CTE Agent AIX Integration Guides

This document covers the following information:

- Using CTE with Oracle
- Using CTE with PowerTech Antivirus

Using CTE with Oracle

This section describes how to install and configure CTE on Oracle RAC ASM, how to use an ASM Filter Driver as well as install and use CTE for AIX with Oracle Automated Storage Management (ASM™) Cluster File System (ACFS™) . It contains the following topics:

- CTE on Oracle ACFS Overview
- Oracle RAC ASM
- Creating an Oracle ASM Disk Group for Guarding
- About Oracle RAC ASM Raw Devices
- Oracle RAC ASM Multi-Disk Online Method
- Oracle RAC ASM Multi-Disk Offline Method (Backup/Restore)
- Surviving the Reboot and Failover Testing
- Basic Troubleshooting Techniques

CTE on Oracle ACFS Overview

CTE enables data protection of Oracle Automatic Storage Management Cluster File System (Oracle ACFS) on **secvm** volumes as part of the Oracle ASM stack. Oracle ACFS configured with **secvm** block devices is intended for use solely by the Oracle RAC application set to store related Oracle generated data such as:

- Oracle-generated related database files:
 - database datafile
 - control files
 - redo log files
 - archive log files
- Oracle-generated database backup files:

- hot/cold
- rman
- datapump exports
- Oracle-generated database TDE local wallet files

Note

CTE on ACFS only provides encryption. It does not provide access control.

For other files such as manually created shell scripts that require staging in a shared storage device, use other shared storage setups such as Veritas shared storage or share NFS mount.

Oracle RAC	Oracle RAC
Oracle ACFS (File System)	Oracle ADVM (Volume Manager)
Oracle ASM (Storage Manager)	SecVM

On Oracle, ACFS is layered on ASM disks, which in turn are built on **secvm** block devices. **secvm** is a proprietary device driver that supports GuardPoint protection to raw devices. **secvm** is inserted in between the device driver and the device itself.

Key Managers and SecVM

Server-side administrators must ensure that all **secvm** guards for an Oracle cluster use the same policies for encryption and access control.

Host Groups and Identical Keys and Policies

Thales recommends that you deploy host groups to ensure that identical policies and keys are applied on all nodes of the ACFS cluster. This is faster and less error-prone.

Restrictions and Caveats

- Thales does not support **secfs** layered on ACFS.
- Oracle ACFS encryption in conjunction with **secvm** encryption might impact performance.

Creating an Oracle ASM Disk Group for Guarding

Creating a new ASM Disk Group

Note

This document is for Oracle 19c on AIX 7.

1. List the available cluster shared disks, type:

```
xiv_devlist
```

Response

```
IBM storage devices
```

```
-----
Device          Size (GB)  Paths  Vol Name                                Vol ID
Storage ID      Storage Type Hyper-Scale Mobility
-----
/dev/hdisk2     51.6      2/2    sjaix81lpar069_sjaix81lpar079_vol_001  1053
7825664         XIV              Idle
-----
/dev/hdisk3     154.9     2/2    sjaix81lpar069_sjaix81lpar079_vol_002  1054
7825664         XIV              Idle
-----
/dev/hdisk4     154.9     2/2    sjaix81lpar069_sjaix81lpar079_vol_003  1055
7825664         XIV              Idle
-----
/dev/hdisk5     154.9     2/2    sjaix81lpar069_sjaix81lpar079_vol_004  1056
7825664         XIV              Idle
-----
/dev/hdisk6     51.6      2/2    sjaix81lpar069_sjaix81lpar079_vol_005  1075
7825664         XIV              Idle
-----
```

2. Ensure that the disks are available, type:

```
/usr/sbin/lssdev -Cc disk
```

Response

```
hdisk0 Available          Virtual SCSI Disk Drive
```

```

hdisk1 Available          Virtual SCSI Disk Drive
hdisk2 Available C5-T1-01 MPIO 2810 XIV Disk
hdisk3 Available C5-T1-01 MPIO 2810 XIV Disk
hdisk4 Available C5-T1-01 MPIO 2810 XIV Disk
hdisk5 Available C5-T1-01 MPIO 2810 XIV Disk
hdisk6 Available C5-T1-01 MPIO 2810 XIV Disk

```

3. To identify the device names for the physical disks that you want to use, type the following on any node:

```
/usr/sbin/lspv | grep -i none
```

Response

```

hdisk1          00fa0087e313f5c9          None
hdisk2          none                      None
hdisk3          none                      None
hdisk4          none                      None
hdisk6          none                      None

```

4. Select available candidate disks for a new ASM disk group. On the Oracle system, type:

```

SYS@+ASM2> COLUMN path format a20

SYS@+ASM2> SELECT name, header_status, path FROM V$ASM_DISK;

```

Response

```

NAME                                HEADER_STATUS PATH
-----
FORMER                               /dev/rhdisk1
FORMER                               /dev/rhdisk2
CANDIDATE                            /dev/rhdisk3
TDE1_0000                            MEMBER        /dev/rhdisk4
GRID_0000                            MEMBER        /dev/rhdisk6

```

5. Prepare the Targeted Disk for CTE and ASM Diskgroup creation:

```

chown grid:dba /dev/rhdisk3
chmod 660 /dev/rhdisk3
dd if=/dev/rhdisk3 of=zzz bs=4k count=1

```

Response

```
1+0 records in.
1+0 records out.
```

6. In CipherTrust Manager, create a key with the following characteristics:
 - Encryption mode: CBC
 - Algorithm: AES
 - Size: 128 or 256
7. Create a CipherTrust Transparent Encryption policy for Oracle on AIX.
 - a. Create a CBC key with CBC-AES128 or CBC-AES256.
 - b. Create a Security Rule:
 - **Action:** all_ops
 - **Effect:** Audit, Permit, Apply Key
 - c. Create a Key Selection Rule:
 - **Key:** cte_cbc_aes256_key
 - d. Guard your targeted RAC raw devices so that you can use the secvm disk to create a guarded Oracle RAC ASM or ASMLib disk group.

```
/dev/rhdisk3
```

- **Type** = Raw or Block Device (Auto or Manual Guard)

Once you guard your target, CipherTrust Transparent Encryption creates the following:

```
/dev/secvm/dev/rhdisk3
```

8. Install the same version of CipherTrust Transparent Encryption on all nodes in the cluster. To check the version, type:

```
vmd -v
```

Response

```
Version 7, Service Pack 3
7.3.0.35
2022-09-23 02:08:46 (PDT)
```

Copyright (c) 2009-2022, Thales Inc. All rights reserved.

9. Guard targeted disk on all cluster nodes.

a. Check the guard status of the disk on all cluster nodes, type:

```
secfsd -status guard
```

Response

GuardPoint	Policy	Type	ConfigState	Status	Reason
-----	-----	----	-----	-----	-----
/dev/rhdisk3	encrypt_cbc_aes256_all	rawdevice	guarded	guarded	N/A

b. List the devices, type:

```
ls -l /dev/secvm/dev/rhdisk3

crw-rw----  1 grid  dba          43,  1 Sep 28 15:21 /dev/secvm/dev/rhdisk3
```

10. Add the following client settings for both RAC nodes that are set in the \$GRID_HOME & \$ORACLE_HOME variables.

```
echo $GRID_HOME
```

Response

```
/u01/app/19.0.0/grid
```

```
echo $ORACLE_HOME
```

Response

```
/u01/app/oracle/product/19.0.0/db_1
```

For each node in the cluster, in the client settings, type:

```
|authenticator_euid|/u01/app/19.0.0/grid/bin/grid
|authenticator_euid|/u01/app/19.0.0/grid/bin/orarootagent.bin
|authenticator_euid|/u01/app/oracle/product/19.0.0/db_1/oracle
```

```
|authenticator_euid|/u01/app/oracle/product/19.0.0/db_1/bin/oracle
```

Note

This step is optional because it does not effect Oracle behavior. However, without these setting, CipherTrust Transparent Encryption can generate authentication error messages in the CTE log in `/var/log/vormetric`. These errors do not interfere with Oracle functions.

11. Launch the GUI for the GRID (`./asmca`) to create the new CipherTrust Transparent Encryption guarded ASM disk group:
12. Update the discovery path to the following in order for both the baseline and guarded disks to be found:

```
/dev/rhdisk*,/dev/secvm/dev/rhdisk*
```

13. Select targeted `rhdisk3` disk with the guarded path of `secvm`.

14. The end result should show your new CTE guarded ASM disk group called CTE1.

15. When creating your RAC database, choose DB files to reside in the CTE guarded ASM disk group that you just created:

You can now use the secvm disk that you created to create a guarded Oracle RAC ASM or ASMLib disk group.

Oracle RAC ASM

This section describes how to install and configure CTE on an Oracle RAC ASM.

Using CTE with an Oracle RAC ASM

You can apply CTE when the Oracle DB is active or inactive. If you choose to use it while the Oracle DB is active, it eliminates any downtime. You can apply CTE during low volume traffic time frames. If you choose to use this option, then use the **rebalance** function of ASM. This allows you to:

1. Migrate data off of a disk so that it can be dropped/removed from a **Diskgroup**.
2. Apply CTE protection.
3. Add the disk back into the diskgroup.

Caution

If you drop a disk from an ASM diskgroup, then add it back to the diskgroup without cleanly wiping the disk, the ASM diskname will be corrupted. To avoid this problem, clear out the disk before you add it back to diskgroup. Example: `dd if=/dev/zero of=/dev/secvm/dev/mapper/asmdg-asm1v002 bs=32k`

- [Important ASM Commands and Concepts](#)
- [Determining the Best Method for Encrypting Disks](#)
- [General Prerequisites](#)
- [Specific Prerequisites](#)

Important ASM Commands and Concepts

Rebalancing Disks

When you drop/remove a disk from the diskgroup, it is important to apply the proper value for the power setting for rebalance and to use the **WAIT** command.

Example ASM Command:

```
SQL> ALTER DISKGROUP <DiskGroupName> DROP DISK <diskName> REBALANCE POWER 8 WAIT;
```

- The rebalance command moves the data off of the disk that you are removing from the diskgroup, distributing the data across the remaining DISKS.
- The power setting is a number from 1 to 11. It determines how much processing power is dedicated to the

rebalance, versus normal operations. Unless the encrypting occurs during heavy traffic volume, the minimum value you should use is 6. Otherwise, consult the customer's DBA for the proper setting. An appropriate value to start with is 8.

Mapping Raw Devices

You can map raw devices for this configuration using:

- **EMC PowerPath**

If using EMC PowerPath then the device names are similar to the following: `/dev/hdiskpowerXX`.

When browsing the CipherTrust Manager through the local host, you cannot find Power Path devices. You must manually input the paths. The guarded disk names are prepended with: `/dev/secvm`.

Checking Rebalance Status

The `wait` command is very important when ASM performs a rebalance. When you specify `wait`, the command prompt does not display until all of the data is rebalanced and migrated off of the disk. If you do not specify `wait`, the command prompt returns immediately, and you must issue the following ASM command to check the status of the rebalance:

```
SQL> select * from v$asm_operation;
```

This command returns information about the:

- State
- Current power level
- Current amount rebalanced
- Estimated work until completion
- Rate
- Estimated minutes
- Any error codes

Note

It is highly recommended that you always specify the `wait` command when performing a **Drop Disk** with Rebalance. If it is not specified, ASM may prematurely release the disk, thereby allowing CTE to place a GuardPoint on the disk before the rebalance completes. This action may corrupt the data.

Oracle cautions against this issue:

Caution

The **ALTER DISKGROUP . . . DROP DISK** statement returns before the drop and rebalance operations complete. Do not reuse, remove, or disconnect the dropped disk until the **HEADER_STATUS** column in the **V\$ASM_DISK** view for this disk changes to **FORMER**. You can query the **V\$ASM_OPERATION** view to determine the amount of time remaining for the drop/rebalance operation to complete. For more information, refer to the *Oracle Database SQL Language Reference and the Oracle Database Reference.

Determining the Best Method for Encrypting Disks

A diskgroup can contain one or multiple disks. You must determine if the diskgroup contains enough disks and free space for encryption. If the diskgroup contains only one disk, or multiple disks but not enough free space, then you must use the **Offline** (backup/restore) method for encryption.

If the diskgroup contains more than one, you can use the **Online** (rebalancing) method. During rebalancing, additional disks allow for migrating data from the original disk so that it can be encrypted, added back into the diskgroup, and then migrated back to the source disk. Therefore, if the customer does not want to permanently add extra disks, they can add disks temporarily, just for rebalancing.

In general, once you have completed the initial setup for the operating system with which you are working, for both ASM or ASMLib, the high-level process is the same for applying CTE protection to raw devices and using them.

Online Method (No Application / Database Downtime)

Typically, when using the online method, follow these steps:

1. Make an ASM disk available for protection by either removing a disk from an existing diskgroup, or allocating a new disk.
2. Apply CTE encryption to the disk.
3. Add each protected disk to the diskgroup.
4. Restart the nodes and the failover test.
5. Repeat the previous steps for each disk in the diskgroup.

Offline Method (Backup the DB)

Typically, when using the offline method, follow these steps:

1. Backup the database.
2. Make an ASM disk available for protection by either removing a disk from an existing diskgroup, or allocating a new disk.

3. Stop the Oracle database.
4. Delete the diskgroup.
5. Apply CTE encryption to the disk.
6. Recreate the diskgroup.
7. Add the protected disk to the diskgroup.
8. Restart the nodes and the failover test.
9. Repeat the previous steps for each disk in the diskgroup.

General Prerequisites

Setup

- Verify that you have a current backup of the database
- Install and register CTE agents on all RAC node Hosts
- Create a **Host Group** and add all RAC node hosts as members
- Create an encryption key for the Oracle RAC Database / Application
- Create an Oracle policy using the proper encryption key

Note

If the raw device mappings for the disk(s) are **not** identical across all nodes in the RAC, then you cannot use a Host Group for managing the GuardPoint within the CipherTrust Manager. You **must** apply the GuardPoint to each Host individually. This is typically not optimal, as a Host Group is the most effective and consistent way to manage GuardPoints for Oracle RAC environments.

Altering ASM_DISKSTRING on ASM

ASM uses the `asm_diskstring` setting to identify the path where ASM will attempt to locate available disks to use. If you are using device names when adding the disk, you must modify the string to include the path to SecVM.

1. To retrieve the `ASM_DISKSTRING` setting, type:

```
SQL> SHOW PARAMETER ASM_DISKSTRING
```

2. To modify the setting, type:

```
SQL> ALTER SYSTEM SET ASM_DISKSTRING='/dev/*', '/dev/secvm/dev/*';
```

Where the path added is the path to SecVM.

Specific Prerequisites

Establishing a Starting Point

In many production environments, you may find that it has been a very long time since the RAC nodes have had the services restarted or have been completely rebooted. This can result in a lack of understanding of the actual state of the RAC cluster and its ability to survive a reboot on its own, prior to installing CTE.

Restarts can uncover issues in the RAC environment that are unrelated to CTE. To avoid issues after a CTE installation, Thales recommends that you restart each RAC node **AFTER** CTE is installed and **PRIOR** to establishing any GuardPoints. This may not be feasible in a single node configuration. However, by doing so, CTE is installed but inactive, and you can ensure that the platform is in a workable state prior to getting started.

The Importance of Device Mapping

It is important to use device naming and mapping in a multi-node RAC configuration. Verify the device names to ensure that the disks are mapped to the same disks on each RAC node before applying any GuardPoints. Thales recommends that RAC nodes use the same device names across all nodes. If they do not match, then problems can occur.

If the RAC nodes use the same device names, use a Host Group to create GuardPoints. If they do not match, do not use a Host Group to create GuardPoints. Set them up independently on each Host.

Important Note about Raw Devices on AIX

In general, raw devices are created as either character or block mode devices. Any I/O performed on character devices is non-buffered, while I/O on block devices is buffered and performed in defined block sizes (that is, 4K bytes).

While the Oracle documentation for using ASM with raw devices indicates that you can use either character or block devices, **CTE REQUIRES a block device for guarding.**

Note

- Attempting to apply a GuardPoint on a character device that does not have a corresponding block device may result in a GuardPoint that never encrypts data. The status of the GuardPoint never shows as guarded.
- The WebUI does not support browsing for the character devices. You would need to manually paste the name into the WebUI.

Once guarded, CTE creates both a character and block mode version of the guarded device. Oracle ASM can use either device.

About Oracle RAC ASM Raw Devices

Standard Devices

In many cases the ASM configuration may be using plain device names, like the following:

`/dev/hdisk1`

Note

If you use standard device names in the ASM configuration to add a disk, you must modify the `ASM_DISKSTRING` parameter to include the `/dev/Secvm/dev/*` path.

Consistent Naming of Devices across RAC Nodes

As previously stated, if the raw device mappings for the disk(s) are **NOT** identical across all nodes in the RAC, then you **CANNOT** use a Host Group and you **MUST** apply the GuardPoints to each Host individually. This is typically NOT optimal, as a Host Group is the most effective way to manage an Oracle RAC environment.

Oracle RAC ASM Multi-Disk Online Method

Performing encryption with the online rebalancing method requires sufficient free space to allow the drop of the largest ASM disk.

Checking for Space

In the Oracle system, use the following commands to check for available disk space:

1. Check total free space in the disk group:

```
SQL> SELECT name, free_mb, total_mb, free_mb/total_mb*100 as percentage FROM
v$asm_diskgroup;
```

NAME	FREE_MB	TOTAL_MB	PERCENTAGE
DATA	7	2109	.331910858

2. Check individual ASM disk size and usage:

```
SQL> select a.name DiskGroup, b.disk_number Disk#, b.name DiskName, b.total_m
b, b.free_mb, b.path, b.header_status FROM v$asm_disk b, v$asm_diskgroup a whe
re a.group_number (+) =b.group_number order by b.group_number, b.disk_number,
b.name
```

DISKGROUP	DISK#	DISKNAME	TOTAL_MB	FREE_MB	PATH
HEADER_STATUS					
-----	-----	-----	-----	-----	
DATA	0	DATA_0000	1874	1273	/dev/oracleasm/disks/D
ATA3	MEMBER				
DATA	1	DATA_0001	1992	608	/dev/oracleasm/disks/D
ATA4	MEMBER				
DATA	3	DATA_0003	117	0	/dev/oracleasm/disks/D
ATA2	MEMBER				
	0	DATA_ENC_0000	109	28	/dev/oracleasm/disks/D
ATA1_ENC	MEMBER				

Adding a Disk to the Diskgroup

Using the Online Method assumes that there is enough free space in the diskgroup so that you can drop/remove a disk, protect it with CTE, and then add it back into the diskgroup.

To add the disk to the diskgroup:

1. Open a terminal session on both RAC Nodes.
2. On **RAC Node 1**, on the ASM, remove the disk from the disk group, type.

```
SQL> ALTER DISKGROUP <diskGroupName> DROP DISK <diskName> REBALANCE POWER 11 WAIT;
```

3. On both **RAC Node 1** and **2** type:

```
chown oracle:oinstall /dev/<rawDevice1Name>
chmod 660 /dev/<rawDevice1Name>
```

4. On the CipherTrust Manager, in the Host Group, apply a GuardPoint to the Raw Device: `<rawDevice1Name>`.
5. From **RAC Node 1**, to display the status of the guarded disks, type:

```
secfsd -status guard
```

6. On both **RAC Node 1** and **2** type:

```
chown oracle:oinstall /dev/secvm/dev/<rawDevice1Name>
```

```
chmod 660 /dev/secvm/dev/<rawDevice1Name>
```

7. From **RAC Node, on the ASM**, add the protected disk to the disk group:

```
SQL> ALTER DISKGROUP <diskGroupName> ADD DISK /dev/secvm/dev/<rawDevice1Name>
NAME <disk1Name>;
```

The disk is now added to the diskgroup and ready for use.

8. The system is now ready for a reboot and failover test. For details, see [Surviving the Reboot and Failover Testing](#).

Oracle RAC ASM Multi-Disk Offline Method (Backup/Restore)

Using the Offline Method assumes that there is not enough free space in the diskgroup.

1. Open a terminal session on both RAC Nodes.
2. On RAC Node 1, on the ASM, type the following to remove the disk group.

```
SQL> DROP DISKGROUP <diskGroupName> FORCE INCLUDING CONTENTS;
```

Note

Make sure that the disk is removed before guarding the raw devices.

3. On both **RAC Node 1** and **2** type:

```
chown oracle:oinstall /dev/<rawDevice1Name>
chmod 660 /dev/<rawDevice1Name>
chown oracle:oinstall /dev/<rawDevice2Name>
chmod 660 /dev/<rawDevice2Name>
chown oracle:oinstall /dev/<rawDevice3Name>
chmod 660 /dev/<rawDevice3Name>
```

4. On the CipherTrust Manager, in the Host Group, apply GuardPoints to the three raw devices:

```
<rawDeviceName1>
<rawDeviceName2>
<rawDeviceName3>
```

- On **RAC Node 1**, to display the status of the guarded disks, type:

```
secfsd -status guard
```

- On both **RAC Node 1** and **2**, type:

```
chown oracle:oinstall /dev/secvm/dev/<rawDeviceName1>
chmod 660 /dev/secvm/dev/<rawDeviceName1>
chown oracle:oinstall /dev/secvm/dev/<rawDeviceName2>
chmod 660 /dev/secvm/dev/<rawDeviceName2>
chown oracle:oinstall /dev/secvm/dev/<rawDeviceName3>
chmod 660 /dev/secvm/dev/<rawDeviceName3>
```

- From **RAC Node 1**, on the **ASM**, add the protected disk to the disk group, type:

```
SQL> ALTER DISKGROUP <diskGroupName> ADD DISK /dev/secvm/dev/<rawDeviceName1>
NAME <diskName1>;
SQL> ALTER DISKGROUP <diskGroupName> ADD DISK /dev/secvm/dev/<rawDeviceName2>
NAME <diskName2>;
SQL> ALTER DISKGROUP <diskGroupName> ADD DISK /dev/secvm/dev/<rawDeviceName3>
NAME <diskName3>;
```

The disks are now added to the diskgroup and ready for use.

- On **RAC Node 1**, restore the database.
- The system is now ready for a reboot and failover test. Go to the [Surviving the Reboot and Failover Testing](#).

Surviving the Reboot and Failover Testing

Failover Testing

Confirm that everything is functional:

- Ensure that the GuardPoints are all operational.
- Ensure that you receive valid results when you query the database.
- Verify that the load order ensures that CTE starts before ASM.

Once verified, you can start the failover testing for each RAC Node.

- Reboot the RAC Node 1 and monitor the startup.
- Once the restart is clean, reboot RAC Node 2 and monitor the startup.

Basic Troubleshooting Techniques

The following are some of the most common configuration issues that prevent the Oracle ASM configuration from working properly.

If you encounter errors similar to:

- ORA-15075: disk(s) are not visible cluster-wide
- ORA-15032: not all alterations performed

This could be the result of improper settings for the I/O layer, meaning that your disks are not properly configured.

Perform the following tasks to verify that the settings are correct:

1. On the CipherTrust Manager, in the Host Group that was created for the RAC cluster, verify that the host group for this configuration does **NOT** have the Cluster Group option set (this option is only for GPFS, which is not supported with CTE).
2. Ensure that the GuardPoints for the block devices are set at the Host Group level. This ensures that each node receives identical GuardPoints.
3. Verify that the GuardPoints are active on all nodes. When the GuardPoints are set, go to each node and verify that they are set and guarded, using the WebUI or the `secfsd -status guard` command. If they do not guard correctly, make sure the device names are the same across all nodes.
4. From ASM, make sure that the `asm_diskstring` parameter is modified to include the CTE devices and that the proper pathname is used, see [Altering ASM_DISKSTRING on ASM](#).

Verifying Database Encryption

Option 1

The best way to verify the state of the data, without impacting anything in the existing environment, is to use the Oracle `kfed` command. You can run this command against the native path of the existing GuardPoints and make sure it returns with valid header information. If it returns valid information with the GuardPoint in place, then this confirms that the data is properly encrypted. If it returns with invalid header information, then that indicates that the data is either clear, double encrypted, or not in the expected encrypted state. The syntax for running this command would look similar to the following but will vary based on your environment.

```
/app/oracle/grid/product/19.0.0/grid/bin/kfed read /dev/<diskName>
```

If the location is properly encrypted, following is an example of the viewable output:

```
/app/oracle/grid/product/19.0.0/grid/bin/kfed read /dev/<diskName>
```

System Response:

```
kfbh.endian: 1 ; 0x000: 0x01
```

```

kfbh.hard:                242 ; 0x001: 0xf2
kfbh.type:                124 ; 0x002: *** Unknown Enum ***
kfbh.datfmt:              66 ; 0x003: 0x42

KFED-00322: Invalid content encountered during block traversal: [kfbtTraverseBlock][Invalid OSM block type][124]

```

Option 2

The second option to verify the state of the data is to use the `dd` command. This requires you to specify some blocks and write it out to a file. After this completes, read the file using the `strings` command. You can do this while the device is in use. In the example below some sectors are skipped and it only dumps 10000 counts.

For example:

```
dd if=/dev/asm_data2p1 of=/tmp/dd2.out skip=1047 count=10000
```

Option 3

The third option to verify the state of the data without impacting the existing environment is to use the `strings` command.

Note

The `strings` command cannot read a busy or large device.

You can run this command against the native path (`/dev/<deviceName>`) of the existing GuardPoints (`/dev/secvm/dev/<deviceName>`). By executing the `strings` command against the native path `strings /dev/devicename | more`, this does not go through the SecVM device and therefore is not be decrypted. If it is encrypted the output should contain illegible text.

Using CTE with PowerTech Antivirus

When Powertech Antivirus is configured to use **on-access scanning**, CipherTrust Transparent Encryption Data Transformation may find files within the Data Transformation GuardPoint that are busy. These files are not processed by Data Transformation and are left unencrypted.

Note

This problem only occurs if Powertech is configured to use **on-access scanning**. This problem **does not** occur when using **on-demand scanning**.

Issue

When Powertech uses **on-access scanning**, it opens a file and keeps it open. Before the Data Transformation program encrypts a file, it checks to see if the file is in use by another process. If the file is in use, Data Transformation does not encrypt the file but rather appends the path to the file in the **dataxform_status_error-<guardpoint>** file located in **/var/log/vormetric/**. This prevents any retry of Data Transformation from succeeding.

Resolving PowerTech/Data Transformation "in-use" Errors

For the following scenario, Powertech is configured with **on_access scanning** and both Powertech and the Thales CTE agent have been installed at default locations. The example assumes the Data Transformation GuardPoint is **/test-dataxform**.

Running Data Transformation with Powertech Antivirus code deactivated

1. Type the following to prevent the Powertech package from starting on system boot.

```
/opt/sgav/avsvcctl disable
```

2. Reboot the system.
3. After the system restarts, verify that Powertech is not running, type:

```
/opt/sgav/avsvcctl status
```

Response

```
The following output indicates Powertech is not running:  
Subsystem Group PID Status  
avsvc powertech inoperative  
Device driver is not loaded
```

4. Perform a Data Transformation conversion on the Data Transformation GuardPoints.

Example

```
dataxform --rekey --gp /test-dataxform
```

5. Enable Powertech to start after system boot, type:

```
/opt/sgav/avsvcctl enable
```

6. Start Powertech, type:

```
/opt/sgav/avsvcctl start
```

Response

There is a delay before Powertech is completely loaded and active. The Powertech status may be found by the following command.

7. Verify the status, type:

```
/opt/sgav/avsvcctl status
```

Response

```
The Powertech avsvc subsystem should be `active' and the device driver loaded:  
Subsystem Group PID Status  
avsvc powertech 5964286 active  
Device driver is loaded  
The avsvc subsystem is configured to run at boot
```

Recovering from Data Transformation/Powertech Antivirus code errors

A Data Transformation rekey performed while Powertech is active can result in failed file conversion due to "busy" faults. The following section describes how to recover from this type of error.

Note

There are many reasons that a data transformation may fail. This topic only considers the failure due to the

interaction of Powertech with CTE. For other error recovery procedures, refer to the [Data Transformation guide](#)

The following section illustrates the process using an example data transformation and describes the steps needed to recover. The Data Transformation GuardPoint `/test-dataxform`.

1. Run Data Transformation.

```
dataxform --rekey --gp /test-dataxform
```

Response

```
Checking if /test-dataxform is a guardpoint with a rekey policy applied
/test-dataxform is a guardpoint with a rekey policy applied
About to perform the requested data transform operation
- Be sure to back up your data
- Please do not attempt to terminate the application
Do you wish to continue (y/n)?y
Scan found 19 files (14 MB) in 1 directories for guardpoint /test-dataxform
File /test-dataxform/xab is busy
File /test-dataxform/xaa is busy
Transformed 17 files (13 MB) of 19 files (14 MB) for guardpoint /test-dataxform
Data transform got errors on some files
File /test-dataxform/xab is busy
File /test-dataxform/xaa is busy
Number of files in error due to file being busy: 2
The data transform operation took 0 hours, 0 minutes and 3 seconds
The data transform program ran from Thu Feb 16 10:58:12 2023 until Thu Feb 16 10:58:15 2023
Data transform for guardpoint /test-dataxform finished but 2 files were not processed due to errors
```

2. Inspect the error file (`dataxform_status_error-_test-dataxform`) for `/test-dataxform`. The file is located in `/var/log/vormetric`. The contents for the file contain the error messages generated by Data Transformation.

Example

```
Skipped, file is busy : /test-dataxform/xab
Skipped, file is busy : /test-dataxform/xaa
```

Note

Other Data Transformation errors may be present besides those caused by the Powertech antivirus code.

3. Create a "todo" file. Using Data Transformation, extract the names of the files that need to be retried for conversion.

```
dataxform --recovery --file_list my-output --gp /test-dataxform
```

This generates two files in the local directory

```
my-output_done  
my-output_todo
```

The `my-output_todo` file contains the list of files to retry applying Data Transformation:

```
/test-dataxform/xaa  
/test-dataxform/xab
```

Note

The `my-output_todo` file may need to be edited to remove entries not caused by the `Skipped, file is busy` error.

