding, Simplified Chinese

Encoding	Description
GBK	GBK, Simplified Chinese
Cp838	IBM Thailand extended SBCS
Cp1140	Variant of Cp037 with Euro character
Cp1141	Variant of Cp273 with Euro character
Cp1142	Variant of Cp277 with Euro character
Cp1143	Variant of Cp278 with Euro character
Cp1144	Variant of Cp280 with Euro character
Cp1145	Variant of Cp284 with Euro character
Cp1146	Variant of Cp285 with Euro character
Cp1147	Variant of Cp297 with Euro character
Cp1148	Variant of Cp500 with Euro character
Cp1149	Variant of Cp871 with Euro character
Cp037	USA, Canada (Bilingual, French), Netherlands, Portugal, Brazil, Australia
Cp1026	IBM Latin-5, Turkey
Cp1047	Latin-1 character set for EBCDIC hosts
Cp273	IBM Austria, Germany
Cp277	IBM Denmark, Norway
Cp278	IBM Finland, Sweden
Cp280	IBM Ital
Cp284	IBM Catalan/Spain, Spanish Latin America
Cp285	IBM United Kingdom, Ireland
Cp297	IBM France
Cp420	IBM Arabic
Cp424	IBM Hebrew
Cp500	EBCDIC 500V1
Cp860	MS-DOS Portuguese
Cp861	MS-DOS Icelandic
Cp863	MS-DOS Canadian French
Cp864	PC Arabic
Cp865	MS-DOS Nordic
Cp868	MS-DOS Pakistan
Cp869	IBM Modern Greek
Cp870	IBM Multilingual Latin-2

Encoding	Description
Cp871	IBM Iceland
Cp918	IBM Pakistan (Urdu)
ISO2022CN	GB2312 and CNS11643 in ISO 2022 CN form, Simplified and Traditional Chinese (conversion to Unicode only)
ISO2022JP	JIS X 0201, 0208, in ISO 2022 form, Japanese
ISO2022KR	ISO 2022 KR, Korean
ISO8859_3	Latin Alphabet No. 3
ISO8859_6	Latin/Arabic Alphabet
ISO8859_8	Latin/Hebrew Alphabet
JIS_X0201	JIS X 0201
JIS_X0212-1990	JIS X 0212
SJIS	Shift-JIS, Japanese
TIS620	TIS620, Thai
Cp1255	Windows Hebrew
Cp1256	Windows Arabic
Cp1258	Windows Vietnamese
MS932	Windows Japanese
Big5_Solaris	Big5 with seven additional Hanzi ideograph character mappings for the Solaris zh_TW.BIG5 locale
EUC_JP_LINUX	JISX 0201, 0208, EUC encoding Japanese
EUC_TW	CNS11643 (Plane 1-7,15), EUC encoding, Traditional Chinese
EUC_JP_Solaris	JISX 0201, 0208, 0212, EUC encoding Japanese
Cp1006	IBM AIX Pakistan (Urdu)
Cp1025	IBM Multilingual Cyrillic: Bulgaria, Bosnia, Herzegovina, Macedonia (FYR)
Cp1046	IBM Arabic - Windows
Cp1097	IBM Iran (Farsi)/Persian
Cp1098	IBM Iran (Farsi)/Persian (PC)
Cp1112	IBM Latvia, Lithuania
Cp1122	IBM Estonia
Cp1123	IBM Ukraine
Cp1124	IBM AIX Ukraine
Cp1381	IBM OS/2, DOS People's Republic of China (PRC)

Encoding	Description
Cp1383	IBM AIX People's Republic of China (PRC)
Cp33722	IBM-eucJP - Japanese (superset of 5050)
Cp834	IBM EBCDIC DBCS-only Korean
Cp856	IBM Hebrew
Cp875	IBM Greek
Cp921	IBM Latvia, Lithuania (AIX, DOS)
Cp922	IBM Estonia (AIX, DOS)
Cp930	Japanese Katakana-Kanji mixed with 4370 UDC, superset of 5026
Cp933	Korean Mixed with 1880 UDC, superset of 5029
Cp935	Simplified Chinese Host mixed with 1880 UDC, superset of 5031
Cp937	Traditional Chinese Host mixed with 6204 UDC, superset of 5033
Cp939	Japanese Latin Kanji mixed with 4370 UDC, superset of 5035
Cp942	IBM OS/2 Japanese, superset of Cp932
Cp942C	Variant of Cp942
Cp943	IBM OS/2 Japanese, superset of Cp932 and Shift-JIS
Cp943C	Variant of Cp943
Cp948	OS/2 Chinese (Taiwan) superset of 938
Cp949	PC Korean
Cp949C	Variant of Cp949
Cp950	PC Chinese (Hong Kong, Taiwan)
Cp964	AIX Chinese (Taiwan)
Cp970	AIX Korean
ISCII91	ISCII91 encoding of Indic scripts
ISO2022_CN_CNS	CNS11643 in ISO 2022 CN form, Traditional Chinese (conversion from Unicode only)
ISO2022_CN_GB	GB2312 in ISO 2022 CN form, Simplified Chinese (conversion from Unicode only)
x-iso-8859-11	Latin/Thai Alphabet
x-JIS0208	JIS X 0208
JISAutoDetect	Detects and converts from Shift-JIS, EUC-JP, ISO 2022 JP (conversion to Unicode only)
x-Johab	Korean, Johab character set

Encoding	Description
MacArabic	Macintosh Arabic
MacCentralEurope	Macintosh Latin-2
MacCroatian	Macintosh Croatian
MacCyrillic	Macintosh Cyrillic
MacDingbat	Macintosh Dingbat
MacGreek	Macintosh Greek
MacHebrew	Macintosh Hebrew
MacIceland	Macintosh Iceland
MacRoman	Macintosh Roman
MacRomania	Macintosh Romania
MacSymbol	Macintosh Symbol
MacThai	Macintosh Thai
MacTurkish	Macintosh Turkish
MacUkraine	Macintosh Ukraine
MS950_HKSCS	Windows Traditional Chinese with Hong Kong extensions
MS936	Windows Simplified Chinese
PCK	Solaris version of Shift_JIS
x-SJIS_0213	Shift_JISX0213
Cp50220	Windows Codepage 50220 (7-bit implementation)
Cp50221	Windows Codepage 50221 (7-bit implementation)
MS874	Windows Thai
MS949	Windows Korean
MS950	Windows Traditional Chinese
x-windows-iso2022jp	Variant ISO-2022-JP (MS932 based)

Behavior of BDT on Container Shutdown

Container shutdown can be either graceful or not.

Graceful Shutdown

For BDT, a shutdown is considered graceful when it receives a `SIGINT` (Interrupt) or `SIGTERM` (Terminate) signal.

In case of graceful shutdown, following actions take place:

- The BDT client stops accepting the new requests and is deleted from the single pane of glass.
- The BDT server shuts down and the container is terminated.
- Any licenses in use are automatically released.

Note

In the scenarios, when shutdown is not graceful, the container is immediately terminated without deleting the client. You can either wait for the CipherTrust Manager to delete the client (When the BDT client skips sending heartbeat, it first enters into warning state. If the number of missed heartbeat count becomes equal to Heartbeat Timeout Count, CipherTrust Manager revokes the client) or can manually delete the client from the single pane of glass. Any licenses in use will be automatically released post client deletion.

Unprocessed Record File

The unprocessed record file holds details of the records that failed during processing. You can configure the location of this file when creating a [job configuration](#) on the CipherTrust Manager. If you specify the location for *Unprocessed Record File Path*, files with below formats (based on the source type) will be created at the specified location.

Source type	File format
Database	<code><job_id>-<source_table>-<timestamp>.txt</code> Example: <code>50cc3d07-ff29-474f-b9b5-bbf484a354ce-SOURCETABLE-2025-05-08.11.44.17.159.txt</code>
File	<code><job_id>-<timestamp>.txt</code> Example: <code>5b6542d4-a867-40a0-a34a-ac56e2bdf622-2025-05-08.04.31.29.535.txt</code>

The location of directory for unprocessed record file should exist inside container's directory structure that is `/opt/app/tmp`. To access this file outside the container, you must mount this path to a host location. For more information on volume mounting refer to [quick start](#).

It is recommended that the *Unprocessed Record File Path* be configured only if required, as it contains sensitive information. If configured, you must delete the created file after use or manage its access control to prevent the sensitive information from invalid access.

Note

The column order in the unprocessed record file when *in-place transformation* is enabled is as follows:

First, the columns to be encrypted as specified in the job configuration, followed by the primary keys.

Using Text Qualifier Characters in Input Files

A text qualifier character can be used to mark the start and end of a column field in a file that is input to the BDT utility. This is useful when the field value itself contains a character that would normally act as a field delimiter.

Use the qualifier to indicate to BDT that the data following the delimiter is part of the same field, and not the beginning of the next field.

Any printable ASCII character can be specified as a text qualifier, except for the backslash (\) character. Also note that the qualifier character cannot be the same as the delimiter character.

For example, in the following input file, the comma is the delimiter character, but it is also part of the address field. To let BDT know that the text after the comma is also part of the same field, the value must be enclosed with a text qualifier.

Example

Data before adding text qualifier:

```
#bash

Firstname, Lastname, Address
James,Brown,1745 E. New St., Apt. 22,Chicago
Scott,Smith,400 South Warren Street,Trenton
```

Data after adding text qualifier:

```
James,Brown,"1745 E. New St., Apt. 22,Chicago"
Scott,Smith,"400 South Warren Street,Trenton"
```

Using JDBC Driver URLs

A `JDBC_DRIVER_DOWNLOAD_URL` is an environment variable that specifies URL or a physical location from where container will download/load the driver jars required to make a JDBC connection with the database. If loading the driver from a physical location make sure the location is mounted inside the mount point `'/opt/app/tmp'` of the container.

Note

Ensure the location from which these URLs are retrieved while processing a job is accessible from the machine where the container is deployed.

Its value consists of comma-separated key-value pairs formatted as:

- **<Key Name>=<url>**

Specify unauthenticated URLs only. Authenticated URLs are not supported.

Note

You can provide URLs for multiple databases simultaneously, formatted like this: `<Key`

```
Name1>=<url1>, <Key Name2>=<url2>
```

- **<Key Name>=<Mounted Path>**

For specifying location to load the JDBC driver, you first need to mount the location of driver at host machine to the container's location (/opt/app/tmp/) when starting the container. Refer to quick start for details.

The following table lists the mapping of supported databases and their respective **KeyName**.

Database Name	Key Name
Oracle	ORACLE
Microsoft SQL Server	MSSQL
MySQL	MYSQL
PostgreSQL	POSTGRESQL
IBM Db2	DB2
SAP HANA	SAPHANA

Note

Key Name is case sensitive.

If the `JDBC_DRIVER_DOWNLOAD_URL` value is not specified during deployment, BDT will use the following default URLs.

Database Name	Default URLs
Oracle	https://repo1.maven.org/maven2/com/oracle/database/jdbc/ojdbc17/23.7.0.25.01/ojdbc17-23.7.0.25.01.jar
Microsoft SQL Server	https://repo1.maven.org/maven2/com/microsoft/sqlserver/mssql-jdbc/12.8.1.jre8/mssql-jdbc-12.8.1.jre8.jar
MySQL	https://repo1.maven.org/maven2/mysql/mysql-connector-java/8.0.30/mysql-connector-java-8.0.30.jar
PostgreSQL	https://repo1.maven.org/maven2/org/postgresql/postgresql/42.7.4/postgresql-42.7.4.jar
IBM Db2	https://repo1.maven.org/maven2/com/ibm/db2/jcc/db2jcc/db2jcc4/db2jcc-db2jcc4.jar
SAP HANA	https://repo1.maven.org/maven2/com/sap/cloud/db/jdbc/ngdbc/2.22.12/ngdbc-2.22.12.jar

Note

When default drivers are used, the MSSQL and MYSQL drivers establish the JDBC connection over SSL.

Thread Count and Batch Sizes

To best configure thread count and batch size, use the following principles:

1. Identify the ideal thread count for your environment depending on your system configuration. BDT gives optimal performance with 16 threads on four core machines. Setting thread count too low or too high will slow down the application.
2. Decide on batch size, configured based on available memory, size of individual record, and configured thread count. Setting batch size too high may result in an out-of-memory error.
3. Use the following formula to calculate the approximate maximum memory utilization by BDT:

$$\text{thread count} * \text{batch size} * \text{record size} = \text{memory utilization}$$

Therefore, thread count and batch size will be less than or equal to about 60% of available memory. The remaining memory is required to run BDT and to maintain transformed batches in the write queue.

Example

If you have 4GB available memory and individual record size of approximately 50MB, you can set either:

- Batch size to 50 and thread count to 1, utilizing $50 * 50\text{MB} = 2500\text{MB}$, approximately 60% of memory.
- Batch size to 10 and thread count to 3, utilizing $10 * 3 * 100\text{MB} = 3000\text{MB}$.

Troubleshooting

This section describes the issues you may run into and how to resolve them. If you face an issue that is not listed here, contact [Thales Customer Support](#).

Error/Issue	Possible Cause and Fix
Resource doesn't exist on Key Manager.	Make sure the resources associated to the job (such as job configuration, data sources, and protection policy) exist on Key Manager.
Client is unable to fetch latest policy even after synchronizing time between client and server.	To get the latest updates, the heartbeat interval must be longer than the delay between the client and server.
Failed to update BDT job status on CipherTrust Manager.	BDT failed to update the job status on CipherTrust Manager. Check liveness probe of the container. If it returns

Error/Issue	Possible Cause and Fix
	HTTP code 503, BDT can't process more jobs. In such scenarios, restart the container.
JDBC driver jar does not exist at location.	JDBC driver JAR is missing from the specified location. Ensure the JAR file exists in the specified location with the exact file name when a job is being processed.
Invalid value provided in database certificate value.	The provided database CA certificate is malformed. Make sure the database CA certificate is a valid certificate in <i>.PEM</i> format.
Failed to download the driver.	The required JDBC driver for database connection could not be downloaded. Ensure to specify correct JDBC driver download URL.
Could not parse JDBC driver download URL.	Unable parse JDBC driver download URL due to following reasons: — Empty or null key value pair in JDBC driver URL. —Invalid key-value pair. Ensure to provide correct JDBC driver download URL. See Using JDBC Driver URLs .
The job could not be stopped successfully.	Unable to stop the job, as it may have already completed or stopped.
Job configuration does not exists.	The job configuration associated with the job is deleted from CipherTrust Manager. Ensure job configuration exists on the CipherTrust Manager.
Primary key column not found. Can't perform in-place update.	Occurs when the Primary Key column is not available in the source/destination table in case of in-place update.
A deadlock error occurs during an in-place transformation in the Microsoft SQL Server database when the table has a primary key with a varchar datatype.	Using a primary key of a varchar datatype can slow down comparisons compared to integer datatypes, potentially leading to a deadlock. Therefore, it is recommended to modify the table to have a primary key of integer datatype. After the transformation is over, these changes can be reverted. 1. Identify the primary key constraint name. <pre>SELECT name FROM sys.key_constraints WHERE type = 'PK' AND parent_object_id = OBJECT_ID('table_name');</pre> 2. Drop composite primary key constraint from the table. <pre>ALTER TABLE table_name DROP CONSTRAINT <constraint_name>;</pre> The <code><constraint name></code> is obtained as the output of 1st query. 3. Alter table to create a new primary column of integer type. <pre>Alter table <table_name> add</pre>

Error/Issue	Possible Cause and Fix
	<pre><new_primary_column> int primary key identity(1,1)</pre> 4. Run the transformation. It will run successfully. 5. Delete the new primary key created in step 3. — Identify its constraint name using the query mentioned in step 1. — Drop the constraint using query mentioned in step 2. 6. Alter the table to add the composite primary key constraint back. <pre>ALTER TABLE <table_name> ADD CONSTRAINT <constraint_name> PRIMARY KEY (<column_name1>, <column_name2>);</pre>

CipherTrust Manager

Version: v2.22 (latest)

30 January 2026

Contents

- Batch Data Transformation (BDT) 3
 - Protection Profiles 3
 - BDT Policies 5
 - BDT Containers 10

Batch Data Transformation (BDT)

The Batch Data Transformation tile of the CipherTrust Manager lets you create data encryption profiles and policies that can be used to standardize your encryption policies across several Thales products. This feature ensures consistency and centralizes control over the types of encryption being used.

Batch Data Transformation currently supports:

- **Protection Profiles** that let you specify the encryption information for a specific input column in a BDT (Batch Data Policy) policy. Future releases will support Protection Profiles for other Thales products, such as the CipherTrust Tokenization Server. For details about creating Protection Policies, refer to [Protection Profiles](#).
- **BDT Policies** that work with the Batch Data Transformation (BDT) utility. BDT policies contain all the information BDT needs to transform and rekey data, and the policies you define in CipherTrust Manager can replace the locally-stored `bdt.config` file. For details, refer to [BDT Policies](#).

Note

BDT policies are supported BDT 2.3 onward.

Protection Profiles

Protection Profiles contain all information needed to perform a cryptographic operation, and they can be used to specify the encryption information for a specific input column in a BDT policy.

Creating a Protection Profile

1. Log on to the CipherTrust Manager as an administrator.
2. On the app selection menu, click **Batch Data Transformation** and select **Protection Profiles**.
3. Click **Create Protection Profile**. The Create Protection Policy wizard is displayed.
4. Enter the following information:

Field	Description
Name	A user defined name for this Protection Profile. The name must be unique.
Description	An optional description of the profile.
Key Name	Click Select and select the name of the key that you want to use. If you need to create a new key, you

Field	Description
	can click Create a New Key on the Select Key page.
Tweak	An optional 16-digit tweak for the encryption key.
IV	An optional 32-digit initialization vector for the encryption key.
Algorithm	The algorithm to use. This can be: • FPE (also called FF3) • FF1 • AES_CBC_PAD • AES_CTR • DESede (also called 3DES, Triple-DES, and DES-EDE)
Mode	Only applicable if the Algorithm is set to DESede. This can be: • CBC (the default) • ECB
Padding	Only applicable if the Algorithm is set to DESede. This can be: • NoPadding • PKCS5Padding
Character Set	The character set that will be encrypted by this profile. Thales provides the following default character sets: • Alphanumeric • All printable ASCII • All digits You can also make as many custom character sets as you need. For details, see Creating a Character Set.
Allow null or single character inputs	If this option is enabled, null or single-character inputs will be passed through to the output without being encrypted. If this option is not selected, the row transformation will fail. This option applies to FPE or FF1 algorithm encryption only. It is ignored if the Algorithm is set to Random.

5. Review the Protection Profile settings and click **Save** when you are done.

Creating a Character Set

1. Log on to the CipherTrust Manager as an administrator.
2. In the left pane, expand **Data Protection** and select **Character Sets**.
3. Click **Create Character Set** and enter the following information:

Field	Description
Name	A user defined name for this character set. The name must be unique.
Unicode Character Range	The Unicode characters included in this character set in HEX format. This field can contain a range of characters, a single Unicode character, or a comma-separated list consisting of any number of ranges and single characters. Examples: • Basic Latin: 0000–007F • Digits: 0031–0039 • Greek: 0370–03FF • Greek and all digits: 0E00–0E7F, 0030–0039 • Greek and the single digit 9: 0E00–0E7F, 0039 As you specify the range, a check mark icon next to the field label indicates that the entry uses valid HEX format. An exclamation mark icon indicates that the value is not valid HEX. You cannot create the character set unless you have a valid HEX expression in this field.

4. When you are done, click **Create**.

BDT Policies

The Batch Data Transformation utility (BDT) provides a policy-based data transformation and re-key service. While you can create a local `bdt.config` file that contains the required encryption information in different sections, you can also define BDT policies in CipherTrust Manager and then use those same policies wherever they are needed.

Creating a BDT Policy

1. Log on to the CipherTrust Manager as an administrator.
2. In the left pane, click **Data Protection > BDT Policies**.
3. Click **Create BDT Policy**. The Create BDT Policy wizard is displayed.

4. Enter the following information:

Field	Description
Name	A user defined name for this BDT policy. The name must be unique.
Description	An optional description of the policy.
FPE Mode	If you are using Format-Preserving Encryption (FPE), enter the FF3-encoding mechanism you want to use. The options are: • ASCII: The default encryption mode. ASCII supports only ASCII characters and is faster than UTF • UTF: Required when using FPE to encrypt Unicode characters. NOTE: The ASCII encryption mode is separate from ASCII character encoding.
In Place Update	Applies only if the source container points to a database. Enable this option if you want BDT to transform the data in place instead of specifying a different destination to hold the transformed data. If you enable this option, BDT transforms the data directly in the source database table and CipherTrust Manager does not display the Add Destination page in the wizard. If you <i>do not</i> enable this option, you can specify any container as the destination on the Add Destination wizard page. NOTE: If you enable this option and you also specify a destination table on the Data Transformation page of this wizard, the destination table is ignored.
Create Bad Record File	Enable this option if you want BDT to create a .failed file that contains information about the input records that could not be transformed.

When you are done, click **Next**. The **Add Source** screen is displayed.

5. Select the container that specifies the database or file that you want to transform. If you want to create a new container, click **Create Container**. For details, see [BDT Containers](#).

When you are done, click **Next**.

6. If you selected the **In Place Update** option on the **General Info** screen, proceed to the next step. Otherwise,

on the **Add Destination** screen, select the container that specifies the database or file into which you want BDT to write the transformed data. If you want to create a new container, click **Create Container**. For details, see [BDT Containers](#).

Note

If you want BDT to write the transformed data to a new table in the source database, the Source and Destination containers should be the same. You will be able to specify the destination table name in the next step.

When you are done, click **Next**. The **Data Transformation** screen is displayed.

- Click **Create Table** and enter the following information.

Note

- You must create a table even if you are using a CSV file or a fixed length file as the input. For these entities, the **Source Table** name field should be left blank.
- This step only specifies the database table names. You will specify the columns you want to use later in this procedure.

Field	Description
Source Table	If the source container points to a database, enter the name of the database table containing the columns that you want to transform. If the source container points to a CSV file or a fixed length file, leave the Source Table field blank.
Destination Table	Applies only when the In Place Update option is not enabled. If that option is enabled, BDT ignores this field. If the destination container points to a database, enter the name of the database table into which you want BDT to write the results of the transformation process. If you want BDT to create the destination table for you, enable the Create Destination Table option. If the destination container points to a CSV file or a fixed length file, leave the Destination Table field

Field	Description
	blank.
In Place Error	Specifies what to do when the In Place Update transformation option is selected and some records fail the transform process. The options are: • <code>rollback</code>: Roll back all changes. The source table returns unchanged to its initial state. • <code>commit</code>: Update the source column with transformed values and replace any failed records with either null or plain text depending on the value selected in the Error Placeholder field. • <code>exit</code>: Keeps source table as it is, with some values already transformed. This allows you to resolve the cause of the failure and restart the transformation (with the <code>-r</code> option).
Error Placeholder	This option applies only if In Place data transformation encounters an error and the In Place Error field is set to <code>commit</code>. The options are: • <code>NULL</code>: Sets the record value to null if the transformation fails. Use caution when selecting this option, as the original plain text data will be lost. • <code>PLAIN_TEXT</code>: Retains the original record contents if transformation fails.

- Repeat the previous step to add any other database tables you want to add to this BDT policy.

When you are done specifying the tables, click **Next**.

- Review the policy settings and click **Save** when you are done.

Now, specify the columns you want BDT to process. Refer to [Specifying Columns to Process](#).

Specifying Columns to Process

To specify which columns you want BDT to process in the input database table, CSV file, or fixed length file:

- On the BDT Policies page, click on the policy name.
- In the **Tables** section, expand the table for which you want to add column information.
- Click **Create Column** and enter the following information:

Field	Description
Name	The name of the column.

Field	Description
Action	This can be ENCRYPT, DECRYPT, TOKENIZE, DETOKENIZE, or REKEY. If you select REKEY, CipherTrust Manager displays two sections, one for the decryption of the existing data and one for the encryption of the same data with the new key. Do not change the Action that is automatically selected in these sections. When you specify the Decryption options, make sure they exactly match how the existing data is encrypted or the rekey operation will not succeed.
Protection Profile	The Protection Profile to use for this column. For details, see Protection Profiles .
Token Template	If you are using a CipherTrust Tokenization Server and you do not have a Protection Profile, you can use this field to specify a CTS template token. This option is only available if the Action is Tokenize, Detokenize, or Rekey. NOTE: If you specify a Protection Profile and a Token Template, CipherTrust Manager ignores the Token Template and uses the Protection Profile.
Token Group	The CTS token group associated with the template specified in the Token Template field. This option is only available if the Action is Tokenize, Detokenize, or Rekey.
Header	The cipher header version for determining the key version. The supported header versions are: V1_5, V1_5_Base64, V2_1, and V2_7.
Tweak Source	Specifies a column in the source database or file that contains the tweak. This allows you to use a different tweak for each row. If you specify a tweak source and a Protection Profile, this value overrides the tweak in the Protection Profile.
IV Source	Specifies a column in the source database or file that contains the IV (initialization vector). This allows you to use a different IV for each row. If you specify an IV source and a Protection Profile, this value overrides the IV in the Protection Profile.

Field	Description
Input Encoding	Specifies how to decode input and create byte array from it. Valid options are BASE2, BASE16, BASE64, UTF8, UTF16LE, UTF16BE, UTF32LE, or UTF32BE. NOTE: BASE2 is supported only with database Blob data type columns.
Output Encoding	Specifies how to encode output byte array to a string. Valid options are BASE16, BASE64, UTF8, UTF16LE, UTF16BE, UTF32LE, or UTF32BE.

- When you are done, click **Create**.
- Repeat this step for any other columns you want BDT to process.

BDT Containers

A container is the connection and encoding information for the input or destination associated with a BDT policy. Containers can point to databases, CSV files, or fixed length files, and they can be created as standalone entities or on-the-fly during BDT policy creation. Whichever method you use, CipherTrust Manager adds the container to the list of available containers for all BDT policies, so make sure you use a descriptive name so that the container can be easily identified in the list.

If you want to create a container during the creation of a BDT policy, click **Create Container** on the **Add Source** or **Add Destination** page of the Create BDT Policy wizard, then see the appropriate section below based on the type of container you want to create.

If you want to create a container as a standalone entity, do the following:

- Log on to the CipherTrust Manager as an administrator.
- In the left pane, click **Data Protection > Containers**.
- Click **Create Container**.
- Refer to one of the following sections depending on the type of container you want to create.
 - Creating a Database Container
 - Creating a CSV Container
 - Creating a Fixed Length File Container

Creating a Database Container

- Enter a user-defined name for the container in the **Name** field. This name must be unique, and it should be descriptive enough that you can easily find this container in the list of available containers.
- In the **Type** field, select one of the following:

- DB2
- ORACLE
- SQL_SERVER
- MYSQL
- HANA

3. Enter the following connection information for the database:

Field	Description
Connection URL	The URL BDT should use to access the database. For example, <code>jdbc:mysql://localhost:3306/world</code>
Username	The user name BDT should use to access the database.
Password	The password for the user account.
Driverclass	The JDBC connection driver class, for example, <code>com.mysql.jdbc.Driver</code>

4. Click **Create**.

Creating a CSV Container

1. Enter a user-defined name for the container in the **Name** field. This name must be unique, and it should be descriptive enough that you can easily find this container in the list of available containers.
2. In the **Type** field, select **CSV_FILE**.
3. Enter the following information for the CSV file:

Field	Description
Delimiter	The character that is used to divide one column from the next in the input file. Any printable ASCII character (except for backslash \) can be used as a delimiter, in addition to space (), tab, and Ctrl-A. NOTE: The delimiter and qualifier characters cannot be the same.
Qualifier	(Optional) The character to enclose fields that contain a delimiter character. Any printable ASCII character (except for backslash \) can be used as a

Field	Description
	qualifier. NOTE: The delimiter and qualifier characters cannot be the same.
File Path	The filepath relative to the <i>inputDir</i> or <i>outputDir</i> path in the BDT config file. The BDT config file resides on the local host where BDT will be running.
Encoding	Used to set character encoding, for example, to enable IBM's EBCDIC. If this container is used as the input source, the encoding type must match the input file. If this container is used as a destination, this is the encoding method BDT will use for the output and failed record files. • If you are using IBM's EBCDIC encoding, set encoding to <i>ibm500</i>. • If you are encrypting ASCII files, set the encoding to <i>ASCII</i>. For a complete list of supported encoding options, see Oracle Documentation .
Column Count	The total number of columns in the input file. This count should include all columns in the input file, regardless of whether the column has a transform rule defined for it or not.
Has Header Row	If you enable this check box, BDT will treat the first row as header row. Values from this row will be treated as column names. The same column names should be mentioned in the transformation action.
Unescape Input	If you enable this check box, BDT will consider delimiter and qualifier characters in the input preceded by a backslash (\) as normal characters and part of the input data. If you are using the BDT output file as input to another process, enable this option.

Creating a Fixed Length File Container

1. Enter a user-defined name for the container in the **Name** field. This name must be unique, and it should be descriptive enough that you can easily find this container in the list of available containers.
2. In the **Type** field, select **FIXED_LENGTH_FILE**.

3. Enter the following information for the fixed length file:

Field	Description
File Path	The filepath relative to the inputDir or outputDir path in the BDT configuration file. The BDT configuration file resides on the local host where BDT will be running.
Encoding	Used to set character encoding, for example, to enable IBM EBCDIC. If this container is used as the input source, the encoding type must match the input file. If this container is used as a destination, this is the encoding method BDT will use for the output and failed record files. • If you are using IBM's EBCDIC encoding, set encoding to ibm500. • If you are encrypting ASCII files, set the encoding to ASCII. For a complete list of supported encoding options, see Oracle Documentation.
Column Count	The total number of columns in the file. This count should include all columns in the input file, regardless of whether the column has a transform rule defined for it or not.
Has Header Row	If you enable this option, BDT will treat the first row as header row. Values from this row will be treated as column names. The same column names should be used in the transformation action.
Unescape Input	If you enable this check box, BDT will consider delimiter and qualifier characters in the input preceded by a backslash (\) as normal characters and part of the input data. If you are using the BDT output file as input to another process, enable this option.
Line Separator	If you enable this option, BDT assumes that the records in the input data are separated by a line separator.
Record Length	The length of one full row in the fixed length file.
Column Position Info	The position of the columns that you want to transform with this BDT policy. For each column, use the following format: <pre>[{"column": "n", "startIndex": "x", "endIndex": "y"}]</pre> Multiple column definitions should be separated with a comma. For example, to specify column 0 with a starting index of 0 and an ending index of 10 along with column 1 with a starting index of 10 and an ending index of 26, you would enter: <pre>[{"column": 0, "startIndex": 0, "endIndex": 10}, {"column": 1, "startIndex": 10, "endIndex": 26}]</pre> If the column definitions are valid, CipherTrust

Field	Description
	Manager displays a green triangle with a white check mark in the corner of this field. If the definitions are not valid, the icon changes to a red triangle with a black X. You cannot save the container until the column definitions are valid.

Product Brief

CipherTrust Batch Data Transformation (BDT)

cpl.thalesgroup.com

THALES
Building a future we can all trust

CipherTrust Batch Data Transformation (BDT) is a bulk transformation tool that is used offline to protect/re-protect data inside your data store. BDT can be part of an ongoing extract and transform operation. BDT may also be the primary means of doing annual key rotations on existing data, and part of the process to securely move production data into QA and staging for test purposes while tokenizing it for protection.

Gain transparent field-level encryption, tokenization, data generalization, data masking or redaction without needing to know anything about cryptography. Developers do not need to be involved. All DevOps needs to do is deploy BDT in communication with the source it is going to protect. The source can be either a database or a file. Your Data Security Admin will handle all data protection including creation of policies for rapid data transformation.

You keep months of Developer time, and Security gains the ability to close vulnerability gaps efficiently.

To sustain your compliance and your capacity per sprint, we removed Developer (Dev) involvement from data transformation.

Data multiplies, but team members don't. So that you can focus on more exciting projects, you need an automated process to prepare an existing database to transform data from clear text to protected text, re-encrypt data to the most current key using version metadata, and move data to Data Lakes or Data Warehouses.

Organizations tell us traditional encryption, tokenization, data generalization, data masking and redaction solutions require their Devs to handle fire drills when ciphers, keys or parameters need to change—taking Devs away from roadmap and/or innovative topics for a minimum of two months each and every time an update is needed for ciphers, keys or parameters.

Their Devs get pulled into projects that are a minimum of two calendar months because the Devs have to change source code, and DBAs/Devs have to migrate current data to the new ciphers/keys/parameters. After all changes are submitted, all of the code must be tested and re-tested until it passes all tests. The Devs are required to become cryptographers and change source code for every individual piece of sensitive data in every database column multiplied by every service protecting data. As a result, organizations report that they typically dedicate resources to revenue generating projects and delay their data protection updates for two years, resulting in a weakened security posture, increases in failed audits and more security breaches.

CipherTrust Batch Data Transformation (BDT) removes the need to learn cryptography and automates batch data transformation to encrypt/decrypt, tokenize/detokenize, or re-key large volumes of data quickly. BDT empowers you to perform data transformation on your schedule of choice with no Developer involvement.

DBAs or Data Security Admins configure BDT's policies and initiate data transformation. Using BDT removes the need to write and maintain scripts to read data from source, protect data and then move the transformed data to target systems.

BDT reduces your workload with centrally-managed policies that define encryption options including standard AES encryption or format preserving encryption, while identifying the database columns

to be protected and the number of records in each batch. Data filtering enables creation of customized destination record subsets.

Since transformation from a source database is read-only, BDT uses production databases transparently.

Data Security Admins manage the policies, entering ciphers, keys or parameters. They update data protection in real time, making a selection from a dropdown menu in the GUI or by REST API. Vulnerability gaps are reduced from months to less than a minute.

Since there are no changes to code, no Dev or Test involvement is required to update ciphers/keys/parameters.

Benefits

Increase Developer Capacity

- Devs are not involved in data transformation. Instead of managing security workflows, automation allows developers to focus on higher-value tasks, such as delivering business logic and innovation
- Human error decreases due to no changes to source code for the initial setup or for updates
- Dev and Test are not involved so vulnerability gaps for sensitive data can be closed in minutes after discovery

Security Experts Manage Security

- Data Security Admins configure protection policies and BDT jobs, identifying which columns of sensitive data need to be Protected/Revealed with which policy and the target column or data source for the transformed data
- Data Security Admins can initiate jobs and view job status using the CM GUI or REST APIs
- Data Security Admins can define centrally-managed access policies describing how people see data, including static data masking and redaction
- Data Security Admins can leverage crypto agility to change ciphers, parameters and keys in real time without taking Devs off of other projects

- Visibility on a single pane of glass shows where protection is deployed

Continuous Compliance

- Compliance teams can easily demonstrate compliance without involving Devs – the audit will be more complete, accurate and faster. Includes tracking of all data access for easy integration with SIEM tools
- Separation of Duties aligns with compliance regulations

Ease of use

- Deploy centrally and scale automatically using containers
- Automate batch transformations and control the schedule
- Flexible data extraction/ingestion

Crypto Agility

BDT supports crypto agility for data protection due to the convergence of three design elements:

- Centrally-managed Protection and Access Policies
- No changes to code, ever
- Separation of duties

Crypto agility enables Data Security Admins to change ciphers, keys and parameters in real time.

High Speed Transformation

Flexible Conversion Between Data Stores

BDT can protect data while it is moving, for example, from a database to a comma-separated values (CSV) file or in reverse. BDT supports:

- File to File
- File to Database
- Database to File
- Database to Database

Supports:

- Databases (Oracle, Microsoft SQL Server, IBM Db2, MySQL, SAP Hana)
- CSV files
- Fixed Length files

Views and Triggers can be built to associate the UDFs to Inserts or Queries automatically.

Diagram 1 shows BDT deployed as a docker container. BDT can be scaled up to provide high availability and performance.

Diagram 1: Extract, Transform, Load (ETL) – CipherTrust Manager handles configuration, policies and keys for BDT.

Protection Policies

We enable the Data Security Admin to define a protection policy by selecting from an ever-growing list of NIST-sanctioned algorithms. The Access Policies can be automated for onboarding/offboarding.

Create Protection Policy

A protection policy specifies how a piece of data should be protected.

Protect Data Across Apps, APIs and Databases

BDT is one of several centrally-managed Thales data protection offerings. CipherTrust Application Data Protection SDK (CADP SDK) offers field-level data protection to developers as a simple-to-integrate library. CipherTrust RESTful Data Protection (CRDP) is a RESTful service that offers field-level data protection across cloud and on-premises applications. CipherTrust Data Protection Gateway (DPG) is a Gateway that transparently intercepts RESTful API calls and protects data with no code changes required on the RESTful service or clients.

CipherTrust Database Protection (CDP) offers transparent, column-level data protection for a wide range of databases.

All centrally-managed Connectors support Static Data Masking and Redaction. CADP, CRDP and DPG additionally support Dynamic Data Masking.

BDT complements our other CipherTrust data protection solutions by automating batch data transformation processes.

Diagram 2: BDT can be used with DPG, CADP, CRDP and CDP to transform data in files or databases and rotate keys to maintain security compliance. BDT can connect to a database or to a server. Diagram 2 shows Connection to a database.

CipherTrust Data Security Platform

BDT is part of the CipherTrust Data Security Platform (CDSP), which unifies data discovery, classification, protection and monitoring with unprecedented granular access controls and centralized key management. Protecting your sensitive data with CDSP decreases time to compliance, simplifies data security operations, secures cloud migrations and reduces risk across your business. You can rely on the Thales CipherTrust Data Security Platform to help you discover, protect, control and monitor your organization's sensitive data, wherever the data resides.

ESG Statement

The Thales CipherTrust Batch Data Transformation (BDT) containerized solution makes a smaller carbon footprint than a full server solution or virtual appliance because BDT elastically scales, in alignment with Thales' ESG (environmental, social, and governance) commitment to a greener, safer world.

About Thales

Thales is a global leader in cybersecurity, helping the most trusted companies and organizations around the world protect critical applications, sensitive data, and identities anywhere at scale. Through our innovative services and integrated platforms, Thales helps customers achieve better visibility of risks, defend against cyber threats, close compliance gaps, and deliver trusted digital experiences for billions of consumers every day.

PREFACE

The *Batch Data Transformation Installation and User Guide* describes how to install, configure, and use Vormetric Batch Data Transformation.

Documentation Version History

The following table describes the documentation changes made for each document version.

Documentation Changes

Product/Document Version	Date	Changes
2.0 v1	1/19/18	Added support for database transformations, fixed-length file format support details, added AES_CTR and FF1 algorithm support. New policy file attributes added and described. 80% of guide material changed or edited.
1.1 v1	11/15/17	(Internal-only release) Added FF1 encryption, character encoding, fixed-length formatting,
1.0 v1	12/16/16	First release of document.

Assumptions

This documentation assumes:

- Familiarity with Vormetric Application Encryption (VAE)
- Familiarity with Vormetric Token Server (VTS)
- Some knowledge of format-preserving encryption, tokenization, or cipher block chaining principles, depending on which technique you will use for Batch Data Transformation.

Vormetric Data Security Platform—Overview

The Vormetric Data Security (VDS) Platform protects data wherever it resides. The platform solves security and compliance issues with encryption, key management, privileged user access control, and security intelligence logging. It protects data in databases, files, and Big Data nodes across public, private, hybrid clouds and traditional infrastructures.

Figure 1: The Vormetric “Solar System”

The platform consists of products that share a common, extensible infrastructure. At the heart of the platform is the Data Security Manager (DSM), which coordinates policies, keys, and the collection of security intelligence, all of which is managed and observed through your browser. In addition to the DSM, the Vormetric Data Security Platform consists of the following:

- **Vormetric Application Encryption (VAE)** provides a framework to deliver application-layer encryption such as column- or field-level encryption in databases, Big Data, or PaaS applications. VAE is an application encryption library providing a standards-based API to do

cryptographic and encryption key management operations into existing corporate applications.

- **Vormetric Cloud Encryption Gateway (VCEG)** safeguards files in cloud-storage environments, including Amazon S3 and Box. VCEG encrypts sensitive data before it is saved to the cloud, enabling security teams to establish visibility and control around cloud assets.
- **Vormetric Key Management (VKM)** centralizes 3rd-party encryption keys and stores certificates securely. It provides standards-based enterprise encryption key management for Transparent Database Encryption (TDE), KMIP-compliant devices, and offers vaulting and inventory of certificates.
- **Vormetric Protection for Teradata Database** provides granular controls to secure assets in Teradata environments. It simplifies the process of using column-level encryption in your Teradata database. It provides documented, standards-based APIs and user-defined functions (UDFs) for cryptographic and key management operations.
- **Vormetric Security Intelligence** provides comprehensive logging combined with Security Information Event Management (SIEM) systems to detect advanced persistent threats and insider threats. In addition, the logs satisfy compliance and regulatory audits.
- **Vormetric Tokenization with Dynamic Data Masking (VTS)** replaces sensitive data in your database with unique identification symbols called tokens. This reduces the number of places that clear-text sensitive data reside, and thus reduces the scope of complying with PCI DSS and corporate security policies.
- **Vormetric Transparent Encryption (VTE)** secures any database, file, or volume across your enterprise without changing the applications, infrastructure, or user experience.

How to Search Documentation Sets

Technical information for Vormetric products can be spread across many documents. Instead of searching through each individual document to find the information you need, you can use the following procedure to search all of the VTE documents with a single search in Windows (the same process should work for UNIX/Linux):

1. Copy all the .pdf files of a specific product into a single directory. For example, using the Vormetric Transparent Encryption:

```
C:\Documents\PDFs\5.2.3>dir
Admin_Guide_V1.pdf
Agent_Install_& Config_Guide_v2.pdf
Data_Transformation_Guide_v1.pdf
DSM_Automation_Reference_v1.pdf
DSM_Install_Guide_v1.pdf
Event_&_Log_Messages_Ref_v1.pdf
```

GettingStarted_v1.pdf
 VSI_Reference_v1.pdf
 RN_DSM.pdf
 RN_Linux.pdf
 RN_RHEL7.pdf
 RN_UNIX.pdf
 RN_Windows.pdf
 VDSCompatibilityMatrix.pdf

2. Bring up Adobe Reader or Adobe Acrobat.
3. Open any pdf file from that directory: **File > Open > Select File.**
4. Click **Edit > Advanced Search.**
5. Under "*Where would you like to search?*" click "**All PDF Documents in**", then select the directory containing all the VTE PDF files. In this case, C:\Documents\PDFs\5.2.3
6. In the "*What word or phrase would you like to search for?*" enter the search phrase and click search.

You can do this with any set of PDF files.

Service Updates and Support Information

The license agreement that you have entered into to acquire the Thales products ("License Agreement") defines software updates and upgrades, support and services, and governs the terms under which they are provided. Any statements made in this guide or collateral documents that conflict with the definitions or terms in the License Agreement, shall be superseded by the definitions and terms of the License Agreement. Any references made to "upgrades" in this guide or collateral documentation can apply either to a software update or upgrade.

- sales@thalesec.net
- (408) 433-6000

Overview

The Batch Data Transformation utility (BDT) provides a policy-based data transformation and re-key service. This chapter contains the following sections:

- [“Overview” on page 5](#)
- [“Architecture” on page 6](#)
- [“System Requirements” on page 7](#)

Overview

The Batch Data Transformation utility (BDT) is a command-line tool that you can use to achieve these main goals:

- Encrypt production data quickly and securely
- Re-key encrypted data
- Migrate data out of a production environment

BDT provides a policy-based data transformation and re-key service. The utility's actions are based on policies, which are defined in policy files. For each action or group of actions that you want to do with the utility, you define a policy file. Each policy file contains one or more configuration sections. Each section defines an action and its attributes. For more information, see [“Creating a BDT Policy” on page 19](#).

BDT 2.0 supports the following transformation options:

- File to file
- File to database table
- Database table to file
- Database to database

To run the Batch Data Transformation utility, invoke it from the command line. See [“Running BDT” on page 15](#).

Architecture

The BDT utility makes use of other Vormetric technology, including Vormetric Application Encryption (VAE) and the Vormetric Tokenization Server (VTS). It can encrypt and decrypt data using format-preserving encryption (FPE), either FF3 or FF1, or Advanced Encryption Standard (AES) block cipher, either cipher block chaining (AES_CBC_PAD) or counter (AES_CTR) modes. Or it can tokenize data using the VTS. In this version of BDT, the user can also designate specific source and destination database tables and columns.

BDT also supports character encoding, such as EBCDIC, and the option of fixed-length and .csv file formats.

System Requirements

Please refer to the *Vormetric Batch Data Transformation 2.0 Release Notes* for system requirements, including:

- Compatible VAE/DSM versions
- Compatible VTS/DSM versions
- Supported databases

BDT supports the same operating systems as Vormetric Application Encryption (VAE), and has a few additional special requirements:

- Java Runtime Environment (JRE) 1.8+
- 4 cores
- 16 GB RAM

Input data requirements

- Per-column data size limit: 128K
- The input data file can contain quoted and unquoted values. Both "field1_Value" and field2_Value are recognized as data values. To use quoted values, you must specify the double quote character as a text qualifier. (See [“Using Text Qualifier Characters in Input Files” on page 43.](#))
- Fields must be separated by the delimiter character specified in the policy file. (See [“Creating a BDT Policy” on page 19.](#))
- If a field value contains the delimiter character, the value must be enclosed by text qualifier characters, as specified in the policy file. (See [“Using Text Qualifier Characters in Input Files” on page 43.](#))
- If a field value contains the text qualifier, the entire value must be enclosed in text qualifier characters.
- Another way to deal with field values having delimiter or qualifier characters is to escape those character using the backslash (\) instead of enclosing the field in text qualifier characters. When using this technique, set the `unescapeInput` attribute in the policy file to true. For example:

Jon, Smith, 400\, \"West Avenue, 5000

If the field value has a backslash character, it must also be escaped using an additional backslash character.

Installing and Configuring BDT

This chapter tells how to install Batch Data Transformation on Windows or Linux and how to modify the software configuration settings. Be sure your system is compatible, as listed in [“System Requirements” on page 7](#).

This chapter contains the following sections:

- [“Installation \(Linux\)” on page 9](#)
- [“Installation \(Windows\)” on page 10](#)
- [“Installed Software Directory Structure” on page 10](#)
- [“Edit the bdt.config File” on page 11](#)

Installation (Linux)

1. Download the BDT distribution.
`wget https://<path to download site>/bdt-2.0.0.tar.gz`
2. Create a BDT home directory at a convenient location.
`cd /usr/local/bin`
`mkdir bdt`
3. Extract the distribution to the BDT home directory.
`sudo tar -xzf filename.tgz -C /usr/local/bin/bdt`
4. Add the Java bin directory path to the PATH environment variable. Edit the `.bashrc` file for the admin user and add the following lines:
`export JAVA_HOME=/usr/lib/java/jre`
`export PATH=$JAVA_HOME/bin:$PATH`
5. Verify installation by checking to be sure the installation directories appear; see [“Installed Software Directory Structure” on page 10](#).

Installation (Windows)

1. Download the BDT distribution file `bdt-2.0.0.zip` through the web browser using the URL obtained from your sales representative.
2. Create a BDT home directory at a convenient location. Use the File Explorer “New Folder” button to create a new folder named BDT under the folder `C:\Program Files`.
3. Extract the distribution to the BDT home directory. Use winzip, pkunzip, 7zip, or your other favorite file compression/extraction utility.
4. Add the Java bin directory path to the PATH environment variable:
 - a. Start the Control Panel
 - b. Click System
 - c. Click Advanced System Settings
 - d. Click the Environment Variables button.
 - e. Under System Variables, select Path, then click Edit.

Be **very careful** not to delete any of the existing text here.

Hit the “End” button, then append this to what’s already in the value:

`;C:\Program Files\BDT`

- f. Click OK.
5. Verify installation by checking to be sure the installation directories appear; see [“Installed Software Directory Structure” on page 10](#).

Installed Software Directory Structure

The directory structure of the installed software is as follows:

bin	Executable scripts for validating configuration, testing and execution.
conf	Default configuration files. Includes <code>bdt.config</code> and logging properties.
lib	Required JAVA library dependencies.
log	Log file directory.
samples	Sample policy and configuration files.

Edit the bdt.config File

Overview

The configuration of the BDT utility is stored in JSON format in the file `bdt.config`. Edit this file to change settings to refer to your own environment and to tune the performance of the utility.

Refer to the [“Example bdt.config file” on page 11](#).

At the top of the file are several global configuration settings, followed by settings that configure the main underlying tools used by BDT:

- The first few lines contain settings for the Batch Data Transformation utility itself. These include `inputDirectory`, `outputDirectory`, `threadCount`, and `batchSize`.
- The `vts{}` object contains settings to customize the behavior of the Vormetric Tokenization Server.
NOTE: When running BDT for the first time, follow the steps in [“Example 3: Set BDT passwords in bdt.config file” on page 17](#) to store encrypted pin and passwords in `bdt.config`.
- The `vae{}` object contains settings related to Vormetric Application Encryption. Note that you will encode and enter the `pin` value using the steps in [“Example 3: Set BDT passwords in bdt.config file” on page 17](#).
- The `characterSets{}` object was added to `bdt.config` to improve compatibility with the Vormetric Tokenization Server (VTS). See [“About characterSets” on page 13](#).

Example bdt.config file

```
{
  "inputDirectory": "/home/user/input",
  "outputDirectory": "/home/user/output",
  "threadCount": 20,                      /* maximum running threads to transform file */
  "batchSize": 1000,                     /* Number of records processed in batch */
  "vts": {
    "hostName": "vtshost",                /* hostname of a machine where tokenization server is
      running */
    "userName": "vtsuser",                /* VTS username */
    "password": "",                       /* VTS password. Don't put plain text here. Use bdt -e option
      to put encrypted value here */
  }
}
```

```

"tokenUrl": "https://vtshost/vts/rest/v2.0/tokenize",      /* VTS tokenize rest
  url */
"detokenUrl": "https://vtshost/vts/rest/v2.0/detokenize", /* VTS detokenize rest
  url */
"ssl" : {
  "server" : {                                           /*ssl configuration for
    server*/
    "sslmode" : "DEFAULT",                               /* ssl mode (DEFAULT, ALLOW_ALL
    - allow everything, SPECIFY_SSL_CERT - communicate if server cert exist in
    specified truststore)*/
    "verifyHostname" : true,                             /* whether to do host
    name verification */
    "truststore": "",                                   /* truststore file path,
    truststore should have server cert. Applicable only for SPECIFY_SSL_CERT
    mode*/
    "password" : ""                                     /* truststore file password.
    Applicable only for SPECIFY_SSL_CERT mode*/
  },
  "client" : {                                           /* ssl configuration for

```

```
    },  
    {  
      "digits":["0030-0039"]  
    },  
    {  
      "alphabets":["0041-005A", "0061-007A"]  
    },  
    {  
      "alphanumeric":["0030-0039", "0041-005A", "0061-007A"]  
    }  
  ]  
}
```

About characterSets

In earlier versions of BDT, users could specify a character set range in a policy file. Now, use the `characterSets` attribute at the `bdt.config` level to define a character set name (such as “digits”) and a range, entered as a name/value pair. Four defaults are listed; users can also define their own name and range for a character set.

Default characterSets names and range values

The sample `bdt.config` file includes the following sample `characterSets` name/value definitions. Value is a list of numeric code ranges for this character set, specified in hex representation. For example, numeric characters range from 0030 to 0039 in hex, which is 48-57 in decimal.