4. Turn off Powertech on boot, type:

```
/opt/sgav/avsvcctl disable
```

5. Reboot the system.
6. Verify the status.

```
/opt/sgav/avsvcctl status
```

Response

```
Subsystem Group PID Status
avsvc powertech inoperative
Device driver is not loaded
```

7. Re-issue Data Transformation to transform files listed in the `my-output_todo` file.

```
dataxform --rekey_list --gp /test-dataxform --file_list ./my-output_todo
```

Response

```
Checking if /test-dataxform is a GuardPoint with a rekey policy applied
/test-dataxform is a GuardPoint with a rekey policy applied
Previous status information does not relate to a --rekey_file operation.
Number of files previously in error due to file being busy: 2
About to perform the requested data transform operation
- Be sure to back up your data
- Please do not attempt to terminate the application
Do you wish to continue (y/n)?y
Starting data transform of /test-dataxform for files listed in ./my-output_todo
0
The data transform operation took 0 hours, 0 minutes and 2 seconds
The data transform program ran from Thu Feb 16 12:33:47 2023 until Thu Feb 16
12:33:49 2023
```

8. Re-enable Powertech on boot.

```
/opt/sgav/avsvcctl enable
```

9. Start Powertech.

```
/opt/sgav/avsvcctl start
```

There is a delay before Powertech is completely loaded and active. The Powertech status may be found by the following command:

```
/opt/sgav/avsvcctl status
```

The Powertech avsvc subsystem should be `active' and the device driver loaded:

Response

```
Subsystem Group PID Status
```

```
avsvc powertech 5964286 active  
Device driver is loaded  
The avsvc subsystem is configured to run at boot
```

CTE Agent AIX User and Configuration Guide

This document covers the following information:

- Overview
- Getting Started with CTE for AIX
- Special Cases for CTE Policies
- Logs
- Enhanced Encryption Mode
- Utilities for CTE Management
- Upgrading CTE on AIX
- Uninstalling CTE from AIX

Overview

This document describes the installation and advanced configuration options for CTE for AIX, as well as detailed information about how to integrate CTE with Oracle.

CTE Terminology

The CTE documentation set uses the following terminology:

The guide uses the following terminology:

Term	Description	OS Applies to
CTE	CipherTrust Transparent Encryption is a suite of products that allow you to encrypt and guard your data. The main software component of CTE is the CTE Agent, which must be installed on every host whose devices you want to protect. Notes • This suite was originally called Vormetric Transparent Encryption (VTE), and some of the names in the suite still use "Vormetric". • For example, the default installation directory is <code>/opt/vormetric/DataSecurityExpert/agent/</code> for Linux and AIX, and <code>C:\Program Files\Vormetric\DataSecurityExpert\agent\</code> for Windows.	Windows/Linux/AIX

Term	Description	OS Applies to
	Windows.	
CTE Agent	The software that you install on a physical or virtual machine in order to encrypt and protect the data on that machine. After you have installed the CTE Agent on the machine, you can use CTE to protect any number of devices or directories on that machine.	Windows/Linux/AIX
CTE Capabilities	CipherTrust Transparent Encryption agent version-specific features like Multi-Factor Authentication.	Linux
CTE-K8s	CipherTrust Transparent Encryption for Kubernetes. Policy-based encryption of data stored on persistent volumes	Linux
CTE-RWP or RWP	CipherTrust Transparent Encryption with Ransomware Protection. Ransomware protection for volume-level (Windows)/GuardPoint (Linux) data storage through process behavior monitoring and analytics.	Windows/Linux
CTE UserSpace (CTE-U)	CipherTrust Transparent Encryption (formerly known as ProtectFile FUSE). File system level encryption and access control solution for Linux servers.	Linux
Data Transformation	Encrypting or decrypting data.	Windows/Linux/AIX
Domain Sharing	This allows Clients in one domain to get cross-domain resources, specifically GPs.	Windows/Linux/AIX
GuardPath	A directory to which a CTE Kubernetes data protection and encryption policy has been applied. CTEK8s will control access to, and monitor changes in, this device and directory, encrypting new or changed information as needed.	Linux
GuardPoint	A device, or directory, to which a CTE data protection and encryption policy has been applied. CTE will control access to, and monitor changes in, this device and directory, encrypting new or changed information as needed.	Windows/Linux/AIX
Host /Client	In this documentation, host and client are used interchangeably to refer to the physical or virtual machine on which the CTE Agent is	Windows/Linux/AIX

Term	Description	OS Applies to
	installed.	
In-place Data transformation	Encryption mechanism for block devices.	Linux
Key Manager	An appliance that stores and manages data encryption keys, data access policies, administrative domains, and administrator profiles. Thales offers CipherTrust Manager, a key manager for use with CTE.	Windows/Linux/AIX
LDT (Live Data Transformation)	After initial GuardPoint enablement, LDT performs initial encryption, or rekeying, in the background, unnoticed by users. The data stays live and available. This accelerates CTE deployments and eliminates the need to block applications and user access to data during encryption or rekey operations, which can inconvenience users and affect operational efficiency.	Windows/Linux
LDT Communication (Comm) Group	A group of LDT clients who communicate with each other, and are responsible for, initial data transformation and future key rotation of CIFS/NFS GuardPoints.	Windows/Linux
LDT GuardPoint Group	An LDT GuardPoint Group contains a collection of LDT-enabled CTE clients that are all on the same network, managed by one CipherTrust Manager, guarding a common NFS/CIFS share and can communicate with each other over that network. An LDT GuardPoint Group enables the primary host of an LDT GuardPoint Group to communicate with the secondary hosts that are members of that LDT GuardPoint Group.	Windows/Linux
LDT Primary node	The LDT GuardPoint Group node that performs LDT rekeying of data.	Windows/Linux
LDT Secondary node	All of the other clients in the LDT GuardPoint Group are assigned as secondary nodes. Note: Secondary nodes do not participate in rekeying data, however, they can be promoted to primary nodes if a primary node fails.	Windows/Linux
LDT Subordinate nodes	The subordinate nodes are the remaining nodes in the LDT Communication Group.	Windows/Linux

Term	Description	OS Applies to
LDT Triad nodes	The triad nodes are the first three servers in the LDT Communication Group.	
Learn Mode	Logging mode for audit logs to help generate security policies. Learn Mode allows access to guarded paths while logging access details. Users can analyze the content users and processes are accessing, the data used, and define GuardPoint policies accordingly.	Windows/Linux
MFA	Multifactor authorization ensures that the access credentials presented belong to the actual person. After logging in to the system, when a user tries to access a CipherTrust Transparent Encryption GuardPoint, it triggers a second factor authorization to verify the user with a second form of authentication, like sending a passcode to the users's registered cell phone, that they then have to input into the application.	Windows/Linux
Profile	Shared configuration resource for Client logging, Quality of Service, Multi-Factor Authentication, Ransomware Protection and key manager communication settings.	Windows/Linux/AIX
Signature	The hash of an entity. Where Entity can be the process or the docker image.	Windows/Linux/AIX
Versioned key and Key versions	Keys whose name remains the same but keybytes are different for each different version.	Windows/Linux/AIX

CTE Components

The CTE solution consists of two parts:

- The *CTE Agent software* that resides on each protected virtual or physical machine (host). The CTE Agent performs the required data encryption and enforces the access policies sent to it by the *key manager*. The communication between the CTE Agent and the key manager is encrypted and secure.

After the CTE Agent has encrypted a device on a host, that device is called a *GuardPoint*. You can use CTE to create GuardPoints on servers on-site, in the cloud, or a hybrid of both.

- A *key manager* that stores and manages data encryption keys, data access policies, administrative domains, and administrator profiles. After you install the CTE Agent on a host and register it with a key manager, you

can use the key manager to specify which devices on the host that you want to protect, what encryption keys are used to protect those devices, and what access policies are enforced on those devices.

Note

For a list of CTE versions and supported operating systems, see the [CTE Compatibility Portal](#).

CTE Compliance with AIX Lock Semantics

CTE is compliant with AIX lock semantics. In the following cases, CTE deviates from AIX lock semantics:

- For a guarded file, an `fcntl(2)` system call will block if the current process file location and specified `fcntl` number of bytes overlaps an existing file lock.
- For a non-guarded file, the `fcntl(2)` system call blocks only if the `fcntl` number of bytes falls within the range limits of a specified file lock.

How to Protect Data with CTE

CTE uses policies created in the associated key manager to protect data. You can create policies to specify file encryption, data access, and auditing on specific directories and drives on your protected hosts. Each GuardPoint must have one and only one associated policy, but each policy can be associated with any number of GuardPoints.

Policies specify:

- Whether or not the resting files are encrypted.
- Who can access decrypted files and when.
- What level of file access auditing is applied when generating fine-grained audit trails.

A Security Administrator accesses the key manager through a web browser. You must have administrator privileges to create policies using either key manager. The CTE Agent then implements the policies once they are pushed to the protected host.

CTE can only enforce security and key selection rules on files inside a guarded directory. If a GuardPoint is disabled, access to data in the directory goes undetected and ungoverned. Disabling a GuardPoint and then allowing unrestricted access to that GuardPoint can result in data corruption.

Getting Started with CTE for AIX

This section describes how to install CTE for AIX, register it with your selected key manager, and then create a simple GuardPoint on the protected host. It contains the following topics:

- [Installation Workflow](#)
- [AIX Package Installation](#)

- [Installing CTE with No Key Manager Registration](#)
- [Configuring CTE for AIX with CipherTrust Manager](#)

Installation Workflow

In order to install and configure CTE, you need to perform the following high-level tasks:

1. If you want to include the CTE Agent software with the AIX distribution files, see [AIX Package Installation](#).
2. If you want to install the CTE Agent without registering with a key manager, see [Installing CTE with No Key Manager Registration](#). However, you cannot protect any data on the host until it has been registered. See [Configuring CTE for AIX with CipherTrust Manager](#).
3. Create your policies, encryption keys, and GuardPoints using the selected key manager. For details, see: [Guarding a Device with CipherTrust Manager](#).

Additional Considerations

The following sections describe some of the things to keep in mind when configuring CTE.

Port Selection

The following port information applies to both Windows and Linux systems.

Communication through a Firewall

If a protected client must communicate with CipherTrust Manager through a firewall, see the CipherTrust Manager documentation to determine which of the ports must be opened through the firewall.

Communication with CipherTrust Manager

The default port for http communication between CipherTrust Manager and the CTE Agent is **443**. If this port is already in use, you can set the port to a different number during the CTE Agent installation.

Communication for LDT over CIFS/NFS

All nodes that intend to use **LDT over CIFS/NFS** GuardPoint must have the following ports open:

- 7024
- 7025

Note

When you are registering a CipherTrust Transparent Encryption client with CipherTrust Manager, you can

manually include a destination port number, (Default: 443). If you enter a port value, using the syntax `<hostname or IP address>:<port number>` then CipherTrust Transparent Encryption **does not** perform a port scan. CipherTrust Transparent Encryption uses the port number provided to verify the target server type using a TLS operation.

If you do not enter a port number, CipherTrust Transparent Encryption performs a port scan to check which ports are listening, including port 443.

Tracking and Preventing Local User Creation

CTE audits any attempts to change user authentication files. It also allows you to prevent any change to user authentication files using the host settings **protect**. This includes, but is not limited to user creation, modification, and deletion, or to deny users.

- The **audit** setting is set to on by default. It logs access to the system credential files but does not prevent account modifications.
- The **protect** setting both audits and prevents local user account modifications. You must manually enable the **protect** setting for tracking and prevention of local user account creation.

The **protect** tag will prevent changes to the files mentioned below. In the absence of the **protect** tag in host/client settings, operations on these files are permitted. When a log entry is generated, it is tagged with an **[audit]** tag.

- `/etc/passwd`
- `/etc/group`
- `/etc/ssh/sshd_config`
- `/etc/ssh/sshrc`

Note

The first time you use the **protect** host setting, you must restart CTE. Subsequent files tagged with the **protect** setting do not require a restart.

Restricted Mode

Caution

If you install or upgrade in restricted mode, you cannot revert to unrestricted mode without

uninstalling CTE.

You can install CTE in restricted mode. This mode prevents any user other than `root` from accessing the following directories:

- `/var/log/vormetric`
- `/opt/vormetric/DataSecurityExpert`

Restricted Mode also prevents non-root users from running the following utilities:

- `agenthealth`
- `agentinfo`
- `check_host`
- `register_host`
- `secfsd`
- `vmd`
- `vmsec`
- `voradmin`

Key Agents and Restricted Mode

- On systems where CTE is installed in restricted mode, you cannot install a key agent (pkcs11) or CipherTrust TDE Key Management.
- On systems where a key agent (pkcs11) or CipherTrust TDE are already installed, you cannot install CTE in restricted mode.

Restricted Mode Installation

To install in restricted mode, use the `-r` option.

```
./vee-fs-<release>-<build>-<system>.bin -r
```

For example:

```
./vee-fs-7.8.0.75-aix71.bin -r
```

Upgrade in Restricted Mode

The upgrade mode is the same as the installation mode.

AIX Package Installation

This section describes how to install AIX packages directly so that the CTE Agent installation integrates with AIX distribution software. The CTE installation `bin` files contain the native packages and are extracted by running the `bin` file with the `-e` flag.

To extract and run the `.bff` file on AIX:

1. Log on to the host system as root and copy or mount the installation file onto the host system.
2. Extract the package files.

```
./vee-fs-7.8.0.75-aix71.bin -e
Contents extracted.
# ls *bff
vee-fs-7.8.0.75-aix71.bff
```

3. Run `installp` and then follow the prompts.

```
installp -aX -d vee-fs-7.8.0.75-aix71.bff vee.fs
```

- If you are going to register the system with a CipherTrust Manager, see [Configuring CTE for AIX with CipherTrust Manager](#).

Installing CTE with No Key Manager Registration

The following procedure installs the CTE Agent on the host but does not register it with a key manager. You cannot protect any data on the host until the CTE Agent is registered with one of the supported key managers. For a comparison of the available key managers, see [CTE Components](#).

1. Log on to the host where you will install the CTE Agent as `root`. You cannot install the CTE Agent without `root` access.
2. Copy or mount the installation file to the host system. If necessary, make the file executable with the `chmod` command.
3. Install the CTE Agent. A typical installation uses the following syntax:

```
./vee-fs-<release>-<build>-<system>.bin
```

For example:

```
./vee-fs-7.8.0.75-aix71.bin
```

To install the CTE Agent in a custom directory, use the `-d <custom-dir>` option. For example:

```
./vee-fs-7.8.0.75-aix71.bin -d /home/my-cte-dir/
```

Note

If possible, Thales recommends that you use the default directory `/opt/vormetric`.

To view all installer options, use the `-h` parameter. For example:

```
./vee-fs-7.8.0.75-aix71.bin -h
```

4. The Thales License Agreement displays. When prompted, type `Y` and press Enter to accept.

The install script installs the CTE Agent software in either `/opt/vormetric` or your custom installation directory and then prompts you about registering the CTE Agent with a key manager.

Welcome to the CipherTrust Transparent Encryption File System Agent Registration Program.

```
Agent Type: CipherTrust Transparent Encryption File System Agent
Agent Version: <Release.build-number>
```

```
In order to register with a CipherTrust Manager you need a valid registration token from the CM.
```

```
Do you want to continue with agent registration? (Y/N) [Y]:
```

5. Type `N` and press Enter to end the installation procedure without registering the CTE Agent with either key manager.

When you are ready to register the CTE Agent with a key manager, see [Configuring CTE for AIX with CipherTrust Manager](#).

Configuring CTE for AIX with CipherTrust Manager

This section describes how to install and configure CTE on AIX systems that you plan to register with a CipherTrust Manager.

The installation and configuration process when you are using CTE with a CipherTrust Manager consists of three basic steps:

1. Installation Prerequisites

Gather the information needed for the installation and set up your network.

2. Interactive Installation and Registration AIX

Install CTE interactively on a protected host and register the protected host with CipherTrust Manager.

Silent Installation on AIX

Install CTE silently (non-interactive) on a protected host and register the protected host with CipherTrust Manager.

3. External Certificates

Use for communication between CTE and CM. Install the external certificate before registering CipherTrust Transparent Encryption with CipherTrust Manager.

4. Validating CipherTrust Manager and CipherTrust Transparent Encryption with a Local CA Certificate

Ensure that registration by the CTE agent is serviced only by the expected key manager by providing a copy of the CA certificate that will be used to authenticate the TLS communications with the key manager.

5. Guarding a Device with CipherTrust Manager

Create as many standard GuardPoints on the client as you need

Installation and Registration Options

CTE provides the following installation and registration options. The options you choose determine the information you need to supply during the actual install procedure.

Installation Method Options

There are two methods for installing CTE on AIX platforms:

- **Typical:** Most common and recommended type of installation. Use this method for installing the CTE Agent on one host at a time. See [Interactive Installation on AIX](#).
- **Silent:** Create pre-packaged installations by providing information and answers to a set of installation questions. Use silent installations when installing on a large number of hosts. See [Silent Installation on AIX](#).

Hardware Association (Cloning Prevention) Option

CTE's hardware association feature associates the installation of CTE with the machine's hardware. When enabled, hardware association prohibits cloned or copied versions of CTE from contacting the key manager and acquiring cryptographic keys. Hardware association works on both virtual machines and hardware clients.

You can enable hardware association during CTE registration process. You can disable hardware association by re-running the registration program.

Installation Prerequisites

This section lists the tasks you must complete, and the information you must obtain, before installing CTE.

Recommendations and Considerations

- Thales recommends that you install CTE in the default location.
- Make the installation root directory `/opt` a real directory. If `/opt` is a symlink, you **must** use the `-d` option to specify the installation directory, which must be a real directory.

For example:

```
./vee-fs-7.8.0.75-aix71.bin -d /home/hello/
```

- Ensure read/write permission is granted to other users accessing your shared resource.
- P8 Hardware Encryption is supported, but there is a required fix from IBM. If the required fix is not found, the installation defaults to Software Encryption for P8.
 - AIX 7.1 requires TL level 7100-04-04 or later.
 - AIX 7.2 requires TL level 7200-01-02 or later.

Network Setup Requirements

- The IP addresses, routing configurations, and DNS addresses must allow connectivity of the AIX system on which you plan to install CTE to the CipherTrust Manager. After the AIX system is registered as a client with the CipherTrust Manager, the client must be able to poll the CipherTrust Manager in case there are any changes to the encryption keys, policies, or GuardPoints.
- It must also allow for connectivity of the CipherTrust Manager to all clients where you install CTE.
- If the system is a virtual machine, the VM must be deployed and running.

Communication with CipherTrust Manager

The default port for http communication between CipherTrust Manager and the CTE Agent is **443**. If this port is already in use, you can set the port to a different number during the CTE Agent installation.

Interactive Installation on AIX

The AIX typical install is an interactive script that asks you a series of questions during the installation. You can also install CTE using a silent installer which pre-packages the install information. This allows you to install CTE on a large number of hosts. (For more information, see [Silent Installation on AIX](#)).

After you install CTE, you are prompted to register it immediately with a key manager. CTE must be registered with a key manager before you can protect any of the devices on the host. However, you may postpone the registration if you plan to register CTE later.

Note

Do not install CTE on network-mounted volumes like NFS.

Before You Begin

The following prerequisites must be met for CTE/CTE-U to install and register to CipherTrust Manager properly:

- CipherTrust Manager installed and configured. See [CipherTrust Manager Documentation](#) for more information.
- CipherTrust Manager must contain a Client Profile. See [Changing the Profile](#) for more information.
- CipherTrust Manager must contain a registration token. See [Creating a Registration Token](#).
- Optionally, the name of the host group you want this client to be a part of.

Procedure

1. Log on to the host where you will install the CTE Agent as **root**. You cannot install the CTE Agent without root access.
2. Copy or mount the installation file to the host system. If necessary, make the file executable with the **chmod** command.
3. Install the CTE Agent. A typical installation uses the following syntax:

```
./vee-fs-<release>-<build>-<system>.bin
```

For example:

```
./vee-fs-7.8.0.75-aix71.bin
```

To install the CTE Agent in a custom directory, use the **-d <custom-dir>** option. For example:

```
./vee-fs-7.8.0.75-aix71.bin -d /home/my-cte-dir/
```

Note

If possible, Thales recommends that you use the default directory **/opt/vormetric**.

To view all installer options, use the `-h` parameter. For example:

```
./vee-fs-7.8.0.75-aix71.bin -h
```

4. The Thales License Agreement displays. When prompted, type Y and press Enter to accept.

The install script installs the CTE Agent software in either `/opt/vormetric` or your custom installation directory and then prompts you about registering the CTE Agent with a key manager.

Welcome to the CipherTrust Transparent Encryption File System Agent Registration Program.

```
Agent Type: CipherTrust Transparent Encryption File System Agent
Agent Version: <Release.build-number>

In order to register with a CipherTrust Manager you need a valid registration token from the CM.

Do you want to continue with agent registration?(Y/N) [Y]:
```

5. Enter Y to continue with the registration process. The install script prompts you to enter the host name or IP address of the CipherTrust Manager with which you want to register CTE.

The default communication port is 443. If you want to specify a different communication port, enter it with the primary key manager host name in the format: `<hostName>:<port#>`

For example:

```
Do you want to continue with agent registration? (Y/N) [Y]: Y

Please enter the primary key manager host name: 10.3.200.141:8445

You entered the host name 10.3.200.141
Is this host name correct? (Y/N) [Y]: Y
```

6. Enter the client host name when prompted.

```
Please enter the host name of this machine, or select from the following list.

[1] sys31186.qa.com
[2] 10.3.31.186

Enter a number, or type a different host name or IP address in manually:
What is the name of this machine? [1]: 2
You selected "10.3.31.186".
```

7. Enter the CipherTrust Manager registration token, profile name, host group and host description. If you omit the profile name, CipherTrust Manager associates the default client profile with this client.

```

Please enter the registration token: 12345
Please enter the profile name for this host: My-Profile
Please enter the host group name for this host, if any:
Please enter a description for this host: West Coast Datacenter server 5

Token           : 12345
Profile name     : My-Profile
Host Group       : (none)
Host description : West Coast Datacenter server 5
Are the above values correct? (Y/N) [Y]: Y

```

8. At the hardware association prompt, select whether you want to enable the hardware association feature to prevent cloned machines from accessing the key manager (for details, see [Hardware Association \(Cloning Prevention\) Option](#)). The default is Y (enabled):

It is possible to associate this installation with the hardware of this machine. If selected, the agent will not contact the key manager or use any cryptographic keys if any of this machine's hardware is changed. This can be rectified by running this registration program again. Do you want to enable this functionality? (Y/N) [Y]: Y

Warning

The registration token, profile name, client group name are case-sensitive. If any of these are entered incorrectly, the client registration will not succeed. If the registration fails, click Back in the installer and verify that the case is correct for all entries on this page.

9. CTE finishes the installation and registration process.

```

Generating key pair for the kernel component...done.
Extracting SECFS key
Generating EC certificate signing request for the vmd...done.
Signing certificate...done.
Enrolling agent with service on 10.3.200.141...done.
Successfully registered the CipherTrust Transparent Encryption File System Agent with the
CipherTrust Manager on 10.3.200.141.

Installation success.

```

10. If you are using CipherTrust Manager version 2.2 or later, you can now use CipherTrust Manager to administer CTE on the client.

If you are using CipherTrust Manager version 2.1 or earlier, change the client password using the manual password creation method. This password allows users to access encrypted data if the client is ever disconnected from the CipherTrust Manager. For details on changing the password, see the CipherTrust Manager documentation.

Validating CM and CTE with a Local CA Certificate

To ensure that registration by the CTE agent is serviced only by the expected key manager, you can provide a copy of the root CA certificate that will be used to authenticate the TLS communications with the key manager, during the registration process.

Note

This feature is not compatible when using CipherTrust Transparent Encryption with CipherTrust Data Security Platform Services (CDSPaaS).

Note

You can only download the CA certificate when you are a root user in the root domain. You cannot download the certificate from a subdomain. It will not work.

Prerequisite

Make sure that you have previously [created the client](#) in CipherTrust Manager.

Using a Local CA Certificate

1. Extract the root CA certificate from the CipherTrust Manager.
 - a. Log on to CipherTrust Manager as an administrator.
 - b. In the left navigation pane, click **CA > Local**. The list of available CAs displays.
 - c. Click the ellipsis icon corresponding to the CA.
 - d. Click **Download** to download the CA.
 - e. Copy the certificate to a directory on the agent system.
2. Present the root certificate data to CTE in one of two ways:

a. Use a file:

When written to a file, it must be in PEM file format, starting and ending with:

```
-----BEGIN CERTIFICATE-----
-----END CERTIFICATE-----
```

b. Use a string parameter:

If you are providing the information in a single string, it must contain the same data as in the preceding case, except that all new lines are replaced by `\n` escape sequences. For example:

```
CA_CERT=-----BEGIN CERTIFICATE-----\n -----END CERTIFICATE-----\n
```

3. To install the root certificate into the CTE client:

```
/opt/vormetric/DataSecurityExpert/agent/vmd/bin/register_host.exe -s <Path-to-install-file> AGENT_HOST_NAME=<Hostname-or-IP-of-agent> REG_TOKEN=<CM registration token> CA_FILE=<Path-to-root-ca-cert>
```

Example

```
/opt/vormetric/DataSecurityExpert/agent/vmd/bin/register_host.exe -s /opt/silent/vte_reg_log.txt AGENT_HOST_NAME=ani-vm-217-35190.sjcicd.com REG_TOKEN=mMEz3Y60b9D4L7QuvK5S0mhulRm8DYI8odV5j30dVuHqk6LhZqE0FeIZHILYtMDiE9 CA_FILE=/cert_files/Austin175.pem
```

4. Confirm in CipherTrust Manager that the client is registered and healthy.

Using external certificates for communication between CTE Agent and CipherTrust Manager

Note

This feature is not compatible when using CipherTrust Transparent Encryption with CipherTrust Data Security Platform Services (CDSPaaS).

Overview

Use for communication between CTE and CipherTrust Manager. Install the external certificate before registering CipherTrust Transparent Encryption with CipherTrust Manager.

Prerequisites

The external certificate must be:

- On the file system
- In PEM format

A key pair must already exist for the client:

- Must have Encryption type of either:
 - sha256WithRSAEncryption
 - ecdsa-with-SHA384
- Must be Encrypted with a pass phrase

Initial setup

1. Obtain your external CA certificate.
2. Create a certificate using the external CA certificate and key.

CipherTrust Manager Setup

To setup CipherTrust Manager to communicate through an external certificate:

1. Import the CA certificate into the CipherTrust Manager, click **CA > External > Add External CA**.

Note

In the Add External CA dialog, copy and paste the `<ca_certificate_name>.pem` file content from the UI page and provide a user-friendly name.

For more information, see [Using an Externally Generated Server Certificate for an Interface](#)

2. Add the CA certificate to the list of trusted sources for the web interface, click **Admin Settings > Interfaces > web > Edit > External Trusted CAs**.
3. Restart the web server, click **Admin Settings > Services > web > Restart**.
4. [Create a Registration Token](#) for the CTE agent.

CTE Agent setup

1. Create a directory on the system to hold the required files, for example:

- `/root/cert_files` (**Linux/AIX**)
- `c:\temp\cert_files` (**Windows**)

2. Copy or create the following files in this directory:

- `client_cert.pem`
- `client_key.pem`
- `passphrase` - this is currently expected as plain text

3. For **Linux/AIX** systems, to add the directory path to the environment, type:

```
$ export EXTERNAL_CERT_DIR=/root/cert_files
```

4. For **Windows** system, invoke `registerhost.exe` from the command line and add this argument:

```
c:\> register_host.exe -extcertdir=c:\temp\cert_files
```

5. Register the CTE client with the CM server as normal. If this is being done as part of an installation, then the above steps should be done before the installation, or, on windows, added to the registration parameters passed to the installer.

Post Registration

During registration, the certificate file is uploaded to the CipherTrust Manager, and the certificate and key files are imported into the CTE pem store. The key is decoded using the provided passphrase, then re-encoded using a random key using the normal CTE key security mechanisms for TLS keys. There is no need to keep the input files after registration is successful, so for security reasons they should be removed / shredded.

Certificate Renewal

The location of the external certificate files (i.e. the `EXTERNAL_CERT_DIR` or `-extcertdir` parameters) will be recorded in the CTE agent configuration file, `agent.conf`. When the current certificate is approaching expiration date (i.e. approx. 60 days prior to expiration) the CTE agent will look in this directory for an updated set of files.

If a new certificate file is present, then the file will be read and pushed to the CM, and if accepted, then the certificate and key will be imported into the CTE pem store, and the VMD process restarted to use the new certificate.

If no new certificate is present, a **WARNING** level message will be written to the logs and/or uploaded to the CM as per the logging settings, and the CTE agent will check again after 24 hours.

If the user wishes to change the directory path to store the new certificates, then the entry in the `agent.conf`

file should be updated and the vmd service restarted. Alternatively, the user can update the external certificate set using the following command (this will not update the saved path):

```
# vmutil -a vmd -d <ext_cert_Dir> updatecerts
```

If the user fails to update the certificate set prior to expiration then communication with the CM may be blocked, and re-registration will be required.

Note

Any renewed certificates must have exactly the same common name field as the original certificate, or the CipherTrust Manager will reject the update.

Silent Installation on AIX

This section describes how to perform a silent (unattended) installation of the CTE on a single host. The silent installation automates the installation process by storing the answers to installation and registration questions in a separate file that you create. You can also use the silent installation to install CTE on multiple hosts simultaneously.

The silent install method installs CTE on the host, and registers the host with the CipherTrust Manager you specify in the silent installation file.

Prerequisites

The following prerequisites must be met for CTE/CTE-U to install and register to CipherTrust Manager properly:

- CipherTrust Manager installed and configured. See [CipherTrust Manager Documentation](#) for more information.
- CipherTrust Manager must contain a Client Profile. See [Changing the Profile](#) for more information.
- CipherTrust Manager must contain a registration token. See [Creating a Registration Token](#).
- Optionally, the name of the host group you want this client to be a part of.