Name	Value (Range)
latin	"0020-007E"
digits	"0030-0039"
alphabets	"0041-005A", "0061-007A"
alphanumeric	"0030-0039", "0041-005A", "0061-007A"

VTS server authentication

You must set up SSL for secure communication between the BDT utility and the Tokenization Server (VTS). In the `vts{}` section of `bdt.config`, the `server{}` object contains the following settings related to SSL authentication:

<code>sslmode</code>	One of the following values: DEFAULT - Trust only a standard valid certificate issued by a Certificate Authority (CA). If the certificate is expired, self-signed, or invalid, communication with the VTS server fails. SPECIFY_SSL_CERT - Trust standard certificates and certificates stored in the provided trust store (specified in the <code>truststore</code> setting). Use to accept self-signed and expired certificates. ALLOW_ALL - Trust all certificates; no trust policy is defined. Any kind of SSL certificate is acceptable, including valid, expired, self-signed, or any other. The <code>truststore</code> setting is not required.
<code>VerifyHostName</code>	Set to <code>"true"</code> to enable hostname verification for SSL communication, <code>"false"</code> to disable hostname verification. Default: <code>true</code> .
<code>truststore</code>	(Used only when <code>sslmode</code> is <code>SPECIFY_SSL_CERT</code>) Truststore file path. To set up the truststore: Get the server's public certificate. If not available, open the VTS URL in a browser and export it from the Security option. Import the certificate and create the truststore. Use the following command. It will output the truststore password. <pre>keytool -import -alias "vts host certificate" -file server.crt -keystore server.truststore</pre> IMPORTANT: Note this password. You need to provide it in the <code>password</code> parameter.
<code>password</code>	(Used only when <code>sslmode</code> is <code>SPECIFY_SSL_CERT</code>) Truststore file password obtained when you imported the VTS certificate and created the truststore.

VTS client authentication

In the `vts{}` section of `bdt.config`, the `client{}` object contains the following settings related to SSL authentication:

<code>sslmode</code>	One of the following values: DEFAULT - Client authentication is disabled. No need to send client identity. ALLOW_ALL - Client authentication is disabled. No need to send client identity. SPECIFY_SSL_CERT - Client authentication is enabled. Create keystore with client certificate and key. Set keystore path in the <code>keystore</code> parameter. Communication succeeds if the VTS server finds a valid certificate set in the keystore.
<code>keystore</code>	Client keystore file path. This assumes a keystore has already been created; for example, using <code>keytool</code>
<code>storepassword</code>	Client keystore file password
<code>keypassword</code>	Client's key password

Using Batch Data Transformation

This chapter tells how to configure Batch Data Transformation policies and run transformations. It contains the following sections:

- [“Running BDT” on page 15](#)
- [“Creating a BDT Policy” on page 19](#)
- [“Using Text Qualifier Characters in Input Files” on page 43](#)
- [“Transforming Databases” on page 44](#)
- [“Filtering Input Data” on page 49](#)
- [“Monitoring and Troubleshooting” on page 51](#)

Running BDT

Overview of running BDT

1. Update the properties in the `bdt.config` file to reflect your environment.
2. Create column transformation rules in the file `bdt.policy` based on your input file and transformation requirements.
3. Change to the `/bin` subdirectory of the BDT installation directory. For example, on Linux:

```
cd /home/bdt/bin
```
4. Run BDT from the command line using either `bdt.sh` or `bdt.bat`. If this is first time you are running BDT, use the `-e` option to set the passwords.

```
./bdt.sh [-e] -t [-c configfilepath] -p policyfilepath
```

Use `-e` the first time you run BDT. After that, use it whenever you want to change the passwords.

Use `-c` to specify the location of `bdt.config`. If `-c` is omitted, the default configuration file `bdt/conf/bdt.config` is used.

See also: [“Example 3: Set BDT passwords in bdt.config file” on page 17](#) and [“Example 3b: Set database passwords in a BDT policy file” on page 18](#).

Output file format

When BDT runs a data transformation (that is, when you run BDT with the `-t` option) it first validates the `bdt.config` and `bdt.policy` files to be sure they are valid. Then it performs the data transformation specified in those files.

BDT stores the transformed data in the output directory specified in `bdt.config`. The output file for each BDT run is marked with a time stamp. The output directory can contain output files from multiple runs of BDT.

If the input file contains records which BDT can not transform, they are stored in the same output directory in `<policy_name-timestamp>.failed`. (Policy name is defined under `name` in a policy file.)

The output file contains fields separated by the delimiter character specified in the policy file. Each line represent a individual record.

If a field value contains a delimiter character, that character is escaped in the output file with a backslash character (`\`). For example:

```
Jon, Smith, 500, "wRui89$ass, 3000
```

is escaped as

```
Jon, Smith, 500\, "wRui89$ass, 3000
```

When using the file BDT output file as input for another transformation, always set the `unescapeInput` flag in the policy file to `true`. (See [“Creating a BDT Policy” on page 19.](#))

BDT command syntax

The Batch Data Transformation utility runs at the command line with the following syntax:

```
bdt [-c <configfilepath>] [-e] [-h | -ld <type> | -ls <type> | -t | -v] [-p <policyfilepath>] [-sv] [-table <tableName>]
```

<code>-c, --configfile <configfilepath></code>	Location of the BDT configuration file. Replace <code><configfilepath></code> with the path to <code>bdt.config</code> . If omitted, the default file <code>bdt/conf/bdt.config</code> is used.
<code>-e, --encryptPassword</code>	Set the VAE library password and VTS password, encrypt them, and store in <code>bdt.config</code> . Use this option the first time you run BDT. You can also use it whenever you want to change the passwords. BDT prompts you to enter the passwords at the console.
<code>-h, --help</code>	Display the BDT command syntax and information about how to use it.
<code>-ld <type></code>	<code>listDestination <type></code> list data destination objects. Object types [tables, columns]
<code>-ls <type></code>	<code>listSource <type></code> list data source objects. Object types [tables, columns]

<code>-p, --policyfile <policyfilepath></code>	Location of the BDT policy file. Replace <code><policyfilepath></code> with the path to <code>bdt.policy</code> .
<code>-sv, --skipvalidation</code>	Run BDT without first checking the <code>bdt.config</code> and <code>bdt.policy</code> files for correctness.  Caution: Use only for testing. Do not use in a production environment.
<code>-t, --transform</code>	Validate <code>bdt.config</code> and <code>bdt.policy</code> , then transform the input file and store the results in the output directory. If this option is omitted, BDT does not perform the data transformation. Running without <code>-t</code> is useful when you only want to set passwords or validate configuration files.
<code>-v, --validate</code>	Validate <code>bdt.config</code> and (optionally) <code>bdt.policy</code> . Use this option when you want to check the files without actually transforming the data. The policy file is validated if the <code>-p</code> option is included in the command. If you are running with <code>-t</code> , you don't need to also include <code>-v</code> . The <code>-t</code> option includes an implicit <code>-v</code> .
<code>-table <tableName></code>	List columns for this table. This option must be accompanied by <code>-ls</code> or <code>-ld</code> option. General syntax: <code>bdt.bat -ls (or -ld) columns -table <table_name> -p <policy file></code>

Example BDT commands

Example 1: Run the BDT utility

Run `bdt.sh` or `bdt.bat` from the `distribution/bin` directory.

Example 2: Display help

Run `./bdt.sh -h` or `./bdt.sh --help`

Example 3: Set BDT passwords in `bdt.config` file

The first time you run BDT, use the `-e` option to store encrypted passwords in the BDT configuration file. Run the following command:

```
./bdt.sh -e [-c configfilepath][-p policyfilepath]
```

This will prompt for the VAE library password and the VTS user password, keystore, truststore and key password. These passwords will be encrypted and stored in the `bdt.config` file specified in the `-c` option. If `-c` is omitted, the default file `bdt/conf/bdt.config` is used.

Example 3b: Set database passwords in a BDT policy file

The `-e` option can also be used to store the database password in a policy file, if the policy file has a database as a source or destination. Database passwords will also be stored in encrypted form.

Run the following command:

```
./bdt.sh -e [-c configfilepath][-p policyfilepath]
```

To change the password at any time, run BDT with the `-e` option again.

Example 4: Validate configuration

If you only want to validate the input files, not perform any other operation, use the `-v` option. You can specify which files to validate by adding `-c` and `-p`.

```
./bdt.sh -v [-c configfilepath -p policyfilepath]
```

`-c` is optional. If not provided, the default configuration file `bdtd/conf/bdtd.config` is validated.

`-p` is optional. If not provided, the policy file is not validated.

To validate `bdtd.config` alone, assuming the file is stored in the expected default location, use `-v` with no other options:

```
./bdt.sh -v
```

Example 5: Transform input file

1. Update properties inside `bdtd.config` file as per your environment.
2. Create `bdtd.policy` based on your input file and transformation requirement. The Samples directory has `bdtd.policy` samples with explanatory comments.
3. Run `./bdt.sh -t [-c configfilepath] -p policyfilepath`

`-c` is optional. If not provided, the default `config` file from the location `BDT/conf/bdtd.config` will be used

This will first validate configuration(`bdtd.config`+`bdtd.policy` validation) and then trigger transformation

The output file will be generated in the output directory specified in `bdtd.config`. Check the output file name with the current timestamp appended.

The same output directory will have a file `<policy_name-timestamp>.failed.` , which records any utility that has failed to transform. (Policy name is defined under `name` in a policy file.)

Example 6: Skip validation

The `-SV` option allows you to trigger transformation without performing any validation, in order to save validation time.

Example 7: Set BDT passwords and transform data

The `-e` option can be used with the `--validate` or `--transform` option. This will first put the encrypted passwords in `bdt.config` and then perform the specified operation: either validate the configuration and policy files or perform data transformation. For example, the following command gets new passwords (`-e`), then transforms the data (`-t`) using the policy specified in the `-p` option:

```
./bdt.sh -e -t -p policyfilepath
```

Example 8: List source tables, columns (for db transformations)

Source connection properties are picked from the policy file source attribute.

Run `./bdt.sh -ls table -p policyfilepath` to list source tables.

Run `./bdt.sh -ls column -table test1 -p policyfilepath` to list the columns of source table `test1`

Example 9: List destination tables, columns (for db transformations)

Destination connection properties are picked from the policy file destination attribute.

Run `./bdt.sh -ld table -p policyfilepath` to list destination tables.

Run `./bdt.sh -ld column -table test1 -p policyfilepath` to list columns of destination table `test1`

Creating a BDT Policy

A BDT policy tells how to perform transformation of the data in the input file. The policy is stored in the file `bdt.policy`.

Each `bdt.policy` file includes the following:

- “Top-level policy attributes”
- “The source/destination attributes”
- “The tables attributes”

Top-level policy attributes

id	A unique identifier for the policy.
name	A unique name for the policy.
source	Defines details of data input. For RDBMS details include connection parameters. For file detail includes file type (CSV_FILE or FIXED_LENGTH_FILE), delimiter, encoding etc. See also “The source/destination attributes” on page 20 .
destination	Defines details of data output. Where to write transformed data. For RDBMS details include connection parameters. For file detail includes file type (CSV_FILE or FIXED_LENGTH_FILE), delimiter, encoding etc. See also “The source/destination attributes” on page 20
tables	List of table to be transformed. See also, “The tables attributes” on page 23
createBadRecordFile	True or false. Set true to create .failed file, otherwise set false.
fpemode	ASCII or UTF. (FPE-only) Set fpemode to ASCII or UTF to define which FF3-encoding mechanism to use. ASCII supports only ascii characters and is faster than UTF. Default is ASCII. Set to UTF when using FPE to encrypt Unicode characters. Note: ASCII encryption mode is separate from ASCII character encoding.

The source/destination attributes

For databases

@type	DB2, ORACLE, MYSQL, SQL_SERVER
connectionurl	Database connection url. For example -jdbc: mysql://localhost:3306/world
username	database username
password	database password. use bdt -e option to add encrypted password
driverclass	jdbc connection driver class, e.g. com.mysql.jdbc.Driver

For CSV files

@type	CSV_FILE
filepath	The filepath relative to the inputDir or outputDir path in the config file
delimiter	The character that is used to divide one column from the next in the input file. The supported delimiters are space (), comma (,), pipe (), slash (/), underscore (_), colon (:), semi-colon (;), and tab.
qualifier	(Optional) Character to enclose fields that contain a delimiter character.

columnCount	Number of columns in the input file. This does not necessarily equal the number of columns that have rules defined for them in this bdt.policy file.
hasHeaderRow	True or false. Default false. If true, the utility will treat the first row as header row. Values from this row will be treated as column names. The same column names should be mentioned in the transformation action.
unescapeInput	True or false. Default: false. If true, delimiter and qualifier characters in input preceded by a backslash (\) are considered as normal characters and part of the input data. If you are using the BDT output file as input to another process, set unescapeInput to true.
encoding	(Semi-optional) Used to set character encoding, for example, to enable IBM's EBCDIC. Input file must use same character encoding. Output and failed record files will be created with same character encoding. Sample: for EBCDIC encoding, set encoding: "ibm500" in policy file. Note: to encrypt ASCII files, you must set encoding: ASCII. Supported encodings: https://docs.oracle.com/javase/7/docs/technotes/guides/intl/encoding.doc.html See "(Semi-optional) Set character encoding" on page 32.

For fixed-length files

@type	FIXED_LENGTH_FILE (See “(Optional) Define fixed-length record format” on page 33 for details.)
filepath	The filepath relative to inputDir or outputDir path in config file
columnCount	The number of columns a row has
encoding	(Semi-optional) Used to set character encoding, for example, to enable IBM’s EBCDIC. Input file must use same character encoding. Output and failed record files will be created with same character encoding. Sample: for EBCDIC encoding, set encoding: "ibm500" in policy file. Supported encodings: https://docs.oracle.com/javase/7/docs/technotes/guides/intl/encoding.doc.html See “(Semi-optional) Set character encoding” on page 32.
columnPositionInfo	Column positioning
recordLength	Record length
lineSeparator	True or false. Is record separated with line separator?
hasHeaderRow	True or false. Default false. If true, the utility will treat the first row as header row. Values from this row will be treated as column names. The same column names should be mentioned in the transformation action.

The tables attributes

source			Source table name. For database only.
destination			Destination table name. For database only.
columns			List of columns to be transformed and transformation operation details Policy rules for transforming one or more columns of data in the input file. For each column where transformation is desired, the <code>bdt.policy</code> file specifies the data transformation action to perform and a set of parameters related to that action. Columns are identified by number using the position parameter. NOTE: The first column is number 0.
	name		Column name
	action		Action to be taken. Supported options: ENCRYPT, DECRYPT, TOKENIZE, DETOKENIZE, REKEY
	config		
		@type	Options: AES_CBC_PAD, AES_CTR, FPE, FF1, TOKENIZE, DETOKENIZE See also: “About Format-Preserving Encryption (FPE)” on page 24
		key	Name of the encryption key
		tweak	(FPE required, FF1 optional) There are two ways of defining tweak: * "tweak":<8-byte value> * "tweak": "auto" Either can be used.
		characterSet	Name of the characterSet that was defined under characterSets in the <code>bdt.config</code> file. Defaults include "latin", "digits", "alphabets", and "alphanumeric". Users can also define their own characterSet in the config file. See also: “About characterSets” on page 13.
subset			Table-specific data filter criteria. filter input data based on these criteria. See also: “Transforming Databases” on page 44
	offset		Start record index. Default to 0.
	limit		Maximum number of records/rows to transform, starting from offset.
	recurrency		Select every Nth record. Default is 1 (process every record).
	filters		Subset-specific filters to be used

		selector	Column name
		operator	Options: "=", "<", ">", "<=", ">=", "!=", "like"
		expression	Expression to evaluate filter on selector using specified operator.
	orderBy		Order by column. E.g. column1. Not supported for file transformation.
	order		ASC (ascending) or DESC (descending) record order. Not supported for file transformation.
create DestinationTable			True or false. Default false. Create destination table if none exists. For DB, the destination table will be created with the schema as source table. For file to DB, datatype of columns in the destination table will be varchar(10000)  Caution: Use only for testing. Do not use in a production environment.

About Format-Preserving Encryption (FPE)

To encrypt/decrypt data using either of the NIST-defined FPE formats — FF3 or FF1 — you will specify the ENCRYPT or DECRYPT policy actions with a `type` value. The value for FF1 is `FF1`. The value for FF3 is `FPE`. Keep in mind that the BDT syntax uses `FPE` as a synonym for `FF3`.

Sample policy

```
{
  "id": "5ec94388-ae95-4c98-8803-b004f83efaa", /* transformation policy id
*/
  "name": "FileTransformation", /* policy name */
  "source": {                                /* data source details */
    "@type": "CSV_FILE", /* source type. supports CSV_FILE,
FIXED_LENGTH_FILE, ORACLE, SQL_SERVER, MYSQL, DB2 */
    "filepath": "input.csv",
    "delimiter": ",", /* source type specific details. */
    "qualifier": "\"",
    "unescapeInput": false,
```

```

        "columnCount": "5",
        "hasHeaderRow": false
    },
    "destination": {
        "@type": "CSV_FILE", /* destination type. supports CSV_FILE,
FIXED_LENGTH_FILE, ORACLE, SQL_SERVER, MYSQL, DB2 */
        "filepath": "output.csv" /* destination type specific details. */
    },
    "tables": [ /* table list to transform. */
        {
            "columns": [ /* list of columns that should be transformed */
                {
                    "name": "COLUMN2", /* column name */
                    "action": "ENCRYPT", /* action. supported- ENCRYPT,
DECRYPT, TOKENIZE, DETOKENIZE, REKEY*/
                    "config": [
                        {
                            "@type": "FPE", /* supported type - AES_CBC_PAD,
AES_CTR, FPE, FF1, TOKENIZE, DETOKENIZE */
                            "key": "KEY-NEW",
                            "tweak": "010ACD5B99F34CF8", /* FPE tweak */
                            "characterSet": "digits" /* charset name */
                        }
                    ]
                }
            ],
            {
                "name": "COLUMN3",
                "action": "ENCRYPT",
                "config": [
                    {
                        "@type": "FPE",
                        "key": "KEY-NEW",
                        "tweak": "010ACD5B99F34CF8",
                        "characterSet": "digits"
                    }
                ]
            }
        ]
    }

```

```
    }  
  ],  
  "subset" : {                                /* table specific data filter  
criteria. filter input data based on this criteria */  
    "limit": 1000,                            /* max number of rows to be  
transformed */  
    "recurrency": 2,                          /* select every nth row for transformation */  
    "filters": [{  
      "selector": "COLUMN1", /* column name */  
      "operator": "!=", /* operator */  
      "expression": "CA" /* expression to evaluate with selector  
column value and operator */  
    }]  
  }  
}  
],  
  "createBadRecordFile": true /* set true to create failed file, else false */  
}
```

Policy actions

For each column of input data, the bdt.policy file can specify one of the following actions:

- ENCRYPT
- DECRYPT
- TOKENIZE
- DETOKENIZE
- REKEY

If you do not specify any of these actions for a column, the contents of the column are copied to the output file without any transformation.

ENCRYPT policy action

The ENCRYPT action requires the following parameters:

type	Encryption mode: AES_CBC_PAD, AES_CTR, FF1, or FPE.
key	Name of the encryption key.
iv	(Required for AES_CTR and AES_CBC_PAD) Initialization vector. Must be 16 bytes.

characterSet	(FPE and FF1 modes only) Name of the characterSet that was defined under characterSets in the bdt.config file. Defaults include "latin", "digits", "alphabets", and "alphanumeric". Users can define their own characterSet in the config file as well. See also: "Edit the bdt.config File" on page 11.
tweak	(FPE required, FF1 optional) Tweak. The size of the tweak must be 8 bytes.

NOTE: Output and input are base-64 encoded for AES_CBC_PAD mode in ENCRYPT, DECRYPT, and REKEY actions.

The following example shows how to define encryption actions for two columns using AES_CBC_PAD and FPE encryption.

```
{
  "name" : "column2",
  "action" : "ENCRYPT",
  "config" : [ {
    "@type" : "AES_CBC_PAD",
    "key" : "c2KeyName",
    "iv": "000102030405060708090A0B0C0D0E0F"
  } ]
}, {
  "name" : "column3",
  "action" : "ENCRYPT",
  "config" : [ {
    "@type" : "FPE",
    "key" : "c3KeyName",
    "characterSet": "digits",
    "tweak": "0102030405060708"
  } ]
}
```

The following example shows how to define encryption actions for 1 column using FF1 encryption.

```
{
  "id": "transformation-id",
  "name": "transformation-name",
  "createBadRecordFile": true,
```

```
"source":{
  "@type":"CSV_FILE",
  "filepath":"input.csv",
  "delimiter":",",
  "columnCount":"12",
  "hasHeaderRow":true
},
"destination":{
  "@type":"CSV_FILE",
  "filepath":"output.csv"
},
"tables":[
  {
    "columns":[
      {
        "name":"latitude",
        "action":"ENCRYPT",
        "config":[
          {
            "@type":"FF1",
            "key":"KEYNAME",
            "tweak":"auto",
            "characterSet":"digits"
          }
        ]
      }
    ]
  }
]
```

DECRYPT policy action

The DECRYPT action requires the same parameters as the ENCRYPT action.

The following example shows how to define decryption actions for two columns using AES_CBC_PAD and FPE decryption.

```
{
  "name" : "column2",
  "action" : "DECRYPT",
  "config" : [ {
    "@type" : "AES_CBC_PAD",
    "key" : "c2KeyName",
    "iv": "000102030405060708090A0B0C0D0E0F"
  } ]
}, {
  "name" : "column3",
  "action" : "DECRYPT",
  "config" : [ {
    "@type" : "FPE",
    "key" : "c3KeyName",
    "characterSet": "digits",
    "tweak": "0102030405060708"
  } ]
}
```

TOKENIZE policy action

The TOKENIZE action requires the following parameters:

type	Encryption mode: Set to "TOKENIZE".
tokenGroup	Name of the token group as defined in VTS.
tokenTemplate	Name of the token template as defined in VTS.

The following sample shows the configuration of a column using tokenization.

```
{
  "name" : "column4",
  "action" : "TOKENIZE",
  "config" : [ {
    "@type" : "TOKENIZE",
    "tokenGroup" : "tokenGroup1",
    "tokenTemplate" : "tokenTemplate1"
  } ]
}
```

DETOKENIZE policy action

The DETOKENIZE action requires the same parameters as in TOKENIZE action. The following sample shows the configuration of a column using detokenization.

```
{
  "name" : "column4",
  "action" : "DETOKENIZE",
  "config" : [ {
    "@type" : "TOKENIZE",
    "tokenGroup" : "tokenGroup1",
    "tokenTemplate" : "tokenTemplate1"
  } ]
}
```

REKEY policy action

BDT can change the encryption key and re-encrypt the data using the new key. This can be done using VTS to tokenize the data, or using VAE to encrypt the data. The same policy can perform both types of rekey.

In a REKEY policy consists of two parts. In fact, REKEY is really just a container for two other actions. First, the data is detokenized or decrypted using the existing key. Then, the data is tokenized or encrypted using the new key.

The following example shows a sample configuration for a column rekey through VTS:

```
{
  "name" : "column6",
  "action" : "REKEY",
  "config" : [ {
    "@type" : "TOKENIZE",
    "tokenGroup" : "group1",
    "tokenTemplate" : "abcdef9876543210",
    "action" : "DETOKENIZE"
  }, {
    "@type" : "TOKENIZE",
    "tokenGroup" : "group2",
    "tokenTemplate" : "abcdef9876543210",
    "action" : "TOKENIZE"
  } ]
}
```

The following example shows a sample configuration for a column rekey through VAE:

```
{
  "name" : "column6",
  "action" : "REKEY",
  "config" : [ {
    "@type" : "FPE",
    "key" : "rekey1",
    "characterSet": "digits",
    "tweak": "0102030405060708",
    "action" : "DECRYPT"
  }, {
    "@type" : "FPE",
    "key" : "rekey2",
    "characterSet": "digits",
    "tweak": "0102030405060708",
    "action" : "ENCRYPT"
  } ]
}
```

As you can see, the two actions within each REKEY action are defined using DETOKENIZE, DECRYPT, TOKENIZE, and ENCRYPT with the same parameters as you would use with each of these actions alone.

(Semi-optional) Set character encoding

Supported encodings are listed in the following table. Note that naming from either column can be used.

<https://docs.oracle.com/javase/7/docs/technotes/guides/intl/encoding.doc.html>

The input file must use same character encoding. Failed record files will be created with the same character encoding. Output file encoding can vary, depending on configurations in the policy file.

NOTE: Encoding is mandatory only for EBCDIC-encoded files.

The following example shows how to set EBCDIC character encoding (Extended Binary Coded Decimal Interchange Code) in the policy file.

```
{
  "id": "transformation-id",
  "name": "transformation-name",
  "createBadRecordFile": true,
  "source": {
    "@type": "CSV_FILE",
    "filepath": "input.csv",
    "delimiter": ",",
    "columnCount": "12",
    "hasHeaderRow": true,
    "encoding": "ibm500"
  },
  "destination": {
    "@type": "CSV_FILE",
    "filepath": "output.csv"
  },
  "tables": [
    {
      "columns": [
```

```
{
  "name": "latitude",
  "action": "ENCRYPT",
  "config": [
    {
      "@type": "FF1",
      "key": "KEYNAME",
      "tweak": "auto",
      "characterSet": "digits"
    }
  ]
}
```

(Optional) Define fixed-length record format

Some systems may require fixed-length record formats. As described by IBM,

“In fixed-length or fixed-format records, each field starts and ends at the same place in every record. A data file that contains data records of equal and constant length might be organized as follows.

Sample file with fixed-length records: aaabbbbccccdddggghhhh

The data file illustrated previously has three records. Each record has a field of three characters followed by a field of four characters, so the total record length is seven characters. The file does not contain any separation between records; delimiters are unnecessary because all fields have the same length. The VARCHAR data types are therefore always the fixed maximum size of the field.”¹

This option is valid for FPE and FF1 (ENCRYPT and DECRYPT), and TOKENIZE actions only. Use the sample policy file `FixedLengthFileTransformation.policy` and the attributes described under [“For fixed-length files” on page 22](#) to define this feature.

1. https://www.ibm.com/support/knowledgecenter/en/SSGU8G_12.1.0/com.ibm.hpl.doc/ids_hpl_132.htm

NOTE: If applying tokenization on fixed-length format records, be sure not to add any prefix or suffix to the tokenized output. Adding such a string will result in failure of detokenization.

The following example defines a fixed-length record format, along with EBCDIC character encoding.

```
{
  "id": "FixedLengthFileSample-5ec94388",
  "name": "FixedLengthFileSample",
  "createBadRecordFile": true,
  "source": {
    "@type": "FIXED_LENGTH_FILE",
    "filepath": "fixed_length.txt",
    "lineSeparator": true,
    "hasHeaderRow": true,
    "columnCount": 7,
    "encoding": "ibm500",
    "recordLength": 59,
    "columnPositions": [
      {
        "column": 0,
        "startIndex": 0,
        "endIndex": 10
      },
      {
        "column": 1,
        "startIndex": 10,
        "endIndex": 20
      },
      {
        "column": 2,
        "startIndex": 20,
        "endIndex": 26
      },
      {
```

```

        "column":3,
        "startIndex":26,
        "endIndex":32
    },
    {
        "column":4,
        "startIndex":32,
        "endIndex":39
    },
    {
        "column":5,
        "startIndex":39,
        "endIndex":48
    },
    {
        "column":6,
        "startIndex":48,
        "endIndex":59
    }
]
},
"destination":{
    "@type":"FIXED_LENGTH_FILE",
    "filepath":"output.txt"
},
"tables":[
    {
        "columns":[
            {
                "name":"latitude",
                "action":"ENCRYPT",
                "config":[
                    {
                        "@type":"FPE",
                        "key":"KEY1",

```

```
        "tweak": "auto",
        "characterSet": "digits"
    }
]
},
{
    "name": "longitude",
    "action": "ENCRYPT",
    "config": [
        {
            "@type": "FPE",
            "key": "KEY1",
            "tweak": "auto",
            "characterSet": "digits"
        }
    ]
}
]
}
```

Example policy

```
{
  "id": "policyId",
  "name": "policyName",
  "source": {
    "@type": "CSV_FILE",
    "filepath": "inputFile",
    "delimiter": ",",
    "qualifier": "",
    "unescapeInput": false,
    "columnCount": 20,
    "hasHeaderRow": false
  },
  "destination": {
    "@type": "CSV_FILE",
    "filepath": "outputFile"
  },
  "fpemode": "ASCII",
  "createBadRecordFile": true,
  "tables": [
    {
      "columns": [
        {
          "name": "Column1",
          "action": "TOKENIZE",
          "config": [
            {
              "@type": "TOKENIZE",
              "tokenTemplate": "demoTemplate",
              "tokenGroup": "tg1"
            }
          ]
        }
      ]
    }
  ],
  {
```

```

        "name": "Column3",
        "action": "DETOKENIZE",
        "config": [
            {
                "@type": "TOKENIZE",
                "tokenTemplate": "demoTemplate",
                "tokenGroup": "tg1"
            }
        ]
    },

      "action": "ENCRYPT",
      "config": [
        {
          "@type": "AES_CBC_PAD",
          "key": "key1",
          "iv": "1ABD0EAB12F345601ABD0EAB12F34560"
        }
      ]
    }
  ]
}

```

```
}  
]  
}
```

Using Text Qualifier Characters in Input Files

A text qualifier character can be used to mark the start and end of a column field in a file that is input to the BDT utility. This is useful when the field value itself contains a character that would normally act as a field delimiter. Use the qualifier to indicate to BDT that the data following the delimiter is part of the same field, and not the beginning of the next field.

The supported text qualifier characters are double quote ("), single quote('), pipe (|), slash (/), at (@), hash (#), percentage (%), and ampersand (&).

For example, in the following input file, the comma is the delimiter character, but it is also part of the address field. To let BDT know that the text after the comma is also part of the same field, the value must be enclosed with a text qualifier.

Example of data before adding the text qualifier:

```
Firstname, Lastname, Address
James,Brown,1745 E. New St., Apt. 22,Chicago
Scott,Smith,400 South Warren Street,Trenton
```

After adding the text qualifier:

```
James,Brown,"1745 E. New St., Apt. 22,Chicago"
Scott,Smith,"400 South Warren Street,Trenton"
```

In most cases, the input file for BDT is created by exporting data from a database. Databases provide the option to specify a character to be used as a qualifier in exported data.

To add text qualifier characters:

1. When exporting data from the database, specify the qualifier using the technique that is supported by the database.
2. In the policy file, add the qualifier parameter to the top of the file, before the column specifications begin. If the qualifier is a double quote character, escape it in the policy file with a backslash.

Example configuration in policy file, including the double quote character (") as a qualifier:

```
"source":{
  "@type":"CSV_FILE",
  "filepath":"input.csv",
  "delimiter":",",
  "qualifier":"\"",
  "unescapeInput":true,
  "columnCount":"12",
  "hasHeaderRow":true
}
```

Transforming Databases

Overview

BDT can be used to encrypt, decrypt or rekey database table data and move it to another database. Multiple tables can be transformed in single execution of the utility. You can choose table columns and specify what action to be performed on particular column.

Terminology

- **source database:** database where tables need to be transformed
- **destination database:** database where transformed data will be moved
- **source table:** table in source db which needs to be transformed
- **destination table:** table of destination database where transformed data will be moved

Supported databases

(See also the *Vormetric Batch Data Transformation 2.0 Release Notes*.)

- MySQL 5.7.20
- Oracle 11g
- Microsoft SQL Server 2017
- IBM DB2 10.5

NOTE: Download the JDBC connector .jar for the required version of database you are using, and place the .jar files under the bdt/lib directory.

Example 1: Transforming database table columns

To transform database table columns, create a bdt.policy file and add source database connection properties to the policy source attribute. Do the same for destination database. In the tables section of the policy, add an entry for table to transform, specify source and destination table, and the columns to transform. Ensure the destination table has the exact same schema as the source table.

DbToDbTransformation.policy sample

```
{  
  "id": "OracleToSqlServerSample-90643295a90sdf5",
```

```

"name":"OracleToSqlServerSample",
"source":{
  "@type":"ORACLE",
  "connectionurl":"jdbc:oracle:thin:@//localhost:1521/XE",
  "username":"admin",
  "password":"",
  "driverclass":"oracle.jdbc.driver.OracleDriver"
},
"destination":{
  "@type":"SQL_SERVER",
  "connectionurl":"jdbc:sqlserver://localhost;databaseName=db",
  "username":"admin",
  "password":"",
  "driverclass":"com.microsoft.sqlserver.jdbc.SQLServerDriver"
},
"tables":[
  {
    "columns":[
      {
        "name":"ADDRESS",
        "action":"ENCRYPT",
        "config":[
          {
            "@type":"AES_CBC_PAD",
            "key":"KEY-NEW",
            "iv":"1ABD0EAB12F345601ABD0EAB12F34560"
          }
        ]
      }
    ]
  },
  "createDestinationTable":true,
  "sourceTable":"employee",
  "destinationTable":"employee"
}
],

```

```
"createBadRecordFile":true
}
```

Example 2: Transforming database tables to files

BDT supports transforming a database table and copying the data to an output file.

Specify the destination type as CSV_FILE or FIXED_LENGTH_FILE in the policy file.

Specify needed attributes of the input file, such as delimiter, encoding etc.

If more than one table is transformed in single execution, BDT creates a separate output file for each table. The source table name is suffixed in output file.

DBToFileTransformation.policy sample

```
{
  "id": "Db2ToFileSample-90643295a90sdf5",
  "name": "Db2ToFileSample",
  "createBadRecordFile": true,
  "source": {
    "@type": "DB2",
    "connectionurl": "jdbc:db2://localhost:50000/SAMPLE",
    "username": "db2admin",
    "password": "",
    "driverclass": "com.ibm.db2.jcc.DB2Driver"
  },
  "destination": {
    "@type": "CSV_FILE",
    "filepath": "output.csv",
    "delimiter": ",",
  },
  "tables": [
    {
      "columns": [
        {
          "name": "POPULATION",
          "action": "ENCRYPT",
          "config": [
```

```

        {
            "@type": "FPE",
            "key": "KEY-NEW",
            "characterSet": "digits",
            "tweak": "auto"
        }
    ]
}
],
"source": "country"
}
]
}

```

Example 3: Transforming input file to database table

To transform an input file and copy data to a database table, in policy file specify the source type as `@CSV_FILE` or `@FIXED_LENGTH_FILE` and set the destination db connection properties in the policy destination attribute. The destination table schema should have all columns specified by the input file header row. If a header row is not present in the input file, columns are named as `COLUMN0`, `COLUMN1`.. `COLUMNn`.

FileToDBTransformation.policy sample

```

{
  "id": "FileToDBSample-b004f83efaa",
  "name": "FileToDBSample",
  "source": {
    "@type": "CSV_FILE",
    "filepath": "input.csv",
    "delimiter": ",",
    "qualifier": "\"\"",
    "columnCount": 12,
    "hasHeaderRow": true,
    "unescapeInput": true,
    "encoding": "UTF-8"
  },

```

```
"destination":{
  "@type":"MYSQL",
  "connectionurl":"jdbc:mysql://localhost:3306/world",
  "username":"username",
  "password":"",
  "driverclass":"com.mysql.jdbc.Driver"
},
"createBadRecordFile":true,
"tables":[
  {
    "columns":[
      {
        "name":"LATITUDE",
        "action":"ENCRYPT",
        "config":[
          {
            "@type":"FPE",
            "key":"KEY-NEW",
            "characterSet":"digits",
            "tweak":"auto"
          }
        ]
      }
    ]
  },
  "createDestinationTable":true,
  "destinationTable":"REALESTATE"
}
]
```

Filtering Input Data

BDT supports filtering of input data. For example, in a case with one million input rows, you can designate a subset for transformation. To do so, specify subset criteria in a policy file to filter the input records.

`subset` is a table-level element, and is applicable only to that table.

See also: [“The tables attributes” on page 23](#).

Example: Filter input rows from a source file

```
"subset":{
  "offset":"10",
  "limit":1000,
  "recurrency": 2,
  "filters":[
    {
      "selector":"name",
      "operator":"like",
      "expression":"'p.*'"
    }
  ]
}
```

Specify the starting `offset` and the `limit`, which define the number of rows to transform.

The `recurrency` attribute specifies whether to transform rows in a sequence or skip rows. If `recurrency` is set to 2, then every second row in the sequence is transformed and the row in between is skipped.

`filters` specifies the list of conditions to match. The row should satisfy all conditions specified in the list.

- `selector` is the name of the column that the filter should evaluate
- `operators` Options: "=", "<", ">", "<=", ">=", "!=", "like".
- `expression` Used to evaluate the filter on the selector using specified operator. For file transformation if operator is specified as `like`, then specify `regex` expression to match in the column value.

To create a regex expression see:

<https://docs.oracle.com/javase/tutorial/essential/regex/index.html>

Example: Filter database table rows

```
"subset":{
  "offset":"10",
  "limit":1000,
  "recurrency": 1,
  "orderBy":"ID",
  "order":"DESC",
  "filters":[
    {
      "selector":"name",
      "operator":"like",
      "expression":"'p.*'"
    },
    {
      "selector":"salary",
      "operator":"<",
      "expression":"100000"
    }
  ]
}
```

Compared with file transformations, the database transformation `subset` can include two additional attributes:

- `orderBy` Use the name of column which should be used to order records. Records are ordered first, then offset and limit attributes are applied.
- `order` Define ascending (ASC) or descending (DESC) order.

For the `like` operator, use database-specific syntax for the expression to evaluate.

Monitoring and Troubleshooting

Log files

BDT stores its log file in the file `BDT_HOME/log/bdt.log`.

The default log level is `DEBUG` for the log file and `INFO` for the console. These log properties can be changed in the `BDT_HOME/conf/log4j.properties` file.

Thread count and batch size best practices

To best configure thread count and batch size, follow the principles below.

1. Identify the ideal thread count for your environment, depending on your system configuration.
BDT gives optimal performance with 16 threads on four core machines.
Setting thread count too low or too high will slow down the application.
2. Decide on batch size, configured based on available memory, size of individual record, and configured thread count. Setting batch size too high may result in an out-of-memory error.

Use the following calculation to calculate the approximate maximum memory utilization by BDT:

$\text{thread count} * \text{batch size} * \text{record size} = \text{memory utilization}$

Therefore, thread count and batch size will be $\leq$ about 60% of available memory.

Remaining memory is required to run the utility and to maintain transformed batches in the write queue.

For example: If you have 4GB available memory, and individual record size of approximately 50MB, you can set:

Batch size to 50 and thread count 1, utilizing approximately 60% of memory:

$50 * 1 * 50\text{MB} = 2500\text{MB}$

Or

Batch size to 10 and thread count to 3, utilizing $10 * 3 * 100\text{MB} = 3000\text{MB}$.

CipherTrust Batch Data Transformation (BDT)

Administration

CipherTrust Batch Data Transformation (BDT) is a command line utility that is used to transform (encrypt/tokenize) data in files and databases. It is a policy-based tool and can efficiently transform bulk data. It can also be used for rekey operations.

BDT Architecture

The BDT utility works with [CipherTrust Manager \(CM\)](#) for key management, and [CipherTrust Vaultless Tokenization \(CT-VL\)](#) for tokenization.

BDT Policy

The BDT utility's actions are based on a policy. For each action or group of actions that you want to perform with the utility, you need to define a policy.

The BDT policy defines the rules on how to perform a transformation of the data provided by the input files or databases. The policy can be configured in a file locally or on a CipherTrust Manager (CM) instance that is serving as a centralized manager for configuration, allowing for easier reuse and maintenance. Refer to [Setting up BDT Policy](#) for details.

Supported File Formats and Databases

BDT supports the following file formats:

- CSV File
- Fixed Length File

BDT is supported with the following databases. The table below lists the versions tested with.

Database	Tested Version
MySQL	8.0, 8.0.27
Oracle	12c, 19c
IBM DB2	10.5, 11.5.7
SAP HANA	2.0
Microsoft SQL Server	2017, 2019

Supported Transformations

- **Database to database** (DB-to-DB): Encrypt, decrypt, tokenize, detokenize, or rekey the data of a database table and move it to another database. Multiple tables can be transformed in a single execution of the utility. You can choose table columns and specify what action needs to be performed on a particular column.
- **Database to file** (DB-to-File): Encrypt, decrypt, tokenize, detokenize, or rekey the data of a database table and move it to another file. You can choose table columns and specify what action needs to be performed on a particular column.
- **File to database** (File-to-DB): Encrypt, decrypt, tokenize, detokenize, or rekey the data of a file and move it to another database. You can choose file columns and specify what action needs to be performed on a particular column.
- **File to file** (File-to-File): Encrypt, decrypt, tokenize, detokenize, or rekey the data of a file and move it to another file. You can choose file columns and specify what action needs to be performed on a particular column.

Refer to [BDT Transformation Process](#) for details.

Supported Encryption Algorithms

Expand (click **+**) to view details.

FF1

Key Size (in bits)	128 (default) 192

	256
Tweak Data	Tweak data is mandatory. The value must be 16 characters HEX encoded string.
Additional Notes	• FF1 supports only non-versioned AES Keys. • FF1 is supported when symmetric key cache is enabled. • FF1 requires minimum two characters to perform encryption. The maximum data length can be 128000 characters. • While performing crypto operations, the characters in the input data other than those specified in the character set range, are preserved and do not get encrypted. • While performing transformation, the character set range cannot be updated. • While performing decryption, do not modify the character set range, it must be same as encrypt.

FF3

Key Size (in bits)	128 (default) 192 256
Tweak Data	Tweak data is mandatory. The value must be 16 characters HEX encoded string.
Additional Notes	• FF3 supports only non-versioned AES Keys. • FF3 is supported when symmetric key cache is enabled. • FF3 requires minimum two characters to perform encryption. The maximum data length can be 128000 characters. • While performing crypto operations, the characters in the input data other than those specified in the character set range, are preserved and do not get encrypted. • While performing transformation, the character set range cannot be updated. • While performing decryption, do not modify the character set range, it must be same as encrypt.

FPE_AES

Note

The number of characters in the character set range are treated as cardinality for the input data.

IV	When cardinality is y, a x characters IV is used when data size is > x characters. Corresponding value of x is derived using the following formula: <pre>double lg = Math.log10(Math.pow((double)2, (double)</pre> The table with cardinality and corresponding IV value based on the above formula is provided here. The value of each HEX encoded byte in the IV value will be in the range 00 to cardinality-1. For example, when CARD62 is used, the maximum value will be 3D (hex encode of 62-1=61). In the following IV for CARD62, the hex 0A lies in the range 00 to cardinality-1, that is, 00 to 3D: <pre>0102030405060708090A0B0C0D0E0F1000303132333435363</pre>
Key Size (in bits)	128 (default) 192 256
Tweak Algorithm	Specify a hashing algorithm to be applied to specified tweak data. Following are the valid values: • None • SHA1 • SHA256
Tweak Data	FPE_AES uses the tweakable cipher concept to protect against statistical attacks due to potentially small input/output space. If tweak data algorithm is None or absent, the value must be HEX encoded string representing 64-bit long (hence, HEX encoding will consume 16 characters).
Additional Notes	• Default tweak algorithm will be None, if invalid or Null value is provided.

	• FPE_AES supports only non-versioned AES Keys. • FPE_AES is supported when symmetric key cache is enabled. • While performing crypto operations, the characters in the input data, other than those specified in the character set range, are preserved and do not get encrypted. • If any character other than those specified in the character set range, are present in the input data, you must calculate the effective input data length and provide IV accordingly. • FPE_AES requires minimum four characters to perform encryption. • While performing transformation, the character set range cannot be updated. • While performing decryption, do not modify the character set range, it must be same as encrypt.

DESede

Block Size	8 bytes
Supported Modes	ECB CBC
Padding Schemes	PKCS5Padding NoPadding
IV	CBC mode requires 8 characters or 8 HEX encoded characters IV.
Key Size	Supported key sizes are 168 (default) and 112 bits. Each key contains an extra 8 bits of parity. Thus, when you create a key of 112 bits, the actual key size is 128 bits; when you create a key of 168 bits, the actual key size is 192 bits.
Additional Notes	• When using DESede with NoPadding, then data for encryption must be in multiples of 8 bytes. • DESede is supported when symmetric key cache is either enabled or disabled.

AES_CTR

Block Size	16 bytes

Padding Schemes	PKCS5Padding NoPadding
IV	CTR mode requires 16 characters or 16 HEX encoded characters IV.
Key Size (in bits)	128 (default) 192 256
Additional Notes	• AES_CTR is supported when symmetric key cache is enabled. • By default, AES_CTR is with NoPadding.

AES_CBC_PAD

Block Size	16 bytes
Padding Schemes	PKCS5Padding NoPadding
IV	CBC mode requires 16 characters or 16 HEX encoded characters IV.
Key Size (in bits)	128 (default) 192 256
Additional Notes	• AES_CBC_PAD is supported when symmetric key cache is either enabled or disabled. • By default, AES_CBC_PAD is with PKCS5Padding.

Supported Tokenization Algorithms

BDT supports the following tokenization algorithms (supported by CT-VL):

- FF1, FF1-luhn
- FF3, FPE-luhn
- Dates, Random, Random-luhn

Refer to [CipherTrust Vaultless Tokenization \(CT-VL\)](#) for details.

Quick Start

Use CipherTrust Batch Data Transformation (BDT) to transform your data through **encryption** and **tokenization**. This section describes how to run BDT in its simplest form, that is, performing a file-to-file transformation through *encryption*.

BDT supports various [other transformations](#), but the scope of this section is limited to [file encryption](#) (file-to-file

transformation) only.

Prerequisites

- To perform **tokenization**, a compatible version (2.2 or higher) of Vormetric Tokenization Server (now renamed as CipherTrust Vaultless Tokenization (CT-VL)) is up and running. Refer to the CT-VL [Quick Start](#) document for details.
- A CipherTrust Manager version compatible with the installed CT-VL/CADP for Java version is up and running. Refer to the CipherTrust Manager [Getting Started](#) document for details.
- Java 17 must be installed.

Encrypting Files

Commands to encrypt files on Linux and Windows are detailed below. Click the desired tab for details.

Installation

Linux

1. Download the BDT distribution file. You can use `wget` at a terminal prompt.

```
wget https://<path to download site>/bdt-x.x.x.tar.gz
```

2. Create a BDT home directory at a convenient location. `sudo` may be required.

```
cd /usr/local/bin  
sudo mkdir bdt
```

3. Extract the distribution to the BDT home directory.

```
sudo tar -xzvf <filename.tgz> -C /usr/local/bin/bdt
```

4. Add the Java bin directory path to the PATH environment variable. Edit the `.bashrc` file (or equivalent for other shells) for the admin user and add the following lines:

```
export JAVA_HOME=/usr/lib/java/jre  
export PATH=$JAVA_HOME/bin:$PATH
```

5. Verify the installation by ensuring the following directory structure is created in the installation directory.

Directory	Description
bin	Contains executable scripts for validating configuration, testing, and execution.
conf	Contains configuration files such as <code>bdt.config</code>, <code>logging.properties</code>, <code>bdt.properties</code>, and <code>bdt.mv.db</code> (H2 database file). Note: H2 database is upgraded from 1.4.199 to 2.1.212 for the backup of old version file. Refer to Backup using the Script Tool and Restore from a Script for details.
lib	Contains required JAVA library dependencies.
log	Contains log file directory.
samples	Contains sample policy and configuration files.

6. Configure at least the following properties in the BDT properties file:

- `NAE_IP.1= CM_IP`
- `NAE_Port= TCP_PORT`
- `Protocol= tcp`

Windows

1. Download the BDT distribution file.
2. Create a BDT home directory at a convenient location. You can use the File Explorer's **New Folder** option to create a new folder named BDT under the folder C:\Program Files, for example.
3. Extract the distribution to the BDT home directory. Use your favorite file compression/extraction utility (winzip, pkzip, or 7zip etc).
4. Add the Java bin directory path to the PATH environment variable:
 - a. Open the Control Panel.
 - b. Click **System**.
 - c. Click **Advanced System Settings**.
 - d. Click the **Environment Variables** button.
 - e. Under System Variables, select **Path** and then click **Edit**.

Note

Do not delete any of the existing text here.

- f. Append the following to whatever you already have:

```
;C:\Program Files\BDT
```

- g. Click **OK**.

Environment Variables

5. Verify the installation by ensuring the following directory structure is created in the installation directory.

Directory	Description
bin	Contains executable scripts for validating configuration, testing, and execution.
conf	Contains configuration files such as <code>bdt.config</code> ,

Directory	Description
	logging properties, <code>bdt.properties</code> , and <code>bdt.mv.db</code> (H2 database file). Note: H2 database is upgraded from 1.4.199 to 2.1.212 for the backup of old version file. Refer to Backup using the Script Tool and Restore from a Script for details.
lib	Contains required JAVA library dependencies.
log	Contains log file directory.
samples	Contains sample policy and configuration files.

6. Configure at least the following properties in the BDT properties file:

- `NAE_IP.1= CM_IP`
- `NAE_Port= TCP_PORT`
- `Protocol= tcp`

File-to-File Transformation

Linux

1. Create a user `test_user` and a key `test_key` for this user on the CipherTrust Manager.
2. On the CipherTrust Manager, configure the NAE interface to work with `No TLS`, `allow anonymous logins`.
3. Download and copy the [QuickStartEncryptInput.csv](#) and [QuickStartEncrypt.config](#) files to the `$BDT_HOME/conf/` directory. The `ContactDetails` column of the `QuickStartEncryptInput.csv` file will get encrypted using these steps.
4. Download and copy the [QuickStartEncrypt.policy](#) file to `$BDT_HOME/samples/`.
5. Configure properties of default crypto library. Open command prompt from `$BDT_HOME/bin/` and run the following command:

```
bdt.sh -f
```

Enter values as per the prompt messages and you are all set to run BDT.

6. Run the following command to write encrypted NAE user `test_user` password in `QuickStartEncrypt.config` file:

```
bdt.sh -e -c ../conf/QuickStartEncrypt.config
```

7. Run the following command:

```
bdt.sh -t -c ../conf/QuickStartEncrypt.config -p ../samples/QuickStartEncrypt.policy
```

8. Check the QuickStartEncryptOutput csv file created in \$BDT_HOME/conf/.

Windows

1. Create a user `test_user` and a key `test_key` for this user on the CipherTrust Manager.
2. On the CipherTrust Manager, configure the NAE interface to work with `No TLS, allow anonymous logins`.
3. Download and copy the `QuickStartEncryptInput.csv` and `QuickStartEncrypt.config` files to the `$BDT_HOME/conf/` directory. The `ContactDetails` column of the `QuickStartEncryptInput.csv` file will get encrypted using these steps.
4. Download and copy the `QuickStartEncrypt.policy` file to `$BDT_HOME/samples/`.
5. Configure properties of default crypto library. Open command prompt from `$BDT_HOME/bin/` and run the following command:

```
bdt.bat -f
```

Enter values as per the prompt messages and you are all set to run BDT.

6. Run the following command to write encrypted NAE user `test_user` password in `QuickStartEncrypt.config` file:

```
bdt.bat -e -c ../conf/QuickStartEncrypt.config
```

7. Run the following command:

```
bdt.bat -t -c ../conf/QuickStartEncrypt.config -p ../samples/QuickStartEncrypt.policy
```

8. Check the QuickStartEncryptOutput csv file created in `$BDT_HOME/conf/`.

Tip

Your demo of the file-to-file transformation using *encryption* is complete. Now, you can explore all the supported transformations and the [transformation process](#). Also, you can explore the tasks that you can perform using BDT, advanced topics, samples, best practices, and troubleshooting information. Use the left pane to navigate to the desired sections.