Procedure

1. Log on as an administrator to the host where you will install CTE.
2. Create a parameter file and store it on your system, or copy an existing file from another location. The file can contain any of the following parameters:

Parameter	Description
AGENT_HOST_NAME	FQDN of the host on which the CTE Agent is being installed. If this value is not specified, the installer uses the host's IP address.

Parameter	Description
AGENT_HOST_PORT	Specifies the port number for this CTE Agent to use.
AGENT_USEIP	Use the IP address of the protected host instead of host name. Used when hostname is not supplied.
CA_CERT	Set to provide CA certificate data to CipherTrust Manager.
CA_FILE	Set to provide a CA certificate file to CipherTrust Manager.
CERT_FIELD_PARAM	Installer option. Default behavior is to use hard-coded values for Root Certificate fields. Uses the same <code><Certificate Parameters></code> string format as is used in the voradmin command <code>voradmin cos ca_cert create <Certificate Parameters></code>
ENABLE_CLOUD	Set to enable cloud in the Key Manager.
ENABLE_HOST_CHECKS	When using CipherTrust Data Security Platform Services (CDSPaaS), set this value to 1 to enable SSL certificate host name checks. Set to 0 to disable. Default: 0 . This also forces CTE to enable the verify peer feature during registration. Use only when the CDSPaaS web server certificates contain the target DNS name or IP address.
ENABLE_LDT	Set this value to 1 to automatically enable and register CTE-LDT (Live Data Transformation) for this host on your key manager during the silent install.
HOST_DESC	Specifies a description for the host. This description is displayed in the CipherTrust Manager. If an entry for this host already exists, and the host already has a description, CipherTrust Manager
HOST_GROUP	Specifies the optional host/client group with which this host/client will be associated.
HOST_PROFILE	Specifies the client profile in the CipherTrust Manager that will be associated with this client. If this value is omitted, the CipherTrust Manager uses the default client profile.
LDTGROUP_NAME	Set the LDT Communication Group for LDT over NFS/CIFS.
REG_TOKEN	The registration token for the CipherTrust Manager with which you plan to register this client. Required for registration.
ENABLE_RWP	Enable Ransomware Protection.
SERVER_HOSTNAME	Required if you want to register CTE with a CipherTrust Manager.
SERVER_IP	Alternative for hostname when registering.
TMPDIR	Specifies a custom temporary directory that the

Parameter	Description
	installer can use during the installation process. If this value is omitted, the installer uses the default temporary directory.
USEHWSIG	Set this value to 1 when you want to associate this installation with the machine hardware for cloning prevention.

Example 1: Registering with CipherTrust Manager

The following example contains just the required information for registration with CipherTrust Manager. In this case, the client will be registered with the CipherTrust Manager using its IP address instead of its host name:

```
SERVER_HOSTNAME=Key-Mgmt-Server.example.com
REG_TOKEN=12345
AGENT_HOST_NAME=10.192.80.86
```

Example 2: Registering with CipherTrust Manager

The following example specifies the required registration information, adds a host name and description, and enables hardware association. In this case, the client will be registered with the CipherTrust Manager using its host name instead of the IP address:

```
SERVER_HOSTNAME=Key-Mgmt-Server.example.com
REG_TOKEN=12345
AGENT_HOST_NAME=myagent.example.com
HOST_DESC="West Coast Server 12"
USEHWSIG=1
CERT_FIELD_PARAM="/C=US/ST=California/L=San Jose/O=Thales eSecurity/OU=Vormetric/CN=localhost/emailAddress=admin@thalesgroup.com"
SUBJECT_ALT_NAME_PARAM="DNS:www.thalesgroup.com,email:admin@thalesgroup.com"
```

1. Copy or mount the CTE installation file to the host system. The installation file is in the format `vee-fs-<release>-<build>-<system>.bin`.
2. Run the installer using the following syntax:

```
./vee-fs-<release>-<build>-<system>.bin [-d <custom-dir>] -s <install-file>
```

where:

- `-d <custom-dir>` is an optional parameter that specifies the installation directory for CTE. If you omit this parameter, CTE is installed in `/opt/vormetric/DataSecurityExpert/agent/`.
- `-s <install-file>` indicates that you want to install silently using the installation options file `<install-file>`

For example, if the installation options file is called `/tmp/unattended.txt`, you would enter:

```
./vee-fs-7.8.0.75-aix71.bin -s /tmp/unattended.txt
```

3. Verify the installation by checking CTE processes on the host:
 - Run `vmd -v` to check the version of CTE matches that just installed.
 - Run `vmsec status` to display CTE kernel status.
 - Look at the log files in `/var/log/vormetric`, especially `install.fs.log.<date>` and `vorvmd_root.log`.
4. In CipherTrust Manager, change the client password using the manual password creation method. This password allows users to access encrypted data if the client is ever disconnected from the CipherTrust Manager. For details on changing the password, see the CipherTrust Manager documentation.

Guarding a Device with CTE and CipherTrust Manager

After you register a client with a CipherTrust Manager, you can create as many standard GuardPoints on the client as you need. These GuardPoints can protect an entire device or individual directories.

In order to guard a device or directory, you need to use the CipherTrust Manager Console to:

1. Access the CipherTrust Manager domain in which the client is registered.
2. Identify or create an encryption key that CTE will use to encrypt the data on the device or directory.
3. Identify or create a policy for the device or directory that specifies the access controls and the encryption keys to use for the device or directory.
4. Assign a GuardPoint to the device or directory.

The following example creates a simple policy and uses it to guard a directory on a registered client. For all of the following procedures, you must be logged into the CipherTrust Manager Console as a CipherTrust Manager Administrator, and you must be in the domain with which the client is registered.

For details about any of these procedures or the options for domains, encryption keys, policies, and GuardPoints, see the CipherTrust Manager documentation.

Access the CipherTrust Manager Domain

1. In a web browser, navigate to the URL of the CipherTrust Manager Console you want to use and log in with CipherTrust Manager Administrator credentials.
2. If the client you want to protect is registered to the default domain (root), proceed to [Create an Encryption Key](#). If you need to change to a different domain, do the following:
 - a. In the top menu bar, click the user name **root/admin** on the right-hand side.
 - b. Select **Switch Domains**, then select the domain in which the client is registered.

- c. The logged in user now shows the new domain name/user name.

Create an Encryption Key

Note

The following procedure is based on CipherTrust Manager version 2.2. If you are using a different version, see the CipherTrust Manager documentation for the version that you are using.

1. From the Products page in the CipherTrust Manager Console, click **Keys** in the left hand pane.

Tip

To navigate to the Products page from anywhere in the CipherTrust Manager Console, click the App Switcher icon in the top left corner.

2. Above the Key table, click **Create a New Key**.
3. In the **Key Name** field, add a name for the key. This name must be unique. For example, Simple-Key.
4. In the **Key Usage** section, make sure **Encrypt** and **Decrypt** are selected.
5. Click **Create**. CipherTrust Manager displays the properties for the new key.
6. In the general options area, enable the **Exportable** option.

You can also enable the **Deletable** option in this section if you want a CipherTrust Manager Administrator to be able to delete the key.

ID	2e58c582...61136313	Owner	Global	Object Type	Symmetric Key
UUID	e3ad9c3e...7f047711	Created	05 Mar 2021, 05:13	Algorithm	AES
MUID	e3ad9c3e...f6333c9f	Last Modified	05 Mar 2021, 05:13	Size	256
KeyID	N/A	Exportable	☒	Deletable	☐

7. In the **Key Access** section, do the following:

a. In the Search Groups box, type "cte".

If no groups are displayed, make sure the **Added Only** option is *disabled*.

b. Click the **All** check box for both the CTE Admins and CTE Clients groups.

KEY ACCESS

Key Owner

Search:

2 Results | 2 group

☐ Added Only

Group	Read	Use	Decrypt	Encrypt	Sign	Sign/Verify	Export	All
CTE Admins	☒	☒	☒	☒	☒	☒	☒	☒
CTE Clients	☒	☒	☒	☒	☒	☒	☒	☒

c. When you are done, click **Update**.

8. Click the **CTE** tab and set the following properties:

- **CTE Versioned:** Specify whether the key is versioned. By default, the key is set as versioned.

For a standard policy, you should clear this check box. If you do not, the key will *not* appear in the keys list when you add the key rule to the standard policy.

- **Persistent on Client:** Specify whether the key is stored in persistent memory on the client.

When the check box is selected, the key is downloaded and stored (in an encrypted form) in persistent memory on the client.

When the check box is left clear, the key is downloaded to non-persistent memory on the client. Every time the key is needed, the client retrieves it from the CipherTrust Manager. This is the default setting.

- **Encryption Mode:** Encryption mode of the key. The options are:
 - CBC

- CBC-CS1
- XTS

Encryption using the XTS and CBC-CS1 keys is known as enhanced encryption. For details, see the *CTE Agent for AIX Installation and Configuration Guide*.

When you are done, click **Update**.

Create a Standard Policy

1. In the Applications page of the CipherTrust Manager Console, select the **Transparent Encryption** application.
2. In the sidebar on the Clients page, click **Policies**.
3. Click **Create Policy**. CipherTrust Manager displays the Create Policy Wizard.
4. On the General Info page, set the following options:

Field	Description
Name	A unique name for the policy. Make sure you use a name that is descriptive and easy to remember so that you can find it quickly when you want to associate it with a GuardPoint. This example uses "Simple-Policy".
Policy Type	The type of policy you want to create. In this example, we will create a Standard policy.
Description	A user-defined description to help you identify the policy later. For example: Standard policy for new GuardPoints.
Learn Mode	Learn Mode provides a temporary method for disabling the blocking behavior of CTE policies. While useful for quality assurance, troubleshooting, and mitigating deployment risk, Learn Mode is not intended to be enabled permanently for a policy in production. This prevents the policy Deny rules from functioning as designed in the policy rule set. Ensure that the policy is properly configured for use in Learn Mode. Any Security Rule that contains a Deny effect must have Apply Key applied as well. This is to prevent data from being written in mixed states, resulting in the loss of access or data corruption.

Field	Description
	Apply Key will have no effect when combined with a Deny rule unless the policy is in Learn Mode.
Data Transformation	If you select Standard as the policy type, also select the Data Transformation option to tell CTE that you want to change the current encryption key used on the data in the GuardPoint, or that you want to encrypt clear-text data for the first time. This option is only displayed for Standard policies.

When you are done, click **Next**.

- On the Security Rules page, define the security rules that you want to use.

CipherTrust Manager automatically adds a default security access rule with an action of **key_op** and the effects **Permit** and **Apply Key**. This rule permits key operations on all resources, without denying user or application access to resources. This allows it to perform a rekey operation whenever the encryption key rotates to a new version.

To add additional security rules, click **Create Security Rule** and enter the requested information. For details about adding security rules, see the CipherTrust Manager documentation.

When you are done, click **Next**.

- On the Create Key Rule page, click **Create Key Rule** and enter the following information:

Field	Description
Resource Set	If you want to select a resource set for this key rule, click Select and either choose an existing resource set or create a new one. Resource sets let you specify which directories or files will either be encrypted with the key or will be excluded from encryption with this key.
Current Key Name	Click Select to choose an existing key or create a new one. If the data has not yet been encrypted, select clear_key. Otherwise select the name of the non-versioned key that is currently being used to encrypt the data. In this example, select clear_key.
Transformation Key Name	Click Select to choose an existing versioned key or to create a new one. CTE uses the versioned key specified in this field to

Field	Description
	encrypt the data in the GuardPoint. If the data is currently encrypted, CTE decrypts it using the key specified in the Current Key Name field and re-encrypts it using the key specified in this field.

When you are done, click **Next**.

- On the Data Transformation page, click **Create Data Transformation Rule** and enter the following information:

Field	Description
Resource Set	If you want to select a resource set for this key rule, click Select and either choose an existing resource set or create a new one. Resource sets let you specify which directories or files will either be encrypted with the key or will be excluded from encryption with this key.
Transformation Key Name	Click Select to choose an existing key or to create a new one. CTE uses the key specified in this field to encrypt the data in the GuardPoint. If the data is currently encrypted, CTE decrypts it using the key specified in the Current Key Name field and re-encrypts it using the key specified in this field. For this example, select the key Simple-Key you created in Create an Encryption Key.

When you are done, click **Next**.

- Click **Next**.
- On the confirmation page, review the information for the policy and click **Save**.

Create a GuardPoint

1. Stop all applications that are accessing the device you want to protect. In this example, we are going to protect the following directories with the same policy and encryption key:
2. In the Applications page of the CipherTrust Manager Console, select the **CTE** application.
3. In the Clients table, click on the name of the client you want to protect.
4. Above the GuardPoints table, click **Create GuardPoint**.
5. In the Create GuardPoint page:
 - a. In the **Policy** field, select the policy you created earlier.
 - b. In the Type field, select the type of device. You can guard a directory or a raw/block device. For this example, select **Auto Directory**.
 - c. In the **Path** field, enter the directories you want to protect with this policy or click **Browse** to select them from a explorer window.

If you want to enter multiple paths, put each path on its own line. For example:

- d. Click **Create**.
- e. If you want to use the same policy and GuardPoint type on another path, click **Yes** when prompted. Otherwise, click **No**. For this example, click No.

The CTE clients pull the GuardPoint configuration information from the CipherTrust Manager.

6. Type the following to transform the data:

```
dataxform --rekey --print_stat --preserve_modified_time --gp <pathToGP>
```

When the data transformation has finished, applications can resume accessing the now-protected data. (See the “*CTE Data Transformation Guide*” for more information.)

Special Cases for CTE Policies

This section describes CTE-specific configuration tasks related to configuring policies in the key manager. It contains the following topics:

- Re-Enabling Automatic Signing for Host Settings
- Restricting Access Overrides from Unauthorized Identities
- Backing up DB2 Databases after Encryption
- Blocking ptrace system calls to prevent process injection attacks

Re-Enabling Automatic Signing for Host Settings

Starting with VTE for AIX release 5.2.6, VTE blocks automatic re-signing of the host settings. Some users may have established procedures for updating system software that are based on the assumption that restarting the **vmd** will generate new signatures when signed software is updated. This is no longer true. However, you can re-enable automatic re-signing if your environment requires it.

Caution

Re-enabling the automatic regeneration of signatures exposes a potential security vulnerability for CTE Agents. When enabled, host setting binaries are re-signed when CTE receives a push from the associated key manager. If an attacker were to replace a binary with a Trojan, and then force a push from the key manager by, for example, restarting the CTE Agent, CTE could generate a signature for the malicious binary and pass it.

To re-enable automatic re-signing for host settings:

1. Change to the directory where the `agent.conf` file resides. For example, type:

```
cd /opt/vormetric/DataSecurityExpert/agent/vmd/etc/
```

2. Edit the `agent.conf` file.
3. Change or add the following line:

```
AUTO_RESIGN_HOST_SETTINGS=TRUE
```

Note

Previously this setting was known as `RE_SIGN_HOST_SETTINGS`. Starting with VTE for AIX 5.3.0, the attribute name is `AUTO_RESIGN_HOST_SETTINGS` as shown above.

4. Save your changes and exit the file.
5. Restart the `vmd` to set the changes. Type:

```
/etc/rc.d/init.d/secfs restart
```

6. Type the following command to verify that the host settings is set to true:

```
vmsec vmdconfig
```

Restricting Access Overrides from Unauthorized Identities

CipherTrust Transparent Encryption host/client settings are the means by which an administrator configures user authorization. Users with root privileges, on Linux or AIX systems, have the unfettered ability to override all file access and execution permissions imposed by the system.

CipherTrust Transparent Encryption access control allows you to restrict privileges of users, groups, application processes and binaries, including root users and setuid programs. By default, CipherTrust Transparent Encryption agent **DOES NOT** trust any process as authenticated. Any attempt to access a resource, by any process, will therefore be flagged with a "User Not Authenticated" notification. The CipherTrust Transparent Encryption agent must be instructed to trust the authenticator process progeny. For example, `/usr/sbin/sshd` is a process that can be trusted to authenticate the user to the system and to CipherTrust Transparent Encryption.

In some setups, when editing a host, system administrators can use the **host settings > |authenticator|** feature with **su** to change identities and gain access to restricted data. You can instruct CipherTrust Transparent Encryption to not trust any authentication attempt performed by certain identities by assigning restricted users to a user shell that CipherTrust Transparent Encryption can block from authenticating other processes.

Any executable path that is marked with a **|path_no_trust|** host setting marks the process, and all child processes, as not trusted. Non-trusted processes are treated as "User Not Authenticated" to prevent access on user-based policies.

CipherTrust Transparent Encryption prevents overrides from other host settings authenticators, using the `|path_no_trust|` status. If a user runs the `su` command from a non-trusted shell, that new shell is still marked as `|path_no_trust|`, even if `|authenticator|/usr/bin/su` is specified in the host-settings. The `|path_no_trust|` feature overrides any and all authenticators under host settings.

Note

Using `|trust|*` before a `|path_no_trust|` host setting no longer disables the `|path_no_trust|` host setting.

For example, the following host setting denies authentication for users accessing through `sshd`:

```
|trust|*
|path_no_trust|/usr/sbin/sshd
```

To restrict access overrides:

1. In the CipherTrust Manager products page, click **Transparent Encryption > Clients**.
2. Click on an existing Client name to edit the host.
3. Click **Client Settings** tab.
4. Add the following to the settings:

```
|path_no_trust|<path of the binary>
```

Example:

```
|path_no_trust|/bin/ksh
```

The above example indicates that no process under the kshell executable will be authenticated.

5. Click **Apply**.

Backing up DB2 Databases after Encryption

After encrypting a DB2 database running on AIX, CipherTrust Transparent Encryption cannot make a backup of the database. Both scheduled and manual backup fail. The problem was the user's policy. An AIX policy used in this scenario must follow a few rules.

With a `CBC_CS1` key, a guarded file is modified to have a 4096 byte header holding key information. When an **Apply Key** effect is specified, the CipherTrust Transparent Encryption code adjusts the length and file offset for this header. Without an **Apply Key** effect, the size and access of the offset include the `CBC_CS1` header.

Thales recommends that you modify the first rule of your policy. Remove the action entry for `f_rd_att` from the first rule and add a new rule before it:

```
**action**: f_rd_att
**effect**: Permit, Apply Key
```

Policy processing starts with the first rule and continues until a matching rule is found. The effect for the matching rule is then applied.

For the `f_rd_att` action, this results in the secfs code including the CBC_CS1 key header and adjusts the file size value. Without the Apply Key effect, the file size includes the CBC_CS1 header size and the file appears as 4096 bytes larger than its real size.

Blocking ptrace system calls to prevent process injection attacks

To prevent a process injection attack, which could lead to access to encrypted data by a tampered process, Thales implemented a global blocking for the ptrace system call. The purpose of this feature is to provide configurable options for disabling the ptrace system call based on user need. CTE provides toggle options on CipherTrust Manager based on the dynamic parameter which allows a security administrator to select which binaries are protected from ptrace attachment.

Note

This change can be very invasive and block legitimate uses of the ptrace system call.

Options

There are three new options:

Enabled_For_Authenticators

The CTE binaries and the binaries specified in the authenticator list are protected from the ptrace attachment. Other binaries are not protected from the ptrace attachment. (Default behavior)

Enabled_For_All

All of the installed binaries are protected from ptrace attachment. This protects from a tampered processes causing process injection attacks through the ptrace attach call.

Disabled_For_All

The CTE binaries are protected from ptrace attachment but the binaries specified in the authenticator list are allowed to attach to a ptrace system call. This solves the problem of a user trying to attach a ptrace system call to one of the binaries specified in the authenticator list for other use cases. Other binaries are not protected from the ptrace attachment.

Note

If you select Disabled for All, make sure that you set the log level on CipherTrust Manager to WARN or higher. If it is set to the default log level of ERROR, there will not be any messages related to ptrace logged

in the vmd.log file.

Configuration

To configure blocking the ptrace system call:

1. Log on to CipherTrust Manager.
2. Click **Transparent Encryption**.
3. Click on the desired client name to open it.
4. In the **Advanced Security Configuration**, click **View/Edit Settings** link.

Advanced Security Configuration [X]

This screen lists the security configuration parameters that can be updated after CTE client registration. Every parameter has the fixed set of values, as given below.

PTRACE_PROTECTION Enable/Disable ptrace capability for installed binaries	☒ Enabled_For_Authenticators ☐ Enabled_For_All ☐ Disabled_For_All

[Cancel](#)

5. Select the appropriate option and click **save**.

Logs

This section contains the following sections:

- [Setting CTE Agent Logging Preferences](#)
- [Audit Logs](#)
- [Analyzing Audit log entries](#)
- [File System Audit Log Effects Codes](#)
- [Concise Logging](#)

Setting CTE Agent Logging Preferences

You can configure the Agent process information that is entered into the Message Log. You can configure the process information globally, in which all the Agents that are added after the configuration change inherit the log attributes, while all current file system configurations remain intact. Alternatively, you can configure log attributes for individual Agent installations.

Always monitor log generation on new server and agent installations, and after changing logging preferences and options.

A variety of logging services are available and configured in the Log tab.

Logging Services

CTE log data may be sent to various different files such as:

- Sys log files, such as:

```
/var/log/messages
```

```
/var/log/syslog
```

Event log on

Note

The CM domain name can include spaces. However, Syslog does not allow spaces in header fields. Therefore, for Syslog purposes, the CTE client replaces the spaces with an underscore. For example: My_Domain instead of My Domain.

- CTE log files local to the agent, such as:

```
/var/log/vormetric/vorvmd_root.log
```

```
C:\ProgramData\Vormetric\DataSecurityExpert\agent\log\vorvmd.log (Windows)
```

- Uploaded to the Key Manager
- Uploaded to a Syslog server

Data Transformation log files are sent to:

```
/var/log/vormetric/vordxf_path_usr.log
```

Audit Logs

```
Example audit log:
CGP2601I: [SecFS, 0] [AUDIT] Policy[allowAllOps_fs] User[root,uid=0,gid=0\root,bin,daemon,sys,adm,disk,wheel\] Process[/bin/cat] Action[write_app] Res[/opt/apps/app1/doc/file2.txt] Key[aes128] Effect[PERMIT Code (1U,2U,3R,4M)]
```

Analyzing Audit log entries

The format of a File System Audit log entry is:

```
CGP2602I: [SecFS, 0] Level: Policy[policyName?] User[userID?] Process[command?] Access[whatIsItDoing?] Res[whatIsItDoingItTo?] Effect[allowOrDeny? Code (whatMatched?)]
```

Parameter	Description
Identifier	The TLA for the error message.
SECFS	Indicates that the message was generated by an Agent. You can enter secfs in the Search Message field in the Logs window to display the Agent policy evaluation and GuardPoint activity for all configured hosts.
Level	Indicates the importance of the message. For example, AUDIT indicates an informational message, whereas ALARM indicates a critical failure that you should not ignore.
Policy	Indicates the name of the policy that is being used to evaluate the access attempt.
User	Identifies the system user attempting to access data in the GuardPoint. It typically displays the user name, user ID, and group ID.
Process	Indicates the command, script, or utility being executed.
Access	Indicates what access is being attempted. Access may be read_dir, remove_file, write_file_attr, write_app, create_file, etc. These correspond to the Access methods that you configure in the policy. Read_dir corresponds to d_rd. Remove_file corresponds to f_rm, etc.
Res	Indicates the object/resource being accessed by the Process[].
Effect	Indicates the rule that matched and, based upon that rule, whether or not the CipherTrust Manager grants access. Access states may be either PERMIT or DENIED.

File System Audit Log Effects Codes

Codes are provided in the audit logs that identify actions by the policy enforcement engine. The code follows the number of the rule being processed.

Code	Definition
A	The Action component of a security rule failed to match.
M	All security rule components match and, unless overridden, the Effect for that security rule is applied.
P	The Process component of a security rule failed to match.
R	The Resource component of a security rule failed to match.
T	The time specified in the When component of a

Code	Definition
	security rule failed to match.
U	The User component of a security rule failed to match.

Refer to the audit log example above:

- The first and second Security Rules fail because of a mismatch in the User component (1U, 2U).
- The third Security Rule fails because of a Resource component (3R) mismatch.
- All of the rules in the fourth Security Rule match (4M), and the actions defined in the policy, such as use an encryption key, are applied.

Concise Logging

Thales' standard operational logging sends audit messages for each file system operation each time a file is opened, read, updated, or written. Thales's standard logging can generate high volumes of log data. Most of these messages might not be useful or required by security administrators to monitor file system activity on the system.

Agent log data can be stored on the local host, sent to a syslog server, or uploaded to the Management Console. On an agent system, log entries can flood the local messages file or Event Log. Extreme logging can also affect network performance.

Concise Logging eliminates the following types of messages:

- Duplicate audit messages for each and every block read by the user or application. With Concise Logging, CTE only sends an audit message the *first* time a user or application performs a read/write activity. Subsequent read/write activity by that user or application is not logged.
- Audit messages that read the attributes, read the basic information of file-set attributes, and other event-based messages.
- Audit messages for directory open, read directory attributes, and directory close.

Configuring Concise Logging for CTE Clients or Client Groups with CipherTrust Manager

In **CipherTrust Manager > CipherTrust Transparent Encryption > Settings > Profiles**, when you create a Client Profile, you can select to Enable Concise Logging. Then, you can apply that Client Profile to a specific client, or to all clients in a Client Group.

- Concise Logging changes the set of log messages that are sent to Security Information and Event Management (SIEM) software systems. If this results in loss of data required for customer reports, then disable Concise Logging.
- Concise Logging is only supported by CTE `secfs`.
- Enable and disable Concise Logging on the client, in the Client Profile. CTE applies it for all users of that Client Profile. There is no finer-grained control, such as per GuardPoint, user, or message type.
- Do not use Learn mode with Concise Logging.

This section describes the enhanced AES-CBC-CS1 encryption mode for keys. It contains the following topics:

- The AES-CBC-CS1 encryption is superior to the existing AES-CBC mode because it uses a unique and unpredictable (random) IV (initialization vector) generated for each individual file. The per-file IV object is generated only at file creation time. It is stored as file metadata.

Note

AES-CBC-CS1 encryption does not require any additional license.

Security Improvements

	AES-CBC	AES-CBC-CS1
Unique IV per-file	No	Yes
IV predictability	Yes	No

File System Support

	AES-CBC	AES-CBC-CS1
Local FS (AIX)	JFS2	JFS2
Remote FS (AIX)	NFS3/NFS4	NFS3/NFS4
Block Device Support (secvm)	Fully supported	No. When a policy contains a key with CBC-CS1 encryption mode, the guarding fails on the CipherTrust Manager, and an error message displays.

Compatibility

- Starting with VTE for AIX version 5.3, CTE is backward compatible with, and fully supports, the existing AES-CBC mode for both new and existing datasets.
- Starting with VTE for AIX version 5.3, CTE fully supports AES-CBC-CS1 encryption for offline data transformation on CTE AIX environments.

Versions of VTE prior to version 5.3 are not backwards compatible with AES-CBC-CS1 encryption. On these earlier versions, attempting to guard a device using a policy containing an AES-CBC-CS1 key will fail.

- Protected hosts supporting AES-CBC-CS1 encryption can be added to host groups.

Difference between AES-CBC and AES-CBC-CS1

The two encryption modes are completely different from a file format standpoint.

- AES-CBC-CS1 encryption only applies to file system directories; AES-CBC encryption applies to both files and block devices.

Note

- If you attempt to use an AES-CBC-CS1 key to guard a block device or partition, the guarding fails with an error reported on the CipherTrust Manager, similar to: Raw or Block Device (Manual and Auto Guard) GuardPoints are incompatible with Policy "policy-xxx" that contains a key that uses the CBC-CS1 encryption mode."
- AES-CBC-CS1 encryption is supported in AIX environments; as long as it is a local JFS2 or remote file system using NFS, the file formats will be compatible. It is possible that an encrypted file created with a specific AES-CBC-CS1 key on AIX cannot be read on a Linux or Windows local file system, even if that specific key were to be used, and vice versa.

- AES-CBC-CS1 uses cipher-text stealing to encrypt the last partial block of a file whose size is not aligned with 16 bytes.
- Each file encrypted with an AES-CBC-CS1 key is associated with a unique and random base IV.
- AES-CBC-CS1 implements a secure algorithm to tweak the IV used for each segment (512 bytes) of a file.

Disk Space

Files encrypted with AES-CBC-CS1 keys consume additional disk space in contrast to files encrypted with AES-CBC keys. This is because AES-CBC-CS1 encryption requires file IVs to be created and persistently stored in contrast to AES-CBC encryption which does not consume any additional disk storage.

Therefore, administrators need to plan and provision additional disk capacity prior to deploying AES-CBC-CS1 encryption.

	AES-CBC	AES-CBC-CS1
Local AIX FS	No change to file size. No extended attribute allocation	Extra 4KB allocation in the form of an embedded header per file. With CTE guarding enabled, file size expansion is hidden.
Remote AIX FS	No change to file size. No extended attribute allocation	Extra 4KB allocation in the form of an embedded header per file. With CTE guarding enabled, file size expansion is hidden.

Encryption Migration

You can use offline dataxform to:

- Transform data encrypted by AES-CBC to AES-CBC-CS1 and vice versa.
- Transform AES-CBC-CS1 encrypted data to clear contents and vice versa.

File Systems Compatibility

On AIX, you can use AES-CBC-CS1 keys to guard currently supported file systems.

AES-CBC-CS1 encrypted files on AIX local file systems can result in additional space consumption.

AES-CBC-CS1 files on AIX local or remote file systems such as JFS2 embed the IV in a 4K-byte header within the file. When these files are guarded, CTE masks the file header to applications and system utilities. The expanded file is only apparent when CTE guarding is disabled.

Note

The file system must have enough extra space to store the extra 4K bytes of the embedded header.

On AIX, with AES-CBC-CS1 encryption, encrypted files on all file systems, both remote or local, have the same file format.

Storing Metadata

AES-CBC-CS1 encrypted files on AIX store the base IV of a file in the embedded header of the file.

To get the value of the base IV, type:

```
voradmin secfs iv get <file-name>
```

Note

The base IV of a file is protected. It cannot be set/modified/removed by commands and applications. However, if a GuardPoint is unguarded, the files in the GuardPoint are no longer protected. An adversary can then corrupt the content of the files, as well as the IVs.