BDT Transformation Process

BDT supports different types of transformations.

Transformation Types

- **Database to database** (DB-to-DB): Encrypt, decrypt, tokenize, detokenize, or rekey the data of a database table and move it to another database. Multiple tables can be transformed in a single execution of the utility. You can choose table columns and specify what action needs to be performed on a particular column.
- **Database to file** (DB-to-File): Encrypt, decrypt, tokenize, detokenize, or rekey the data of a database table and move it to another file. You can choose table columns and specify what action needs to be performed on a particular column.
- **File to database** (File-to-DB): Encrypt, decrypt, tokenize, detokenize, or rekey the data of a file and move it to another database. You can choose file columns and specify what action needs to be performed on a particular column.
- **File to file** (File-to-File): Encrypt, decrypt, tokenize, detokenize, or rekey the data of a file and move it to another file. You can choose file columns and specify what action needs to be performed on a particular column.

Prerequisites

- BDT is installed. Refer to [Installation](#) for instructions on installing BDT on Linux and Windows.
- To perform **tokenization**, a compatible version (2.2 or higher) of Vormetric Tokenization Server (now renamed as CipherTrust Vaultless Tokenization (CT-VL)) is up and running. Refer to the CT-VL [Quick Start](#) document for details.
- A CipherTrust Manager version compatible with the installed CT-VL/CADP for Java version is up and running. Refer to the CipherTrust Manager [Getting Started](#) document for details.
- Java 17 must be installed.

Click the desired tab to view transformation-specific prerequisites.

DB-to-DB

- Download the JDBC connector `.jar` compatible to your database version.

The following table captures the details of database drivers and their versions that have explicitly been tested.

Database	Driver
SQL Server	mssql-jdbc-9.2.1.jre8.jar
MYSQL	mysql-connector-java-8.0.15.jar
Oracle	ojdbc6.jar
SAP HANA	ngdbc-2.4.70.jar
DB2	db2jcc4.jar

- Place the driver `.jar` files in the `bdt/lib` directory.
- Prepare input databases. Refer to [Filtering Input Data](#) for details.

DB-to-File

- Download the JDBC connector `.jar` compatible to your database version.

The following table captures the details of database drivers and their versions that have explicitly been tested.

Database	Driver
SQL Server	mssql-jdbc-9.2.1.jre8.jar
MYSQL	mysql-connector-java-8.0.15.jar
Oracle	ojdbc6.jar
SAP HANA	ngdbc-2.4.70.jar
DB2	db2jcc4.jar

- Place the driver `.jar` files in the `bdt/lib` directory.
- Prepare input databases. Refer to [Filtering Input Data](#) for details.
- For the output file, BDT accepts the output files in the following file formats:
 - CSV File
 - Fixed Length File
- Prepare input databases. Refer to [Filtering Input Data](#) for details.

File-to-DB

Input Data

BDT accepts the input files in the following file formats:

- CSV File
- Fixed Length File

The input files must meet the following data requirements:

- Per-column data size limit: 128K
- The input data file can contain quoted and unquoted values. Both `field1_value` and `field2_value` are recognized as data values. To use quoted values, you must specify the double quote character as a text qualifier.
- Fields must be separated by the delimiter character specified in the policy file.
- If a field value contains the delimiter character, the value must be enclosed by text qualifier characters as specified in the policy file.
- If a field value contains the text qualifier, the entire value must be enclosed in text qualifier characters.
- Another way to deal with field values having delimiter or qualifier characters is to escape those character using the backslash (\) instead of enclosing the field in text qualifier characters. When using this technique, set the `unescapeInput` attribute in the policy file to true. For example:

If the field value has a backslash character, it must also be escaped using an additional backslash character.

- If you are using fixed length file format, you must set up input files accordingly. Refer to [Setting up Input Files with Fixed-Length Record Format](#) for details.
- Prepare input files. Refer to [Filtering Input Data](#) for details.

Output Data

BDT is supported with the following databases. The table below lists the versions tested with.

Database	Tested Version
MySQL	8.0, 8.0.27
Oracle	12c, 19c
IBM DB2	10.5, 11.5.7
SAP HANA	2.0
Microsoft SQL Server	2017, 2019

File-to-File

Input Data

BDT accepts the input files in the following file formats:

- CSV File
- Fixed Length File

The input files must meet the following data requirements:

- Per-column data size limit: 128K
- The input data file can contain quoted and unquoted values. Both `field1_value` and `field2_value` are recognized as data values. To use quoted values, you must specify the double quote character as a text qualifier.
- Fields must be separated by the delimiter character specified in the policy file.
- If a field value contains the delimiter character, the value must be enclosed by text qualifier characters as specified in the policy file.
- If a field value contains the text qualifier, the entire value must be enclosed in text qualifier characters.
- Another way to deal with field values having delimiter or qualifier characters is to escape those character using the backslash (`\`) instead of enclosing the field in text qualifier characters. When using this technique, set the `unescapeInput` attribute in the policy file to true. For example:

If the field value has a backslash character, it must also be escaped using an additional backslash character.

- If you are using fixed length file format, you must set up input files accordingly. Refer to [Setting up Input Files with Fixed-Length Record Format](#) for details.
- Prepare input files. Refer to [Filtering Input Data](#) for details.

Transformation Process

1. Set up BDT Config

Update properties inside the `bdt.config` file as per your environment. Refer to [BDT Config file](#) for the file settings.

If you want to perform encryption using the CipherTrust Manager, then follow the below step, else move to step 3.

2. Set up BDT Properties

Update properties inside the `bdt.properties` file as per your environment. Refer to [BDT Properties File](#) for details.

3. Set up BDT Policy

DB-to-DB

Create `bdt.policy` based on your input DB and transformation requirement. The `Samples` directory has `bdt.policy` samples with explanatory comments. Refer to [Setting up BDT Policy](#) for details.

To transform database table columns:

1. Create a `bdt.policy` file and add source database connection properties to the policy source attribute. Do the same for destination database. Refer to [Listing Source](#) and [Destination](#) tables and columns for details.
2. In the `tables` section of the policy, add an entry for table to transform, specify source and destination table, and the columns to transform.
3. Ensure the destination table has the exact same schema as the source table.
4. Specify the transformation operation for each column of the input data.

Note

If you do not specify any of these actions for a column, the contents of the column are copied to the output file without any transformation.

Listing Source Tables and Columns

Source connection properties are picked from the policy file `source` attribute.

- Run `./bdt.sh -ls table -p policyfilepath` to list source tables.
- Run `./bdt.sh -ls column -table test1 -p policyfilepath` to list the columns of source table `test1`

Listing Destination Tables and Columns

Destination connection properties are picked from the policy file `destination` attribute.

- Run `./bdt.sh -ld table -p policyfilepath` to list destination tables.
- Run `./bdt.sh -ld column -table test1 -p policyfilepath` to list columns of destination table `test1`

Performing Inplace Transformations

You can choose to have BDT create a separate database table with the transformed data, or instead perform an in-place transformation where the source database is itself transformed with new data, and no new database created. Specify either behavior with the `inPlaceUpdate` attribute value in the policy file.

If you specify an in-place transformation (by setting the `inPlaceUpdate` attribute to `true`), where the source and destination are the same, the `destination` attribute is ignored.

Sample DB-to-DB Transformation Policy

Sample `DbToDbTransformation.policy` for reference.

DB-to-File

Create `bdt.policy` based on your input DB and transformation requirement. The `Samples` directory has `bdt.policy` samples with explanatory comments. Refer to [Setting up BDT Policy](#) for details.

BDT supports transforming a database table and copying the data to an output file. To do so:

1. Specify the destination type as `CSV_FILE` or `FIXED_LENGTH_FILE` in the policy file.
2. Specify needed attributes of the input file, such as delimiter, encoding, and so on.
 - If more than one table is transformed in a single execution, BDT creates a separate output file for each table.
 - The source table name is suffixed in the output file.
3. You can specify the [Transformation Operations](#) that needs to be performed.

Note

If you do not specify any of these actions for a column, the contents of the column are copied to the output file without any transformation.

Listing Source Tables and Columns

Source connection properties are picked from the policy file `source` attribute.

- Run `./bdt.sh -ls table -p policyfilepath` to list source tables.
- Run `./bdt.sh -ls column -table test1 -p policyfilepath` to list the columns of source table `test1`

Sample DB-to-File Transformation Policy

Sample `DBToFileTransformation.policy` for reference.

File-to-DB

Create `bdt.policy` based on your input file and transformation requirement. The `Samples` directory has `bdt.policy` samples with explanatory comments. Refer to [Setting up BDT Policy](#) for details.

To transform an input file and copy data to a database table:

1. In the policy file, specify the source type as `@CSV_FILE` or `@FIXED_LENGTH_FILE`. You can also [add text qualifier characters in input files](#) while setting up the BDT policy.
2. Set the destination DB connection properties in the policy destination attribute. The destination table schema should have all columns specified by the input file header row. If a header row is not present in the input file, columns are named as `COLUMN0`, `COLUMN1` . . . `COLUMNn`. Refer to [BDT Policy Attributes](#) for the list of all attributes.
3. You can specify the [Transformation Operations](#) that needs to be performed.

Note

If you do not specify any of these actions for a column, the contents of the column are copied to the output file without any transformation.

Listing Destination Tables and Columns

Destination connection properties are picked from the policy file `destination` attribute.

- Run `./bdt.sh -ld table -p policyfilepath` to list destination tables.
- Run `./bdt.sh -ld column -table test1 -p policyfilepath` to list columns of destination table `test1`

Sample File-to-DB Transformation Policy

Sample `FileToDBTransformation.policy` for reference.

See Also

[Setting up Character Encoding in the Policy](#)

[Validating Configuration and Policy Files](#)

File-to-File

Create `bdt.policy` based on your input file and transformation requirement. The `Samples` directory has `bdt.policy` samples with explanatory comments. Refer to [Setting up BDT Policy](#) for details.

- You can also [add text qualifier characters in input files](#) while setting up BDT policy for file-to-file transformation.
- You can specify the [Transformation Operations](#) that needs to be performed.

Note

If you do not specify any of these actions for a column, the contents of the column are copied to the output file without any transformation.

Sample File-to-File Transformation policy

Refer to [sample File Transformation Policy](#) for reference.

See Also

[Setting up Character Encoding in the Policy](#)

[Validating Configuration and Policy Files](#)

4. Set up Access Credentials (for CM and Database)

You must set up BDT passwords and other access credentials after setting up BDT policy. Refer to [Setting up Access Credentials \(for CM and Database\)](#) for details.

5. Run Transformation**Linux**

Run `./bdt.sh -t [-c configfilepath] -p policyfilepath` for transforming files.

Windows

Run `bdt.bat -t [-c configfilepath] -p policyfilepath` for transforming files.

Note

`-c` is optional. If not provided, the default `config` file from the location `bdt/conf/bdt.config` is used.

- This command first validates configuration (`bdt.config` and `bdt.policy` validation) and then triggers transformation.
- The `transformation_id` is optional. When provided as a value to the `-t` option, the specified ID overrides the ID field value that is set in the policy file. Refer to [Restarting Transformation](#) for details.

See Also

[BDT Command Syntax](#)

6. Verify Output

DB-to-DB

Verify the output in the column mentioned in the policy file.

DB-to-File

- The output file is generated in the output directory specified in `bdt.config`. Check the output file name with the current timestamp appended.
- The same output directory can also contain a file named `<policy_name-timestamp>.failed`, which records any utility that has failed to transform. (The `policy_name` is defined with the `name` attribute in the policy file.)

File-to-DB

Verify the output in the column mentioned in the policy file.

File-to-File

- The output file is generated in the output directory specified in `bdt.config`. Check the output file name with the current timestamp appended.
- The same output directory can also contain a file named `<policy_name-timestamp>.failed`, which records any utility that has failed to transform. (The `policy_name` is defined with the `name` attribute in the policy file.)

Note

BDT does not support the following transformations:

- CSV to Fixed-length
- Database to Fixed-length

Tasks

This section describes BDT tasks:

- [Setting up BDT Policy](#)
 - [Setting up Access Credentials \(for CM and Database\)](#)
 - [Performing Encryption Through VAE](#)
 - [Restarting Transformation](#)
 - [Configure Logging](#)
-

- Filtering Input Data
- Setting up Character Encoding in the Policy
- Setting up Input Files with Fixed-Length Record Format
- Using Text Qualifier Characters in Input Files
- Validating Configuration and Policy Files
- Performing Initial Data Transformation for DPG Compatibility
- Storing Output of Crypto Operations in a New Column
- Using TU Features in BDT
- Operations

Setting up BDT Policy

The BDT policy provides instructions to the utility on how to perform transformation of the data in the input source. The policy is stored in the `bdt.policy` file or on a [CipherTrust Manager \(CM\)](#) instance that serves as a centralized manager for configuration, for easier reuse and maintenance.

See Also

[Sample BDT policy](#)

Using Local File

To configure your transformation policies using a local file:

1. Update the BDT Policy File attributes as applicable.
2. Open the command prompt, run `bdt.sh` or `bdt.bat`, and use `-p` option. This option identifies the local policy file.

For example:

```
./bdt.sh [-e] -t [-c configfilepath] {-p policyfilepath}
```

Using CipherTrust Manager (CM)

Note

CADP-JCE must be installed on your system to set up policies on the CipherTrust Manager for performing tokenization.

Refer to [BDT Policies](#) for details.

Setting up BDT Policy Using Local File

Use the following steps to configure your transformation policies through a local file:

1. Update the [BDT Policy File attributes](#) as applicable.
2. While running BDT from the command line using `bdt.sh` or `bdt.bat`, use `-p` to identify the local policy file.

For example:

```
./bdt.sh [-e] -t [-c configfilepath] {-p policyfilepath}
```

See Also

[Sample BDT policy](#)

Setting up Access Credentials (for CM and Database)

The first time you run BDT, use the `-e` option to store encrypted passwords in the BDT configuration file. Run the following command:

```
./bdt.sh -e [-c configfilepath] [-p policyfilepath]
```

The `-e` option can be used with the `--validate` or `--transform` option. This first puts the encrypted passwords in `bdt.config` and then performs the specified operation:

- Validates the configuration and policy files
- Performs data transformation

For example, the following command gets new passwords (`-e`), then transforms the data (`-t`) using the policy specified in the `-p` option:

```
./bdt.sh -e -t -p policyfilepath
```

Note

The `policyfilepath` option is not needed to be provided for the centralized policy.

Based on the configuration given in the config file, this command prompts for different passwords such as user password, keystore, truststore, and key password, to encrypt and update them in the config file.

These passwords will be encrypted and stored in the `bdt.config` file specified in the `-c` option. If `-c` is omitted, the default file `bdt/conf/bdt.config` is used.

Performing Encryption Through VAE

By default, BDT encryption is configured to use CipherTrust Manager (CM) as its key manager, as described in [Quick Start](#).

You can also configure BDT to use as its cryptographic server Vormetric Application Encryption (VAE) connected to a DSM security manager.

To do so, perform the following steps:

1. Open the `bdt.config` file, and under the `crypto` heading, set the cryptographic server to `vae`.

Sample for vae

```
"crypto": {
  "@type": "vae", /* Specify @type field as "vae" if vae is used as cryptographic
  c server, else skip @type field. */
  "pin": "", /* Key manager passphrase. */
  "libPath": "" /* Path to vae library. */
},
```

2. Follow steps described in the [transformation process](#).

Note

VAE does not support CM as the key manager.

Restarting Transformation

If a transformation run fails (for example, because of a system or process failure), the user can restart BDT with the `-r` option so that the utility resumes processing from the last committed batch. Such a restart is a more efficient and faster way to resume transformation, rather than rerunning from the beginning.

The following requirements must be met to successfully restart a transformation run:

- The destination must be empty at the time of the first run.
- There cannot be any new records in either source file or table.

To restart a BDT transformation at the point of failure, use the `-r` option:

```
bdm -r <transformation_id>
```

Where, by default `transformation_id` is the ID attribute in the policy file. If there are duplicate policy IDs in the internal BDT database, find the proper transformation ID from the failed transformation log file entry.

The `transformation_id` can be explicitly provided with `bdm -t` in the failed run.

```
bdm -t <transformation_id>
```

BDT launches the new transformation job to process the remaining records from the point of the failed transformation. If the number of records in the committed state and the number of actual written records are not identical, BDT cannot restart the transformation. This is a rare case where the system failed just after a record batch write but before writing the commit state.

Note

Do not change the policy file while restarting BDT. Doing so might result in inconsistent data transfers.

Configure Logging

BDT uses the standard `log4j` framework to record the logs, and allows you to configure log levels using `log4j.properties` file at `$BDT_HOME/conf`. Log levels can be configured for log files and console.

Configure Log Level for Log Files and Console

To configure log level for log files and console, you can set the log level in the `log4j.properties` file manually. To configure log level for log files via CLI, use `-f` option (before performing the transformation).

Note

The log file path can be absolute or relative to your application. Do not use the quotes even if the path contains spaces.

Log Levels

Log Level	Description
FATAL	Reserved for internal errors.
ERROR	Only error messages are logged.
WARN	Logs error messages and warnings.
INFO	Logs error messages, warnings, and informational messages.
DEBUG	Logs the diagnostic information.

Note

When you set a log level, all log events with equal or more severe levels are included. Logs with less severe levels are excluded. For example, if `ERROR` is set as the log level, only the `ERROR` and `FATAL` events are included.

Configuring TLS for use with CipherTrust Vaultless Tokenization (CT-VL)

Authentication can be done using server authentication or using client authentication. The end user can do either, both, or none of them.

Users can configure TLS in one of the following ways:

- [Configure SSL using Default Settings](#)
- [Configure SSL using all Certificates](#)
- [Configure SSL using Specified Certificates](#)

Setting up SSL using `Default` Setting

CT-VL Server Authentication

1. Go to the `vtls{}` section of the `bdtd.config` file.
2. Specify the following values for the `server{}` object commands:
 - `sslmode`: **Default**. Indicates trust only a standard valid certificate issued by a Certificate Authority (CA). If the certificate is expired, self-signed, or invalid, communication with the CT-VL server fails. The other `sslmode` values available for CT-VL server authentication are `Allow-All` and `Specify_SSL_Cert`. Refer to [Configuring TLS](#) for details.

-
- `VerifyHostName`: By default, it is set to **true** to enable hostname verification for SSL communication.

CT-VL Client Authentication

1. Go to the `mts{}` section of the `bdt.config` file.
2. Specify the following values for the `client{}` object commands:
 - `sslmode`: **Default**. Indicates client authentication is disabled. No need to send client identity. The other `ssl-mode` values available for CT-VL client authentication are `Allow-All` and `Specify_SSL_Cert`. Refer to [Configuring TLS](#) for details.
 - `Keystore`: **Client keystore file path**. This assumes a keystore has already been created; for example, using `keytool`.
 - `storepassword`: **Client keystore file password**.
 - `keypassword`: **Client's key password**.

Setting up SSL using `Allow-All` Setting

User can opt for server and client authentication by configuring `bdt.config`.

Perform the following steps to set up SSL for secure communication between the BDT utility and the CipherTrust Vaultless Tokenization (CT-VL) using all trust certificates:

CT-VL Server Authentication

1. Go to the `mts{}` section of the `bdt.config` file.
2. Specify the following values for the `server{}` object commands:
 - `sslmode`: Select **Allow-All**. Indicates Trust all certificates; no trust policy is defined. Any kind of SSL certificate is acceptable, including valid, expired, self-signed, or any other. The truststore setting is not required.
 - `VerifyHostName`: By default, it is set to **true** to enable hostname verification for SSL communication.

CT-VL Client Authentication

1. Go to the `mts{}` section of the `bdt.config` file.
2. Specify the following values for the `client{}` object commands:
 - `sslmode`: Select **Allow-All**. Indicates client authentication is disabled and there is no need to send client identity.

When passing `sslmode` as **ALLOW_ALL**, you don't need to configure following 3 params:

- `keystore`: **Client keystore file path**. This assumes a keystore has already been created; for example, using `keytool`.
- `storepassword`: **Client keystore file password**.
- `keypassword`: **Client's key password**.

Setting up SSL using `Specify_SSL_Cert` Setting

Perform the following steps to set up SSL for secure communication between the BDT utility and the CipherTrust Vaultless Tokenization (CT-VL) using valid certificates:

CT-VL Server Authentication

1. Go to the `mts{}` section of the `bdm.config` file.
2. Specify the following values for the `server{}` object commands:
 - `sslmode`: Select **Specify_SSL_Cert**. Indicates trust standard certificates and certificates stored in the provided trust store (specified in the truststore setting). Use to accept self-signed and expired certificates.
 - `VerifyHostName`: By default, it is set to **true** to enable hostname verification for SSL communication. Set to "false" to disable hostname verification.
 - `truststore`: Truststore file path. To set up the truststore:
 - Get the server's public certificate. If not available, open the VTS URL in a browser and export it from the Security option.
 - Import the certificate and create the truststore. Use the following command, it will output the truststore password.

```
keytool -import -alias "mts host certificate" -file server.crt -keystore
server.truststore
```

Important: Note this password. You need to provide it in the password parameter.

- `password`: Truststore file password obtained when you imported the VTS certificate and created the truststore.

CT-VL Client Authentication

1. Go to the `mts{}` section of the `bdm.config` file.
2. Specify the following values for the `client{}` object commands:
 - `sslmode`: **Specify_SSL_Cert** Indicates Client authentication is enabled. Create keystore with client certificate and key. Set keystore path in the keystore parameter. Communication succeeds if the VTS

server finds a valid certificate set in the keystore.

- `Keystore`: **Client keystore file path**. This assumes a keystore has already been created; for example, using `keytool`.
- `storepassword`: **Client keystore file password**.
- `keypassword`: **Client's key password**.

Filtering Input Data

BDT supports filtering of input data. For example, in a case with one million input rows, you can designate a subset for transformation. To do so, specify subset criteria in a policy file to filter the input records.

The element `subset` is a table-level element, and is applicable only to that table. Refer to [BDT Policy Files](#) for more information on Table attributes.

Filter Input Rows from Source Files

The following example shows how to filter input rows from source files:

```
"subset":{
  "offset":"10",
  "limit":1000,
  "recurrency": 2,
  "filters":[
    {
      "selector":"name",
      "operator":"like",
      "expression":"'p.*'"
    }
  ]
}
```

Specify the starting `offset` and the `limit`, which define the number of rows to transform.

The `recurrency` attribute specifies whether to transform rows in a sequence or skip rows. If recurrency is set to 2, then every second row in the sequence is transformed and the row in between is skipped.

`filters` specifies the list of conditions to match. The row should satisfy all conditions specified in the list.

- `selector` is the name of the column that the filter should evaluate.
- `operators` Options: "=", "<", ">", "<=", ">=", "!=", "like".
- `expression` Used to evaluate the filter on the selector using specified operator. For file transformation if `operator` is specified as `like`, then specify `regex expression` to match in the column value.

Note

To create a regex expression, see [Regex Tutorial](#) for details.

Filter Database Table Rows

The following example shows how to filter input database table rows:

```
"subset":{
  "offset":"10",
  "limit":1000,
  "recurrency": 1,
  "orderBy":"ID",
  "order":"DESC",
  "filters":[
    {
      "selector":"name",
      "operator":"like",
      "expression":"'p.*'"
    },
    {
      "selector":"salary",
      "operator":"<",
      "expression":"100000"
    }
  ]
}
```

Compared with file transformations, the database transformation `subset` can include two additional attributes:

- `orderBy`: Use the name of column which should be used to order records. Records are ordered first, then offset and limit attributes are applied.
- `order`: Define ascending (ASC) or descending (DESC) order.

For the `like` operator, use database-specific syntax for the expression to evaluate.

Setting up Character Encoding in the Policy

Note

Character encoding is mandatory only for the Extended Binary Coded Decimal Interchange Code (EBCDIC)-encoded files.

The supported encodings are listed in the linked [table](#) with the following caveats:

- The naming from either columns in the table *Canonical Name for `java.nio` API* and *Canonical Name for `java.io` API and `java.lang` API* can be used.
- The input file must use the same character encoding. Failed record files are created with the same character encoding. Output file encoding can vary, depending on configurations in the policy file.

Example

Example showing how to set Extended Binary Coded Decimal Interchange Code (EBCDIC) character encoding in the policy file.

BDT Policy File

Setting up Input Files with Fixed-Length Record Format

Some systems may require fixed-length record formats. As described by IBM:

“In fixed-length or fixed-format records, each field starts and ends at the same place in every record. A data file that contains data records of equal and constant length might be organized as follows.

Sample file with fixed-length records: `aaabbbbccccdddddggghhhh`

The data file illustrated previously has three records. Each record has a field of three characters followed by a field of four characters, so the total record length is seven characters. The file does not contain any separation between records; delimiters are unnecessary because all fields have the same length. The VARCHAR data types are therefore always the fixed maximum size of the field.”

Reference: [IBM® Informix® 12.10](#)

This option is valid for FPE and FF1 (ENCRYPT and DECRYPT), and TOKENIZE actions only. Refer to the sample policy file `FixedLengthFiletransformation.policy` in the BDT Sample folder.

Note

If applying tokenization on fixed-length format records, be sure not to add any prefix or suffix to the tokenized output. Adding such a string will result in failure of detokenization.

Example with a fixed-length record format along with EBCDIC character encoding.

Using Text Qualifier Characters in Input Files

A text qualifier character can be used to mark the start and end of a column field in a file that is input to the BDT utility. This is useful when the field value itself contains a character that would normally act as a field delimiter. Use the qualifier to indicate to BDT that the data following the delimiter is part of the same field, and not the beginning of the next field.