Using the AES-CBC-CS1 Encryption Mode in CM

When you create a key in CTE, you enable Encryption Mode by selecting CTE Key Properties. See *Creating a New Key* in the [Managing Policies](#) chapter in the [CTE Administrator Guide](#).

Best Practices for AES-CBC-CS1 Keys and Host Groups

In a host group, do not deploy policies associated with AES-CBC and AES-CBC-CS1 keys unless all hosts are running VTE for AIX version 5.3 or CTE version 7.0.0 or later.

Exceptions and Caveats

Note the following when using AES-CBC-CS1 keys.

Guarding Existing Files Without Data Transformation

You must convert an existing file with clear text through offline data transformation. If you do not transform the file, then after you guard using an AES-CBC key, the file displays garbled characters.

If you use an AES-CBC-CS1 key, access to the file is blocked with an I/O error.

Utilities for CTE Management

Thales provides a variety of utilities that augment the standard AIX utilities. This combination of tools helps administrators manage CTE. The following utilities are described in this section:

- [Agent Health Return Codes](#)
- [Agentinfo \(Java version\)](#)
- [Backup](#)
- [Check_host](#)
- [Displaying Information for Nested File Systems with the DF tool](#)
- [Protecting Files with Client Settings](#)
- [Restricting Access Overrides with Client Settings](#)
- [Register_host](#)
- [SecFSD](#)
- [Using Client Settings with Shell Scripts](#)
- [Vmutil](#)
- [VMsec](#)
- [VMD](#)

Agent Health Utility

The `agenthealth` utility validates:

- Super-user privilege
- CTE Agent installation
- CTE registration to CipherTrust Manager Server
- CTE processes/ modules that are running

- Available disk resources
- Current GuardPoints
- Tests if the agent can reach the GuardPoints
- CTE log directory resource status
- This directory contains pending CTE log files for upload. This utility reports the size and number of pending files for upload. These text files are logs that contain vmd/SecFS information. They are regenerated whenever secfs restarts. If the number of files is unexpectedly large, this can indicate a problem.

The Agent Health check script

By default, the `agenthealth` script is installed in `/opt/vormetric/DataSecurityExpert/agent/vmd/bin`.

To run the `agenthealth` check script, type:

```
./opt/vormetric/DataSecurityExpert/agent/vmd/bin/agenthealth
```

System Response

```
Checking for super-user privilege ..... OK
CipherTrust Agent installation ..... OK
CipherTrust policy directory ..... OK
Registration to server ..... OK
Kernel modules are loaded ..... OK
VMD is running ..... OK
SECFSD is running ..... OK
dsm4209.sjinternal.com is resolvable ..... OK
dsm4209.sjinternal.com port 8446 is reachable .... OK
dsm4209.sjinternal.com port 8447 is reachable .... OK
Can communicate to at least one server ..... OK
VMD is listening on port 7024 ..... OK
Time of last update from server ..... 2021-07-07 15:47:08.290
Checking available disk space ..... OK
Checking logging space ..... OK
    Log directory is "/var/log/vormetric"
    File system for log data is "/", 48G free (5% full)
    Log directory contains 9 of maximum 200 files (4% full)
    Log directory contains 1 of maximum 100 Mbytes used (1% full)
Testing access to /media ..... OK
Testing access to /usr/data/sub1 ..... OK
[root@agt4206 bin]#
```

Agent Health Return Codes

Previously, the agent health return codes were only available in `/var/log/vormetric/agenthealth.log`. Now, the following options are also available through the help pages:

Help

This agent health script checks various facets of the CipherTrust agent to make sure that everything is functioning properly. Results are also logged to `/var/log/vormetric/agenthealth.log`.

Syntax

```
./opt/vormetric/DataSecurityExpert/agent/vmd/bin/agenthealth --help
```

Return Codes

Use the return code option to get a list of the return codes and what they mean. The codes are returned if the Agent is not running.

Syntax

```
./opt/vormetric/DataSecurityExpert/agent/vmd/bin/agenthealth --return_codes
```

Response

Return Code	Definition
EPERM	User is not root.
ENOENT	One of the programs used in this script does not exist. See <code>/var/log/vormetric/agenthealth.log</code> for which program is missing.
ENOPKG	Agent software is not properly installed. Agent configuration directory is missing or corrupt. See <code>/var/log/vormetric/agenthealth.log</code> for more details.
EPROTO	Agent is not registered to a key manager. Register the agent to a key manager and try again. Try the wait option if the agent has never started correctly after registration. See <code>/var/log/vormetric/agenthealth.log</code> for more details.
EIO	Kernel modules are not loaded. To load a kernel module, type: <code>/etc/vormetric/secfs start</code>
ESRCH	VMD is not running. To start vmd manually, type: <code>/usr/bin/vmd</code>
SECFSD	Secfsd is not running. To start the secfsd manually, type <code>/usr/bin/secfsd</code>
EHOSTUNREACH	Unable to reach the Key Manager. Check network connectivity.
ECONNREFUSED	VMD is not listening. VMD did not finish initialization. See <code>/var/log/vormetric/vmd.log</code>
EWOULDBLOCK	VMD is attempting to connect to the Key Manager but has exceeded the designated wait time. Check <code>/var/</code>

Return Code	Definition
	log/vormetric/vmd.log to fix any issues and retry.

Wait Time

Use --w to set a maximum wait time in seconds. The minimum is 10 seconds to test for the VMD to Key Manager initial contact. The default setting is 0, which means that there is no wait. Maximum is 1200 seconds.

Syntax

```
[root@agt4206 bin]# ./opt/vormetric/DataSecurityExpert/agent/vmd/bin/agenthealth
--w <value>
```

Example

```
[root@agt4206 bin]# ./opt/vormetric/DataSecurityExpert/agent/vmd/bin//agenthealth
--w 60
```

Response

```
Checking for super-user privilege ..... OK
CipherTrust Agent installation ..... OK
CipherTrust policy directory ..... OK
Registration to server ..... OK
Kernel modules are loaded ..... OK
VMD is running ..... OK
SECFSD is running ..... OK
dsm148.i.vormetric.com is resolvable ..... OK
dsm148.i.vormetric.com port 8446 is reachable .... OK
dsm148.i.vormetric.com port 8447 is reachable .... OK
Can communicate to at least one server ..... OK
VMD is listening on port 7024 ..... OK
Time of last update from server ..... 2021-08-18 10:34:56.665
Checking available disk space ..... OK
Checking logging space ..... OK
Log directory is "/var/log/vormetric"
File system for log data is "/", 29G free (23% full)
Log directory contains 1 of maximum 200 files (0% full)
Log directory contains 0 of maximum 100 Mbytes used (0% full)
```

If the customer did not use the wait time options, the output would look similar to the following:

```
/opt/vormetric/DataSecurityExpert/agent/vmd/bin/agenthealth
Checking for super-user privilege ..... OK
CipherTrust Agent installation ..... OK
CipherTrust policy directory ..... OK
Registration to server ..... OK
Kernel modules are loaded ..... OK
VMD is running ..... OK
SECFSD is running ..... OK
Can communicate to at least one server ..... FAILED
```

For more information consult the log file `/var/log/vormetric/agenthealth.log`

agentinfo Utility (Java version)

The `agentinfo` utility collects system and CTE configuration data. The `agentinfo` utility is used to take a configuration snapshot of the system that you will send to Thales Customer Support to debug an issue, (This section describes the Java version.)

The `agentinfo` utility is a Java Script file. You can open it in a text editor to see specific functions.

The `agentinfo` utility displays status information on the screen and outputs the results to a compressed tar file. The compressed tar file name format is `ai.<os_name_ver>.qa.com.tar.gz` and it is located in the current working directory.

To create an `agentinfo` file, type:

```
/opt/vormetric/DataSecurityExpert/agent/vmd/bin/agentinfo
```

Backup Utility

When a backup is performed, certain files and directories may be protected against access. Therefore, those files and directories are not written to the backup repository. These include files located in Data Transformation GuardPoints or files in GuardPoints with appropriate policies. Additionally, the following files are locked by default by CTE agent:

```
/opt/vormetric/DataSecurityExpert/agent/secfs/.sec/.access
/opt/vormetric/DataSecurityExpert/agent/secfs/.sec/etc/*
/opt/vormetric/DataSecurityExpert/agent/secfs/.sec/pem/*
```

The following describes how to bypass the issue for multiple scenarios:

Agent is installed in the default location

1. Stop SecFS, type:

```
/etc/vormetric/secfs stop           //Linux

/etc/rc.d/rc2.d/S99secfs stop       //AIX
```

2. Run the backup application with the desired arguments.
3. Restart SecFS, type:

```
/etc/vormetric/ start
```

Using a backup image to install to other agents or restore to a different system

Note

When the image is used to reinstall the system, the agent will automatically start at system boot and will attempt to connect to the key manager to which it was originally registered.

To prevent multiple systems with the same agent ID, you must uninstall CTE from the system before running the backup application. The restore/install from the backup will not have an agent running.

1. Uninstall the agent, type

```
/opt/vormetric/DataSecurityExpert/agent/secfs/bin/uninstallsfs
```

2. Run the backup application with the desired arguments.
3. Re-install CTE agent.

Performing a backup while the agent is running

Before running the backup application, add the files that are protected by the agent to the exclusion rules to exclude them from the backup:

```
/opt/vormetric/DataSecurityExpert/agent/secfs/.sec/.access  
/opt/vormetric/DataSecurityExpert/agent/secfs/.sec/etc/*  
/opt/vormetric/DataSecurityExpert/agent/secfs/.sec/pem/*
```

The GuardPoint policy may implement access restrictions which would also cause the backup application to generate error messages. These GuardPoint/directories will also need to be added to the exclusion rule method to exclude them from the backup. Alternatively, you can temporarily unguard them while the backup application is running.

If the CTE agent reports a status of incomplete in the backup application and does not start properly, or partially starts but generates error messages at system boot time, then uninstall and reinstall the agent. The restore/clone image contains everything needed to uninstall the agent. Use the following command to perform this operation:

```
/opt/vormetric/DataSecurityExpert/agent/secfs/bin/uninstallsfs
```

Backing up Databases after Encryption

After encrypting a database, CipherTrust Transparent Encryption cannot make a backup of the database. Both scheduled and manual backup fail. The problem was the user's policy. A policy used in this scenario must follow a few rules.

With a CBC_CS1 key, a guarded file is modified to have a 4096 byte header holding key information. When an

Apply Key effect is specified, the CipherTrust Transparent Encryption code adjusts the length and file offset for this header. Without an **Apply Key** effect, the size and access of the offset include the CBC_CS1 header.

Thales recommends that you modify the first rule of your policy. Remove the action entry for `f_rd_att` from the first rule and add a new rule before it:

```
**action**: f_rd_att

**effect**: Permit, Apply Key
```

Policy processing starts with the first rule and continues until a matching rule is found. The effect for the matching rule is then applied.

For the `f_rd_att` action, this results in the secfs code including the CBC_CS1 key header and adjusts the file size value. Without the Apply Key effect, the file size includes the CBC_CS1 header size and the file appears as 4096 bytes larger than its real size.

check_host Utility

If a CTE software installation fails during the certificate generation and exchange stage, use the `check_host` utility to list the network addresses for the host. The utility checks network interfaces, `/etc/hosts`, DNS, and so on, to compare, test, and evaluate possible addresses for the host, and weights them based upon their network efficiency. FQDNs are the most preferred and stand-alone IP addresses are the least preferred. Some applications, such as silent-mode installation, use `check_host` to determine the best host address to submit to the CipherTrust Manager during registration.

Run the `check_host` utility on a system that is hosting CTE to display available network host names, FQDNs, and IP numbers for the host.

Type:

```
/opt/vormetric/DataSecurityExpert/agent/vmd/bin/check_host
```

check_host Syntax

```
check_host [[-h | -i | -a ] [-s name]] |
-l name:port[,name:port] | -r name
```

Syntax	Description
-h	Print the best host name for this machine
-i	Print the best IP address
-a	Print all the host names and IP addresses
-s	The name of the server (optional hint)
-r	The name of the server for name resolution checks
-l	The name and port of the server for listening checks

Displaying Information for Nested File Systems with the DF tool

When a file system mounts on top of another file system, the command `df -a` does not display the attributes for the covered file system.

On Linux environments, this is the expected behavior for any file system that is overlayed by another file system.

The secfs driver properly handles the call, which is made by the `statfs` system call, which is issued by the `df` tool. When the system call returns, its structures are correctly populated with the details of the nested file system. On examining the source of the `df` tool, it is found that when the `-a` switch is on, it nullifies the stats which are received for overlayed mounts. When the `-a` option is not enforced, the stats are maintained.

Issue the `df` command for a specific mount point, for example `df /xfs/nested-xfs` (where `/xfs` is a secfs GuardPoint). It works correctly.

Protecting Files with Client Settings

When any file is now marked as protected (`|protect|`) in the client settings, that file is protected from being modified or deleted, (even from a root process).

Note

The file is not guarded and it can be external to a GuardPoint.

Previously, the only files that were protected were the following:

```
/etc/passwd
/etc/group
/etc/security/passwd
/etc/ssh/sshd_config
/etc/ssh/sshrd
/opt/testfile
```

If the file marked as `|protect|` does not exist, then CipherTrust Transparent Encryption creates a 0-length file in its place. This provides an efficient means to identify and implement file protection. When the agent is stopped or uninstalled, these 0-length files are deleted and then re-created if the agent is restarted. Additionally, an audit record is generated when a file operation is denied.

The `|protect|` status is displayed using `secfsd -status auth`.

Restricting Access Overrides with Client Settings

CipherTrust Transparent Encryption host/client settings are the means by which an administrator configures user authorization. Users with root privileges, on Linux or AIX systems, have the unfettered ability to override all file access and execution permissions imposed by the system.

CipherTrust Transparent Encryption access control allows you to restrict privileges of users, groups, application processes and binaries, including root users and setuid programs. By default, CipherTrust Transparent Encryption agent **DOES NOT** trust any process as authenticated. Any attempt to access a resource, by any process, will therefore be flagged with a "User Not Authenticated" notification. The CipherTrust Transparent Encryption agent

must be instructed to trust the authenticator process progeny. For example, `/usr/sbin/sshd` is a process that can be trusted to authenticate the user to the system and to CipherTrust Transparent Encryption.

In some setups, when editing a host, system administrators can use the **host settings** > **|authenticator|** feature with **su** to change identities and gain access to restricted data. You can instruct CipherTrust Transparent Encryption to not trust any authentication attempt performed by certain identities by assigning restricted users to a user shell that CipherTrust Transparent Encryption can block from authenticating other processes.

Any executable path that is marked with a **|path_no_trust|** host setting marks the process, and all child processes, as not trusted. Non-trusted processes are treated as "User Not Authenticated" to prevent access on user-based policies.

CipherTrust Transparent Encryption prevents overrides from other host settings authenticators, using the **|path_no_trust|** status. If a user runs the **su** command from a non-trusted shell, that new shell is still marked as **|path_no_trust|**, even if **|authenticator|/usr/bin/su** is specified in the host-settings. The **|path_no_trust|** feature overrides any and all authenticators under host settings.

Note

Using **|trust|*** before a **|path_no_trust|** host setting no longer disables the **|path_no_trust|** host setting.

For example, the following host setting denies authentication for users accessing through `sshd`:

```
|trust|*
|path_no_trust|/usr/sbin/sshd
```

To restrict access overrides:

1. In the CipherTrust Manager products page, click **Transparent Encryption > Clients**.
2. Click on an existing Client name to edit the host.
3. Click **Client Settings** tab.
4. Add the following to the settings:

```
|path_no_trust|<path of the binary>
```

Example:

```
|path_no_trust|/bin/ksh
```

The above example indicates that no process under the kshell executable will be authenticated.

5. Click **Apply**.

register_host Utility

Use the `register_host` utility to create certificate requests, exchange certificates between the CipherTrust Manager and the host, and to register CTE on the CipherTrust Manager. After the host is registered, you can configure CTE, apply GuardPoints, or perform database backups. Run the `register_host` utility in text mode on a terminal window.

Caution

The default host registration timeout is 10 minutes. If the host is unable to reach the CipherTrust Manager within the allotted period because of an extremely slow network connection, set the **REGISTER_HOST_TIMEOUT** environment variable to extend the registration timeout. The variable value is an integer expressed in seconds. You might also have to extend the default TCP timeout.

secfsd Utility

The `secfsd` utility displays the following attributes of CTE:

- GuardPoints defined in the *GuardPoints* tab
- Authentication parameters defined in the *Host Settings* tab
- Lock status set by enabling **FS Agent Locked** and **System Locked**
- Web destination and SSL certificate for uploading log entries
- Policies applied in the **GuardPoints** tab
- Status of required processes (`secfsd` and `vmd`)
- Version of `secfs`

The `secfs` utility is also used to mount GuardPoints for **Directory (Manual Guard)**. Normally, CTE automatically mounts the `secfs` file system when you apply a GuardPoint to a directory. On AIX, the `secfsd` utility is located in `<install_dir>/secfs/.sec/bin` and a symbolic link to this file is placed in `/usr/bin/secfsd`.

secfsd syntax

Command	Description
<code>-help</code>	display <code>secfsd</code> options

Status Options

Command	Description
<code>-status guard [-v -tree]</code>	list all GuardPoints

Command	Description
<code>-status keys</code>	show current encryption key state
<code>-status auth</code>	list authentication settings
<code>-status lockstat</code>	show CTE lock status
<code>-status logger</code>	list logging details
<code>-status policy</code>	list configured policies
<code>-status pslist</code>	list protected processes
<code>-status devmap</code>	list guarded devices

Manual GuardPoint options

Command	Description
<code>-guard path [container ID]</code>	manually guard path
<code>-unguard path [container ID]</code>	manually unguard path

Version option

Command	Description
<code>-version</code>	list version of kernel module <code>secfs2</code>

Encryption Mode option information

Command	Description
<code>crypto</code>	Displays the encryption modes that are supported.

Configuration Mode option information

Command	Description
<code>config <config_param> <value></code>	Displays the encryption modes that are supported.

secfsd Examples

Display GuardPoint Information

To display the GuardPoint paths, applied policies, policy type, and guard status, use the `secfsd -status guard` command. For example:

```
secfsd -status guard
```

GuardPoint	Policy	Type	ConfigState	Status	Reason
-----	-----	----	-----	-----	-----
/opt/apl/lib	allow AllOps_fs	local	guarded	guarded	N/A
/dev/sdb	watchaccess_rd	rawdevice	guarded	guarded	N/A

/dev/sdc	watchaccess_rd	manualrawdevice	guarded	guarded	N/A
/dev/sdd	watchaccess_rd	manualrawdevice	unguarded	not guarded	Inactiv
/opt/apl/tmp	MSSQL00123	manual	unguarded	not guarded	Inactiv

Column	Description
GuardPoint	Full path of the GuardPoint.
Policy	Name of the policy applied to the GuardPoint.
Type	Can be local, automount, manual, raw device, or manual raw device. Configured in the GuardPoints tab.
ConfigState	Guard status of the GuardPoint, as recognized by the key manager. It can be guarded or unguarded.
Status	Current guard status, as recognized by CTE. State can vary.
Reason	Additional information about the status, if any.

Note

- Config State and Status can vary. As an example, if you apply a GuardPoint and someone is currently working in the GuardPoint, the policy cannot be applied at that time. In this case, the ConfigState is guarded and the Status is not guarded.
- When the user removes an auto-mounted GuardPoint from CipherTrust Manager, the CTE Agent is only deleted after the configured `autofs` timeout expires. This timeout does not start until the GuardPoint is free.

Display GuardPoint Information in a Different Format

To display the same information in a block format, use the `secfsd -status guard -v` command. For example:

```
secfsd -status guard -v

GuardPoint: 1
  Policy:      allowAllOps_fs
  Directory:   /opt/apps/apps1/tmp
  Type:        local
  ConfigState: guarded
  Status:      guarded
  Reason:      N/A
GuardPoint: 2
  Policy:      allowAllRootUsers_fs
  Directory:   /opt/apps/apps1/lib
```

```
Type:          local
ConfigState:   guarded
Status:        guarded
Reason:        N/A
```

Display Host Settings

To display the SHA2 hash signature for each protected host setting, use the `secfsd -status auth` command. For example:

```
secfsd -status auth

|authenticator|/bin/su 3E765375897E04C39AB17D4C755F50A35195535B6747DBA28DF9BD4AA6
72DFF9
|authenticator|/usr/sbin/sshd 98FC599D459EDEA52A60AB394B394803B5DAB96B53148DC6087
32DDA6777FA1A
|authenticator|/usr/sbin/in.rlogind 5C9A0EDD8BF54AE513F039476D21B3032507CF957AA0C
B28C368EB8AB6E684FB
|authenticator|/bin/login 0D2EE0B995A30AE382B4B1CA5104715FC8902F457D283BDABAAD857
B09259956
|authenticator|/usr/bin/gdm-binary 363780522E3CCF9ABF559F059E437743F9F97BBBB0EE85
769007A464AD696BD1
|authenticator|/usr/bin/kdm BAD41BBCDD2787C7A33B5144F12ACF7ABC8AAA15DA9FDC09ECF93
53BFCE614B5
```

Display Key Status

To display the status of CTE keys, use the `secfsd -status keys` command. For example:

```
secfsd -status keys
Encryption keys are available
```

Display Lock Status

To display the status of CTE locks, use the `secfsd -status lockstat` command. For example:

```
secfsd -status lockstat
FS Agent Lock: false
System Lock: false
```

The value is **true** if the lock is applied. The value is **false** if the lock is not applied. **System Lock** corresponds to **System Locked** in the *Host* window. **FS Agent Lock** corresponds to **FS Agent Locked** in the *Host* window.

Note

Before you upgrade, remove CTE software, or change operating system files, the status of FS Agent Lock and System Lock must be false.

Agent Security Configuration Protection

The Agent lock directory, `/opt/vormetric/DataSecurityExpert/agent/secfs/.sec` contains secfs secret files, configuration files, host setting signatures, etc. Thales recommends protecting the directory whenever secfs is online.

Applying improved directory protection ensures that only CTE applications (`vmd`, `secfsd`, `voradmin`, etc.) can modify the `.sec` directory and the files in it. All users, including root, are denied read/write access to the files. They also do not have permissions to modify `conf` and `bin` directories, using other tools.

A new command has been created to protect the directory: `voradmin secfs config`

Syntax

```
voradmin secfs config <configuration_parameter> <value>
```

Example

```
voradmin secfs config pagecache_writeback 1
```

Previously, you would have had to use the following command to achieve the same results as the example above:

```
echo 1 > /opt/vormetric/DataSecurityExpert/agent/secfs/.sec/conf/pagecache_writeback
```

Note

When CTE is upgraded to v7.2.0 from the previous release, it may display 'Permission Denied' warnings which display when files are removed from subdirectories of the `.sec` directory. You can ignore these warnings. They are harmless.

Display CTE Log Status

To display the status of CTE log service, use the `secfsd -status logger` command. For example:

```
secfsd -status logger

Upload URL: https://vmSSA06:8444/upload/logupload,https://vmSSA07:8444/upload/logupload, \
https://vmSSA05:8444/upload/logupload
Logger Certificate directory: /opt/vormetric/DataSecurityExpert/agent/vmd/pem
```

This command sequence returns the URL to which the log service sends log data. It also returns the directory that contains the CTE certificate. CTE uses the certificate to authenticate CTE when it uploads the log data to the CipherTrust Manager.

Display Applied Policies

To display the policies that are applied to CTE, use the `secfsd -status policy` command. For example:

```
secfsd -status policy

Policy: enc-audit
Type: ONLINE
```

Display CTE Process Information

To display CTE processes, use the `secfsd -status pslist` command. This command shows the process number associated with each CTE process. To show the details about a specific CTE process, use the `ps -fp <process #>` command, where `<process #>` is the process number from the `secfsd -status pslist` command.

For example:

```
secfsd -status pslist
Protected pid list:      739    731

ps -fp 739
UID      PID    PPID   C   STIME      TTY   TIME   CMD
root     739     1      0   11:04:56   -    0:00 /opt/vormetric/ \
        DataSecurityExpert/agent/vmd/bin/vmd
```

Display CTE Version Information

To display CTE version information, use the `secfsd -version` command. For example:

```
secfsd -version
version: <Release.build-number>
```

Manually Enable a GuardPoint in CipherTrust Manager

To manually enable a GuardPoint on an AIX host:

1. Click **CTE > Clients > <clientName> GuardPoints**
2. Click **Create GuardPoint**.
3. In the Policy field, select a policy.
4. Set Type to **Manual Directory**.
5. Click **Browse** and enter the GuardPoint path.
6. Click **Create**.
7. Log onto the system hosting CTE as the root user.

8. To manually enable the GuardPoint, use the `secfsd -guard <path>` command. For example:

```
secfsd -guard /opt/apps/etcsecfsd: Path is Guarded
```

9. To verify the change, use the `secfsd -status guard` command. For example:

```
secfsd -status guard
```

GuardPoint	Policy	Type	ConfigState	Status	Reason
-----	-----	----	-----	-----	-----
/opt/apps/etc	allowAllOps_fs	manual	guarded	guarded	N/A

secfsd and Raw Devices

CTE only creates block devices. To display them, use the `ls -l /dev/secvm/dev` command. For example:

```
ls -l /dev/secvm/dev
```

```
brw----- 1 root    system    38,  1 Jan 29 16:37 hdisk1
brw----- 1 root    system    38,  2 Jan 29 16:37 hdisk2
crw----- 1 root    system    38,  3 Jan 29 16:37 rhdisk1
crw----- 1 root    system    38,  4 Jan 29 16:37 rhdisk2
```

Using Client Settings with Shell Scripts

Client settings on a shell script do not work as expected in AIX. This is because a shell script is not executed as a binary by a shell, rather, it is interpreted by the shell as a sequence of commands.

This limitation may be overcome by running the shell script in the context of a binary. A program is constructed to issue an `exec1(2)` of a shell with the desired script as its argument.

The client settings are then applied to the binary. When it executes, the client setting is applied to it by the agent code. Therefore, when it runs the shell, the client setting is inherited by the shell and is subsequently applied to all of the commands run as the script executes.

Following is an example program for implementing Client Settings:

```
cc testcode.c -o testcode
-----

#include <unistd.h>
#include <errno.h>
#include <stdlib.h>

int
main(int argc, char *argv)
{
    int rv;
```

```

    rv = execl("/usr/bin/ksh", "ksh", "./testdata", NULL);
    if (rv < 0) {
        printf("execl errno %d\n", errno);
        exit(1);
    }

    exit(0);
}

```

- The file, testdata, contains the shell script text.
- For test purposes, use a shell script that contains:

```
/usr/bin/cat
```

- The client setting is applied to the testcode binary. When it runs, the client settings are applied to the components of the script, testdata.

vmsec Utility

The vmsec utility allows you to manage security aspects of CTE on the host. On AIX hosts, the **vmsec** utility is located in:

```
/opt/vormetric/DataSecurityExpert/agent/vmd/bin/vmsec
```

vmsec Syntax

Syntax	Description
checkinstall	Show vmd kernel status
challenge	Enter the dynamic host password
vmdconfig	Display the vmd configuration
check_hwenc	Display kernel configuration
hwok	Report status of hardware signature
passwd [-p <password>]	Enter the static host password
version	Display CTE version

vmsec Examples

- Display CTE Challenge String
- Display CTE Status
- Entering a Password

- Display Kernel Status
- Display CTE Build Information
- Display Contents of Conf files

Display CTE Challenge String

To display a CTE password challenge string and enter the response string when the CipherTrust Manager is not network accessible, use the `vmsec challenge` command. This command displays a challenge string that you can send to your key manager administrator, who will then send you back the correct response information.

For example:

```
vmsec challenge
Contact a Security Server administrator for a response.
Your hostname is host120.my.domain.com
Your challenge is: F5TL-42HU-5H6Y-EJCK
Response (part 1) -> 6B2T-Q3DV-5EK3-Q0FD
Response (part 2) -> XBP5-LQXB-TDWA-SILG
Response (part 3) -> XSEA-CQB5-S6U5-3YWV
Response (part 4) -> KXRS-QYXB-BP74-C4RN
Success!
```

Contact your key manager administrator and give them the challenge string. The administrator will give you four response strings. Enter the first response string in the **Response (part 1)** field and press **Enter**, then enter the second, third, and fourth response strings in the same way. You have 15 minutes to enter the first response string.

Tip

If you are using CipherTrust Manager, the ability to change the contact string will be added in a future release. For CipherTrust Manager, the contact string says "Contact your CM administrator".

Display CTE Status

This utility shows you if CTE is configured and running. If it is not running, you might need to start it manually. To display CTE status, use the `vmsec checkinstall` command. For example:

```
vmsec checkinstall
The kernel component is installed and running.
```

Entering a Password

To enter the CTE static host password, use the `vmsec passwd` command. For example:

```
vmsec passwd
Please enter password:
```

```
OK passwd
```

To enter CTE static host password on the command line so you can specify it in a batch script, specify the password using the `-p` option. For example:

```
vmsec passwd -p myPass123
OK passwd
```

Display Kernel Status

To display the kernel status, use the `vmsec status` command. For example:

```
vmsec status
FILE_FORMAT=2

```

Display CTE Build Information

To see the CTE build version, use the `vmsec version` command. For example:

```

vmsec version
version 7
2020-07-31 10:03:59 (PDT)
Copyright (c) 2009-2022, Thales. All rights reserved.

```

Display Contents of Conf files

To display the contents of the `agent.conf` and `.agent.conf.defaults` files, use the `vmsec vmdconfig` command. For example:

```

vmsec vmdconfig
appender_syslogdest_Syslog_Appender_0=127.0.0.1
VMSDK_AGENT_CONFIG_FILE=/opt/vormetric/DataSecurityExpert/agent/vmd/etc/agent.conf

layouts=Upload_Layout, File_Layout, Syslog_Layout, Simple

```

```
CONNECT_TIMEOUT=180000
URL=https://srv.my.thales.com:8443
STRONG_ENTROPY=false
```

Configuring Dynamic Host Settings for AIX

Previously, when host settings were changed, currently executing processes for the specified images were not modified. Only when a new process started would the changed host settings take effect. To make an already running process use the new host setting values, you had to terminate the process and restart it. The Dynamic Host Setting feature now permits the modified host settings take effect when the new entries are pushed from the CipherTrust Manager to the agent.

If the Dynamic Host Setting feature is enabled, then when a host setting is altered, all running processes with that signature are affected and their existing security attributes are modified to the new host settings parameters. Future actions by a process will contain authorization(s) derived from the new attributes. It is important to note that all descendent processes are affected by a process's host setting change. If an existing host setting entry is modified, the same situation occurs.

If an existing process did not have a host setting and one is applied, then all processes with that signature are updated with the new values. All of the existing descendent processes are affected by the changes. New child processes inherit the host setting parameters and authorizations.

In v7.2 of CTE, three new `vmadmin` commands are provided to enable, disable, and report the status of the Dynamic Host Settings:

- To turn on dynamic host settings, type:

```
voradmin secfs config dhs_on 1
```

Note

You must restart the agent for this to setting to take effect.

- To turn off dynamic host settings, type:

```
voradmin secfs config dhs_on 0
```

Note

You must restart the agent for this to setting to take effect.

- To report the state of the dynamic host settings, type:

```
voradmin secfs config dhs_state
```

Note

State information is added to the secfs.log file.

- To immediately enable dynamic host settings without restarting the agent, type:

```
voradmin cmd dhs_enable
```

Note

You must restart the agent for this to setting to take effect. Perform this command after turning on DHS.

- To immediately disable dynamic host settings without restarting the agent, type::

```
voradmin cmd dhs_enable
```

Note

Restarting the agent will enable it unless you turn the dynamic host settings off first.

vmutil

Usage

```
vmutil <options> <operations>
```

Options

Option	Function	Description
-a	--agent <name>	Specify agent type (vmd or pkcs11)
-d	--extdir <string>	Specify location of external certificate and key set

Option	Function	Description
-e	--error <string>	Specify one or more errors for state report
-h	--help	Display help and exit
-l	--loglevel <level>	Specify log output level (debug, info, warn, error or fatal)
-f	--force enabled	Force option for delete host operation
-v	--version	Display program version and exit

Operations

Operation	Description
certexpiry	Report the certificate expiration date for this agent
deletehost	Delete this client from the server
renewcerts	Renew certificate set for this agent
reportstate	Report agent state and error conditions to server
unregister	Unregister this agent/client from the server
updatecerts	Update external certificate and key set for this agent/client

vmd utility

The **vmd** utility displays CTE software version information.

The **vmd** utility is located in `/opt/vormetric/DataSecurityExpert/agent/vmd/bin` and a symbolic link to this file is placed in `/usr/bin/vmd`.

Syntax

vmd [OPTIONS...]

-h show utility syntax

-v display CTE version

-f runs **vmd** in the foreground

Display the Installed Version

To display the installed CTE version, type:

```
vmd -v
```

```
Version 7  
<Release.build-number>  
2022-02-04  
Copyright (c) 2009-2022, Thales.. All rights reserved.
```

Upgrading CTE on AIX

This chapter describes how to upgrade an existing VTE for AIX host to CipherTrust Transparent Encryption (CTE) for AIX.

Scheduling a CTE Agent Upgrade

You can schedule an upgrade of the CTE Agent to occur the next time the server on which a CTE Agent is installed reboots normally. Scheduling an upgrade can minimize CTE service interruptions and reduce coordination issues in organizations where the security roles are separated.

Note

Scheduled upgrade on reboot is available in VTE for AIX version 5.3.0 GA and onwards. You cannot schedule an upgrade from an earlier version of VTE to version 5.3.0 GA or to CTE version .

Before You Begin

Keep in mind the following prerequisites for using scheduled upgrade, usage notes, and how scheduled upgrade behaves when errors occur:

- If a crash/power failure occurs before a user-initiated reboot, the scheduled upgrade runs when the system comes up after the crash/power failure.
- CipherTrust Manager connectivity is required during the scheduled upgrade process.
- All databases must be configured to automatically stop before CTE services stop during reboot/shutdown.
- Stopping and restarting the CTE Agent does not trigger a scheduled upgrade.
- The installation binary used to run the scheduled upgrade is stored in `/var/tmp` until the scheduled upgrade runs. Ensure that no scheduled maintenance jobs periodically delete files in `/var/tmp`. All temporary files used by scheduled upgrade are removed following a successful scheduled upgrade.

Using the Scheduled Upgrade Feature

Note

If a scheduled upgrade has been enabled but has not run because the system wasn't rebooted, you can override the existing scheduled upgrade with a newer CTE version by using the procedure described here with the newer installation binary.

1. Verify that the version of CTE you currently have installed is eligible for scheduled upgrade:

```
vmd -v
```

The version listed must be version 5.3.0 or later.

2. Log in as root, change to the directory containing the installation binary, and run the binary with the `-u` scheduled upgrade option. For example:

```
./vee-fs-7.8.0.75-aix71.bin -u
```

The following upgrade confirmation is displayed:

```
upgrade on reboot configured
```

Note

If syslog is properly configured, appropriate logs will be logged in syslog.

3. When you are ready, reboot the server.

```
shutdown -Fr
```

When the system restarts, the scheduled upgrade runs without any intervention needed.

4. After the system is up and running, log in and run `vmd -v` to verify that the new version has been installed.

Performing an Upgrade Manually When an Upgrade is Already Scheduled

If you want to upgrade without waiting for the system to reboot, follow these steps to perform an upgrade manually when a scheduled upgrade is already enabled:

1. Log in as root, change to the directory containing the installation binary, and run the binary without the `-u` scheduled upgrade option. For example:

```
./vee-fs-7.8.0.75-aix71.bin
```

The following upgrade confirmation is displayed:

```
upgrade on reboot pending
do you wish to continue [y/n]: y
```

2. Enter “Y” to cancel the scheduled upgrade and proceed with an immediate installation. If you enter “N”, the scheduled upgrade remains enabled and occurs on the next reboot.

If you enter “Y”, the binary runs and displays the license agreement.

3. When prompted, enter “Y” to accept the license agreement or “N” to exit.

After accepting the license agreement, the normal upgrade proceeds, the scheduled upgrade is canceled, and temporary files used by the scheduled upgrade are removed.

Uninstalling CTE from AIX

Considerations

- The CTE Agent must be removed from the AIX host before the host is removed from the key manager with which it is registered.
- Database applications like DB2 and Oracle can lock the user space while they run. If the uninstall fails because a GuardPoint is in use, determine which applications are using the files in the GuardPoint and stop them. Then run the uninstall again.
- Commands like `fuser` and `lsof` might not reveal an active GuardPoint because they detect active usage, not locked states. Although it may appear that a GuardPoint is inactive, it may be in a locked state. Under this condition, software removal may fail with an error similar to the following:

```
/home: device is busy.
```

Procedure

1. Stop any application from accessing files in the GuardPoint.
2. In the key manager with which this host is registered, do the following:
 - Decrypt any data you want to use after uninstall. After the CTE Agent software is removed, access to data

is no longer controlled. If data was encrypted, it will remain encrypted. If decrypted or copied out of the GuardPoint, the data is visible as clear text.

This decryption must be done on every GuardPoint on the host if you want to access all existing data on the host.

- Make sure the Agent and System locks have been disabled for the host.
- Thales recommends that you remove all GuardPoints from the host before you uninstall the CTE Agent.

Do not remove the host from the key manager yet.

3. Log on to the host as **root**.
4. Change the directory to an unguarded location (for example, /.).

Caution

Do not change (cd) into the /opt/vormetric directory or into any directory below /opt/vormetric. If you run the uninstaller from /opt/vormetric or any of its subdirectories, the package removal utility may fail and return the following message:

You are not allowed to uninstall from the /opt/vormetric directory or any of its sub-directories.
Agent uninstallation was unsuccessful.

5. Start the uninstall. Type:

```
/opt/vormetric/DataSecurityExpert/agent/vmd/bin/uninstall
would you like to uninstall the vee-fs package? (Y/N) [Y]: Y
.....
Success!
```

6. Remove the host record from the key manager.

CipherTrust Transparent Encryption

CTE Agent Linux Advanced Configuration Guide

This document covers the following information:

- Overview of CTE
- Getting Started with CTE for Linux
- Special Cases for CTE Policies
- Logging
- Enhanced Encryption Mode
- CTE and systemd
- Utilities for CTE Management
- CipherTrust in-Place Data Transformation for Linux
- Upgrading CTE on Linux
- Uninstalling CTE from Linux
- Migrating CTE-U Agents to CTE

Overview of CTE

For very large data sets, initial encryption deployments can affect data availability, require unacceptable maintenance windows or require cloning and synchronizing data. Encrypting millions of files can span hours or even days, which can delay encryption, or require extra disk space and data synchronization, which can be labor-intensive. Rekeying large data sets can demand significant processing time and lengthy maintenance windows. Security and IT teams face tough tradeoffs, having to choose between security and availability.

CipherTrust Transparent Encryption operates with minimal disruption, effort, and cost. Its transparent approach enables security organizations to implement encryption without changing application, networking, or storage architectures. CipherTrust Live Data Transformation builds on these advantages, offering patented capabilities that deliver breakthroughs in availability, resiliency and efficiency.

CTE includes several unique utilities to help you encrypt and manage your data. It also integrates with several third-party platforms such as Oracle, Teradata Database Appliances, and Amazon S3.

This document describes the installation and advanced configuration options for CTE, as well as detailed information about how to integrate CTE with the supported third-party products.

CTE Terminology

The guide uses the following terminology:

Term	Description	OS Applies to
CTE	CipherTrust Transparent Encryption is a suite of products that allow you to encrypt and guard your data. The main software component of CTE is the CTE Agent, which must be installed on every host whose devices you want to protect. Notes • This suite was originally called Vormetric Transparent Encryption (VTE), and some of the names in the suite still use "Vormetric". • For example, the default installation directory is /opt/vormetric/DataSecurityExpert/agent/ for Linux and AIX, and C:\Program Files\Vormetric\DataSecurityExpert\agent\ for Windows.	Windows/Linux/AIX
CTE Agent	The software that you install on a physical or virtual machine in order to encrypt and protect the data on that machine. After you have installed the CTE Agent on the machine, you can use CTE to protect any number of devices or directories on that machine.	Windows/Linux/AIX
CTE Capabilities	CipherTrust Transparent Encryption agent version-specific features like Multi-Factor Authentication.	Linux
CTE-K8s	CipherTrust Transparent Encryption for Kubernetes. Policy-based encryption of data stored on persistent volumes	Linux
CTE-RWP or RWP	CipherTrust Transparent Encryption with Ransomware Protection. Ransomware protection for volume-level (Windows)/GuardPoint (Linux) data storage through process behavior monitoring and analytics.	Windows/Linux
CTE UserSpace (CTE-U)	CipherTrust Transparent Encryption (formerly known as ProtectFile FUSE). File system level encryption and access control solution for Linux servers.	Linux
Data Transformation	Encrypting or decrypting data.	Windows/Linux/AIX
Domain Sharing	This allows Clients in one domain to get cross-domain resources, specifically GPs.	Windows/Linux/AIX
GuardPath	A directory to which a CTE Kubernetes data protection and	Linux

Term	Description	OS Applies to
	encryption policy has been applied. CTEK8s will control access to, and monitor changes in, this device and directory, encrypting new or changed information as needed.	
GuardPoint	A device, or directory, to which a CTE data protection and encryption policy has been applied. CTE will control access to, and monitor changes in, this device and directory, encrypting new or changed information as needed.	Windows/Linux/AIX
Host /Client	In this documentation, host and client are used interchangeably to refer to the physical or virtual machine on which the CTE Agent is installed.	Windows/Linux/AIX
In-place Data transformation	Encryption mechanism for block devices.	Linux
Key Manager	An appliance that stores and manages data encryption keys, data access policies, administrative domains, and administrator profiles. Thales offers CipherTrust Manager, a key manager for use with CTE.	Windows/Linux/AIX
LDT (Live Data Transformation)	After initial GuardPoint enablement, LDT performs initial encryption, or rekeying, in the background, unnoticed by users. The data stays live and available. This accelerates CTE deployments and eliminates the need to block applications and user access to data during encryption or rekey operations, which can inconvenience users and affect operational efficiency.	Windows/Linux
LDT Communication (Comm) Group	A group of LDT clients who communicate with each other, and are responsible for, initial data transformation and future key rotation of CIFS/NFS GuardPoints.	Windows/Linux
LDT GuardPoint Group	An LDT GuardPoint Group contains a collection of LDT-enabled CTE clients that are all on the same network, managed by one CipherTrust Manager, guarding a common NFS/CIFS share and can communicate with each other over that network. An LDT GuardPoint Group enables the primary host of an LDT GuardPoint Group to	Windows/Linux

Term	Description	OS Applies to
	communicate with the secondary hosts that are members of that LDT GuardPoint Group.	
LDT Primary node	The LDT GuardPoint Group node that performs LDT rekeying of data.	Windows/Linux
LDT Secondary node	All of the other clients in the LDT GuardPoint Group are assigned as secondary nodes. Note: Secondary nodes do not participate in rekeying data, however, they can be promoted to primary nodes if a primary node fails.	Windows/Linux
LDT Subordinate nodes	The subordinate nodes are the remaining nodes in the LDT Communication Group.	Windows/Linux
LDT Triad nodes	The triad nodes are the first three servers in the LDT Communication Group.	
Learn Mode	Logging mode for audit logs to help generate security policies. Learn Mode allows access to guarded paths while logging access details. Users can analyze the content users and processes are accessing, the data used, and define GuardPoint policies accordingly.	Windows/Linux
MFA	Multifactor authorization ensures that the access credentials presented belong to the actual person. After logging in to the system, when a user tries to access a CipherTrust Transparent Encryption GuardPoint, it triggers a second factor authorization to verify the user with a second form of authentication, like sending a passcode to the users's registered cell phone, that they then have to input into the application.	Windows/Linux
Profile	Shared configuration resource for Client logging, Quality of Service, Multi-Factor Authentication, Ransomware Protection and key manager communication settings.	Windows/Linux/AIX
Signature	The hash of an entity. Where Entity can be the process or the docker image.	Windows/Linux/AIX
Versioned key and Key versions	Keys whose name remains the same but keybytes are different for	Windows/Linux/AIX

Term	Description	OS Applies to
	each different version.	

CTE Components

The CTE solution consists of two parts:

- The *CTE Agent software* that resides on each protected virtual or physical machine (host). The CTE Agent performs the required data encryption and enforces the access policies sent to it by the *key manager*. The communication between the CTE Agent and the key manager is encrypted and secure.

After the CTE Agent has encrypted a device on a host, that device is called a GuardPoint. You can use CTE to create GuardPoints on servers on-site, in the cloud, or a hybrid of both.

- A *key manager* that stores and manages data encryption keys, data access policies, administrative domains, and administrator profiles. After you install the CTE Agent on a host and register it with a key manager, you can use the key manager to specify which devices on the host that you want to protect, what encryption keys are used to protect those devices, and what access policies are enforced on those devices.

Note

For a list of CTE versions and supported operating systems, see the [CTE Compatibility Portal](#).

How to Protect Data with CTE

CTE uses policies created in the associated key manager to protect data. You can create policies to specify file encryption, data access, and auditing on specific directories and drives on your protected hosts. Each GuardPoint must have one and only one associated policy, but each policy can be associated with any number of GuardPoints.

Policies specify:

- Whether or not the resting files are encrypted.
- Who can access decrypted files.
- What level of file access auditing is applied when generating fine-grained audit trails.

A Security Administrator accesses key manager through a web browser. You must have administrator privileges to create policies using key Manager. The CTE Agent then implements the policies once they are pushed to the protected host.

CTE can only enforce security and key selection rules on files inside a guarded directory. If a GuardPoint is disabled, access to data in the directory goes undetected and ungoverned. Disabling a GuardPoint and then allowing unrestricted access to that GuardPoint can result in data corruption.

Getting Started with CTE for Linux

This section describes how to install CTE for Linux, register it with your selected key manager, and then create a simple GuardPoint on the protected host. It contains the following topics:

- [Additional Considerations](#)
- [CTE Agent Installation with UEFI Secure Boot](#)
- [Linux Package Installation](#)
- [Verifying Kernel Compatibility](#)
- [Installing and Configuring CTE for Linux with CipherTrust Manager](#)
- [Multifactor Authentication for CTE GuardPoints](#)
- [Ransomware Protection](#)

Additional Considerations

The following sections describe some of the things to keep in mind when configuring CTE.

Tracking and Preventing Local User Creation

CTE audits any attempts to change user authentication files. It also allows you to prevent any change to user authentication files using the host settings **protect**. This includes, but is not limited to user creation, modification, and deletion, or to deny users.

- The **audit** setting is set to on by default. It logs access to the system credential files but does not prevent account modifications.
- The **protect** setting both audits and prevents local user account modifications. You must manually enable the **protect** setting for tracking and prevention of local user account creation.

The **protect** tag will prevent changes to the files mentioned below. In the absence of the **protect** tag in host/client settings, operations on these files are permitted. When a log entry is generated, it is tagged with an **[audit]** tag.

- `/etc/passwd`
- `/etc/group`
- `/etc/shadow`
- `/etc/gshadow`
- `/etc/ssh/sshd_config`
- `/etc/ssh/sshr`

Note

You do not have to restart CTE after applying or removing these host settings.

Restricted Directories

Linux does not allow you to guard the following directories:

- <secfs install root>/agent/secfs/
- /etc
- /tmp
- /usr
- /usr/lib
- /usr/lib/pam
- /var/log/vormetric

Linux does not allow you to guard the following directories and all of their subdirectories:

- <install root>/agent/secfs/bin
- <secfs install root>/agent/vmd
- /etc/vormetric
- /etc/pam.d
- /etc/security
- /usr/lib/security
- /etc/rc*

Restricted Mode

Caution

If you install or upgrade in restricted mode, you cannot revert to unrestricted mode without uninstalling CTE.

You can install CTE in restricted mode. This mode prevents any user other than `root` from accessing the following directories:

- `/var/log/vormetric`
- `/opt/vormetric/DataSecurityExpert`

Restricted Mode also prevents non-`root` users from running the following utilities:

- `agenthealth`
- `agentinfo`
- `check_host`
- `register_host`
- `secfsd`
- `vmd`
- `vmsec`
- `voradmin`

Key Agents and Restricted Mode

- On systems where CTE is installed in restricted mode, you cannot install a key agent (pkcs11) or CipherTrust TDE Key Management.
- On systems where a key agent (pkcs11) or CipherTrust TDE are already installed, you cannot install CTE in restricted mode.

Restricted Mode Installation

To install in restricted mode, use the `-r` option.

```
./vee-fs-<release>-<build>-<system>.bin -r
```

For example:

```
./vee-fs-7.8.0.75-rh8-x86_64.bin -r
```

RPM Installation

If installing from an RPM directly, prior to installation, type:

```
export VOR_RESTRICTED_INSTALL_MODE=yes
```

Upgrade in Restricted Mode

The upgrade mode is the same as the installation mode.

CTE Agent Installation with UEFI Secure Boot

If you want to install the CTE Agent software on a Linux system that has UEFI Secure Boot enabled, you must first download the appropriate Thales public certificate for your version of CipherTrust Transparent Encryption, and add that certificate to the MOK (Machine Owner Key) list.

Note

- The Thales public certificate is valid for three years from the date of issuance. Six months before the current public certificate is set to expire, Thales will release an advisory, along with the new certificate, that will become valid after the six month grace period expires. All future builds of CipherTrust Transparent Encryption will be built with the new certificate.

Warning

- You can only use the new certificate if the CTE build has been signed with the new certificate. If you are using an older version of CipherTrust Transparent Encryption that was signed with a previous certificate, then you **must** use that certificate with CipherTrust Transparent Encryption.

Public Certificate Naming Convention

The Thales public certificate name is `CTE_Secure_Boot_Cert_MM-DD-YYYY.der`:

Example

```
CTE_Secure_Boot_Cert_05-15-2023.der
```

Getting the Current Public Certificate

There are two options for getting the certificate:

Option 1: Install the DER file

1. Download the CipherTrust Transparent Encryption binaries to your local system.
2. Use the `-e` option to extract the public certificate from the downloaded binary:

```
./<cte-binary-name>.bin -e
```

Example

```
./vee-fs-7.8.0.75-95-rh8-x86_64.bin -e
```

3. Add the certificate to the MOK list.

Option 2: Convert the PEM file to DER

1. Download the certificate from the Thales public directory [CTE_Secure_Boot Repository](#)

```
curl -O https://packages.vormetric.com/pub/CTE_Secure_Boot/<certificate_name>.pem
```

Example

```
curl -O https://packages.vormetric.com/pub/CTE_Secure_Boot/CTE_Secure_Boot_Cert_05-15-2023.pem
```

Note

You can also download it from the [Thales Customer Support Portal: KB0027431](#).

2. Convert the certificate from a PEM file to a DER file using the following command:

```
openssl x509 -inform PEM -outform DER -in <certificate_name>.pem -out <certificate_name>.der
```

Example

```
openssl x509 -inform PEM -outform DER -in CTE_Secure_Boot_Cert_05-15-2023.pem -out CTE_Secure_Boot_Cert_05-15-2023.der
```

3. Add the certificate to the MOK list.

Adding the Certificate to the MOK List

Note

During this procedure, you **must** reboot the Linux host and then respond to a system prompt as soon as the host restarts.

1. Log into the host as `root`.
2. Add the certificate to the MOK list:

```
mokutil --import <cert-name>
```

Example

```
mokutil --import CTE_Secure_Boot_Cert_05-15-2023.der
```

3. Enter and confirm a password for this request when prompted.
4. Reboot the host and follow the instructions on the console when the host is back online. You will need to enter the password you created in the previous step when prompted. For detailed information, refer to the specific instructions from each linux distribution.

Note

If you do not respond to the system prompt to update the MOK when the host restarts, the prompt will time out and you will need to run the `mokutil` command again.

5. When prompted, reboot the host again.
6. After the host has rebooted for the second time, verify that the certificate has been properly added to the MOK list:

```
mokutil --test-key <cert-name>
```

Example

```
mokutil --test-key CTE_Secure_Boot_Cert_05-15-2023.der
```

Response

```
CTE_Secure_Boot_Cert_05-15-2023.der is already enrolled.
```

Linux Package Installation for Linux Distributions

- [Linux Package Installation for RHEL](#)
- [Linux Package Installation for SLES](#)
- [Linux Package Installation for Ubuntu](#)

Linux Package Installation for RHEL

This section describes how to access the Linux RPM installation package so that the CTE Agent installation integrates with the distribution software. To access the Linux RPM file, you can:

- Extract the RPM file from the CTE Agent install bin file. This is the easiest method, but the files in the package are not signed and therefore cannot be verified. For details, see [Installing the Unsigned RPM Package](#).
- Download the package from the Yum repository. If you use Yum, the files in the package are signed and the signatures are automatically verified when the package is installed. For details, see [Installing the Signed RPM Package with Yum](#).
- Manually download the RPM package outside of Yum and manually verify the package signatures. For details, see [Installing the Signed RPM Package Manually](#).

Prerequisites

Note

Before you can download and install the package using the Yum repository, you must contact [Thales Support](#) to get the username and password for the package repository on which the package resides.

Installing the Unsigned RPM Package

The CTE installation `bin` files contain the unsigned native packages. Extract them by running the `bin` file with the `-e` flag.

1. Log on to the host system as root and copy, or mount, the installation file to the host system.
2. Extract the RPM file using the following command:

```
./vee-fs-<release>-<build>-<distro>-<architecture>.bin -e
```

Example

```
./vee-fs-7.8.0.75-rh9-x86_64.bin -e
```

Response

```
Contents extracted.
```

3. Verify that the package extracted correctly:

```
ls *rpm
```

Example Response

```
vee-fs-7.8.0.75-rh9-x86_64.rpm
```

4. To start the installation using the RPM file, use the following command:

```
rpm -ivh vee-fs-<release>-<build>-<distro>-<architecture>.rpm
```

5. Follow the prompts to install and register CTE.

For details about the installation and registration process, see the appropriate installation procedure.

6. If you are going to register the system with a CipherTrust Manager, see [Configuring CTE for Linux with CipherTrust Manager](#).

Installing the Signed RPM Package with Yum

To install the latest released version with the `yum` command:

1. Create the repository file, `/etc/yum.repos.d/Vormetric-VTE.repo`, with the following content:

```
[vormetric-vte]
releasever=REL_VERSION
name=Vormetric VTE Packages $releasever - $basearch - Source
baseurl=https://USER:PASSWORD@packages.vormetric.com/vte/DIST_VERSION/Latest
gpgkey=https://packages.vormetric.com/pub/PKG-GPG-KEY-vormetric
enabled=1
gpgcheck=1
```

```
repo_gpgcheck=1
sslverify=1
```

Where:

- **USER:PASSWORD:** Username/password obtained from Thales Support
- **DIST_VERSION:** RHEL release version directory name. Ex: RH8, RH9
- **REL_VERSION:** RHEL release version. Ex: rhel-8, rhel-9

2. Clean up the Yum cache directory:

```
yum clean all
```

3. List all available versions of CTE:

```
yum list --showduplicates vee-fs
```

4. Use Yum to install the CTE binary. For example:

If the CTE binary name is vee-fs-7.8.0.75-rh9-x86_64, type:

```
yum install vee-fs-7.8.0.75-rh9-x86_64
```

To install the latest version, type:

```
yum install vee-fs
```

Note

The first time you install CTE through Yum, you will be asked to import the GPG key. Make sure that you download this key or the installation will fail. For example:

```
vormetric-vte/7Server/signature | 198 B 00:00:00
Retrieving key from https://packages.vormetric.com/pub/PKG-GPG-KEY-
vormetric
Importing GPG key 0x628536B7:
Userid : "Vormetric (PKG-GPG-KEY) <support@vormetric.com>"
Fingerprint: 7cb5 4f55 40d4 1b63 bf91 c896 f00a 13b0 6285 36b7
From : https://packages.vormetric.com/pub/PKG-GPG-KEY-vormetric
```

```
Is this ok [y/N]: y
```

5. Follow the prompts to install and register CTE.

For details about the installation and registration process, see the appropriate installation procedure.

6. If you are going to register the system with a CipherTrust Manager, see [Configuring CTE for Linux with CipherTrust Manager](#).

Installing the Signed RPM Package Manually

If you want to manually verify the signed version of the CTE RPM package, you can download the public key from the Thales package repository and manually verify the rpm signature.

1. Download the `rpm` file for the latest release, type:

```
wget -c --user USER --password PASSWORD https://packages.vormetric.com/vte/DIST_VERSION/Latest/TARGET_RPM_NAME
```

Example

```
wget -c --user ctetest --password abcdef12345678ab https://packages.vormetric.com/vte/RH9/Latest/vee-fs-7.8.0.75-rh9-x86_64.rpm
```

Where:

- **DIST_VERSION:** RHEL release version directory name. Ex: RH8, RH9
- **USER/PASSWORD:** Username/password obtained from Thales Support
- **TARGET_RPM_NAME:** Target rpm filename to download. Ex: vee-fs-7.8.0.75-rh9-x86_64.rpm

2. Import the public key from the Thales package repository:

```
sudo rpm --import https://packages.vormetric.com/pub/PKG-GPG-KEY-vormetric
sudo rpm -qa grep gpg-pub*
```

Response

```
gpg-pubkey-628536b7-56f9887b : Imported CTE GPG public key.
gpg-pubkey-fd431d51-4ae0493b
```

3. Verify the signature of the package.

```
sudo rpm -Kv vee-fs-<release>-<build>-<distro>-<architecture>.rpm
```

Example

```
sudo rpm -Kv vee-fs-7.8.0.75-rh9-x86_64.rpm
```

4. To start the installation using the RPM file, use the following command:

```
sudo rpm -ivh vee-fs-<release>-<distro>-x86_64.rpm
```

5. Follow the prompts to register CTE.

For details about the installation and registration process, see the appropriate installation procedure.

6. If you are going to register the system with a CipherTrust Manager, see [Configuring CTE for Linux with CipherTrust Manager](#).

Installing a previous version

To install a previous version with the YUM command, use the following URL for the baseurl in the file, `/etc/yum.repos.d/Vormetric-VTE.repo`:

```
baseurl=https://USER:PASSWORD@packages.vormetric.com/vte/CTE_VERSION/rhel-$releasever/
```

To install an previous version manually, use the following URL for the download URL.

```
https://packages.vormetric.com/vte/CTE_VERSION/REL_VERSION/TARGET_RPM_NAME
```

Where:

- **USER/PASSWD**: contact Thales Support to obtain the credential
- **TARGET_RPM_NAME**: Target rpm filename to download. Ex: vee-fs-7.8.0.75-rh9-x86_64.rpm
- **CTE_VERSION**: CTE release version. Ex: 7.7.0
- **REL_VERSION**: Distribution version. Ex: rhel-8, rhel-9

Upgrading from RHEL 9.6 to RHEL 10

This section describes an In-place upgrade of an RHEL 9.6 system to RHEL 10 using the [RHEL Leapp utility](#), with the added objective of upgrading CTE in the process.

Note

This procedure **only** applies to when upgrading RHEL 9.6 to RHEL 10. IT does not apply for any other versions.

Leapp allows you to:

- Preserve the configuration of your system
- Reinstall RHEL
- Retain existing subscription data on the client as long as the system is subscribed to using subscription-manager

Note

The upgrade process may take several hours.