Any printable ASCII character can be specified as a text qualifier, except for the backslash (\) character. Also note that the qualifier character cannot be the same as the delimiter character.

For example, in the following input file, the comma is the delimiter character, but it is also part of the address field. To let BDT know that the text after the comma is also part of the same field, the value must be enclosed with a text qualifier.

Example of data before adding the text qualifier:

```
Firstname, Lastname, Address
James,Brown,1745 E. New St., Apt. 22,Chicago
Scott,Smith,400 South Warren Street,Trenton
```

After adding the text qualifier:

```
James,Brown,"1745 E. New St., Apt. 22,Chicago"
Scott,Smith,"400 South Warren Street,Trenton"
```

In most cases, the input file for BDT is created by exporting data from a database. Databases provide the option to specify a character to be used as a qualifier in exported data.

To add text qualifier characters:

1. When exporting data from the database, specify the qualifier using the technique that is supported by the database.
2. In the policy file, add the qualifier parameter to the top of the file, before the column specifications begin. If the qualifier is a double quote character, escape it in the policy file with a backslash.

Example configuration in policy file, including the double quote character (") as a qualifier:

```
"source":{
  "@type":"CSV_FILE",
  "filepath":"input.csv",
  "delimiter":",",
  "qualifier":"\"",
  "unescapeInput":true,
  "columnCount":"12",
  "hasHeaderRow":true
}
```

Validating Configuration and Policy Files

Perform the following steps to validate the BDT config and policy files.

Validating Configuration Files

If the config file is named as `bdtd.config` and assuming the file is stored in the expected default location, then to validate `bdtd.config` alone, use `-v` with no other options:

```
./bdtd.sh -v
```

If your config file is named differently, then to validate config files, use the `-c` option:

```
./bdt.sh -v [-c configfilepath]
```

Note

- `-c` is optional. If not provided, the default configuration file `bdt/conf/bdt.config` is validated.
- Replace `bdt.sh` with `bdt.bat` in the Windows environment wherever using commands with `bdt.sh`.

Validating Policy Files

If you want to only validate the policy files but not perform any other operation, you can specify which files to validate by adding `-p` for local policy file and `-central` for central policy.

For example, to validate the files `configfilepath` and `policyfilepath`, use the following command:

```
./bdt.sh -v [-c configfilepath] [-p <policyfilepath> | -central centralized_policyfile]
```

Note

- `-c` is optional. If not provided, the default configuration file `bdt/conf/bdt.config` is validated.
- `-p` and `-central` are optional. If not provided, the policy file is not validated.
- Replace `bdt.sh` with `bdt.bat` in the Windows environment wherever using commands with `bdt.sh`.

Performing Initial Data Transformation for DPG Compatibility

CipherTrust Batch Data Transformation (BDT) performs the initial, one-time encryption of existing plaintext data to make it compatible with the CipherTrust Data Protection Gateway (DPG). This process uses a BDT policy file to encrypt the data with the same protection policy that DPG will use for ongoing operations.

Note

- Initial encryption is needed only for the plaintext data.
- Initial encryption is supported only through BDT policy file and not from BDT tile on CipherTrust Manager UI.

- Initial encryption is supported only up to DPG version 1.2.0.

Steps for Initial Transformation of Data

- Create protection policy on CipherTrust Manager. Refer to the [Creating Protection Policy](#) for details.
- Create a BDT policy file using the same protection policy configurations defined in the previous step. Refer to the table below to map the attribute of BDT policy with the corresponding protection policy fields.

Protection Policy Fields	BDT Policy Attributes
Algorithm	@type
Key Name	key
IV	iv
Tweak	tweak
Tweak Algorithm	tweakAlgo
Character Set	characterSet
Version	policyVersion

Refer to the table below for algorithm name mappings between CipherTrust Manager and BDT policy file.

Algorithm name on CipherTrust Manager	Algorithm name in BDT Policy
AES/CBC/PKCS5Padding	AES_CBC_PAD
FPE/AES	FPE_AES

Following are the snippets of BDT policy for `FPE_AES` and `AES_CBC_PAD` respectively:

BDT policy configuration for FPE_AES

```
"config": [
  {
    "@type": "FPE_AES",
    "key": "key1",
    "tweak": "010ACD5B99F3C343",
    "characterSet": "alphanumeric",
    "policyVersion": 1 /* Version of protection policy on ${cm} GU
I to be used only for Initial Encryption of DPG. */
```

```
    }
  ]
}
```

BDT policy configuration for AES_CBC_PAD

```
"config" : [
  {
    "@type" : "AES/CBC/PKCS5Padding",
    "key" : "example_key",
    "iv" : "1234567812345678",
    "policyVersion" : 1 /* Version of protection policy on ${cm} G
UI to be used only for Initial Encryption of DPG. */
  }
]
```

- Run the transformation using the configured BDT policy. After the transformation is complete, DPG can process data using the existing protection policy created in the previous steps, or you may choose to create a new one.

Note

- BDT reads the encryption properties and protection policy version information from the policy file.
- A `policyVersion` parameter is used in the policy file to get version information of the protection policy.
- Refer to [BDT Policy File Attributes](#) for the attribute details and [Sample BDT Policy](#) for the sample policy file.

Storing Output of Crypto Operations in a New Column

BDT allows you to store the output of the crypto operations (encrypt/decrypt/rekey) in a new column. To enable this feature, add the `targetColName` parameter to the BDT policy file.

If the `targetColName` parameter is specified, the new column will hold the output of the crypto operations (encrypt/decrypt/rekey).

You can also add the `srcColumnAction` parameter to the BDT policy file to specify the action (preserve/remove/empty) to be performed on the source column.

Refer to [Columns Attributes](#) for details about the possible options regarding the `srcColumnAction` parameter.

Destination Types

Following are the different destination types:

- Destination File
- Destination DB

Destination File

The new column is created with the same name as specified in the `targetColName` parameter. The case sensitivity of the new column is based on the `targetColName` parameter.

If the column name specified in the `targetColName` parameter (irrespective of the case sensitivity) exists anywhere in the input file, the transformation is interrupted and the BDT throws an error as shown below:

```
Column "targetColName" exists in the input file.
```

Destination DB

The target column name in the table will be created as per value of the `caseSensitive` parameter (`true` or `false`) in the BDT policy file.

Following are the possible scenarios and errors:

Scenario	Error
The target column name already exists in the table with a different datatype.	<pre>Column "targetColName" exists in the input file.</pre>
The target column name already exists in the table with same datatype and length.	<pre>Column "targetColName" exists in the input file.</pre>

Refer to [Destination CSV File](#), [Destination Fixed Length File](#), and [Destination DB](#) for details.

Using TU Features in BDT

Supported Algorithms

Supported in TU	Supported in BDT
FPE/AES/CARD10	<pre>"@type": "FPE_AES"</pre> <pre>"characterSet": "digits"</pre>
FPE/AES/CARD62	<pre>"@type": "FPE_AES"</pre>

Supported in TU	Supported in BDT
	"characterSet": "alphanumeric"
AES/CBC/PKCS5Padding	"@type": "AES_CBC_PAD"
DESede/CBC/PKCS5Padding	"@type": "DESede" "Padding": "PKCSPADDING" "mode": "CBC"
DESede/ECB/PKCS5Padding	"@type": "DESede" "Padding": "PKCSPADDING" "mode": "ECB"
DESede/CBC/NoPadding	"@type": "DESede" "Padding": "PKCSPADDING" "mode": "ECB"
DESede/ECB/NoPadding	"@type": "DESede" "Padding": "PKCSPADDING" "mode": "CBC"

Note

- The minimum data length required for the FPE_AES type in BDT is 4.
- For FPE algorithms, BDT supports only UTF-8 encoding.
- BDT does not support the FPE formats.

Example

TU Config

```
<Column>
<Name>CREDITCARD</Name>
<MaxLength>16</MaxLength>
  <Transformation>
    <Type>Encrypt</Type>
    <Key>KEY_NAME</Key>
    <Algorithm>FPE/AES/CARD10</Algorithm>
    <TweakAlgo>SHA1</TweakAlgo>
    <TweakData>12345</TweakData>
    <IVType>Column</IVType>
```

```
<IV>0401030003040604090301030705020505030507040108080102020704020702010304070
400090105020603000002020906070004010200</IV>
<NewName>CREDITCARD_NEW</NewName>
</Transformation>
</Column>
```

BDT Config

```
"columns": [
  {
    "name": "CREDITCARD",
    "targetColName": "CREDITCARD_NEW",
    "srcColumnAction": "empty",
    "action": "ENCRYPT",
    "config": [
      {
        "@type": "FPE_AES",
        "key": "KEY_NAME",
        "iv": "040103000304060409030103070502050503050704010808010202070402
0702010304070400090105020603000002020906070004010200",
        "tweak": "12345",
        "tweakAlgo": "SHA1",
        "characterSet": "digits"
      }
    ]
  }
]
```

Supported Datatypes

The following table lists the datatypes supported by BDT corresponding to the databases supported by TU:

Database (TU)	Datatypes (BDT)
SQL Server	CHAR VARCHAR
DB2	CHAR NUMBER RAWBINARY VARCHAR
Oracle	CHAR NUMBER RAW VARCHAR

Storing Output of Crypto Operations in a New Column

BDT allows you to store the output of the crypto operations (encrypt/decrypt/rekey) in a new column. To enable this feature, add the `targetColName` parameter to the BDT policy file. Click [here](#) for more information.

Operations

- Encryption Examples
- Decryption Example
- Tokenize Example
- Detokenize Example
- Rekey Examples

Encryption Examples

The following example shows how to define encryption actions for two columns using `AES_CBC_PAD` and `FPE` encryption:

```
{
  "name" : "column2",
  "action" : "ENCRYPT",
  "config" : [ {
    "@type" : "AES_CBC_PAD",
    "key" : "c2KeyName",
    "iv" : "000102030405060708090A0B0C0D0E0F"
  } ]
}, {
  "name" : "column3",
  "action" : "ENCRYPT",
  "config" : [ {
    "@type" : "FPE",
    "key" : "c3KeyName",
    "characterSet" : "digits",
    "tweak" : "0102030405060708"
  } ]
}
```

The following example shows how to define encryption actions for one column using `FF1` encryption:

```
{
  "id" : "transformation-id",
  "name" : "transformation-name",
  "createBadRecordFile" : true,
  "source" : {
    "@type" : "CSV_FILE",
    "filepath" : "input.csv",
    "delimiter" : ",",
    "columnCount" : "12",
    "hasHeaderRow" : true
  },
  "destination" : {
    "@type" : "CSV_FILE",
    "filepath" : "output.csv"
  },
}
```

```

"tables": [
  {
    "columns": [
      {
        "name": "latitude",
        "action": "ENCRYPT",
        "config": [
          {
            "@type": "FF1",
            "key": "KEYNAME",
            "tweak": "auto",
            "characterSet": "digits"
          }
        ]
      }
    ]
  }
]

```

The following example shows how to define encryption actions for a column using `DESede` encryption:

```

{
  "name" : "column",
  "action" : "ENCRYPT",
  "config" : [
    {
      "@type" : "DESede",
      "key" : "DESedekey",
      "mode" : "CBC",
      "padding" : "PKCS5Padding",
      "iv": "010ACD5B99F3C343"
    }
  ]
}

```

Note

Output and input are base-64 encoded for `AES_CBC_PAD` mode in `ENCRYPT`, `DECRYPT`, and `REKEY` actions.

Decryption Example

The following example shows how to define decryption actions for two columns using `AES_CBC_PAD` and `FPE` decryption:

```

{
  "name" : "column2",
  "action" : "DECRYPT",
  "config" : [ {
    "@type" : "AES_CBC_PAD",

```

```

        "key" : "c2KeyName",
        "iv": "000102030405060708090A0B0C0D0E0F"
    } ]
}, {
    "name" : "column3",
    "action" : "DECRYPT",
    "config" : [ {
        "@type" : "FPE",
        "key" : "c3KeyName",
        "characterSet": "digits",
        "tweak": "0102030405060708"
    } ]
}

```

Tokenize Example

The following example shows the configuration of a column using tokenization:

```

{
    "name" : "column4",
    "action" : "TOKENIZE",
    "config" : [ {
        "@type" : "TOKENIZE",
        "tokenGroup" : "tokenGroup1",
        "tokenTemplate" : "tokenTemplate1"
    } ]
}

```

Detokenize Example

The following example shows the configuration of a column using detokenization:

```

{
    "name" : "column4",
    "action" : "DETOKENIZE",
    "config" : [ {
        "@type" : "TOKENIZE",
        "tokenGroup" : "tokenGroup1",
        "tokenTemplate" : "tokenTemplate1"
    } ]
}

```

Rekey Examples

BDT can perform key rotation by re-encrypting the data using the new key. Key rotation can be done for both [encryption](#) and [tokenization](#) operations.

A [REKEY](#) policy consists of two parts. In fact, [REKEY](#) is just a container for two other following actions:

1. The data is detokenized or decrypted using the existing key.

2. The data is tokenized or encrypted using the new key.

The two actions within each REKEY action are defined using ENCRYPT, DECRYPT, TOKENIZE, and DETOKENIZE with the same parameters as you would use with each of these actions alone.

To know more about these parameters, refer to [BDT Policy File](#).

The following example shows a sample configuration for a column rekey through CT-VL:

```
{
  "name" : "column6",
  "action" : "REKEY",
  "config" : [ {
    "@type" : "TOKENIZE",
    "tokenGroup" : "group1",
    "tokenTemplate" : "abcedf9876543210",
    "action" : "DETOKENIZE"
  }, {
    "@type" : "TOKENIZE",
    "tokenGroup" : "group2",
    "tokenTemplate" : "abcedf9876543210",
    "action" : "TOKENIZE"
  } ]
}
```

The following example shows a sample configuration for a column rekey through BDT default crypto library:

```
{
  "name" : "column6",
  "action" : "REKEY",
  "config" : [ {
    "@type" : "FPE",
    "key" : "rekey1",
    "characterSet": "digits",
    "tweak": "0102030405060708",
    "action" : "DECRYPT"
  }, {
    "@type" : "FPE",
    "key" : "rekey2",
    "characterSet": "digits",
    "tweak": "0102030405060708",
    "action" : "ENCRYPT"
  } ]
}
```

Advanced Topics

This section contains the following pages:

- [BDT Command Syntax](#)
- [BDT Config File](#)
- [BDT Properties File](#)

- BDT Policy File
- Encryption Key Versioning
- Configure TLS for CipherTrust Vaultless Tokenization (CT-VL)
- Configure SSL on CipherTrust Manager for NAE Interface
- FPE/AES/Unicode Cardinality Block-Size Table

BDT Command Syntax

The CipherTrust Batch Data Transformation utility runs at the command line with the following syntax:

```

bdt [-c <configfilepath>] [-e] [-f] [-h | -ld <type> | -ls <type> | -t [<transfor
mation_id>]
| -v] [-p <policyfilepath> | -central <centralized_policyfile>] [-sv] [-table
<tableName>] [-r <transformation_id>] [-rb <transformation_id>]

```

Command Options

Option	Description
<code>-c, --configfile <configfilepath></code>	Location of the BDT configuration file. Replace <code><configfilepath></code> with the path to <code>bdt.config</code> . If omitted, the default file <code>bdt/conf/bdt.config</code> is used.
<code>-e, --encryptPassword</code>	Sets the CADP-JCE library password and CT-VL password, encrypt them, and store in <code>bdt.config</code> . Use this option the first time you run BDT. You can also use it whenever you want to change the passwords. BDT prompts you to enter the passwords at the console.
<code>-f, --populatePropertyFile</code>	Populates the <code>bdt.properties</code> file. Use this option to configure the minimum required parameters of the default crypto library. It also allows you to configure log file path and log level.
<code>-h, --help</code>	Displays the BDT command syntax and information about how to use it.
<code>-ld <type></code>	Lists destination objects. Object types [tables, columns]
<code>-ls <type></code>	Lists source objects. Object types [tables, columns]
<code>-p, --policyfile <policyfilepath></code>	Location of the BDT policy file. Replace <code><policyfilepath></code> with the path to <code>bdt.policy</code> .
<code>-central <centralized_policyfile></code>	This configuration is applicable if the BDT policy is configured in CM. Provides name of the BDT Policy in CM.

Option	Description
<code>-sv, --skipvalidation</code>	Runs BDT without first checking the <code>bdt.config</code> and <code>bdt.policy</code> files for correctness. It is advisable to run transformation with skip validation option only when policy and configuration are validated beforehand. Caution: Use only for testing. Do not use it in a production environment.
<code>-t, --transform [<transformation_id>]</code>	Validates <code>bdt.config</code> and <code>bdt.policy</code> , then transform the input file and store the results in the output directory. If this option is omitted, BDT does not perform the data transformation. Running without <code>-t</code> is useful when you only want to set passwords or validate configuration files. You can optionally include the transformation ID here. When provided as a value to this option the specified ID overrides the ID field value that is set in the policy file.
<code>-v, --validate</code>	Validates <code>bdt.config</code> and (optionally) <code>bdt.policy</code> . Use this option when you want to check the files without actually transforming the data. The policy file is validated if the <code>-p</code> option is included in the command. If you are running with <code>-t</code> , you do not need to include <code>-v</code> . The <code>-t</code> option includes an implicit <code>-v</code> .
<code>--table <tableName></code>	Lists columns for this table. This option must be accompanied by <code>-ls</code> or <code>-ld</code> option. General syntax: <code>bdt.bat -ls (or -ld) columns --table <tableName> -p <policyfile></code>
<code>-r <transaction_id></code>	Restarts a transformation run at the point of a failed transaction. Only uncommitted records are transformed.
<code>-rb, --rollback<transaction_id></code>	Rolls back a failed row during in-place transformation.

BDT Config File

Refer to the [Sample BDT Config File](#) for details.

Global Config File Attributes

The configuration of the BDT utility is stored in JSON format in the file `bdt.config`. At the top of the file are several global configuration settings, followed by settings that configure the main underlying tools used by BDT:

Attribute	Default Value	Mandatory/Optional	Description
<code>inputDirectory</code>	No default	Mandatory	The path to the directory in which the input file or DB is placed.

Attribute	Default Value	Mandatory/Optional	Description
<code>outputDirectory</code>	No default	Mandatory	The path to the directory in which the output file or DB needs to be placed.
<code>threadCount</code>	No default	Mandatory	The maximum number of running threads required to transform a file.
<code>batchSize</code>	No default	Mandatory	The total number of records in the batch.
<code>dataProtectionConfig</code>	No default	Mandatory (if policy is fetched from Key Manager)	Contains credential information which will be used to get centralized policy.
<code>characterSets</code>	No default	Mandatory	Contains configurable list of charset names and their range. Users can also define their own <code>characterSets</code> in the <code>bdt.config</code> file as shown below: <pre>"characterSets" : [{ "Name of CharacterSets" : ["Range of CharacterSets"] }]</pre>
<code>mts</code>	No default	Mandatory (for tokenization and detokenization)	Contains settings to customize the behavior of the CipherTrust Vaultless Tokenization (CT-VL).
<code>crypto</code>	No default	Mandatory (for encryption and decryption)	Contains settings for the cryptographic provider used in this BDT configuration i.e <code>jce</code> (CADP-JCE).

Data Protection Attributes

BDT has a separate section for 'Data Protection Profile' to add its user information. The `dataProtectionConfig` object contains the following settings:

Attribute	Default Value	Mandatory/Optional	Description
<code>@type</code>	No default	Mandatory	For the <code>dataProtectionConfig</code> , BDT supports two login methods:

Attribute	Default Value	Mandatory/Optional	Description
			password - The user logs in using password. user_certificate - The user logs in using a user certificate.
userName	No default	Optional	(Used only when @type value is password). User name having access to batch data transformation on key manager.
password	No default	Optional	(Used only when @type value is password). User password having access to batch data transformation on key manager. Run <code>bdt -e</code> option to set password.
hostName	No default	Optional	(Used only when @type value is user_certificate). Hostname of the machine where tokenization server is running.
serverConfig	No default	Optional	(Used only when @type value is user_certificate).
clientConfig	No default	Optional	(Used only when @type value is user_certificate).

Below is the sample for @type is set to password:

```
"dataProtectionConfig":
{
  "@type": "password",
  "username": "test_user",
  "password": ""
}
```

Below is the sample for @type is set to user_certificate:

```
"dataProtectionConfig":
{
  "@type": "user_certificate",
  "hostName": "",
  "serverConfig":
  {
```

```

    "truststore": "",
    "password": "",
    "verifyHostname": "true"
  },
  "clientConfig":
  {
    "keystore": "",
    "storePassword": "",
    "keyPassword": ""
  },
}

```

Refer to [Sample BDT Config File](#) for details.

Server Configuration Attributes

Attribute	Default Value	Mandatory/Optional	Description
truststore	No default	Mandatory	Truststore file path, truststore should have server certificate.
password	No default	Mandatory	Truststore file password.
verifyHostname	false	Optional	Set to <code>true</code> to enable hostname verification for SSL communication, and <code>false</code> to disable hostname verification.

Client Configuration Attributes

Attribute	Default Value	Mandatory/Optional	Description
keystore	No default	Mandatory	Keystore file path of the client.
storePassword	No default	Mandatory	Keystore file password of the client.
keyPassword	No default	Mandatory	Key file password, usually same as keystore password.

Transformation Specific Attributes

vts Attributes

CT-VL Attributes

BDT has a separate section for the 'CT-VL Attributes'. The `vts` object contains the following settings:

Attribute	Default Value	Mandatory/Optional	Description
hostName	No default	Mandatory	Hostname of the machine where tokenization server is running.
userName	No default	Mandatory	The CT-VL username.
password	No default	Mandatory	The CT-VL password. Use the <code>bdt -e</code> option to enter encrypted value here. Do not use plaintext.
tokenUrl	No default	Mandatory	The CT-VL tokenize REST URL.
detokenUrl	No default	Mandatory	The CT-VL detokenize REST URL.
sslConfig	No default	Mandatory	Contains the server and client authentication configuration attributes.

Server Authentication Attributes

You must set up SSL for secure communication between the BDT utility and the CT-VL. In the `vts` section of `bdt.config`, the `server` object contains the following settings related to SSL authentication:

Attribute	Default Value	Mandatory/Optional	Description
sslmode	DEFAULT	Optional	One of the following values: DEFAULT - Trust only a standard valid certificate issued by a Certificate Authority (CA). If the certificate is expired, self-signed, or invalid, communication with the VTS server fails. SPECIFY_SSL_CERT - Trust standard certificates and certificates stored in the provided trust store (specified in the <code>truststore</code> setting). Use to accept self-signed and expired certificates. ALLOW_ALL - Trust all certificates; no trust policy is defined. Any kind of SSL certificate is acceptable, including valid, expired, self-signed, or any other. The

Attribute	Default Value	Mandatory/Optional	Description
			truststore setting is not required.
<code>verifyHostname</code>	false	Optional	Set to <code>true</code> to enable hostname verification for SSL communication, and <code>false</code> to disable hostname verification.
<code>truststore</code>	No default	Optional	(Used only when <code>sslmode</code> is <code>SPECIFY_SSL_CERT</code>). Truststore file path. To set up the truststore: 1. Get the server's public certificate. If not available, open the VTS URL in a browser and export it from the Security option. 2. Import the certificate and create the truststore. Use the following command. It will output the truststore password. <pre>keytool -import -alias "vts host certificate" -file server.crt -keystore server.truststore</pre> Important: Note this password. You need to provide it in the password parameter.
<code>password</code>	No default	Optional	(Used only when <code>sslmode</code> is <code>SPECIFY_SSL_CERT</code>). Truststore file password is obtained on importing the CT-VL certificate and creating the truststore.

Client Authentication Attributes

In the `vts` section of `bdt.config`, the `client` object contains the following settings related to SSL authentication:

Attribute	Default Value	Mandatory/Optional	Description
<code>sslmode</code>	DEFAULT	Optional	One of the following

Attribute	Default Value	Mandatory/Optional	Description
			values: <code>DEFAULT</code> - Client authentication is disabled. No need to send client identity. <code>ALLOW_ALL</code> - Client authentication is disabled. No need to send client identity. <code>SPECIFY_SSL_CERT</code> - Client authentication is enabled. Create keystore with client certificate and key. Set keystore path in the keystore parameter. Communication succeeds if the CT-VL server finds a valid certificate set in the keystore.
<code>keystore</code>	No default	Optional	(Used only when <code>sslmode</code> is <code>SPECIFY_SSL_CERT</code>). Client's keystore file path. This assumes a keystore has already been created; for example, using <code>keytool</code> .
<code>storepassword</code>	No default	Optional	(Used only when <code>sslmode</code> is <code>SPECIFY_SSL_CERT</code>). Client's keystore file password.
<code>keypassword</code>	No default	Optional	(Used only when <code>sslmode</code> is <code>SPECIFY_SSL_CERT</code>). Client's key password.

crypto Attributes

Cryptographic Provider Attributes

BDT has a separate section to configure 'Cryptographic Provider'. The `crypto` object contains the following settings:

Attribute	Default Value	Mandatory/Optional	Description
<code>@type</code>	<code>jce</code>	Optional	BDT supports the cryptographic provider <code>jce</code> . If any value is not

Attribute	Default Value	Mandatory/Optional	Description
			specified, BDT will use jce, which is a default crypto provider.
userName	No default	Optional	(Used only when using default crypto provider). Key owner user name.
password	No default	Optional	(Used only when using default crypto provider). Key owner user password.

BDT Properties File

The unified BDT package includes the `bdt.properties` file that is saved at `BDT_HOME/conf/bdt.properties` after installation.