Prerequisites

- Requires an active RHEL subscription on the source system
- Backup your data using the recommendations in the upgrade guide

Installation with the Leapp Utility

1. Check the subscription status, type:

```
subscription-manager status
```

2. Set the subscription manager release, type:

```
subscription-manager release --set 9.6
```

3. Open the global configuration file, `/etc/dnf/dnf.conf`, in a text editor for editing.
4. Add an exception for updating CTE so that Leapp can ignore the CTE package. This lets you upgrade CTE with the CTE Upgrade on Reboot feature. Add the following line to the end of the file:

```
exclude=libns12, vee-fs
```

-
5. Install the Leapp tools, type:

```
yum install leapp leapp-repository leapp-upgrade
```

6. Update the software, type:

```
yum update
```

7. Reboot the system.

8. Enable **Upgrade on Reboot** using the attached `schedule.sh` file, type:

```
./schedule.sh <cte-binary>
```

Example

```
./schedule.sh vee-fs-7.8.0-100-rh10-x86_64.bin
```

Note

The Leapp utility installs the latest CVE kernel package on the target RHEL 10 system. Ensure that the CTE binary provided to the Upgrade on Request scheduler is certified for this kernel version.

9. Run the pre-upgrade tool, type:

```
leapp preupgrade
```

10. Examine the pre-upgrade details in `/var/log/leapp/leapp-report.txt`. Resolve any error or inhibitor conditions.
11. Rerun the tool after resolving the conditions to verify that they have been resolved.
12. Set the upgrade target, type:

```
leapp preupgrade --target 10.0
```

13. Examine the pre-upgrade details again, in `/var/log/leapp/leapp-report.txt`. Resolve any error or inhibitor conditions.
14. Rerun the tool after resolving the conditions to verify that they have been resolved.
-

15. Start the upgrade, type:

```
leapp upgrade --target 10.0
```

16. If a failure occurs due to a package or dependency, Leapp logs the error to the console. Fix the issues and then proceed.

If there are no error or inhibitor conditions displayed on the console, **reboot**.

17. Wait for the system to upgrade and return to the online state. Verify the CTE service status.

Linux Package Installation for SLES

This section describes how to access the Linux RPM installation package so that the CTE Agent installation integrates with the distribution software. To access the Linux RPM file, you can:

- Extract the RPM file from the CTE Agent install bin file. This is the easiest method, but the files in the package are not signed and therefore cannot be verified. For details, see [Installing the Unsigned RPM Package](#).
- Download the package from the RPM repository. If you use Zypper Package Manager, the files in the package are signed and the signatures are automatically verified when the package is installed. For details, see [Installing the Signed RPM Package with Zypper](#).
- Manually download the RPM package outside of Zypper and manually verify the package signatures. For details, see [Installing the Signed RPM Package Manually](#).

Prerequisites

Note

Before you can download and install the package using the Zypper repository, you must contact [Thales Support](#) to get the username and password for the package repository on which the package resides.

Installing the Unsigned RPM Package

The CTE installation **bin** files contain the unsigned native packages. Extract them by running the **bin** file with the **-e** flag.

1. Log on to the host system as root and copy or mount the installation file to the host system.
2. Extract the RPM file using the following command:

```
./vee-fs-<release>-<build>-<distro>-<architecture>.bin -e
```

Example

```
./vee-fs-7.8.0.75-sles15-x86_64.bin -e
```

Response

```
Contents extracted.
```

3. Verify that the package extracted correctly:

```
ls *rpm
```

Example Response

```
vee-fs-7.8.0.75-sles15-x86_64.rpm
```

4. To start the installation using the RPM file, use the following command:

```
sudo rpm -ivh vee-fs-<release>-<distro>-x86_64.rpm
```

5. Follow the prompts to install and register CTE.

For details about the installation and registration process, see the appropriate installation procedure.

6. If you are going to register the system with a CipherTrust Manager, see [Configuring CTE for Linux with CipherTrust Manager](#).

Installing the Signed RPM Package with Zypper Package Manager

To install the latest released version:

1. Create the repository file `/etc/zypp/repos.d/Vormetric-VTE.repo`, with the following contents:

```
/etc/zypp/repos.d/Vormetric-VTE.repo
```

2. Add with the following contents:

```
[vormetric-vte]
name=Vormetric VTE Packages for SLES
enabled=1
autorefresh=0
baseurl=https://USER:PASSWORD@packages.vormetric.com/vte/DIST_VERSION/Latest
```

```
type=rpm-md
```

Where:

- **USER/PASSWD:** contact Thales Support to obtain the credential
- **DIST_VERSION:** SLES release version. Ex: SLES12, SLES15

3. Import public key from the repository:

```
sudo rpm --import https://packages.vormetric.com/pub/PKG-GPG-KEY-vormetric
```

4. Clean up cached data:

```
$ sudo zypper clean
$ sudo zypper refresh
```

5. List available versions of the CTE.

```
$ zypper se --match-exact -t package -s vee-fs
```

6. Install CTE binary:

```
$ zypper in vee-fs                : download the latest
$ zypper in vee-fs=<CTE_VERSION> : download the specific version
```

7. Follow the prompts to install and register CTE. For details about the installation and registration process, see the appropriate installation procedure.
8. If you are going to register the system with a CipherTrust Manager, see [Configuring CTE for Linux with CipherTrust Manager](#).

Installing the Signed RPM Package Manually

If you want to manually verify the signed version of the CTE RPM package, you can download the public key from the Thales package repository and manually verify the rpm signature.

1. Download the `rpm` file for the latest release, type:

```
$ wget -c --user USER --password PASSWORD https://packages.vormetric.com/vt
e/DIST_VERSION/Latest/TARGET_RPM_NAME
```

Example

```
$ wget -c --user USER --password PASSWORD https://packages.vormetric.com/vte/SLES15/Latest/vee-fs-7.8.0.75-sles15-x86_64.rpm
```

Where:

- **DIST_VERSION:** SLES release version. Ex: SLES12, SLES15,
- **USER/PASSWORD:** Username/password obtained from Thales Support
- **TARGET_RPM_NAME:** Target rpm filename to download. Ex: vee-fs-7.8.0.75-sles15_64.rpm

2. Import the public key from the Thales package repository:

```
sudo rpm --import https://packages.vormetric.com/pub/PKG-GPG-KEY-vormetric
sudo rpm -qa grep gpg-pub*
```

Response

```
gpg-pubkey-628536b7-56f9887b : Imported CTE GPG public key.
gpg-pubkey-fd431d51-4ae0493b
```

3. Verify the signature of the package using the `rpm -Kv` command.

```
sudo rpm -Kv vee-fs-<release>-<build>-<distro>-<architecture>.rpm
```

Example

```
sudo rpm -Kv vee-fs-7.8.0.75-sles15-x86_64.rpm
```

Response

```
Header V4 DSA/SHA1 Signature, key ID 628536b7: OK
Header SHA1 digest: OK (ed3d33dca580c66c70961cfee143e9877a09544c)
MD5 digest: OK (95273b36ef1c205a7cea444e14bef15f)
V4 DSA/SHA1 Signature, key ID 628536b7: OK
The output should show that the keys match is OK.
```

4. To start the installation using the RPM file, use the following command:

```
sudo rpm -ivh vee-fs-<release>-<build>-<distro>-<architecture>.rpm
```

5. Follow the prompts to register CTE.

For details about the installation and registration process, see the appropriate installation procedure.

6. If you are going to register the system with a CipherTrust Manager, see [Configuring CTE for Linux with CipherTrust Manager](#).

Installing a previous version

To install a previous version with the `zypper` command, use the following URL for baseurl in file: `/etc/zypp/repos.d/Vormetric-VTE.repo`

```
baseurl=https://USER:PASSWORD@packages.vormetric.com/vte/CTE_VERSION/REL_VERSION
```

To install a previous version manually, use the following URL for the download URL.

```
https://packages.vormetric.com/vte/CTE_VERSION/REL_VERSION/TARGET_RPM_NAME
```

Where:

- **USER/PASSWD**: contact Thales Support to obtain the credential
- **REL_VERSION**: SLES release version. Ex: sles12, sles15
- **TARGET_RPM_NAME**: Target rpm filename to download. Ex: vee-fs-7.8.0.75-sles15-x86_64.rpm
- **CTE_VERSION**: CTE release version. Ex: 7.7.0

Linux Package Installation for Ubuntu

Prerequisites

Note

Before you can download and install the package using the Apt repository, you must contact [Thales Support](#) to get a username and password for the package repository on which the packages reside.

Installing the Unsigned DEB Package

The CTE installation `bin` files contain the unsigned native packages. Extract them by running the `bin` file with the `-e` flag.

1. Log on to the host system as root and copy or mount the installation file to the host system.
2. Extract the DEB file using the following command:

```
./vee-fs-<release>-<build>-<distro>-<architecture>.bin -e
```

Example

```
./vee-fs-7.7.0-87-ubuntu22-x86_64.bin -e
```

Response

```
Contents extracted.
```

3. Verify that the package extracted correctly:

```
ls *deb
```

Example Response

```
vee-fs-7.7.0-87-ubuntu22-x86_64.deb
```

4. To start the installation using the deb file, use the following command:

```
dpkg -i vee-fs-7.7.0-87-ubuntu22-x86_64.deb
```

5. Follow the prompts to install and register CTE.

For details about the installation and registration process, see the appropriate installation procedure.

6. If you are going to register the system with a CipherTrust Manager, see [Configuring CTE for Linux with CipherTrust Manager](#).

Installing the Signed DEB Package with the latest version

To install the latest released version:

1. Create the source list file, `/etc/apt/sources.list.d/Vormetric-VTE.list`, with the following contents:
 - a. Add the following contents from the Vormetric Source repository.

```
deb https://packages.vormetric.com/vte/DIST_VERSION/Latest/
```

Where:

- **DIST_VERSION:** Ubuntu distribution release version. Ex: UBUNTU20, UBUNTU22

b. Create the login configuration file, type:

```
vi /etc/apt/auth.conf
```

c. Enter the login information, type:

```
machine packages.vormetric.com/vte/DIST_VERSION/Latest login USER password PAS  
SWD
```

Where:

- **USER:PASSWORD:** Username/password obtained from Thales Support

2. Import public key from the repository.

```
$ sudo curl -O https://packages.vormetric.com/pub/PKG-GPG-KEY-vormetric-ubuntu  
$ sudo gpg --import PKG-GPG-KEY-vormetric-ubuntu  
$ sudo apt-key add PKG-GPG-KEY-vormetric-ubuntu  
$ sudo apt-key update
```

3. Retrieve the new list of packages.

```
$ sudo apt-get update
```

4. List all versions of the CTE binary:

```
$ apt-cache madison vee-fs
```

5. Install CipherTrust Transparent Encryption.

```
$ sudo apt-get install vee-fs : installs the latest version of CTE  
$ sudo apt-get install vee-fs=<release>-<build> : installs the specific versio  
n of CTE
```

6. Follow the prompts to install and register CTE. For details about the installation and registration process, see the appropriate installation procedure.
7. If you are going to register the system with a CipherTrust Manager, see [Configuring CTE for Linux with CipherTrust Manager](#).

Installing the Signed DEB Package Manually with the latest version

If you want to manually verify the signed version of the CTE DEB package, you can download the public key from the Thales package repository and manually verify the DEB signature.

1. Download the `deb` file, type:

```
wget -c --user USER --password PASSWORD https://packages.vormetric.com/vte/DIST_VERSION/Latest/TARGET_PKG_NAME
```

Example

```
wget -c --user USER --password PASSWORD https://packages.vormetric.com/vte/UBUNTU22/Latest/vee-fs-7.7.0-87-ubuntu22-x86_64.deb
```

Where:

- **DIST_VERSION:** Ubuntu DISTRIBUTION release version. Ex: UBUNTU20, UBUNTU22
- **TARGET_PKG_NAME:** Target PKG filename to download. Ex: `vee-fs-7.7.0-87-ubuntu22-x86_64.rpm`

2. Import the public key from the Thales package repository:

```
$ sudo gpg --import PKG-GPG-KEY-vormetric-ubuntu  
$ sudo apt-key add PKG-GPG-KEY-vormetric-ubuntu  
$ sudo apt-key update
```

3. Verify the signature of the package.

```
sudo dpkg-sig --verify vee-fs-<release>-<build>-<distro>-<architecture>.deb
```

Example

```
sudo dpkg-sig --verify vee-fs-7.7.0-87-ubuntu22-x86_64.deb
```

Response

```
Processing vee-fs-7.7.0-119-ubuntu20-x86_64.deb...  
GOODSIG _gpgvormetric 7CB54F5540D41B63BF91C896F00A13B0628536B7 1698960263
```

4. To start the installation using the deb file, use the following command:

```
sudo dpkg -i vee-fs-7.7.0-87-ubuntu22-x86_64.deb
```

5. Follow the prompts to register CTE.

For details about the installation and registration process, see the appropriate installation procedure.

6. If you are going to register the system with a CipherTrust Manager, see [Configuring CTE for Linux with CipherTrust Manager](#).

Installing a previous version

To download a previous deb package using `wget` on the command line, use the following URL:

```
https://packages.vormetric.com/vte/CTE_VERSION/REL_VERSION/TARGET_PKG_NAME
```

Where:

- **REL_VERSION**: Ubuntu distribution version. Ex: ubuntu20, ubuntu22
- **TARGET_PKG_NAME**: Target rpm filename to download. Ex: vee-fs-7.7.0-87-ubuntu22-x86_64.deb
- **CTE_VERSION**: CTE release version. Ex: 7.7.0.

To install a previous version of CTE with the `apt` command, use the following URL in `/etc/apt/sources.list.d/Vormetric-VTE.list`:

```
deb https://packages.vormetric.com/vte/CTE_VERSION/REL_VERSION /
```

Use the following URL in `/etc/apt/auth.conf`:

```
machine packages.vormetric.com/vte/CTE_VERSION/REL_VERSION login USER password PASSWD
```

Verifying Kernel Compatibility

Thales maintains a compatibility matrix in a JSON file that maps all CTE Agent releases to the Operating Systems and kernels that support those releases. The information in this file allows you to verify the compatibility between any Linux host and the version of the CTE Agent that you want to install on that host.

You can view the current compatibility information in CipherTrust Manager by downloading the most recent compatibility JSON file from Thales and then uploading it to CipherTrust Manager. After the JSON file has been uploaded, the CipherTrust Manager displays the compatibility of all Linux hosts registered with the CipherTrust Manager in the **Compatibility View** on the **Hosts** page.

For details about how to do this in CipherTrust Manager refer to: [Kernel Compatibility Matrix](#).

The following procedure describes how to download the compatibility JSON file and verify its authenticity.

1. Download the `cte_compatibility_matrix.tgz` file from <https://packages.vormetric.com/pub/> or from the [Thales Customer Support Portal](#).
2. Extract the files from the TGZ file. The resulting files are:
 - `CTE_Compatibility_Matrix_Cert_mm-dd-yyyy.pem` — The X.509 Public Key Certificate.
 - `cte_compatibility_matrix.json` — The compatibility JSON file.
 - `cte_compatibility_matrix.sign.sha256` — The SHA256 signature for the JSON file.

For example:

```
tar -xvzf cte_compatibility_matrix.tgz
```

`CTE_Compatibility_Matrix_Cert_12-17-2020.pem`

`cte_compatibility_matrix.json`

`cte_compatibility_matrix.sign.sha256`

3. Extract the Public Key from the X.509 Public Key Certificate. For example:

```
openssl x509 -in CTE_Compatibility_Matrix_Cert_12-17-2020.pem -pubkey \
-noout > cte_compatibility_matrix_public_key.pem
```

The Public Key is in PEM format in the file `cte_compatibility_matrix_public_key.pem`.

4. Verify the SHA signature using the Public Key. For example:

```
openssl dgst -sha256 -verify cte_compatibility_matrix_public_key.pem \
-signature cte_compatibility_matrix.sign.sha256 cte_compatibility_matrix.json
Verified OK
```

Installing CTE with No Key Manager Registration

The following procedure installs the CTE Agent on the host but does not register it with a key manager. You cannot protect any data on the host until the CTE Agent is registered with one of the supported key managers. For a comparison of the available key managers, see [CTE Components](#).

1. Log on to the host where you will install the CTE Agent as `root`. You cannot install the CTE Agent without `root` access.
2. Copy or mount the installation file to the host system. If necessary, make the file executable with the `chmod` command.

3. Install the CTE Agent. A typical installation uses the following syntax:

```
./vee-fs-<release>-<build>-<system>.bin
```

For example:

```
./vee-fs-7.8.0.75-rh8-x86_64.bin
```

To install the CTE Agent in a custom directory, use the `-d <custom-dir>` option. For example:

```
./vee-fs-7.8.0.75-rh8-x86_64.bin -d /home/my-cte-dir/
```

Note

If possible, Thales recommends that you use the default directory `/opt/vormetric`.

To view all installer options, use the `-h` parameter. For example:

```
./vee-fs-7.8.0.75-rh8-x86_64.bin -h
```

4. The Thales License Agreement displays. When prompted, type **Y** and press Enter to accept.

The install script installs the CTE Agent software in either `/opt/vormetric` or your custom installation directory and then prompts you about registering the CTE Agent with a key manager.

Welcome to the CipherTrust Transparent Encryption File System Agent Registration Program.

```
Agent Type: CipherTrust Transparent Encryption File System Agent
Agent Version: <Release.build-number>
```

```
In order to register with a CipherTrust Manager you need a valid registration token from the CM.
```

```
Do you want to continue with agent registration? (Y/N) [Y]:
```

5. Type **N** and press Enter to end the installation procedure without registering the CTE Agent with either key manager.

When you are ready to register the CTE Agent with a key manager, see [Configuring CTE for Linux with CipherTrust Manager](#).

Configuring CTE for Linux with CipherTrust Manager

This section describes how to install and configure CTE on Linux systems that you plan to register with a CipherTrust Manager.

Installation Overview

The installation and configuration process when you are using CTE with a CipherTrust Manager consists of the following steps:

1. Installation Prerequisites

Gather the information needed for the installation and set up your network.

2. Interactive Installation on Linux

Install CTE interactively on a protected host and register the protected host with CipherTrust Manager.

Silent Installation on Linux

Install CTE silently (non-interactive) on a protected host and register the protected host with CipherTrust Manager.

3. Installing CTE with No Key Manager Registration

Install CTE without registering to a CipherTrust Manager.

4. External Certificates

Use for communication between CTE and CM. Install the external certificate before registering CipherTrust Transparent Encryption with CipherTrust Manager.

5. Validating CipherTrust Manager and CipherTrust Transparent Encryption with a Local CA Certificate

Ensure that registration by the CTE agent is serviced only by the expected key manager by providing a copy of the CA certificate that will be used to authenticate the TLS communications with the key manager.

6. Registration

Register the protected host with CipherTrust Manager and make sure that CipherTrust Manager and CipherTrust Transparent Encryption can communicate with each other. This can be done as part of the initial installation or at any point after the CTE Agent has been installed.

7. Guard Devices

Create GuardPoint to protect sensitive data.

Installation Prerequisites

This section lists the tasks you must complete, and the information you must obtain, before installing CTE.

Recommendations and Considerations

- The host on which you want to install CTE *must* support AES-NI hardware encryption. If it does not, any attempt to install or upgrade CTE to release 7.0.0 or later will fail.
- Thales recommends that you install CTE in the default location.
- Make the Installation root directory `/opt` a real directory. If `/opt` is a symlink, you **must** use the `-d` option to specify the installation directory, which must be a real directory.

For example:

```
./vee-fs-7.8.0.75-rh8-x86_64.bin -d /home/hello/
```

- Ensure read/write permission is granted to other users accessing your shared resource.

Network Setup Requirements

Recommendations and Considerations

- The host on which you want to install CTE *must* support AES-NI hardware encryption. If it does not, any attempt to install or upgrade CTE to release 7.0.0, or any subsequent version, will fail.
- Thales recommends that you install CTE in the default location.
- Do not install CTE on network-mounted volumes such as NFS.
- Make the Installation root directory `/opt` a real directory. If `/opt` is a symlink, you **must** use the `-d` option to specify the installation directory, which must be a real directory.

For example:

```
./vee-fs-7.8.0.75-rh8-x86_64.bin -d /home/hello/
```

Port Configuration Requirements

The following port information applies to both Windows and Linux systems.

Communication through a Firewall

If a protected client must communicate with CipherTrust Manager through a firewall, see the CipherTrust Manager documentation to determine which of the ports must be opened through the firewall.

Communication with CipherTrust Manager

The default port for http communication between CipherTrust Manager and the CTE Agent is **443**. If this port is

already in use, you can set the port to a different number during the CTE Agent installation.

Communication for LDT over CIFS/NFS

All nodes that intend to use **LDT over CIFS/NFS** GuardPoint must have the following ports open:

- 7024
- 7025

Note

When you are registering a CipherTrust Transparent Encryption client with CipherTrust Manager, you can manually include a destination port number, (Default: 443). If you enter a port value, using the syntax `<hostname or IP address>:<port number>` then CipherTrust Transparent Encryption **does not** perform a port scan. CipherTrust Transparent Encryption uses the port number provided to verify the target server type using a TLS operation.

If you do not enter a port number, CipherTrust Transparent Encryption performs a port scan to check which ports are listening, including port 443.

Interactive Installation on Linux

The Linux typical install is an interactive script that asks you a series of questions during the installation. You can also install CTE using a silent installer which pre-packages the install information. This allows you to install CTE on a large number of hosts. (For more information, see [Silent Installation on Linux](#)).

After you install CTE, you are prompted to register it immediately with a key manager. CTE must be registered with a key manager before you can protect any of the devices on the host. However, you may postpone the registration if you plan to register CTE later.

Note

Do not install CTE on network-mounted volumes like NFS.

Prerequisites

The following prerequisites must be met for CTE/CTE-U to install and register to CipherTrust Manager properly:

- CipherTrust Manager installed and configured. See [CipherTrust Manager Documentation](#) for more information.
- CipherTrust Manager must contain a Client Profile. See [Changing the Profile](#) for more information.
- CipherTrust Manager must contain a registration token. See [Creating a Registration Token](#).
- Optionally, the name of the host group you want this client to be a part of.

- CipherTrust Manager must contain an LDT Communication Group if you will use CTE to guard data over CIFS/ NFS shares using LDT policies. See [Managing LDT Communication Groups](#) for more information.

Procedure

1. Log on to the host where you will install the CTE Agent as **root**. You cannot install the CTE Agent without **root** access.
2. Copy or mount the installation file to the host system. If necessary, make the file executable with the **chmod** command.
3. Install the CTE Agent. A typical installation uses the following syntax:

```
./vee-fs-<release>-<build>-<system>.bin
```

For example:

```
./vee-fs-7.8.0.88-rh8-x86_64.bin
```

To install the CTE Agent in a custom directory, use the **-d <custom-dir>** option. For example:

```
./vee-fs-7.8.0.88-rh8-x86_64.bin -d /home/my-cte-dir/
```

Note

- If possible, Thales recommends that you use the default directory **/opt/vormetric**.
- Custom directories are **only available** for RHEL and SLES.
- Custom directories are **not available** for COS (Cloud Object Storage).

To view all installer options, use the **-h** parameter. For example:

```
./vee-fs-7.8.0.88-rh8-x86_64.bin -h
```

4. The Thales License Agreement displays. When prompted, type **Y** and press Enter to accept.

The install script installs the CTE Agent software in either **/opt/vormetric** or your custom installation directory and then prompts you about registering the CTE Agent with a key manager.

Welcome to the CipherTrust Transparent Encryption File System Agent Registration Program.

```
Agent Type: CipherTrust Transparent Encryption File System Agent
Agent Version: <Release.build-number>
```

```
In order to register with a CipherTrust Manager you need a valid registration token from the CM.
```

```
Do you want to continue with agent registration? (Y/N) [Y]:
```

5. Type **N** and press Enter to end the installation procedure without registering the CTE Agent with a key manager.
6. Enter **Y** to continue with the registration process. The install script prompts you to enter the host name or IP address of the CipherTrust Manager with which you want to register CTE. For example:

CTE for CipherTrust Manager

```
Do you want to continue with agent registration? (Y/N) [Y]: Y
```

```
Please enter the primary key manager host name: 10.3.200.141
```

```
You entered the host name 10.3.200.141
```

```
Is this host name correct? (Y/N) [Y]: Y
```

CTE for CDSPaaS

```
Do you want to continue with agent registration? (Y/N) [Y]: Y
```

```
Enter the primary key manager host name of the service:
```

```
You entered the host name us1.ciphertrust.dpondemand.io
```

```
Is this host name correct? (Y/N) [Y]: Y
```

Host names:

- **Europe:** ciphertrust.dpondemand.io
- **North America:** us1.ciphertrust.dpondemand.io

Note

The default communication port is 443. If you want to specify a different communication port, enter it with the primary key manager host name in the format: <hostName>:<port#>. For example, 10.3.200.141:8445.

7. Enter the client host name when prompted.

```
Please enter the host name of this machine, or select from the following list.

[1] sys31186.qa.com
[2] 10.3.31.186

Enter a number, or type a different host name or IP address in manually:
What is the name of this machine? [1]: 2
You selected "10.3.31.186".
```

8. Enter the CipherTrust Manager registration token, profile name, host group and host description. If you omit the profile name, CipherTrust Manager associates the default client profile with this client.

```
Please enter the registration token: 12345
Please enter the profile name for this host: My-Profile
Please enter the host group name for this host, if any:
Please enter a description for this host: RHEL7 system West Coast Datacenter

Token           : 12345
Profile name     : My-Profile
Host Group      : (none)
Host description : RHEL7 system West Coast Datacenter
Are the above values correct? (Y/N) [Y]: Y
```

9. At the hardware association prompt, select whether you want to enable the hardware association feature to prevent cloning. The default is Y (enabled):

It is possible to associate this installation with the hardware of this machine. If selected, the agent will not contact the key manager or use any cryptographic keys if any of this machine's hardware is changed. This can be rectified by running this registration program again. Do you want to enable this functionality? (Y/N) [Y]: Y

10. Type Y to support Filesystem encryption and to choose other features. Type N if you only want to support Ransomware Protection. If you type N, then LDT and COS are not supported.

```
Do you want this host to have Filesystem encryption support enabled on the server? (Y/N) [Y]:
```

11. At the LDT prompt, specify that you want this client to use CTE-LDT by typing **Y** and pressing Enter:

```
Do you want this host to have LDT support enabled on the server? (Y/N) [N]: Y
```

12. If you are planning to create GuardPoints on NFS shares, enter the name of the LDT Communication Group that this node will join.

```
Enter the LDT Communication Group name: LCG1
```

Warning

The registration token, profile name, client group name and LDT Communication Group name are case-sensitive. If any of these are entered incorrectly, the client registration will not succeed. If the registration fails, click Back in the installer and verify that the case is correct for all entries on this page.

13. The installation checks for Confidential Computing adapter types. If it finds one, it states:

```
The following confidential computing adapter types have been identified.
1. Intel Trust Domain Extensions (tdx)
Do you want this host to have confidential computing enabled? (Y/N) [N]:
```

Type **Y** to enable Confidential Computing.

14. At the Cloud Object Storage (COS) prompt, specify whether you want this client to use CTE COS.

```
Do you want to configure this host for Cloud Object Storage? (Y/N) [N]:
```

15. Specify if you want to enable Ransomware Protection.

```
Do you want this host to have Ransomware Protection support enabled on the server? (Y/N) [N]:
```

16. CTE finishes the installation and registration process.

```
Generating key pair for the kernel component...done.
```

```

Extracting SECFS key
Generating EC certificate signing request for the vmd...done.
Signing certificate...done.
Enrolling agent with service on 10.3.200.141...done.
Successfully registered the CipherTrust Transparent Encryption CTE Agent with
the CipherTrust Manager on 10.3.200.141.

Installation success.

```

- In CipherTrust Manager, change the client password using the manual password creation method. This password allows users to access encrypted data if the client is ever disconnected from the CipherTrust Manager. For details on changing the password, see the CipherTrust Manager documentation.

Silent Installation for CTE or CTE-U on Linux

This section describes how to perform a silent (unattended) installation on CTE or CTE-U on a single host. The silent installation automates the installation process by storing the answers to installation and registration questions in a separate file that you create. It installs CTE/CTE-U on the host, and registers the host with the CipherTrust Manager you specify in the silent installation file. You can also use the silent installation to install CTE/CTE-U, on multiple hosts simultaneously.

Prerequisites

The following prerequisites must be met for CTE/CTE-U to install and register to CipherTrust Manager properly:

- CipherTrust Manager installed and configured. See [CipherTrust Manager Documentation](#) for more information.
- CipherTrust Manager must contain a Client Profile. See [Changing the Profile](#) for more information.
- CipherTrust Manager must contain a registration token. See [Creating a Registration Token](#).
- Optionally, the name of the host group you want this client to be a part of.

Procedure

- Log on as an administrator to the host where you will install CTE/CTE-U.
- Create a parameter file and store it on your system, or copy an existing file from another location. The file can contain any of the following parameters:

Parameter	Description
AGENT_HOST_NAME	FQDN of the host on which the CTE Agent is being installed. If this value is not specified, the installer uses the host's IP address.
AGENT_HOST_PORT	Specifies the port number for this CTE Agent to use.
AGENT_USEIP	Use the IP address of the protected host instead of

Parameter	Description
	host name. Used when hostname is not supplied.
CA_CERT	Set to provide CA certificate data to CipherTrust Manager.
CA_FILE	Set to provide a CA certificate file to CipherTrust Manager.
CERT_FIELD_PARAM	Installer option. Default behavior is to use hard-coded values for Root Certificate fields. Uses the same <code><Certificate Parameters></code> string format as is used in the voradmin command <code>voradmin cos ca_cert create <Certificate Parameters></code>
ENABLE_CLOUD	Set to enable cloud in the Key Manager.
ENABLE_HOST_CHECKS	When using CipherTrust Data Security Platform Services (CDSPaaS), set this value to 1 to enable SSL certificate host name checks. Set to 0 to disable. Default: 0 . This also forces CTE to enable the verify peer feature during registration. Use only when the CDSPaaS web server certificates contain the target DNS name or IP address.
ENABLE_LDT	Set this value to 1 to automatically enable and register CTE-LDT (Live Data Transformation) for this host on your key manager during the silent install.
HOST_DESC	Specifies a description for the host. This description is displayed in the CipherTrust Manager. If an entry for this host already exists, and the host already has a description, CipherTrust Manager
HOST_GROUP	Specifies the optional host/client group with which this host/client will be associated.
HOST_PROFILE	Specifies the client profile in the CipherTrust Manager that will be associated with this client. If this value is omitted, the CipherTrust Manager uses the default client profile.
LDTGROUP_NAME	Set the LDT Communication Group for LDT over NFS/ CIFS.
REG_TOKEN	The registration token for the CipherTrust Manager with which you plan to register this client. Required for registration.
ENABLE_RWP	Enable Ransomware Protection.
SERVER_HOSTNAME	Required if you want to register CTE with a CipherTrust Manager.
SERVER_IP	Alternative for hostname when registering.
TMPDIR	Specifies a custom temporary directory that the installer can use during the installation process. If this value is omitted, the installer uses the default temporary directory.