To perform encryption using the default crypto library, it is mandatory to configure the `bdt.properties` file. Use `-f` option to configure the minimum required parameters from the command line using the following command:

```
./bdt.sh -f
```

The BDT configuration parameters are classified as follows:

- Network Configuration Parameters
- Connection Configuration Parameters
- SSL/TLS Configuration Parameters
- Client Key Caching Parameters

Network Configuration Parameters

Parameter	Default Value	Description
NAE_IP.1	No default	The <code>NAE_IP.1</code> parameter specifies the IP address of the Key Manager and multiple IP addresses separated by colons (:) when load balancing is used. For example, <code>192.168.1.10:192.168.1.11:192.168.1.12</code> servers must have the same value for the <code>NAE_Port</code>. For IPv6, the IP address must be

Parameter	Default Value	Description
		specified in curly braces, such as {2002:0dc8:85k3:0000:0000:9a2e:0370:5221}. Combination of IPv4 and IPv6 addresses can be separated by colons (:) provided each IPv6 address must be within curly braces. Refer to Limitations for details.
NAE_Port	9000	The NAE_Port parameter specifies the port of the Key Manager. Note: Both clients and servers must use the same port.
Protocol	tcp	The Protocol parameter is used to communicate between BDT and the Key Manager. Possible settings are: • tcp • ssl The ssl option uses TLSv1.0, TLSv1.1, and TLSv1.2. To establish SSL connections between BDT and Key Manager, at least one of TLSv1.0, TLSv1.1, and TLSv1.2 must be enabled on the servers. Both BDT and the Key Manager must use the same protocol. If the Key Managers are executing SSL requests, and BDT is not sending SSL requests, problems will occur. Note: It is recommended to gradually increase security after confirming connectivity between BDT and the Key Manager. Once a TCP connection is established between BDT and the Key Manager, it is safe to move on to SSL. Initially configuring BDT under the most stringent security constraints can complicate troubleshooting.

Connection Configuration Parameters

Parameter	Default Value	Description
Verify_SSL_Certificate	no	The <code>Verify_SSL_Certificate</code> parameter directs BDT to verify the IP address or hostname against the Subject Common Name (CN) or the Subject Alternative Name (SAN) in the server certificate presented by the Key Manager during authentication. SSL must be configured to use this feature. Possible settings are: • yes: Enables the feature. • no: Disables the feature. The feature is disabled by default.
SSL_Handshake_Timeout	No default	The <code>SSL_Handshake_Timeout</code> parameter allocates time for the SSL handshake. SSL must be configured to use this feature. Set to any positive integer.
Use_Persistent_Connections	yes	The <code>Use_Persistent_Connections</code> parameter enables the persistent connections functionality. Possible settings are: • yes: Enables the feature. BDT establishes persistent connections with the Key Manager. • no: Disables the feature. A new connection is made for each connection request. The connection is closed as soon as BDT receives the server response.
Size_of_Connection_Pool	300	The <code>Size_of_Connection_Pool</code> parameter specifies the total number of client-server connections that the configuration could possibly allow. It does not specify the connections that actually exist at a given moment. Possible setting is: • Any positive integer: Connections in the pool can be

Parameter	Default Value	Description
		active or waiting, TCP or SSL. A connection is created and the pool scales as needed. The pool starts at size 0, and can grow to the value set here. Once the pool is full, new connection requests must wait for an existing connection to close.
Load_Balancing_Algorithm	round-robin	The <code>Load_Balancing_Algorithm</code> parameter is used to determine how BDT selects a Key Manager (server) from a load balancing group. Possible settings are: • round-robin: Directs the connection to the next server in the load balancing group. This is the default. • random: Directs the connection to a randomly selected member of the load balancing group.
Connection_Idle_Timeout	600000ms (10 min)	The <code>Connection_Idle_Timeout</code> parameter specifies the amount of time connections in the connection pool can remain idle before the client closes them. Possible setting is: • Any positive integer: Note: There are two different connection timeout values; one on the Key Manager, and one in the properties file. The value of the timeout in the properties file must be less than what is set on the server. This lets the client control when idle connections are closed. Otherwise, the client can maintain a connection that is closed on the server side, which can lead to error.
Unreachable_Server_Retry_Period	60000ms	The <code>Unreachable_Server_Retry_Period</code> parameter specifies the amount of time the client will spend attempting to establish a

Parameter	Default Value	Description
		connection to a load balancing group. An error is returned after the specified period if no server in the group is reachable. If logging is enabled, error messages are written to the log file. Possible settings are: • -1: This is the infinite retry interval. The client keeps trying to connect to a server until a connection is established. This setting is not compatible with multi-tier load balancing as the load balancer will never switch tiers. • Any positive integer: If multi-tier load balancing is enabled, set this value between 1 and twice the value of the <code>Connection_Retry_Interval</code>.
Maximum_Server_Retry_Period	0	The <code>Maximum_Server_Retry_Period</code> parameter specifies the total amount of time that BDT (client) will spend trying to make connections to any Key Manager (server) on any tier. This value is used when multi-tiered load balancing is enabled. Possible settings are: • -1: BDT will try every server on every tier until any response is received. • 0: The default value is set to 0; there is no overall limit. Setting value to 0 disables this feature. • Any positive integer: BDT will try to make connections for at least the duration set in <code>Maximum_Server_Retry_Period</code> and will return an error if no connection can be made on the tier in use when the try period expires.
Connection_Timeout	1 minute	The <code>Connection_Timeout</code> parameter specifies how long BDT (client) waits for the TCP connection function before timeout.

Parameter	Default Value	Description
		Possible settings are: • 0: Disables this setting. The client uses the operating system's connection timeout. • Any positive integer: Setting this parameter a few hundred ms less than the operating system's connection timeout makes connection attempts to a downed Key Manager (server) fail faster, and failover happens sooner. If a connection cannot be made before the timeout expires, the server is marked as down, and taken out of the rotation. Note: If the client is working with many versions of a key, do not set the <code>Connection_Timeout</code> parameter too low. Otherwise the client connection may close before the operation is complete.
Connection_Read_Timeout	7000ms	The <code>Connection_Read_Timeout</code> parameter controls how long BDT(client) waits when reading data from the Key Manager before determining that it is down. Requests should only timeout if the Key Manager is physically down (e.g. powered off, or not responding because of misconfiguration). Possible settings are: • 0: Disables this setting. The client waits indefinitely until the Key Manager can be reached. Requests remain outstanding until the client's request is successfully satisfied. • Any positive integer: The purpose of this parameter is to control how the client should react when the Key Manager is down. If it should timeout eventually and return an error back to the application, set this parameter to an appropriate number of milliseconds to allow requests to complete in high load and high latency situations.

Parameter	Default Value	Description
Connection_Retry_Interval	60000ms (1 minute)	The <code>Connection_Retry_Interval</code> parameter determines how long BDT (client) waits before trying to reconnect to a disabled Key Manager (server). If one of the Key Managers in a load balanced configuration is not reachable, the client assumes that the server is down, and then waits for the specified time period before trying to connect again. Possible settings are: • 0: This is the infinite retry interval. The disabled server will never be brought back into use. • Any positive integer: If the server or network is under a high load, a connection timeout could occur for a running sever. If your <code>Connection_Retry_Interval</code> is not long enough, another connection attempt will be made to the busy server - adding to its already high load.

SSL/TLS Configuration Parameters

Refer to [Configure SSL on CipherTrust Manager for NAE Interface](#) for instructions on how to configure SSL.

Parameter	Default Value	Description
Client_Cert_Alias	the first certificate in the keystore	The client certificate sent to the Key Manager when client certificate authentication is enabled. If you have multiple client certificates in a keystore, you might want to specify which client certificate is sent to the Key Manager during the SSL handshake. If you do not specify a client certificate in the properties file, the first certificate in the keystore is sent to the Key Manager.
Client_Cert_Passphrase	the keystore password	The passphrase needed to access the client certificate listed in the <code>Client_Cert_Alias</code> .

Parameter	Default Value	Description
		If you specify a value for the <code>Client_Cert_Alias</code> , you should also specify a value for the <code>Client_Cert_Passphrase</code> , otherwise the keystore password is used.
<code>Key_Store_Location</code>	No default	The <code>Key_Store_Location</code> parameter specifies the location of the Java keystore that contains the client certificate. The path can be absolute or relative to your application. Don't use quotes, even if the path contains spaces.
<code>Key_Store_Password</code>	No default	The <code>Key_Store_Password</code> parameter specifies the password to unlock the keystore.

Note

Remember that the properties file is NOT encrypted. Make sure this file has appropriate permissions so that it is readable only by the appropriate user.

Client Key Caching Parameters

Parameter	Default Value	Description
<code>Symmetric_Key_Cache_Enabled</code>	no	The <code>Symmetric_Key_Cache_Enabled</code> parameter determines if the symmetric key caching feature is enabled. Symmetric keys can be cached. Possible settings are: • no: Key caching for symmetric keys is disabled. Crypto operations for symmetric key are performed on the Key Manager. • yes: Key caching for symmetric keys is enabled. Protocol must be set to <code>ssl</code> (and <code>ssl</code> must be configured). • tcp_ok: Key caching for symmetric keys is enabled over both <code>tcp</code> and <code>ssl</code> connections.

Parameter	Default Value	Description
Symmetric_Key_Cache_Expiry	43200s (12 hours)	The <code>Symmetric_Key_Cache_Expiry</code> parameter specifies the minimum amount of time that a key will remain in BDT (client) key cache. Possible settings are: • 0: This is the infinite timeout setting. Keys are never purged from the client cache. • A positive integer: At the end of this interval, the key will be purged from the cache the next time the library is called. The default value is 43200 seconds (12 hours).
Symmetric_Key_Cache_AutoRefresh_Interval	0	The <code>Symmetric_Key_Cache_AutoRefresh_Interval</code> parameter specifies the time after which the cached key becomes eligible for refresh. The actual refresh operation occurs only when a cached key is queried from the cache before the key expires. It can be specified in any time unit; the default is seconds. If the eligible key is not queried from the symmetric cache, it is removed from the cache after its expiry. This parameter is applicable only if the symmetric key cache is enabled. Possible settings are: • 0: Auto refresh feature is disabled. • Any positive integer: The time after which the cached key is eligible for refresh.
Local_Cipher_Cache_Expiry	0	The <code>Local_Cipher_Cache_Expiry</code> parameter determines the minimum amount of time after which the cipher initialized with the key expires and is reinitialized with the cached key. Possible settings are: • -1: This is the infinite timeout setting. Cipher is never purged from

Parameter	Default Value	Description
		the client cache. • 0: The cipher will expire after every operation. • Any positive integer: At the end of this interval, the cipher will be purged from the cache the next time the library is called. Note: The <code>Local_Cipher_Cache_Expiry</code> time should be less than or equal to the <code>Symmetric_Key_Cache_Expiry</code> time and <code>Symmetric_Key_Cache_Enabled</code> parameter should be set as yes or tcp_ok.
Local_Crypto_Provider	SunJCE or IBMJCE (depends on JVM)	The <code>Local_Crypto_Provider</code> parameter specifies the name of the JCE provider that will perform local cryptography if symmetric key caching is enabled. For example, SunJCE provider is the default on Sun JVM.
Key_non_exportable_policy	no	The <code>Key_non_exportable_policy</code> parameter is used to perform the crypto operations remotely when symmetric cache is enabled, and the key is non exportable. By default, this parameter is disabled. Possible settings are: • yes: Enables the feature. • no: Disables the feature.

BDT Policy File

Refer to the [Sample BDT Policy File](#) for details.

Top-level Policy Attributes

BDT Policy File Top-level Policy Attributes

Attribute	Default Value	Mandatory/Optional	Description
id	No default	Mandatory	A unique identifier for the

Attribute	Default Value	Mandatory/Optional	Description
			policy. The length of the policy ID must not exceed 100 characters.
name	No default	Mandatory	A unique name for the policy. The length of the policy name must not exceed 100 characters.
description	String	Optional	Description of the policy.
caseSensitive	false	Optional	True or false. If set to <code>true</code>, all the database objects mentioned in the policy file will be processed in the same case as input. If set to <code>false</code>, all the database objects mentioned in the policy file will be automatically converted to CAPITAL case. Note: Setting <code>caseSensitive</code> parameter to <code>true</code> allows SQL reserved words to be used as database objects in BDT. Refer to Sample BDT Policy File for details.
trimSpaces	false	Optional	True or false. If set to <code>true</code>, it will trim initial and trailing white spaces from the data present in the column to be transformed. If set to <code>false</code>, the flag is disabled, and no processing is done on the data present in the column to be transformed.
enableHexLiteral	false	Optional	Input type: Boolean

Attribute	Default Value	Mandatory/Optional	Description
			If set to <code>true</code> , the ciphertext will be enclosed with hex literal. For example, <code>x'<ciphertext>'</code>
source	No default	Mandatory	Defines details of data input. For databases, such details include connection parameters. For files, such details include file type (CSV_FILE or FIXED_LENGTH_FILE), delimiter, encoding, and so on.
destination	No default	Mandatory (if <code>inPlaceUpdate</code> attribute is set to <code>false</code>)	Defines details of data output, such as where to write transformed data. For databases, such details include connection parameters. If the policy file defines an in-place transformation of data (with <code>inPlaceUpdate</code> attribute set to <code>true</code>), the destination value is ignored if defined. For files, such details include file type (CSV_FILE or FIXED_LENGTH_FILE), delimiter, encoding, and so on.
tables	No default	Mandatory	List of the tables to be transformed.
fpemode	ASCII	Optional	ASCII or UTF. (FPE-only) Set <code>fpemode</code> to define which FF3-encoding mechanism to use. ASCII supports only ASCII characters and is faster than UTF. Default is ASCII. Set to UTF when using FPE to encrypt Unicode characters.

Attribute	Default Value	Mandatory/Optional	Description
			Note: ASCII encryption mode is separate from ASCII character encoding.
createBadRecordFile	false	Optional	True or false. Set to true to create a file with <code>.failed</code> extension, otherwise set to false. Note: It is recommended to delete the <code>BadRecordsFile</code> after being used as it contains sensitive information.
inPlaceUpdate	false	Optional	Set to true to transform data in-place within the database (that is, in-place transformation), rather than the default behavior that creates a new destination table containing the transformed data. If true, the <code>destination</code>, <code>destinationTable</code>, and <code>createDestinationTable</code> attributes are ignored. Note: - For <code>inPlaceUpdate</code> transformation, <code>Primary Key</code> column should be available in the table. If this column is not available, below error message is displayed: <code>"Primary key column not found. Can't perform in-place update."</code> - Ensure to take the backup of the source table before performing <code>inplaceUpdate</code>.

Source and Destination Attributes

For JDBC Connections

Attribute	Default Value	Mandatory/Optional	Description
@type	No default	Mandatory	Specify the database type as one of either DB2, ORACLE, MYSQL, SQL_SERVER, HANA.
connectionurl	No default	Mandatory	Database connection URL. For example: jdbc:mysql://localhost:3306/world.
username	No default	Mandatory	Database username.
password	No default	Mandatory	Database password. Use <code>bdt -e</code> option to add encrypted password.
driverclass	No default	Mandatory	DBC connection driver class. For example: com.mysql.cj.jdbc.Driver.

```

"source" :
{
  "@type" : "HANA",
  "connectionurl" : "jdbc:sap://host:port",
  "username" : "",
  "password" : "",
  "driverclass" : "com.sap.db.jdbc.Driver"
},
"destination" :
{
  "@type" : "HANA",
  "connectionurl" : "jdbc:sap://host:port",
  "username" : "",
  "password" : "",
  "driverclass" : "com.sap.db.jdbc.Driver"
}

```

For CSV Files

Attribute	Default Value	Mandatory/Optional	Description
@type	No default	Mandatory	CSV_FILE.
filepath	No default	Mandatory	The file path relative to the inputDir or outputDir path in the config file.
delimiter	No default	Mandatory	The character that is used to divide one column from the next in the input file.

Attribute	Default Value	Mandatory/Optional	Description
			Any printable ASCII character except for backslash (\) can be used as a delimiter, in addition to space (), tab, and Ctrl-A. Not mandatory in destination if it is same as source. Note: The delimiter and qualifier characters cannot be the same.
qualifier	double opening quote ("), if source is any database	Optional	A character used to enclose fields that contain a delimiter or a qualifier character itself. Any printable ASCII character except a backslash ("\") can be used as a qualifier. To identify which qualifier character is used for the input/output file, either go to the properties of your CSV editor or open the input file in any text editor and check which character is used as a qualifier to enclose that data. Example Data in CSV File asdf,asdf asdf"asdf Data in Text Editor "asdf,asdf" "asdf""asdf" In the above example, (") is the qualifier character. Note • The delimiter and qualifier characters cannot be the same. • If data includes delimiter characters, qualifier characters, or both, it is recommended to specify the qualifier character, otherwise the output may be ambiguous.
columnCount	No default	Mandatory	Number of columns in the input file. This does not necessarily equal the number of columns that have rules defined for them in this <code>bdt.policy</code> file.

Attribute	Default Value	Mandatory/Optional	Description
hasHeaderRow	false	Optional	True or false. Default false. If true, the utility will treat the first row as a header row. Values from first row will be treated as column names. The same column names should be mentioned in the transformation action. If false, the utility will treat all the rows as data to be transformed.
encoding	UTF8	Optional	Used to set character encoding, for example, to enable IBM's EBCDIC. Input file must use same character encoding. Output and failed record files will be created with the same character encoding. Sample: For EBCDIC encoding, set <code>encoding:"ibm500"</code> in the policy file. To encrypt ASCII files, you must set encoding: ASCII. Refer to Supported Encodings for details.

For file-to-file (CSV) transformation, if the delimiter or qualifier is not configured for destination, the delimiter or qualifier configured in the source will be considered.

For Fixed-Length Files

Attribute	Default Value	Mandatory/Optional	Description
@type	No default	Mandatory	FIXED_LENGTH_FILE.
filepath	No default	Mandatory	The file path relative to inputDir or outputDir path in config file.
columnCount	No default	Mandatory	The number of columns a row has.
encoding	No default	Optional	Used to set character encoding, for example, to enable IBM's EBCDIC.

Attribute	Default Value	Mandatory/Optional	Description
			Input file must use same character encoding. Output and failed record files will be created with the same character encoding. Sample: For EBCDIC encoding, set encoding:"<code>ibm500</code>" in the policy file. Refer to Supported Encodings for details.
columnPositionInfo	No default	Mandatory	Column positioning.
recordLength	No default	Mandatory	Record length.
lineSeparator	false	Optional	True or false. Is record separated with line separator?
hasHeaderRow	false	Optional	True or false. Default false. If <i>true</i>, the utility will treat the first row as a header row. Values from this row will be treated as column names. The same column names should be mentioned in the transformation action.

Tables Attributes

Attribute	Default Value	Mandatory/Optional	Description
sourceTable	No default	Mandatory	Source table name. For database only. Refer to Limitations for details.
destinationTable	No default	Mandatory (if <code>inPlaceUpdate</code> attribute is set to <code>false</code>)	Destination table name. For database only. If the policy file defines an in-place transformation of data (with <code>inPlaceUpdate</code> attribute set to <code>true</code>), the destination value is ignored if defined. By

Attribute	Default Value	Mandatory/Optional	Description
			definition, source and destination tables are the same.
sourceSchema	Username specified in the JDBC connections or the default schema name for the databases that support schema (for example, "dbo for MSSQL")	Optional	Database username or schema (for the databases that support schema) where source table belongs to.
destinationSchema	Username specified in the JDBC connections or the default schema name for the databases that support schema (for example, "dbo for MSSQL")	Optional	Database username or schema (for the databases that support schema) where destination table belongs to.
columns	No default	Mandatory	List of the columns to be transformed. Policy rules for transforming one or more columns. For each column where transformation is desired, the <code>bdt.policy</code> file specifies the data transformation action to be performed and a set of parameters related to that action.
subset	No default	Optional	Table-specific data filter criteria. Filter input data based on these criteria.
createDestinationTable	false	Optional	True or false. Create destination table if none exists. If in-place transformation is defined (when <code>inPlaceUpdate</code> attribute is set to <code>true</code>), <code>createDestinationTable</code> is ignored, because no new destination table is created. For File to DB, datatype of columns in the destination table will be <code>varchar(10000)</code>. Note: The

Attribute	Default Value	Mandatory/Optional	Description
			<code>createDestinationTable</code> attribute is not supported for HANA databases. Caution: Use only for testing. Do not use in a production environment. Refer to Limitations for details.

Columns Attributes

Attribute	Default Value	Mandatory/Optional	Description
name	No default	Mandatory	Column name. If <code>hasHeaderRow</code> is set to false, then configure this parameter as "columnN" where N is the position of column. Note: The position of column is starting from 0. For example: If the user wants to transform first column, then the value will be "column0", for second column; the value will be "column1", and so on.
targetColName	No default	Optional	Name of the new column. Refer to Storing Output of Crypto Operations in a New Column for details.
srcColumnAction	preserve (if <code>targetColName</code> is set)	Optional	Following are the options: preserve: The source column remains preserved. remove: The source column is removed. empty: The source column is empty, that is, contains no data. Note: If <code>srcColumnAction</code> is

Attribute	Default Value	Mandatory/Optional	Description
			set and no <code>targetColName</code> is present, BDT throws an error.
<code>targetColLength</code>	No default	Mandatory (if <code>targetColName</code> is set during fixed file transformation)	The column length of <code>targetColName</code> .
<code>action</code>	No default	Mandatory	For each column of input data, the <code>bdt.policy</code> file can specify any of these actions - ENCRYPT, DECRYPT, TOKENIZE, DETOKENIZE, and REKEY. Refer to Attributes for ENCRYPT/DECRYPT Actions and Attributes for TOKENIZE/DETOKENIZE Actions for details. Visit the following for the examples of each action: • ENCRYPT • DECRYPT • TOKENIZE • DETOKENIZE • REKEY Note: If you do not specify any of these actions for a column, the contents of the column are copied to the output file without any transformation.
<code>config</code>	No default	Mandatory	Configuration for Encryption or Tokenization operations.

Configuration Attributes

ENCRYPT/DECRYPT Actions

Attribute	Default Value	Mandatory/Optional	Description
<code>@type</code>	No default	Mandatory	Options: AES_CBC_PAD, AES_CTR, FPE, FF1, FPE_AES, and DESede (signifying the triple operations of DES of

Attribute	Default Value	Mandatory/Optional	Description
			encrypt-decrypt-encrypt). To encrypt/decrypt data using either of the NIST-defined FPE formats - FF3 or FF1, the user must specify the ENCRYPT or DECRYPT policy actions with @type value. The value for FF1 is FF1, and for FF3 is FPE. Note: The BDT syntax uses FPE as a synonym for FF3.
key	No default	Mandatory	Name of the encryption key.
characterSet	No default	Mandatory (if @type is FPE or FF1 or FPE_AES)	Name of the characterSet that was defined under characterSets in the bdt.config file. Defaults include "latin", "digits", "alphabets", and "alphanumeric". Users can also define their own characterSets in the bdt.config file. Note: characterSets are not applicable (if @type is AES_CBC_PAD or AES_CTR or DESede).
tweak	No default	Mandatory (if @type is FPE or FF1 or FPE_AES)	It uses the tweakable cipher concept to protect against statistical attacks due to potentially small input/output space. There are two ways of defining tweak: <pre>"tweak":<16 characters long HEX encoded string></pre> <pre>"tweak": "auto"</pre>

Attribute	Default Value	Mandatory/Optional	Description
			Either of these ways can be used. Refer to the <code>tweakSource</code> attribute for details. Note: <code>tweak</code> is not applicable (if <code>@type</code> is <code>AES_CBC_PAD</code> or <code>AES_CTR</code> or <code>DESede</code>).
<code>tweakSource</code>	No default	Optional	Specifies a column in the source for the <code>tweak</code>, to allow different tweaks to be used for each row. For example: <code>"tweakSource": "columnName"</code>. <code>tweakSource</code> is not supported when <code>inPlaceUpdate</code> is set to true.
<code>allowSmallInputs</code>	false	Optional	True or false. Default is false. Applicable to FPE, FF1, and FPE_AES. If true, the following scenarios occur: • Data is passed as untransformed if effective data length is less than 2 characters for FPE and FF1, and less than 4 characters for FPE_AES. • Transformation continues if effective data length is greater than 2 characters for FPE and FF1, and greater than 4 characters for FPE_AES. If false, transformation fails if effective data length is less than 2 characters for FPE and FF1, and less than 4 characters for FPE_AES.

Attribute	Default Value	Mandatory/Optional	Description
			Note: • <code>allowSingleCharInputs</code> is not applicable to DPG initial encryption as DPG doesn't support single characters. • To provide backward compatibility, <code>allowSingleCharInputs</code> is also supported, but it is recommended to use <code>allowSmallInputs</code>.
keepleft	No default	Optional	Number of characters to be preserved from left. It is applicable only if @type is FPE or FF1 or FPE_AES.
keepright	No default	Optional	Number of characters to be preserved from right. It is applicable only if @type is FPE or FF1 or FPE_AES.
policyVersion	0	Optional	Specifies the protection policy version information. If policy version > 0, then the version header in hex will be prepended to the ciphertext. If not, then no policy version header will be prepended to the ciphertext. Note: Applicable only for DPG initial encryption.
iv	No default	Mandatory (if @type is AES_CBC_PAD or AES_CTR or DESede with mode as CBC)	Initialization Vector. Refer to supported encryption algorithms for details. Note: • It is recommended to specify random generated IV, and do not reuse any IV.

Attribute	Default Value	Mandatory/Optional	Description
			• IV is not applicable (if @type is FPE or FF1 or DESede with mode as ECB).
ivSource	No default	Optional	Specifies a column in the source for the IV, to allow different IVs to be used for each row. For example: <code>"ivSource": "columnName"</code>. Value to be specified in hexadecimal format. For example: 01A40933B401A409. If value is not valid hexadecimal, then it is treated as an ASCII string. ivSource is not supported when inplaceUpdate is set to true. Note: It is recommended to specify random generated IV, and do not reuse any IV.
inputEncoding	No default	Optional	Specifies how to decode input and create byte array from it. Valid options are BASE2, BASE16, BASE64, UTF8, UTF16LE, UTF16BE, UTF32LE, or UTF32BE. — The inputEncoding attribute is not used by the FPE algorithm; BDT internally uses UTF-8. —BASE2 is supported only with database Blob data type columns.
outputEncoding	No default	Optional	Specifies how to encode output byte array to a string. Valid options are BASE16, BASE64, UTF8,

Attribute	Default Value	Mandatory/Optional	Description
			UTF16LE, UTF16BE, UTF32LE, or UTF32BE. — The outputEncoding attribute is not used by FPE algorithm; BDT internally uses UTF-8.
mode	No default	Mandatory (if @type is DESede)	Specifies the supported algorithm mode, either CBC or ECB. The mode must be specified when using the DESede (that is, the 3DES) algorithm (as specified by the @type attribute). DESede means DES encrypt-decrypt-encrypt, a common synonym for 3DES that summarizes the basic three-step process underlying it. Note: ECB mode is not recommended.
padding	No default	Mandatory (if @type is DESede)	Valid options are PKCS5Padding or NoPadding. Note: padding is supported (if @type is DESede). Refer to Supported Encryption Algorithms for details.

TOKENIZE/DETOKENIZE Actions

Attribute	Default Value	Mandatory/Optional	Description
@type	No default	Mandatory	Valid value is TOKENIZE.
tokenGroup	No Default	Mandatory (if action is TOKENIZE or DETOKENIZE)	Name of the token group as defined in VTS.
tokenTemplate	No Default	Mandatory (if action is TOKENIZE or DETOKENIZE)	Name of the token template as defined in VTS.

Attributes to Transform a Subset of Records

Attribute	Default Value	Mandatory/Optional	Description
offset	0	Optional	Start record index.
limit	No default	Mandatory (if filtering data for transformation)	Maximum number of records/rows to transform, starting from <code>offset</code> .
recurrency	1	Optional	Select every Nth record. Default is 1 (process every record).
orderBy	First column	Optional	Order by column, for example: <code>column1</code> . Not supported for file transformation.
order	ASC	Optional	ASC (ascending) or DESC (descending) record order. Not supported for file transformation.
filters	No default	Mandatory (if filtering data for transformation)	Subset-specific filters to be used.

Attributes to Filter a Subset

Attribute	Default Value	Mandatory/Optional	Description
selector	No default	Mandatory (if filtering data for transformation)	Column name.
operator	No default	Mandatory (if filtering data for transformation)	Options: "=", "<", ">", "<=", ">=", "!=", "like".
expression	No default	Mandatory (if filtering data for transformation)	Expression to evaluate filter on selector using specified operator.

The following is a sample policy file excerpt for table attributes (Subset, Offset, Limit, Filters, Selector, Operator, Expression) meant for filtering input data:

```
"subset":{
  "offset":"10",
  "limit":1000,
  "filters":[
    {
      "selector":"salary",
      "operator":">",
      "expression":"10000"
    },
    {
      "selector":"name",
      "operator":"like",
```

```

    "expression":"'p%'"
  }
]
}

```

Encryption Key Versioning

Encryption key versioning allows developers to simplify their applications by requesting automated key version advances, changing the key material automatically (“rekeying,” or “rotation”), and placing the current version of the key in the header of the encrypted data.

Note

Versioned keys are supported when using Vormetric Data Security Manager (DSM) with Vormetric Application Encryption (VAE). Versioned keys are not supported:

- With DESede encryption.
- When using CipherTrust Application Data Protection (CADP-JCE) with the CipherTrust Manager as a key manager.

BDT detects the key version from the header that is prefixed with cipher text. Configure header version with the `header` table attribute along with with `action` configuration in the policy file. You can specify different header versions for different columns. Valid combinations are shown below:

Supported Header Versions per Encryption Mode

Header	AES_CBC_PAD	AES_CTR	FPE/FF1
v 1.5	Yes	No	No
v 1.5 Base 64	Yes	No	No
v 2.1	Yes	Yes	No
v 2.7	Yes	Yes	No

The following shows policy code for a versioned key:

```

"columns": [
  {
    "name": "COLUMN0",
    "action": "REKEY",
    "config": [
      {
        "@type": "AES_CTR",
        "action": "DECRYPT",
        "key": "bdtVersionKey",
        "iv": "010203040506070809100A0B0C0D0E0F",
        "header": "V2_1"
      }
    ]
  }
]

```

```

    },
    {
      "@type": "AES_CTR",
      "action": "ENCRYPT",
      "key": "bdtVersionKey",
      "iv": "010203040506070809100A0B0C0D0E0F",
      "header": "V2_7"
    }
  ]
}
]

```

Configure TLS for use with CipherTrust Vaultless Tokenization (CT-VL)

Authentication can be done using server authentication or using client authentication. The end user can do either, both, or none of them.

Users can configure TLS in one of the following ways:

- Configure SSL using Default Settings
- Configure SSL using all Certificates
- Configure SSL using Specified Certificates

Setting up SSL using `Default` Setting

CT-VL Server Authentication

1. Go to the `mts{}` section of the `bdtd.config` file.
2. Specify the following values for the `server{}` object commands:
 - `sslmode`: **Default**. Indicates trust only a standard valid certificate issued by a Certificate Authority (CA). If the certificate is expired, self-signed, or invalid, communication with the CT-VL server fails. The other `sslmode` values available for CT-VL server authentication are `Allow-All` and `Specify_SSL_Cert`. Refer to [Configuring TLS](#) for details.
 - `VerifyHostName`: By default, it is set to **true** to enable hostname verification for SSL communication.

CT-VL Client Authentication

1. Go to the `mts{}` section of the `bdtd.config` file.
2. Specify the following values for the `client{}` object commands:
 - `sslmode`: **Default**. Indicates client authentication is disabled. No need to send client identity. The other `sslmode` values available for CT-VL client authentication are `Allow-All` and `Specify_SSL_Cert`.

Refer to [Configuring TLS](#) for details.

- `keystore`: **Client keystore file path**. This assumes a keystore has already been created; for example, using `keytool`.
- `storepassword`: **Client keystore file password**.
- `keypassword`: **Client's key password**.

Setting up SSL using `Allow-All` Setting

User can opt for server and client authentication by configuring `bdt.config`.

Perform the following steps to set up SSL for secure communication between the BDT utility and the CipherTrust Vaultless Tokenization (CT-VL) using all trust certificates:

CT-VL Server Authentication

1. Go to the `mts{}` section of the `bdt.config` file.
2. Specify the following values for the `server{}` object commands:
 - `sslmode`: Select **Allow-All**. Indicates Trust all certificates; no trust policy is defined. Any kind of SSL certificate is acceptable, including valid, expired, self-signed, or any other. The truststore setting is not required.
 - `VerifyHostName`: By default, it is set to **true** to enable hostname verification for SSL communication.

CT-VL Client Authentication

1. Go to the `mts{}` section of the `bdt.config` file.
2. Specify the following values for the `client{}` object commands:
 - `sslmode`: Select **Allow-All**. Indicates client authentication is disabled and there is no need to send client identity.

When passing `sslmode` as **ALLOW_ALL**, you don't need to configure following 3 params:

- `keystore`: **Client keystore file path**. This assumes a keystore has already been created; for example, using `keytool`.
- `storepassword`: **Client keystore file password**.
- `keypassword`: **Client's key password**.

Setting up SSL using `Specify_SSL_Cert` Setting

Perform the following steps to set up SSL for secure communication between the BDT utility and the CipherTrust Vaultless Tokenization (CT-VL) using valid certificates:

CT-VL Server Authentication

1. Go to the `mts{}` section of the `bdm.config` file.
2. Specify the following values for the `server{}` object commands:
 - `sslmode`: Select **Specify_SSL_Cert**. Indicates trust standard certificates and certificates stored in the provided trust store (specified in the truststore setting). Use to accept self-signed and expired certificates.
 - `VerifyHostName`: By default, it is set to **true** to enable hostname verification for SSL communication. Set to "false" to disable hostname verification.
 - `truststore`: Truststore file path. To set up the truststore:
 - Get the server's public certificate. If not available, open the VTS URL in a browser and export it from the Security option.
 - Import the certificate and create the truststore. Use the following command, it will output the truststore password.

```
keytool -import -alias "mts host certificate" -file server.crt -keystore server.truststore
```

Important: Note this password. You need to provide it in the password parameter.

- `password`: Truststore file password obtained when you imported the VTS certificate and created the truststore.

CT-VL Client Authentication

1. Go to the `mts{}` section of the `bdm.config` file.
2. Specify the following values for the `client{}` object commands:
 - `sslmode`: **Specify_SSL_Cert** Indicates Client authentication is enabled. Create keystore with client certificate and key. Set keystore path in the keystore parameter. Communication succeeds if the VTS server finds a valid certificate set in the keystore.
 - `Keystore`: **Client keystore file path**. This assumes a keystore has already been created; for example, using `keytool`.
 - `storepassword`: **Client keystore file password**.

- `keypassword`: Client's key password.

Configure SSL on CipherTrust Manager for NAE Interface

SSL with Server Certificate Authentication

When communicating with the CipherTrust Manager, you must configure both the server and the client to have SSL with server certificate authentication.

Configure the server

1. Create a local Certificate Authority (CA) on the CipherTrust Manager management console.
2. Create a server certificate and sign it with the local CA.
3. Configure the NAE interface.

Configure the client

1. Add the local CA Certificate, downloaded from the CipherTrust Manager management console, to keystore.
2. Update the `bdt.properties` file.

Create Local CA on CipherTrust Manager

1. Log on to the CipherTrust Manager management console as an administrator.
2. Click the **CA** tab on the left.
3. Under Local Certificate Authorities section, click **New Local CA**.
4. On the New Local CA screen, enter or select the details as required (The Common Name parameter is mandatory).
5. Click **Create Local CA**. The local CA created is listed beside the Pending CAs label.
6. Click the local CA beside the Pending CAs label. The local CA with its detail is displayed on screen.
7. Set the Duration for the local CA. You can either self-sign the certificate or upload an external CA to sign the local CA. The CA gets listed in the Local Certificate Authorities section.

Note

Only a local CA can sign certificate on the CipherTrust Manager. If you are using a CA that does not reside on the CipherTrust Manager, you cannot use the Management Console to sign the sever/client certificate.

-
- Click the ellipsis icon corresponding to local CA and then click the download button to download the local CA certificate. Save the certificate in .pem format in the system where BDT is used.

Create a Certificate on CipherTrust Manager

- Log on to the CipherTrust Manager management console as an administrator.
- Click the **CA** tab on the left.
- Navigate to the Local Certificate Authorities section and click on the name of local CA (under the heading Subject) using which you want to generate and sign the certificate.
- Click **Create New Certificate**. The Create New Certificate screen is displayed.
- Enter or select the details as required (Common Name parameter is mandatory).
- Click **New Certificate*.
- Click save private key to download and save the private key with .pem extension.
- From the Certificate Purpose drop-down, select server.
- Click **Issue Certificate**.
- The server certificate is created and gets signed with the local CA. This certificate can be used as the server certificate for the NAE server.
- Click the ellipsis icon corresponding to the server certificate and then click the download button to save the server certificate in .pem format.

Configure Interface on CipherTrust Manager

- Log on to the CipherTrust Manager management console as an administrator.
- Click to expand **Admin Settings** and then click **Interfaces**.
- On the Interface Configurations page, click **Add Interface**.
- On the Configure Interface tab, select the **Interface Type** as **NAE** and click **Next**.
- On the Network Form screen, enter/select the following details :
 - Select the **Allow unregistered clients** check-box.
 - Enter the port.
 - Select the desired **Network Interface** from the available options.
 - Select the **TLS, user must supply password, verify client cert** option from the drop-down list.

- click **Next**.

6. On the Add Certificate tab, enter/select the details.

- In the Username Location in Certificate, enter CN.
- In the Local CA for Automatic Server Certificate Generation field, select **Turn off auto generation from a Local CA**.
- Select Local Trusted CAs.
- If available, select External Trusted CAs.
- Click **Save**.

Note

Restart the application (Settings >> Services >> Restart button) after interface is configured.

Add the Local CA Certificate to Keystore

Run the following command to add the local CA certificate downloaded from CipherTrust Manager to the keystore:

```
keytool -keystore <name_of_the_keystore> -import -alias <alias_name_of_CAcertificate> -file
</certificate_location/LocalCA_certificate_file.pem>
```

Update bdt.properties File

Update the following parameters in the bdt.properties file:

- NAE_Port=Specify the port used by CipherTrust Manager for SSL connection.
- Protocol=Set it to ssl.
- Key_Store_Location=Location of the keystore . For example /tmp/KYLO_utility_keystore/cacerts, where /tmp/KYLO_utility_keystore/ is the keystore path and cacert is the keystore name. For windows machine, the keystore path will be \\tmp\\KYLO_utility_keystore\\cacerts.
- Key_Store_Password=Password of the keystore.

SSL with Client Certificate Authentication

This section describes the procedures to follow when configuring SSL with Client Certificate Authentication. It explains the following processes:

-
- Generating a Client Certificate with Keytool
 - Signing a Certificate and Downloading the Certificate
 - Configuring TLS Option in NAE Interface
 - Adding the Client Certificate to the Java Keystore
 - Updating the Parameters in bdt.properties

Generate Client Certificate with Keytool

1. Open a command prompt window on your client and navigate to the Java security directory (`<Java_Home>\lib\security`).
2. Generate a public/private key pair by executing the following command. In this step, an alias for the key pair is created.

```
keytool -keystore <KeystoreName> -genkey -alias <KeyPairAlias> -keyalg RSA
```

3. The key generation process will then request the following data:
 - A keystore password
 - The distinguished name - This is a series of fields whose values are incorporated into the certificate request. These fields include country name, state or province name, city or locality name, organization name, organizational unit name, and the users first and last name.
 - The key password- The certificate password must be the same as the keystore password. You can simply hit Return/Enter key to set the password. You need not retype the keystore password.
4. Create the certificate by issuing the following command. Reference the key pair alias, created in step 2.

```
keytool -certreq -alias <KeyPairAlias> -file <CertReqFileName> -keystore <KeystoreName>
```

You will now have a certificate in the `<CertReqFileName>` file.

Sign and Download Certificate

This section describes how to sign a certificate with a local CA and then download the certificate. You must download the certificate immediately after it is signed by the CA.

1. Open the certificate request in a text editor.
2. Copy the text of the certificate request. The copied text must include the header (-----BEGIN CERTIFICATE REQUEST-----) and the footer (-----END CERTIFICATE REQUEST-----).

3. Log on to the CipherTrust Manager management console as an administrator.
4. Click the **CA** tab on the left.
5. In the Local Certificate Authorities section, click the **Subject** corresponding to the local CA with which you want to sign the certificate.
6. Click **Upload and Sign CSR**.
7. Paste the text of the certificate in the text field highlighted as Paste external CSR here in PEM format.
8. Select Certificate Purpose as client and specify the life span of the certificate in days in Duration in days field.
9. Click **Issue Certificate**.
10. Click download button against the certificate to be downloaded.
11. Save the certificate in the machine where BDT is installed.

Configure TLS Option in NAE Interface

1. Log on to the CipherTrust Manager management console as an administrator.
2. Click to expand **Admin Settings** and then click **Interfaces**.
3. Click the edit button under column **Action** against the nae interface. The Configure NAE popup window is displayed.
4. In the **Mode** field, select the **TLS, user must supply password, verify client cert** option.
5. Click **Update**.

Note

Restart the application (Settings >> Services >> Restart button) after the TLS option is updated.

Add Client Certificate to Java Keystore

1. Open a command prompt window on your client and navigate to the Java security directory (\\lib\\security).
2. Import the signed client certificate using the following command. Use the key pair alias you used to create the certificate request. When prompted, enter the keystore password.

```
keytool -keystore <KeystoreName> -alias <KeyPairAlias> -import -file <Cert  
FileName.pem>
```

- Verify that the client certificate was properly imported by executing the following command. Reference the key pair alias you used above. The system should display the certificate.

```
keytool -keystore <KeystoreName> -alias <KeyPairAlias> -list -v
```

Note

To enable Client Certificate Authentication, your keystore must have a copy of the CA certificate downloaded from CipherTrust Manager management console.

Update bdt.properties File

Update the following parameters in the bdt.properties file:

- Key_Store_Location=Location and name of keystore that contains a copy of the server's local CA, the client certificate, and the CA that signed the client certificate. For example `/tmp/KYLO_utility_keystore/cacerts`, where `/tmp/KYLO_utility_keystore/` is the keystore path and `cacerts` is the keystore. For windows machine, the keystore path will be `\\tmp\\KYLO_utility_keystore\\cacerts`.
- Key_Store_Password=Password associated with the keystore.
- Client_Cert_Alias=<client certificate alias>.
- Client_Cert_Passphrase=<client certificate password, if used>

FPE/AES/Unicode Cardinality Block-Size Table

This table provides the cardinality size and the corresponding IV/block-size for the FPE/AES/Unicode usage. In FPE/AES/Unicode, the cardinality and IV/block-size is defined in character length.

Cardinality	IV/Block-size
10	56
11	54
12	52
13	50
14	50

assword, usually same as keystore password. */
    }
}
}

```

Best Practices

This section describes the best practices for:

- [Thread Count and Batch Sizes](#)

Thread Count and Batch Sizes

To best configure thread count and batch size, use the following principles:

1. Identify the ideal thread count for your environment depending on your system configuration. BDT gives optimal performance with 16 threads on four core machines. Setting thread count too low or too high will slow down the application.
2. Decide on batch size, configured based on available memory, size of individual record, and configured thread count. Setting batch size too high may result in an out-of-memory error.
3. Use the following formula to calculate the approximate maximum memory utilization by BDT:

```
thread count * batch size * record size = memory utilization
```

Therefore, thread count and batch size will be less than or equal to about 60% of available memory. The remaining memory is required to run the utility and to maintain transformed batches in the `write` queue.

Example

If you have 4GB available memory and individual record size of approximately 50MB, you can set either:

- Batch size to 50 and thread count to 1, utilizing $50 * 1 * 50\text{MB} = 2500\text{MB}$, approximately 60% of memory.
- Batch size to 10 and thread count to 3, utilizing $10 * 3 * 100\text{MB} = 3000\text{MB}$.

Troubleshooting

Log Files

- BDT stores its logs in the file `BDT_HOME/log/bdt.log`.
- The default log level is `DEBUG` for the log file and `INFO` for the console. These log properties can be changed in the `BDT_HOME/conf/log4j.properties` file.

Note

BDT_home points to your installation directory.

Error and Description

Error / Exception	Description
Value too long for column "PARAMETER_NAME CHARACTER VARYING(100)"	This error occurs if the length of the policy ID or the policy name exceeds 100 characters.
Thread count must be greater than or equal to number of tables.	This error occurs if the number of tables transforming are greater than the thread count.
NAE_IP.1 contains invalid IP addresses in the IngrianNAE.properties	The <code>bdt.properties</code> file is not configured, and the parameter <code>NAE_IP.1</code> is blank. Refer to BDT Properties File for configuring the properties.
Failed to obtain JDBC Connection; nested exception is java.sql.SQLException: Cannot create PoolableConnectionFactory (Access denied for user 'userName'@'xx.xx.xx.xx').	This exception occurs if: - Database user's password is empty. - Database user's password is incorrect.
Driver class not found:	Copy the required database driver to <code>BDT_HOME/lib</code> path.
PreparedStatementCallback; SQL [Insert into MYTESTDB.CUSTOMERYD27 values(?,?)]: Duplicate entry '3' for key 'customeryd27.PRIMARY'; nested exception is java.sql.BatchUpdateException: Duplicate entry '3' for key 'customeryd27.PRIMARY'.	This error occurs when a table contains primary key, <code>createDestinationTable</code> is set to true and destination table already exists. So, the same value for a primary key can not be written.
Loading class 'com.mysql.jdbc.Driver': This is deprecated. The new driver class is <code>com.mysql.cj.jdbc.Driver</code> . The driver is automatically registered via the SPI and manual loading of the driver class is generally unnecessary.	Change the driver class from <code>com.mysql.jdbc.Driver</code> to <code>com.mysql.cj.jdbc.Driver</code> in the BDT policy.
Could not create the destination table: Make sure the source table exists.	If the source table exists, ensure table name is configured correctly in the BDT policy file.
Invalid Object Name:	If <code>caseSensitive</code> flag is enabled in the policy file, the database object names should not be enclosed in double quotes.
Ciphertext version header does not match to policy version for this record:	The value of <code>policyVersion</code> field in the BDT policy file during decryption must be same as the one used during encryption.

Error / Exception	Description
Record parsing failed: The value of <code>columnCount</code> in the BDT policy file and parsed records does not match.	Ensure that all the records in the input file have the same column count as mentioned in the <code>columnCount</code> field of the BDT policy file.
Invalid or missing algorithm: The encryption algorithm used in <code>config@type</code> is not supported when symmetric key cache is disabled.	Refer to supported encryption algorithms for details.
Column <code>targetColName</code> exists in the input file	This error occurs if the column name specified in the <code>targetColName</code> parameter (irrespective of the case sensitivity) exists anywhere in the input file. Refer to Storing Output of Crypto Operations in a New Column for details.
<code>targetColName</code> is not specified, cannot modify the source column	This error occurs if <code>srcColumnAction</code> is specified without <code>targetColName</code> .
**Value of <code>srcColumnAction</code> "entered-value" is invalid **	This error occurs if "entered-value" in <code>srcColumnAction</code> is other than <code>preserve</code> , <code>empty</code> , <code>remove</code> . Refer to BDT Policy File for details.
Exception <code>java.lang.NoSuchMethodError</code> in the "main" thread <pre> org.apache.logging.log4j.spi.LoggerContextFactory .isClassLoaderDependent() Z org.apache.logging.slf4j.Log4jLoggerFactory .getContext(Log4jLoggerFactory.java:55) org.apache.logging.log4j.spi.AbstractLoggerAdapter .getLogger(AbstractLoggerAdapter.java:46) org.apache.logging.slf4j.Log4jLoggerFactory .getLogger(Log4jLoggerFactory.java:33) org.slf4j.LoggerFactory.getLogger(LoggerFactory.java:358) org.slf4j.LoggerFactory.getLogger(LoggerFactory.java:383) com.vormetric.bdt.cli.BDTCli. (BDTCli.java:50) </pre>	If you are using OpenJDK, try reinstalling it. If the issue persists, use Sun JDK.
SQL0668N operation not allowed for reason code "7" on table	This error occurs while performing any operation on destination table after a successful transformation with destination database as DB2. Note: This error is applicable only for DB2. Workaround: Run the following query after the transformation:

Error / Exception	Description
	<code>call sysproc.admin_cmd ('reorg table <schema>.<TableName>')</code>

Limitations

- If a source table contains spaces in its column name, then that source table cannot be transformed.
- Multiple IP addresses are not supported in the `NAE_IP.x` field of `bdt.properties` file when running BDT using the centralized policy `-central` option.
- When `createDestinationTable` is set to `true`:
 - For Oracle databases, only CAPITAL casing is supported for database user names.
 - If multiple tables with the same name but different casing (for example, "testtable" and "TestTable") exist in any source/destination and owner/schema, such tables cannot be transformed.
 - For MSSQL and MYSQL databases, if the parameter `caseSensitive` is set to `false`, then `sourceTable` name in policy should be in the same case as it is created in the database.

In case of casing mismatch, transformation will give the following error:

```
Could not create destination table. Make sure source table exists.
```

- In a multi-threaded environment, the sequence of the output order will be different than the one provided in the input order. To maintain the same sequence in the input and output order, it is recommended to use `threadCount` as 1 in [BDT Config File](#).

FAQs

- **Can I use FPE with BDT? If yes, which FPE algorithms are supported in BDT?**

BDT supports FF1 and FF3 algorithms. To do so, update the BDT config file as shown here:

- For FF3, set `@type` to `FPE`
- For FF1, set `@type` to `FF1`

- **Is there a way to configure BDT to not remove the double quotes from the header row?**

As of now, BDT removes qualifiers from headers and input data. To avoid it, the user can use any other character UTF-8 character as qualifier; for example, `#`, `@`, or `%`. But then the column name must also be changed from `ADRES_ID` to `\ "ADRES_ID\ "`.

```
{
  "id": "policyId",
  "name": "policyName",
  "source": {
    "@type": "CSV_FILE",
    "filepath": "persoonexample.csv",
    "delimiter": ",",
    "qualifier": "#",
    "unescapeInput": false,
    "columnCount": 51,
    "hasHeaderRow": true
  },
  "destination": {
    "@type": "CSV_FILE",
    "filepath": "persoonout.csv"
  },
  "fpemode": "ASCII",
  "createBadRecordFile": true,
  "tables": [
    {
      "columns": [
        {
          "name": "\"ADRES_ID\"",
          "action": "ENCRYPT",
          "config": [
            {
              "@type": "FPE",
              "key": "bdt_key",
              "characterSet": "alphanumeric",
              "tweak": "AUTO"
            }
          ]
        }
      ]
    }
  ]
}
```

- **Can BDT be configured for both encryption and tokenization?**

Yes, BDT can be configured for both encryption and tokenization. For this, the user needs to configure both `vt`s and `crypto` attributes in BDT, refer to [Sample BDT Config File](#) for details.

For a common policy of encryption and tokenization, refer to [Sample BDT Policy File](#).

- **Can I store my encrypted/decrypted/rekeyed data in a new column?**

Yes, BDT allows you to store the output of the crypto operations (encrypt/decrypt/rekey) in a new column. To do so, specify the `targetColName` parameter in the BDT policy file under [Columns Attributes](#).

Refer to [Storing Output of Crypto Operations in a New Column](#) for details.

- **Can I store my encrypted/decrypted/rekeyed data in the same column?**

If you want to store the encrypted/decrypted/rekeyed data in the same column, do not specify the `targetColName` parameter in the BDT policy file, leave `targetColName` column empty, or specify `targetColName` as `null`.