Parameter	Description
USEHWSIG	Set this value to 1 when you want to associate this installation with the machine hardware for cloning prevention.

Example 1: Registering with CipherTrust Manager

The following example contains just the required information for registration with CipherTrust Manager. In this case, the client will be registered with the CipherTrust Manager using its IP address instead of its host name:

```
SERVER_HOSTNAME=Key-Mgmt-Server.example.com
REG_TOKEN=12345
AGENT_HOST_NAME=10.192.80.86
```

Example 2: Registering with CipherTrust Manager

The following example specifies the required registration information, adds a host name and description, enables hardware association, and CTE-LDT. In this case, the client will be registered with the CipherTrust Manager using its host name instead of the IP address:

```
SERVER_HOSTNAME=Key-Mgmt-Server.example.com
REG_TOKEN=12345
AGENT_HOST_NAME=myagent.example.com
HOST_DESC="West Coast Server 12"
USEHWSIG=1
CERT_FIELD_PARAM="/C=US/ST=California/L=San Jose/O=Thales eSecurity/OU=Vormetric
s/CN=localhost/emailAddress=admin@thalesgroup.com"
SUBJECT_ALT_NAME_PARAM="DNS:www.thalesgroup.com,email:admin@thalesgroup.com"
```

1. Copy or mount the installation file to the host system. The installation file is in the format:

CTE

```
vee-fs-<release>-<build>-<system>.bin
```

CTE-U

```
cte-fuse_<version>.<build>_<processor>.rpm
```

2. Run the installer using the following syntax:

CTE

```
./vee-fs-<release>-<build>-<system>.bin [-d <custom-dir>] -s <install-file>
```

where:

- **-d <custom-dir>** is an optional parameter that specifies the installation directory for CTE. If you omit

this parameter, CTE is installed in: `/opt/vormetric/DataSecurityExpert/agent/`

- `-s <install-file>` indicates that you want to install CTE silently using the installation options file `<install-file>`

For example, if the installation options file is called `/tmp/unattended.txt`, you would enter:

```
./vee-fs-7.8.0.75-rh8-x86_64.bin -s /tmp/unattended.txt
```

CTE-U

```
rpm -i cte-fuse_<version>.<build>_<processor>.rpm
```

- Invoke Registration for CTE-U:

```
/opt/vormetric/DataSecurityExpert/agent/vmd/bin/register_host silent <silent_reg_file>
```

Note

You can also invoke registration by replacing 'register_host' with the following two options:

- `REG_HOST_CLEAN`: Register and remove certificates used for communication
- `REG_HOST_SILENT_<fileName>`: Use silent/non-interactive mode; get name=value input from

3. Verify the installation by checking the CTE/CTE-U processes on the host:
 - Run `vmd -v` to check that the version of CTE/CTE-U matches that just installed.
 - Run `vmsec status` to display CTE kernel status. (CTE only)
 - Look at the log files in `/var/log/vormetric`, especially `install.fs.log.<date>` and `vorvmd_root.log`.
4. In CipherTrust Manager, change the client password using the manual password creation method. This password allows users to access encrypted data if the client is ever disconnected from the CipherTrust Manager. For details on changing the password, see the [CipherTrust Manager documentation](#).

Validating CM and CTE with a Local CA Certificate

Note

This feature is not compatible when using CipherTrust Transparent Encryption with CipherTrust Data Security Platform Services (CDSPaaS).

To ensure that registration by the CTE agent is serviced only by the expected key manager, you can provide a copy of the root CA certificate that will be used to authenticate the TLS communications with the key manager, during the registration process.

Note

This feature is not compatible when using CipherTrust Transparent Encryption with CipherTrust Data Security Platform Services (CDSPaaS).

Note

You can only download the CA certificate when you are a root user in the root domain. You cannot download the certificate from a subdomain. It will not work.

Prerequisite

Make sure that you have previously [created the client](#) in CipherTrust Manager.

Using a Local CA Certificate

1. Extract the root CA certificate from the CipherTrust Manager.
 - a. Log on to CipherTrust Manager as an administrator.
 - b. In the left navigation pane, click **CA > Local**. The list of available CAs displays.
 - c. Click the ellipsis icon corresponding to the CA.
 - d. Click **Download** to download the CA.
 - e. Copy the certificate to a directory on the agent system.
2. Present the root certificate data to CTE in one of two ways:
 - a. Use a file:

When written to a file, it must be in PEM file format, starting and ending with:

```
-----BEGIN CERTIFICATE-----
-----END CERTIFICATE-----
```

- b. Use a a string parameter:

If you are providing the information in a single string, it must contain the same data as in the preceding case, except that all new lines are replaced by `\n` escape sequences. For example:

```
CA_CERT=-----BEGIN CERTIFICATE-----\n -----END CERTIFICATE-----\n
```

3. To install the root certificate into the CTE client:

```
/opt/vormetric/DataSecurityExpert/agent/vmd/bin/register_host.exe -s <Path-to-install-file> AGENT_HOST_NAME=<Hostname-or-IP-of-agent> REG_TOKEN=<CM registration token> CA_FILE=<Path-to-root-ca-cert>
```

Example

```
/opt/vormetric/DataSecurityExpert/agent/vmd/bin/register_host.exe -s /opt/silent/vte_reg_log.txt AGENT_HOST_NAME=ani-vm-217-35190.sjcicd.com REG_TOKEN=mMEz3Y60b9D4L7QuvK5S0mhulRm8DYI8odV5j30dVuHqk6LhZqE0FeIZHILYtmDiE9 CA_FILE=/cert_files/Austin175.pem
```

4. Confirm in CipherTrust Manager that the client is registered and healthy.

Using external certificates for communication between CTE Agent and CipherTrust Manager

Note

This feature is not compatible when using CipherTrust Transparent Encryption with CipherTrust Data Security Platform Services (CDSPaaS).

Overview

Use for communication between CTE and CipherTrust Manager. Install the external certificate before registering CipherTrust Transparent Encryption with CipherTrust Manager.

Prerequisites

The external certificate must be:

- On the file system
- In PEM format

A key pair must already exist for the client:

- Must have Encryption type of either:
 - sha256WithRSAEncryption
 - ecdsa-with-SHA384
- Must be Encrypted with a pass phrase

Initial setup

1. Obtain your external CA certificate.
2. Create a certificate using the external CA certificate and key.

CipherTrust Manager Setup

To setup CipherTrust Manager to communicate through an external certificate:

1. Import the CA certificate into the CipherTrust Manager, click **CA > External > Add External CA**.

Note

In the Add External CA dialog, copy and paste the `<ca_certificate_name>.pem` file content from the UI page and provide a user-friendly name.

For more information, see [Using an Externally Generated Server Certificate for an Interface](#)

2. Add the CA certificate to the list of trusted sources for the web interface, click **Admin Settings > Interfaces > web > Edit > External Trusted CAs**.
3. Restart the web server, click **Admin Settings > Services > web > Restart**.
4. [Create a Registration Token](#) for the CTE agent.

CTE Agent setup

1. Create a directory on the system to hold the required files, for example:

- `/root/cert_files` (**Linux/AIX**)
- `c:\temp\cert_files` (**Windows**)

2. Copy or create the following files in this directory:

- `client_cert.pem`
- `client_key.pem`
- `passphrase` - this is currently expected as plain text

3. For **Linux/AIX** systems, to add the directory path to the environment, type:

```
$ export EXTERNAL_CERT_DIR=/root/cert_files
```

4. For **Windows** system, invoke `registerhost.exe` from the command line and add this argument:

```
c:\> register_host.exe -extcertdir=c:\temp\cert_files
```

5. Register the CTE client with the CM server as normal. If this is being done as part of an installation, then the above steps should be done before the installation, or, on windows, added to the registration parameters passed to the installer.

Post Registration

During registration, the certificate file is uploaded to the CipherTrust Manager, and the certificate and key files are imported into the CTE pem store. The key is decoded using the provided passphrase, then re-encoded using a random key using the normal CTE key security mechanisms for TLS keys. There is no need to keep the input files after registration is successful, so for security reasons they should be removed / shredded.

Certificate Renewal

The location of the external certificate files (i.e. the `EXTERNAL_CERT_DIR` or `-extcertdir` parameters) will be recorded in the CTE agent configuration file, `agent.conf`. When the current certificate is approaching expiration date (i.e. approx. 60 days prior to expiration) the CTE agent will look in this directory for an updated set of files.

If a new certificate file is present, then the file will be read and pushed to the CM, and if accepted, then the certificate and key will be imported into the CTE pem store, and the VMD process restarted to use the new certificate.

If no new certificate is present, a **WARNING** level message will be written to the logs and/or uploaded to the CM as per the logging settings, and the CTE agent will check again after 24 hours.

If the user wishes to change the directory path to store the new certificates, then the entry in the `agent.conf`

file should be updated and the vmd service restarted. Alternatively, the user can update the external certificate set using the following command (this will not update the saved path):

```
# vmutil -a vmd -d <ext_cert_Dir> updatecerts
```

If the user fails to update the certificate set prior to expiration then communication with the CM may be blocked, and re-registration will be required.

Note

Any renewed certificates must have exactly the same common name field as the original certificate, or the CipherTrust Manager will reject the update.

Installation and Registration Options

CTE provides the following installation and registration options. The options you choose determine the information you need to supply during the actual install procedure.

Installation Method Options

There are two methods for installing CTE on Linux platforms:

- **Typical:** Most common and recommended type of installation. Use this method for installing the CTE Agent on one host at a time. See [Interactive Installation on Linux](#).
- **Silent:** Create pre-packaged installations by providing information and answers to a set of installation questions. Use silent installations when installing on a large number of hosts. See [Silent Installation on Linux](#).

Hardware Association (Cloning Prevention) Option

CTE's hardware association feature associates the installation of CTE with the machine's hardware. When enabled, hardware association prohibits cloned or copied versions of CTE from contacting the key manager and acquiring cryptographic keys. Hardware association works on both virtual machines and hardware clients.

You can enable hardware association during CTE registration process. You can disable hardware association by re-running the registration program.

To verify if hardware association (cloning prevention) is enabled on a Linux host, on the command line enter the following:

```
cat /opt/vormetric/DataSecurityExpert/agent/vmd/etc/access
```

If you see `usehw:true`, then hardware association is enabled. If you see `usehw:false`, it's disabled.

Guarding a Device with CipherTrust Manager

After you register a client with a CipherTrust Manager, you can create as many standard GuardPoints on the client as you need. These GuardPoints can protect an entire device or individual directories.

Note

For guarding using LDT on a local drive, or on a CIFS/Share drive, refer to [CTE-Live Data Transformation with CipherTrust Manager guide](#).

In order to guard a device or directory, you need to use the CipherTrust Manager Console to:

1. Access the CipherTrust Manager domain in which the client is registered.
2. Identify or [create an encryption key](#) that CTE will use to encrypt the data on the device or directory.
3. Identify or [create a policy](#) for the device or directory that specifies the access controls and the encryption keys to use for the device or directory.
4. [Assign a GuardPoint](#) to the device or directory.

The following example creates a simple policy and uses it to guard a directory on a registered client. For all of the following procedures, you must be logged into the CipherTrust Manager Console as a CipherTrust Manager Administrator, and you must be in the domain with which the client is registered.

For details about any of these procedures or the options for domains, encryption keys, policies, and GuardPoints, see the CipherTrust Manager documentation.

Access the CipherTrust Manager Domain

1. In a web browser, navigate to the URL of the CipherTrust Manager Console you want to use and log in with CipherTrust Manager Administrator credentials.
2. If the client you want to protect is registered to the default domain (root), proceed to [Create an Encryption Key](#). If you need to change to a different domain, do the following:
 - a. In the top menu bar, click the user name **root/admin** on the right-hand side.
 - b. Select **Switch Domains**, then select the domain in which the client is registered.
 - c. The logged in user now shows the new domain name/user name.

Create an Encryption Key

Note

The following procedure is based on CipherTrust Manager version 2.2. If you are using a different version, see the CipherTrust Manager documentation for the version that you are using.

1. From the Products page in the CipherTrust Manager Console, click **Keys** in the left hand pane.

Tip

To navigate to the Products page from anywhere in the CipherTrust Manager Console, click the App Switcher icon in the top left corner.

2. Above the Key table, click **Create a New Key**.
3. In the **Key Name** field, add a name for the key. This name must be unique. For example, Simple-Key.
4. In the **Key Usage** section, make sure **Encrypt** and **Decrypt** are selected.
5. Click **Create**. CipherTrust Manager displays the properties for the new key.
6. In the general options area, enable the **Exportable** option.

You can also enable the **Deletable** option in this section if you want a CipherTrust Manager Administrator to

be able to delete the key.

ID	2e58c582...61136313	Owner	Global	Object Type	Symmetric Key
UUID	e3ad9c3e...7047711	Created	05 Mar 2021, 05:13	Algorithm	AES
MUID	e3ad9c3e...f6333c9f	Last Modified	05 Mar 2021, 05:13	Size	256
KeyID	N/A	Exportable	☒	Deletable	☐

7. In the **Key Access** section, do the following:

a. In the Search Groups box, type "cte".

If no groups are displayed, make sure the **Added Only** option is *disabled*.

b. Click the **All** check box for both the CTE Admins and CTE Clients groups.

KEY ACCESS

Key Owner

2 Results | 2 groups

☐ Added Only

Group	Read	Use	Decrypt	Encrypt	Sign	Sign/Verify	Export	All
CTE Admins	☒	☒	☒	☒	☒	☒	☒	☒
CTE Clients	☒	☒	☒	☒	☒	☒	☒	☒

c. When you are done, click **Update**.

8. Click the **CTE** tab and set the following properties:

- **CTE Versioned:** Specify whether the key is versioned. By default, the key is set as versioned.

For a standard policy, you should clear this check box. If you do not, the key will *not* appear in the keys list when you add the key rule to the standard policy.

- **Persistent on Client:** Specify whether the key is stored in persistent memory on the client.

When the check box is selected, the key is downloaded and stored (in an encrypted form) in persistent memory on the client.

When the check box is left clear, the key is downloaded to non-persistent memory on the client. Every time the key is needed, the client retrieves it from the CipherTrust Manager. This is the default setting.

- **Encryption Mode:** Encryption mode of the key. The options are:

- CBC

- CBC-CS1
- XTS

Encryption using the XTS and CBC-CS1 keys is known as enhanced encryption.

When you are done, click **Update**.

Create a Standard Policy

1. In the Applications page of the CipherTrust Manager Console, select the **Transparent Encryption** application.
2. In the sidebar on the Clients page, click **Policies**.
3. Click **Create Policy**. CipherTrust Manager displays the Create Policy Wizard.
4. On the General Info page, set the following options:

Field	Description
Name	A unique name for the policy. Make sure you use a name that is descriptive and easy to remember so that you can find it quickly when you want to associate it with a GuardPoint. This example uses "Simple-Policy".
Policy Type	The type of policy you want to create. In this example, we will create a Standard policy.
Description	A user-defined description to help you identify the policy later. For example: Standard policy for new GuardPoints.
Learn Mode	Learn Mode provides a temporary method for disabling the blocking behavior of CTE/LDT policies. While useful for quality assurance, troubleshooting, and mitigating deployment risk, Learn Mode is not intended to be enabled permanently for a policy in production. This prevents the policy Deny rules from functioning as designed in the policy rule set. Ensure that the policy is properly configured for use in Learn Mode. Any Security Rule that contains a Deny effect must have Apply Key applied as well. This is to prevent data from being written in mixed states, resulting in the loss of access or data corruption. Apply Key will have no effect when combined with a

Field	Description
	Deny rule unless the policy is in Learn Mode.
Data Transformation	If you select Standard as the policy type, also select the the Data Transformation option to tell CTE that you want to change the current encryption key used on the data in the GuardPoint, or that you want to encrypt clear-text data for the first time. This option is only displayed for Standard policies.

When you are done, click **Next**.

- On the Security Rules page, define the security rules that you want to use.

CipherTrust Manager automatically adds a default security access rule with an action of **key_op** and the effects **Permit** and **Apply Key**. This rule permits key operations on all resources, without denying user or application access to resources. This allows it to perform a rekey operation whenever the encryption key rotates to a new version.

To add additional security rules, click **Create Security Rule** and enter the requested information. For details about adding security rules, see the CipherTrust Manager documentation.

When you are done, click **Next**.

- On the Create Key Rule page, click **Create Key Rule** and enter the following information:

Field	Description
Resource Set	If you want to select a resource set for this key rule, click Select and either choose an existing resource set or create a new one. Resource sets let you specify which directories or files will either be encrypted with the key or will be excluded from encryption with this key.
Current Key Name	Click Select to choose an existing key or create a new one. If the data has not yet been encrypted, select clear_key. Otherwise select the name of the non-versioned key that is currently being used to encrypt the data. In this example, select clear_key.
Transformation Key Name	Click Select to choose an existing versioned key or to create a new one. CTE uses the versioned key specified in this field to encrypt the data in the GuardPoint. If the data is

Field	Description
	currently encrypted, CTE decrypts it using the key specified in the Current Key Name field and re-encrypts it using the key specified in this field.

When you are done, click **Next**.

- On the Data Transformation page, click **Create Data Transformation Rule** and enter the following information:

Field	Description
Resource Set	If you want to select a resource set for this key rule, click Select and either choose an existing resource set or create a new one. Resource sets let you specify which directories or files will either be encrypted with the key or will be excluded from encryption with this key.
Transformation Key Name	Click Select to choose an existing key or to create a new one. CTE uses the key specified in this field to encrypt the data in the GuardPoint. If the data is currently encrypted, CTE decrypts it using the key specified in the Current Key Name field and re-encrypts it using the key specified in this field. For this example, select the key Simple-Key you created in Create an Encryption Key.

When you are done, click **Next**.

- Click **Next**.
- On the confirmation page, review the information for the policy and click **Save**.

Create Policy ✕

[Back](#)
[Save](#)

Create a GuardPoint

- Stop all applications that are accessing the device you want to protect. In this example, we are going to protect the following directories with the same policy and encryption key.
 - /dir/hr/files
 - /dir/accounting/files
 - /dir/shared/hr
 - /dir/shared/accounting

Tip

If you want to encrypt data without taking the device offline, you must use CipherTrust Transparent Encryption - Live Data Transformation.

- In the Applications page of the CipherTrust Manager Console, select the **CTE** application.

3. In the Clients table, click on the name of the client you want to protect.
4. Above the GuardPoints table, click **Create GuardPoint**.
5. In the Create GuardPoint page:
 - a. In the **Policy** field, select the policy you created earlier.
 - b. In the Type field, select the type of device. You can guard a directory or a raw/block device. For this example, select **Auto Directory**.
 - c. In the **Path** field, enter the directories you want to protect with this policy or click **Browse** to select them from a explorer window.

If you want to enter multiple paths, put each path on its own line. For example:

- d. Click **Create**.
- e. If you want to use the same policy and GuardPoint type on another path, click **Yes** when prompted. Otherwise, click **No**. For this example, click No.

The CTE clients pull the GuardPoint configuration information from the CipherTrust Manager.

6. Type the following to transform the data:

```
dataxform --rekey --print_stat --preserve_modified_time --gp <pathToGP>
```

When the data transformation has finished, applications can resume accessing the now-protected data. (See the [CTE Data Transformation Guide](#) for more information.)

Ransomware Protection

- [Ransomware Protection Overview](#)
- [Creating GuardPoints](#)
- [Use Cases for Ransomware Protection](#)

Ransomware Protection Overview

Compatibility

Operating System	CipherTrust Manager version
Ransomware Protection for Windows	v2.12 and subsequent versions
Ransomware Protection for Linux	v2.17 and subsequent versions

Overview

Ransomware is a type of malicious software that is designed to block access to a computer system until a sum of money is paid. CTE for supports detection of Ransomware and protection of sensitive data from Ransomware.

CTE Agent monitors volumes and looks for processes that perform suspicious behavior such as processes that try to encrypt files or open thousands of files. If a process displays suspicious behavior, then it is either audited, which means it is flagged in a log file, or it is blocked. The action taken is pre-configured by the user in the profile linked to the client.

Licensing

Ransomware Protection is supported with RWP-enabled CTE clients. A CTE for Ransomware Protection license must be activated on the CipherTrust Manager to register an RWP-enabled CTE client. Refer to [CTE Licensing Model](#) for details.

Protecting Non-Sensitive Data

Use the Ransomware Protection mode to protect systems that do not contain sensitive data, but have access to your network.

A use case of this scenario is when you have users with laptops who frequently use your network and access servers on it, but they do not have any sensitive data locally on their laptops. A system like this might belong to a salesperson who travels and frequently uses other networks to access the internet. When such users log on to your network, they access the sales network server and upload data to it. They could easily pick up a Ransomware from another network and accidentally upload it to your company's network. Using the Ransomware Protection mode would protect the data on the local volumes, mounted volumes, and the network servers from being infected with Ransomware.

Protecting Sensitive Data

The Ransomware Protection mode protects data on servers and endpoints from Ransomware attacks by auditing

and blocking malicious IPs. Users can strengthen the security posture with CTE access and encryption policies and Ransomware protection for complete control on their data.

To protect sensitive data against Ransomware:

1. Ensure that the CTE Ransomware Protection license is activated and available on the CipherTrust Manager. Refer to [CTE Licensing Model](#) for details.
2. Install the CTE Agent with the Ransomware Protection capability enabled. The Ransomware Protection support uses the same registration process as CTE clients. Refer to [Configuring CTE with CipherTrust Manager](#) for information on installing and configuring CTE Agents.
3. Configure the Ransomware Protection settings in the linked client profile. Refer to [Setting Ransomware Protection Configuration](#) for details.
4. Create a Ransomware Protection GuardPoint on a volume (Windows)|directory (Linux) and on the directory for Linux to be protected. Refer to the [Creating Ransomware GuardPoints](#) for details.

CTE Registration

During CTE registration with CipherTrust Manager, the following question displays:

```
Do you want this host to have Filesystem encryption support enabled on the server? (Y/N) [Y]:
Do you want this host to have Ransomware Protection support enabled on the server? (Y/N) [N]
```

CTE Ransomware Protection can support the following protection modes:

- **Filesystem protection (CTE)**

Allows you to protect and encrypt files with policies **without** Ransomware Protection. (Available if you answer Y to the first question.)

- **Ransomware Protection (RWP)**

CTE is deployed to monitor volumes (Windows)|GuardPoints (Linux), for suspicious behavior from processes, and supports auditing or blocking of the processes while file encryption and protection is not supported. (Available if you answer Y to the second question.)

- **Filesystem and Ransomware Protection (CTE-RWP)**

Protects GuardPoints from Ransomware and allows you to protect and encrypt CTE files with policies. Therefore, all types of GuardPoints are available. (Available if you answer Y to both questions.)

Use Ransomware Protection GuardPoints to monitor or block Ransomware access attempts to a protected GuardPoints on the CTE clients. Note that if the GuardPoint type is "Ransomware Protection Only", Ransomware Protection GuardPoint does not require any policy.

Locking the System after a Ransomware Attack

After enabling Ransomware Protection during installation, turn on the agent lock and the system lock in CipherTrust Manager. The Agent lock protects the CTE Agent files from modification and deletion. The System lock protects a system files from modification and deletion. Agent Lock automatically enables when System Lock enables. You can manually enable or disable the Agent Lock only when the System Lock is disabled.

Make sure that no one is currently accessing the Agent installation directories while applying the locks.

To apply the locks:

1. In CipherTrust Manager, open the **Transparent Encryption** application.
2. Click on the **Client Name** or **Client Group Name**.
3. On the lock bar, click **Agent Lock**.

4. Click **System Lock**.

5. Click **Apply**.

Reference Information

- [Setting Client Locks](#)

Disabling Ransomware Protection

To disable Ransomware Protection for all GuardPoints on the clients linked with a profile.

1. In CipherTrust Manager, open the **Transparent Encryption** application.
2. In the left pane, click **Settings > Profiles**.
3. Under **Name**, click the desired profile.
4. Expand **RANSOMWARE PROTECTION CONFIGURATION**.
5. Select the **Operation** to **Disable**.
6. Click **Update**.

Creating GuardPoints for Ransomware Protection

Steps to create GuardPoints on individual clients and client groups are similar. GuardPoints can be created on the GuardPoints tab of individual clients and client groups.

To create a Ransomware Protection GuardPoint:

1. In CipherTrust Manager, open the **Transparent Encryption** application.
2. Select the client or client group on which you want to create a GuardPoint.
 - Click an Ransomware Protection-enabled client under the **Client Name** column (**Clients > Clients**). These are the clients with either Ransomware Protection, or CTE Ransomware Protection, protection mode.
 - Click a client group under the **Client Group Name** column (**Clients > Client Groups**).
3. On the **GuardPoints** tab, click **Create GuardPoint**:

Note

Once Ransomware Protection is enabled during CTE registration, Ransomware Protection is applied to all GuardPoints.

Ransomware Protection is supported in 2 Protection Modes:

- **RWP**: In CipherTrust Manager, when creating a GuardPoint, you cannot assign a policy and type is automatically set to Ransomware Protection Only.
- **CTE-RWP**: On clients with **CTE RWP** mode, you can create a Ransomware Protection GuardPoint set to Ransomware Protection Only, as well as other types of GuardPoints that use policies as shown below. In Linux, Ransomware Protection is also available for other GuardPoints if the GuardPoints are set on a directory.

Status	Policy Name	Protected Path	Type	Client Group	Enabled	LEP Progress	Multistep Authentication	
	Active	/usr/bin/cryptolib	Auto Cleaning		Yes	100%		
	Active	/usr/bin/cryptolib	Ransomware Protection Only		Yes	100%		

4. Specify the **Path** to be protected. This is a mandatory field. Options to specify the GuardPoint paths are:
 - **Enter/Browse Path**: Select this option, and enter the path by either typing or clicking the **Browse** button.

Note

- For **CTE Windows**, Ransomware Protection GuardPoints are applied at the volume level. Even if you specify the path of a folder or a file, the GuardPoint will be applied at the volume level.
- For **CTE Linux**, Ransomware Protection is applied at GuardPoint level.
- If you specify a network share, all of the network shares to be mounted subsequently will be protected.
- A CTE client administrator can configure protection of all existing GuardPoints, and those to be added to the client subsequently.
- A maximum of 200 GuardPaths can be specified using the **Enter/Browse Path** option.

Browse Method

- a. Click **Browse** to select the path by browsing the client file system. This method prevents typographical errors and verifies client availability. This is the recommended method to specify individual paths. Note that the client must be registered with CipherTrust Manager in order to browse its file system.
- b. In the **Enter Path** field, specify the path. Alternatively, in the **Select Path** field, select the path from the on-screen file system browser, and click **Select Path**.
- c. Click **Add**.

Manual Method

Alternatively, if you know the path, manually enter path in the given text box. Enter one path per line.

- **Upload CSV**: Select this option and click **Browse** to upload the CSV file containing the list of one or more paths. This is the recommended method to specify a large number of paths in one step.

Note

If a manually entered path does not yet exist, check that you entered the path correctly. The CipherTrust Manager does not parse manually entered paths for correct syntax.

5. Click **Create**. A message appears prompting to confirm the reuse of these GuardPoint settings on another path.
 - Click **Yes** to use the same settings on another path. The Use Settings on Another Path dialog box is displayed. Perform the following steps:

- a. In the **Enter Path** field, specify the path. Alternatively, in the **Select Path** field, select the path from the on-screen file system browser, and click **Select Path**.
- b. Click **Add Path**. The newly added path appears under the Paths list on the left. Similarly, add as many paths as required.
- c. Click **OK**.

- Click **No** if you do not want to use the same settings on another path.

6. Check the GuardPoint status, type:

```
secfsd -status guard
```

Multifactor Authentication for CTE GuardPoints

CipherTrust Transparent Encryption is supporting Multifactor Authentication through integration with an MFA provider. CipherTrust Transparent Encryption will continue to integrate with additional providers and release that information in the future.

Note

Multifactor Authentication for CipherTrust Transparent Encryption Linux is only supported with CipherTrust Manager v2.14 and subsequent versions.

- [Introduction to Multifactor Authentication](#)
- [Set up your account with KeyCloak](#)
- [Use Cases for Multifactor Authentication](#)
- [Exempting some users from authentication with a Whitelist](#)
- [Setting up Multifactor Authentication with a One-Time-Password](#)
- [Setting up Multifactor Authentication with a Time Out](#)
- [Administration for Multifactor Authentication](#)
- [Troubleshooting Multifactor Authentication](#)

Introduction to Multifactor Authentication

Why do companies need Multifactor Authentication

Every day, the threat of ransomware attacks increase in frequency, sophistication, and effectiveness. Victims of

ransomware attacks can be blocked from data, applications, and systems – making an organization unable to function.

Credential compromise is the leading cause of ransomware attacks, because credentials give hackers the access they need to hold your systems hostage. Unfortunately, credentials can be stolen, shared, bought or hacked. Once the hackers gain entry, the threat actors will often look to compromise privileged access credentials to further infiltrate your network and steal sensitive data.

What is Multifactor Authentication

Multifactor authorization ensures that the access credentials presented belong to the actual person. After logging in to the system, when a user tries to access a CipherTrust Transparent Encryption GuardPoint, it triggers a second factor authorization to verify the user with a second form of authentication, like sending a passcode to the users's registered cell phone, that they then have to input into the application.

How does Multifactor Authentication work

The following diagram explains how Multifactor Authentication operates in a CipherTrust Transparent Encryption environment.

OTP (One-Time-Password)

Step	Description
1	A Multifactor Authentication administrator configures the MFA provider to use OTP (one-time password) for CTE multifactor authentication.
2	Multifactor Authentication is performed when either an SSH connection with MFA has already been enabled by a root user using the command <code>voradmin mfa ssh_enable</code> , and a user starts an SSH connection; or after an SSH connection is already established and a user uses the command: <code>voradmin mfa login</code> .

Step	Description
3	A CTE user who has previously registered the CTE site URL with an authenticator application (such as Google Authenticator), running on his/her registered mobile device, uses the authenticator to generate a one time password.
4	CTE user enters the OTP from their mobile phone into CTE.
5	CipherTrust Transparent Encryption sends a message to the Multifactor Authentication provider to verify the user.
6	Multifactor Authentication provider confirms/denies user access.
7	If authenticated using <code>voradmin mfa login</code> , the user's current shell, and all of the programs running inside that same shell, are authenticated. If authenticated during an ssh login, the entire ssh session is authenticated for the user.

Password

Step	Description
1	Multifactor Authentication is performed when either an SSH connection with MFA has already been enabled by a root user using the command <code>voradmin mfa ssh_enable</code> and a user starts an SSH connection, or after an SSH connection is already established and a user uses the command: <code>voradmin mfa login</code> and enters their Multifactor Authentication password.
2	CTE sends a verification request to the Multifactor Authentication.

Step	Description
3	Multifactor Authentication provider confirms/denies user access.
4	If authenticated using <code>voradmin voradmin mfa login</code> , the user's current shell, and all of the programs running inside that same shell, are authenticated. If authenticated during an ssh login, the entire ssh session is authenticated for the user.

Note

Multifactor Authentication is **NOT** supported on RHEL 7 or SLES 12.

For more information on Multifactor Authentication, see [Multifactor Authentication](#).

Using Keycloak for Multifactor Authentication for CTE GuardPoints

Integration with Keycloak requires creating an OIDC connection in CipherTrust Manager, after you create an OIDC template in Keycloak.

Prerequisites

- Have a CipherTrust Manager set up with:
 - Client Profile enabled for Multifactor Authentication
 - Registration token

On the Keycloak platform

The following is the minimum setup for a Keycloak platform. Refer to [Keycloak documentation](#) for more information.

1. Create an admin user.
2. Login to the realm and create one or more users.
3. Create a password for the user.
4. Create an OIDC client in realm with the following settings enabled:
 - **General Settings:**
 - **Client Type:** OpenID Connect
 - **Client ID:** Client name

- **Capability Config:**
 - **Client Authentication:** On
- **Authentication flow:**
 - **Select:** Standard flow and Direct access grants

5. Note three OIDC parameters:

- **OIDC Provider:** `https://<keycloak-name>:<keycloak-port>/realms/<realm-name>/well-known/openid-configuration`
- Client-ID as configured for the OIDC client
- Client-Secret as shown for the OIDC client

Create an OIDC connection on CipherTrust Manager

1. Log on to the CipherTrust Manager GUI as an administrator.
2. In the left pane, click **Access Management > Connections**.
3. In the Connections, click **Add Connection**.
4. Click **OIDC** and then click **Next**.
5. Provide a name for the connection and click **Next**.
6. Enter values for the configuration information.

Note

Refer to your Multifactor Authentication provider profile for the values:

- URL of OIDC provider:

Linux

- For KeyCloak, select the URL of the OIDC provider

Windows

- For Thales SafeNet Trusted Access, select **Well Known Configuration URL**
- For all other providers, select the URL of the OIDC provider
- Client-ID as configured for the OIDC client
- Client-Secret as shown for the OIDC client

7. Click **Next** and in the Add Products window, select **CTE** for product.
8. Click **Add Connection**.

Exempting some users from authentication with a Whitelist

When you activate CTE Multifactor Authentication, all users attempting to log in to the CTE client must successfully pass through CTE Multifactor Authentication to gain entry to the MFA-enabled GuardPoints. However, there are specific exemptions to this rule. Users whose system services, or applications, initiate automatically during system boot-up cannot undergo authentication though CTE Multifactor Authentication, as Multifactor Authentication necessitates user interaction. To accommodate such cases, exempt these users from Multifactor Authentication enforcement within the Client Profile by including them in the user set exemption list. Typically, only system users responsible for running system services are included in this list. However, since many system applications operate under the root user, or even under normal application user accounts, you must also add these system administrator/application users to the list. These users form part of the user set, commonly referred to as a whitelist.

Caution

Be careful when adding a user to the whitelist. The exemption applies for the entire client. Users on this list can bypass Multifactor Authentication and access all MFA-enabled GuardPoints. If a system service, or application, accesses only one GuardPoint among multiple GuardPoints, Thales advises you to leave that specific GuardPoint without Multifactor Authentication enforcement.

Note

You **cannot** share the whitelist between Windows and Linux operating systems. Each client profile must contain a unique Multifactor Authentication whitelist. Therefore, the User Set contains different users in Windows and Linux platforms. A CTE Windows client and a CTE Linux client **cannot** share the same client profile when Multifactor Authentication is enabled.

Creating a User Set

See [Creating User Sets](#) for information on creating a User Set in a Policy Element.

Adding the User Set to the Client Profile

To add an Multifactor Authentication whitelist to the client profile:

1. Create your [Client Profile](#) if it is not already created.
2. Click on your client profile to open it.
3. Click **Multifactor Authentication**.
4. In the **Select OIDC connection** field, select the OIDC connection that you created.

5. In the **Select the MFA exempted User Set** field, select the User Set that contains the people/applications that are exempted from authorization.
6. Click **Update**.

Setting up Multifactor Authentication with a One-Time-Password

CipherTrust Transparent Encryption Multifactor Authentication supports KeyCloak OTP through direct grant flow. This topic explains how to configure OTP support in KeyCloak.

Prerequisites

- [Setup Keycloak](#)

Enabling OTP Authentication in KeyCloak

1. Log in to the KeyCloak Admin Console. See [KeyCloak documentation](#) for more information.
2. Select **Authentication** from the menu for your CTE realm, e.g. cte-linux. This is the area where you can configure the different credential types.
3. Select the Browser Flow:
 - a. Conditional OTP: **Required**
 - b. Condition: User configured: **Required**
 - c. OTP Form: **Required**
4. Modify, clone, or create a new Direct Grant flow:

Option 1:

Modify the built-in direct grant flow, or clone a direct grant flow, by clicking **Action > Duplicate**.

Update the flow as the follows:

- a. Username Validation: **Required**
- b. Password: **Disabled**
- c. Direct Grant: Conditional OTP: **Required**
- d. Condition: User configured: **Required**
- e. OTP: **Required**

Option 2:

Create a new direct grant flow:

- a. Select **Create Flow**
 - b. Fill out the Name and Description
 - c. Select flow type: **Basic Flow**
 - d. Select **Add step**
 - e. Select Username Validation: **Required**
 - f. Select **Add step**
 - g. Select OTP: **Required**
5. Bind the generated direct grant flow to the client defined for CTE Linux:
- a. Choose the client setup for CTE Linux, and select **Advanced**
 - b. Select Browser Flow: **Browser**
 - c. Select Direct Grant Flow: **<the new direct grant>**

Configuring OTP Policy

CTE Linux Multifactor Authentication only supports time-based OTP, which is the default KeyCloak OTP policy. To verify the policy configuration:

1. Navigate to the **CTE realm > Authentication**.
2. Select **Policies > OTP Policy**.
3. Ensure that Time-based is selected.

Note

Counter-based is **NOT** supported with CipherTrust Transparent Encryption.

4. Change other configurations as needed.

Note

Google authenticator only supports the algorithm: **SHA1**.

Setting Up User's OTP Authenticator

1. Add a user that has permissions to access CTE clients.
2. The user must install an authenticator that is able to provide an OTP token on their mobile phone.

Note

Thales recommends using Google Authenticator.

3. Instruct the user to login through a web browser to the CTE realm account. See [KeyCloak documentation](#) for more information.
4. Once authenticated, the OTP token form displays.
5. The user needs to finish the setup of OTP authentication in the OTP token form.

Conclusion

After a successful setup, the local users of the CTE Linux hosts can perform OTP authentication through `voradmin mfa login` or `SSH login`.

Setting up Multifactor Authentication with a Time Out

You can set Multifactor Authentication so that it times out after a specified period. The timeout value for an MFA session is set in minutes. The default is 0, meaning no timeout.

Note

MFA timeout only applies to new processes. Once a process, like Bash, for example, is MFA-authenticated, it does not time out. Additionally, when a timeout value changes, all MFA-authenticated processes remain authenticated. The timeout change does not affect them.

Administrator Tasks for Multifactor Authentication

Note

Root user privilege is required for all commands except for logging in.

Voradmin Commands

The Multifactor Authentication command group contains the following commands:

Syntax voradmin mfa [config | login | ssh_enable | ssh_disable | set_auth | set_timeout]

voradmin mfa config

Displays configuration information.

Syntax

```
voradmin mfa config
```

Response

```
Host Mfa Enable is not set.
MFA enabled guardpath(s) (Number of paths: 2):
    /home/work1/gp_mfa
    /home/work1/gp_mfa
MFA Exempt-List: (Number of entries: 1)
    uid:1001,      gid:1001,      user: "malfoy", group: "wizards", dom
ain(s): ""
OIDC configuration:
    client-id : cte-client-malfoy-1
    url : https://www.keycloak-sj1.org:8443/realms/cte-linux/.well-known/openid-configuration
ssh with MFA : enabled
```

voradmin mfa login

Enables Multifactor Authentication for the current shell, and commands and programs running in that shell, so that it can access MFA-enabled GuardPoints. You must provide a login name and password for Multifactor Authentication enablement.

Syntax

```
voradmin mfa login
```

Response

```
CTE MFA username: #####
CTE MFA password: #####
CTE MFA authentication successful
```

voradmin mfa ssh enable

Enables the option to use Multifactor Authentication once a user has established an ssh login to the current host. After running this command, user is asked if they want to use Multifactor Authentication. Once logged in successfully, user is asked if they want to enable Multifactor Authentication. Once you enable MFA successfully, CTE Agent can access Multifactor Authentication-enabled GuardPoints.

Syntax

```
voradmin mfa ssh_enable
```

voradmin mfa ssh_disable

Disables the option to use Multifactor Authentication once a user has established an ssh login to the current host.

Syntax

```
voradmin mfa ssh_disable
```

voradmin mfa set_auth

Set up the authentication method (either OTP or password) to use during CTE multi- factor authentication. If not setup, users have to choose a method during ssh login or voradmin mfa login.

Syntax

```
voradmin mfa set_auth
```

Response

```
Choose authentication method (type p for password, or o for OTP, default o):`<type p or o>`: o
```

```
MFA authentication method is set.
```

voradmin mfa set_timeout

You can set Multifactor Authentication so that it times out after a specified period. The timeout value for an MFA session is set in minutes. The default is 0, meaning no timeout.

Note

MFA timeout only applies to new processes. Once a process, like Bash, for example, is MFA-authenticated, it does not time out. Additionally, when a timeout value changes, all MFA-authenticated processes remain authenticated. The timeout change does not affect them.

Syntax

```
voradmin mfa set_timeout <minutes>
```

Example 1

```
voradmin mfa set_timeout 5
```

Response

```
MFA session will expire after 5 minute(s).
```

Example 2

```
voradmin mfa set_timeout 0
```

Response

```
Disabled MFA session timeout.
```

Troubleshooting Multifactor Authentication

Multifactor Authentication Client Profile Failed on CipherTrust Manager enrollment**

Switching existing Multifactor Authentication Client Profile using `register_host` failed on CipherTrust Manager enrollment.*

Work-around

- In CipherTrust Manager, change the existing Multifactor Authentication `Select MFA Exempted User Set` parameter to your new target user set

Special Cases for CTE Policies

This section describes some CTE-specific configuration tasks related to configuring policies in the key manager. It contains the following topics:

- [Re-Enabling Automatic Signing for Host Settings](#)
- [Restricting Access Overrides from Unauthorized Identities](#)
- [Blocking ptrace system calls to prevent process injection attacks](#)

Re-Enabling Automatic Signing for Host Settings

Starting with VTE for Linux release 6.0.2, VTE blocks automatic re-signing of the host settings. Some users may have established procedures for updating system software that are based on the assumption that restarting the vmd will generate new signatures when signed software is updated. This is no longer true. However, you can re-enable automatic re-signing if your environment requires it.

Caution

Re-enabling the automatic regeneration of signatures exposes a potential security vulnerability for CTE Agents. When enabled, host setting binaries are re-signed when CTE receives a push from the associated key manager. If an attacker were to replace a binary with a Trojan, and then force a push from the key manager by, for example, restarting the CTE Agent, CTE could generate a signature for the malicious binary and pass it.

To re-enable automatic re-signing for host settings:

1. Change to the directory where the `agent.conf` file resides. For example, type:

```
cd /opt/vormetric/DataSecurityExpert/agent/vmd/etc/
```

2. Edit the `agent.conf` file.
3. Change or add the following line:

```
AUTO_RESIGN_HOST_SETTINGS=TRUE
```

Note

Previously this setting was known as `RE_SIGN_HOST_SETTINGS`. Starting with VTE for Linux 6.1.3, the attribute name is `AUTO_RESIGN_HOST_SETTINGS` as shown above.

4. Save your changes and exit the file.
5. Restart the `vmd` to set the changes. Type:

```
/etc/vormetric/secfs restart
```

6. Type the following to verify that the host settings is set to true:

```
vmsec vmdconfig
```

Restricting Access Overrides from Unauthorized Identities

CipherTrust Transparent Encryption host/client settings are the means by which an administrator configures user authorization. Users with root privileges, on Linux or AIX systems, have the unfettered ability to override all file access and execution permissions imposed by the system.

CipherTrust Transparent Encryption access control allows you to restrict privileges of users, groups, application

processes and binaries, including root users and setuid programs. By default, CipherTrust Transparent Encryption agent **DOES NOT** trust any process as authenticated. Any attempt to access a resource, by any process, will therefore be flagged with a “User Not Authenticated” notification. The CipherTrust Transparent Encryption agent must be instructed to trust the authenticator process progeny. For example, `/usr/sbin/sshd` is a process that can be trusted to authenticate the user to the system and to CipherTrust Transparent Encryption.

In some setups, when editing a host, system administrators can use the **host settings > |authenticator|** feature with **su** to change identities and gain access to restricted data. You can instruct CipherTrust Transparent Encryption to not trust any authentication attempt performed by certain identities by assigning restricted users to a user shell that CipherTrust Transparent Encryption can block from authenticating other processes.

Any executable path that is marked with a `|path_no_trust|` host setting marks the process, and all child processes, as not trusted. Non-trusted processes are treated as “User Not Authenticated” to prevent access on user-based policies.

CipherTrust Transparent Encryption prevents overrides from other host settings authenticators, using the `|path_no_trust|` status. If a user runs the **su** command from a non-trusted shell, that new shell is still marked as `|path_no_trust|`, even if `|authenticator| /usr/bin/su` is specified in the host-settings. The `|path_no_trust|` feature overrides any and all authenticators under host settings.

Note

Using `|trust| *` before a `|path_no_trust|` host setting no longer disables the `|path_no_trust|` host setting.

For example, the following host setting denies authentication for users accessing through `sshd`:

```
|trust|*
|path_no_trust|/usr/sbin/sshd
```

To restrict access overrides:

1. In the CipherTrust Manager products page, click **Transparent Encryption > Clients**.
2. Click on an existing Client name to edit the host.
3. Click **Client Settings** tab.
4. Add the following to the settings:

```
|path_no_trust|<path of the binary>
```

Example:

```
|path_no_trust|/bin/ksh
```

The above example indicates that no process under the kshell executable will be authenticated.

5. Click **Apply**.

Blocking ptrace system calls to prevent process injection attacks

To prevent a process injection attack, which could lead to access to encrypted data by a tampered process, Thales implemented a global blocking for the ptrace system call. The purpose of this feature is to provide configurable options for disabling the ptrace system call based on user need. CTE provides toggle options on CipherTrust Manager based on the dynamic parameter which allows a security administrator to select which binaries are protected from ptrace attachment.

Note

This change can be very invasive and block legitimate uses of the ptrace system call.

Options

There are three new options:

Enabled_For_Authenticators

The CTE binaries and the binaries specified in the authenticator list are protected from the ptrace attachment. Other binaries are not protected from the ptrace attachment. (Default behavior)

Enabled_For_All

All of the installed binaries are protected from ptrace attachment. This protects from a tampered processes causing process injection attacks through the ptrace attach call.

Disabled_For_All

The CTE binaries are protected from ptrace attachment but the binaries specified in the authenticator list are allowed to attach to a ptrace system call. This solves the problem of a user trying to attach a ptrace system call to one of the binaries specified in the authenticator list for other use cases. Other binaries are not protected from the ptrace attachment.

Note

If you select Disabled for All, make sure that you set the log level on CipherTrust Manager to WARN or higher. If it is set to the default log level of ERROR, there will not be any messages related to ptrace logged in the vmd.log file.

Configuration

To configure blocking the ptrace system call:

1. Log on to CipherTrust Manager.

2. Click **Transparent Encryption**.
3. Click on the desired client name to open it.
4. In the **Advanced Security Configuration**, click **View/Edit Settings** link.

5. Select the appropriate option and click **save**.

Logging

This chapter contains the following sections:

- [Setting CTE Agent Logging Preferences](#)
- [Audit Logs](#)
- [Concise Logging](#)

Setting CTE Agent Logging Preferences

You can configure the Agent process information that is entered into the Message Log. You can configure the process information globally, in which all the Agents that are added after the configuration change inherit the log attributes, while all current file system configurations remain intact. Alternatively, you can configure log attributes for individual Agent installations.

Always monitor log generation on new server and agent installations, and after changing logging preferences and options.

A variety of logging services are available and configured in the Log tab.

Logging Services

CTE log data may be sent to various different files such as:

- Sys log files, such as:

```
/var/log/messages
```

```
/var/log/syslog
```

Event log on

Note

The CM domain name can include spaces. However, Syslog does not allow spaces in header fields. Therefore, for Syslog purposes, the CTE client replaces the spaces with an underscore. For example: My_Domain instead of My Domain.

- CTE log files local to the agent, such as:

```
/var/log/vormetric/vorvmd_root.log
```

```
C:\ProgramData\Vormetric\DataSecurityExpert\agent\log\vorvmd.log (Windows)
```

- Uploaded to the Key Manager
- Uploaded to a Syslog server

Data Transformation log files are sent to:

```
/var/log/vormetric/vordxf_path_usr.log
```

Audit Logs

Example audit log:

```
CGP2601I: [SecFS, 0] [AUDIT] Policy[allowAllOps_fs] User[root,uid=0,gid=0\root,bin,daemon,sys,adm,disk,wheel\] Process[/bin/cat] Action[write_app] Res[/opt/apps/apps1/doc/file2.txt] Key[aes128] Effect[PERMIT Code (1U,2U,3R,4M)]
```

Analyzing Audit log entries

The format of a File System Audit log entry is:

```
CGP2602I: [SecFS, 0] Level: Policy[policyName?] User[userID?] Process[command?] Access[whatIsItDoing?] Res[whatIsItDoingItTo?] Effect[allowOrDeny? Code (whatMatched?)]
```

Parameter	Description
Identifier	The TLA for the error message.
SECFS	Indicates that the message was generated by an Agent. You can enter secfs in the Search Message field in the Logs window to display the Agent policy evaluation and GuardPoint activity for all configured hosts.

Parameter	Description
Level	Indicates the importance of the message. For example, AUDIT indicates an informational message, whereas ALARM indicates a critical failure that you should not ignore.
Policy	Indicates the name of the policy that is being used to evaluate the access attempt.
User	Identifies the system user attempting to access data in the GuardPoint. It typically displays the user name, user ID, and group ID.
Process	Indicates the command, script, or utility being executed.
Access	Indicates what access is being attempted. Access may be read_dir, remove_file, write_file_attr, write_app, create_file, etc. These correspond to the Access methods that you configure in the policy. Read_dir corresponds to d_rd. Remove_file corresponds to f_rm, etc.
Res	Indicates the object/resource being accessed by the Process[].
Effect	Indicates the rule that matched and, based upon that rule, whether or not the CipherTrust Manager grants access. Access states may be either PERMIT or DENIED.

File System Audit Log Effects Codes

Codes are provided in the audit logs that identify actions by the policy enforcement engine. The code follows the number of the rule being processed.

Code	Definition
A	The Action component of a security rule failed to match.
M	All security rule components match and, unless overridden, the Effect for that security rule is applied.
P	The Process component of a security rule failed to match.
R	The Resource component of a security rule failed to match.
T	The time specified in the When component of a security rule failed to match.
U	The User component of a security rule failed to match.

Refer to the audit log example above:

- The first and second Security Rules fail because of a mismatch in the User component (1U, 2U).

- The third Security Rule fails because of a Resource component (3R) mismatch.
- All of the rules in the fourth Security Rule match (4M), and the actions defined in the policy, such as use an encryption key, are applied.

Concise Logging

Thales' standard operational logging sends audit messages for each file system operation each time a file is opened, read, updated, or written. Thales's standard logging can generate high volumes of log data. Most of these messages might not be useful or required by security administrators to monitor file system activity on the system.

Agent log data can be stored on the local host, sent to a syslog server, or uploaded to the Management Console. On an agent system, log entries can flood the local messages file or Event Log. Extreme logging can also affect network performance.

Concise Logging eliminates the following types of messages:

- Duplicate audit messages for each and every block read by the user or application. With Concise Logging, CTE only sends an audit message the *first* time a user or application performs a read/write activity. Subsequent read/write activity by that user or application is not logged.
- Audit messages that read the attributes, read the basic information of file-set attributes, and other event-based messages.
- Audit messages for directory open, read directory attributes, and directory close.

Configuring Concise Logging for CTE Clients or Client Groups with CipherTrust Manager

In **CipherTrust Manager > CipherTrust Transparent Encryption > Settings > Profiles**, when you create a Client Profile, you can select to Enable Concise Logging. Then, you can apply that Client Profile to a specific client, or to all clients in a Client Group.

Considerations

- Concise Logging changes the set of log messages that are sent to Security Information and Event Management (SIEM) software systems. If this results in loss of data required for customer reports, then disable Concise Logging.
- Concise Logging is only supported by CTE `secfs`.
- Enable and disable Concise Logging on the client, in the Client Profile. CTE applies it for all users of that Client Profile. There is no finer-grained control, such as per GuardPoint, user, or message type.
- Do not use Learn mode with Concise Logging.

Enhanced Encryption Mode

This section describes the enhanced AES-CBC-CS1 encryption mode for keys. It contains the following topics:

- [Compatibility](#)
- [Disk Space](#)
- [Encryption Migration](#)
- [File Systems Compatibility](#)
- [Container Compatibility](#)
- [Using the AES-CBC-CS1 Encryption Mode in CM](#)
- [Exceptions and Caveats](#)
- [Best Practices for AES-CBC-CS1 Keys and Host Groups](#)

The AES-CBC-CS1 encryption is superior to the existing AES-CBC mode because it uses a unique and unpredictable (random) IV (initialization vector) generated for each individual file. The per-file IV object is generated only at file creation time. It is stored as file metadata.

Note

AES-CBC-CS1 encryption does not require any additional license.

Security Improvements

	AES-CBC	AES-CBC-CS1
Unique IV per-file	No	Yes
IV predictability	Yes	No

File System Support

	AES-CBC	AES-CBC-CS1
Local FS	EXT3/EXT4/XFS	EXT3/EXT4/XFS
Remote FS	NFS3/NFS4/CIFS	NFS3/NFS4
Block Device Support (secdm)	Fully supported	No. When a policy contains a key with CBC-CS1 encryption mode, the guarding fails on the CipherTrust Manager, and an error message displays.

Compatibility

- CTE is backward compatible with, and fully supports, the existing AES-CBC mode for both new and existing datasets.
- CTE fully supports AES-CBC-CS1 encryption for LDT and offline data transformation on CTE Linux environments.

Versions of VTE prior to version 6.1.0 are not backwards compatible with AES-CBC-CS1 encryption. On these earlier versions, attempting to guard a device using a policy containing an AES-CBC-CS1 key will fail.

- Protected hosts supporting AES-CBC-CS1 encryption can be added to host groups.

Difference between AES-CBC and AES-CBC-CS1

The two encryption modes are completely different from a file format standpoint.

- AES-CBC-CS1 encryption only applies to file system directories; AES-CBC encryption applies to both files and block devices.

Note

- If you attempt to use an AES-CBC-CS1 key to guard a block device or partition, the guarding fails with an error reported on the CipherTrust Manager, similar to: Raw or Block Device (Manual and Auto Guard) GuardPoints are incompatible with Policy "policy-xxx" that contains a key that uses the CBC-CS1 encryption mode."

- AES-CBC-CS1 uses cipher-text stealing to encrypt the last partial block of a file whose size is not aligned with 16 bytes.
- Each file encrypted with an AES-CBC-CS1 key is associated with a unique and random base IV.
- AES-CBC-CS1 implements a secure algorithm to tweak the IV used for each segment (512 bytes) of a file.

Disk Space

Files encrypted with AES-CBC-CS1 keys consume additional disk space in contrast to files encrypted with AES-CBC keys. This is because AES-CBC-CS1 encryption requires file IVs to be created and persistently stored in contrast to AES-CBC encryption which does not consume any additional disk storage.

Therefore, administrators need to plan and provision additional disk capacity prior to deploying AES-CBC-CS1 encryption.

	AES-CBC	AES-CBC-CS1
Local Linux (CTE)	No change to file size. No extended attribute allocation	Internal use of extended attribute per file. Extra 4KB increase in file size.
Local Linux (CTE-U)	Internal use of extended attribute per file. Extra 4KB increase in file size.	Internal use of extended attribute per file. Extra 4KB increase in file size.
Remote Linux (CTE)	No change to file size. No extended attribute allocation	Extra 4KB allocation in the form of an embedded header per file. With CTE guarding enabled, file size expansion is hidden.
Remote Linux (CTE-U)	Internal use of extended attribute per file. Extra 4KB increase in file size.	Internal use of extended attribute per file. Extra 4KB increase in file size.

Encryption Migration

You can use either LDT or offline dataxform to:

- Transform data encrypted by AES-CBC to AES-CBC-CS1 and vice versa.
- Transform AES-CBC-CS1 encrypted data to clear contents and vice versa.

File Systems Compatibility

On Linux, you can use AES-CBC-CS1 keys to guard currently supported file systems.

AES-CBC-CS1 encrypted files on Linux remote file systems like NFS and CIFS increase the file size compared to encrypted files on Linux local file systems which retain the original file size.

AES-CBC-CS1 encrypted files on Linux local file systems, in conjunction with LDT policies, can result in additional space consumption. Unlike the current AES-CBC encryption where encrypted files on all file systems, both remote or local, have the same file format, AES-CBC-CS1 encrypted file formats differ based on whether or not they were created on local or remote file systems.

AES-CBC-CS1 files on Linux remote file systems such as NFS and CIFS embed the IV in a 4K-byte header within the file. When these files are guarded, CTE masks the file header -- to applications and system utilities. The expanded file is only apparent when CTE guarding is disabled.

Note

The remote file system must have enough extra space to store the extra 4K bytes of the embedded header. You can run the following script in the GuardPoint to identify how much space to reserve before data transformation:

```
x=$(find . -type f | wc -l); y=$(echo "$x * 4 /1024" | bc); echo ${y}MB
```

File System Requirements

Unlike with AES-CBC encryption, files encrypted with AES-CBC-CS1 on remote file systems cannot be copied over to local file systems in the absence of CTE guarding. Similarly, AES-CBC-CS1 encrypted files on local file systems cannot be copied over to remote file systems in the absence of CTE guarding.

The fundamental reason for this incompatibility is the usage of extended attributes on local file systems to store the IV, in contrast to its storage as a part of the file metadata on remote file systems. This is why files cannot be transferred across these file system boundaries in the absence of CTE guarding.

Storing Metadata

AES-CBC-CS1 encrypted files on Linux store the base IV of a file in either the extended attributes or in the file metadata:

- On local FS (EXT3/EXT4/XFS), Linux saves it as an extended attribute associated with the file. The underlying file system requires that you mount it with the extended attribute mount option.
- On remote FS (NFS and CIFS), Linux saves it in the embedded header of the file.
- For CipherTrust Transparent Encryption UserSpace, all files have an embedded header.

To get the value of the base IV, type:

```
voradmin secfs iv get <file-name>
```

Note

The base IV of a file is protected. It cannot be set/modified/removed by commands and applications. However, if a GuardPoint is unguarded, the files in the GuardPoint are no longer protected. An adversary can then corrupt the content of the files, as well as the IVs.

AES-CBC-CS1 depends on the physical file system's support for extended attributes.

Missing IV file

If the IV for a file is missing, or CTE is unable to read the IV, then CTE denies access to the file. This access denied message may trigger an application to display an error message. This message may vary from application

to application.

HDFS

The AES-CBC-CS1 key is compatible with the current Hadoop File System support.

Backups

Backups and other data protection utilities should take into account the extended attributes present in each AES-CBC-CS1 encrypted file on a Linux local file system to ensure that they are safely backed up. An AES-CBC-CS1 encrypted file whose IV is corrupted, renders the files to be corrupted and therefore unreadable. Hence all data protection software must preserve the file's extended attributes.

CTE Linux can inspect a file's IV using the following command:

```
voradmin secfs iv get file
```

On Linux, the backup utility specified in the guarding policy should automatically backup/restore extended attributes as well. For example, you must use the options to preserve extended attributes when running `cp` or `rsync.normal`.

Due to the different file formats, the backup/restore process across the local and remote file systems are not allowed. If you want to backup a GuardPoint from a local directory, you must restore it to a local directory. If a GuardPoint is backed up on a remote file system, you must restore it to a remote file system.

Backup/Restore Process	AES-CBC	AES-CBC-CS1
General backup utility requirement (all platforms)	Backup utility defined in guarding policy with clear view	Backup utility defined in guarding policy with clear view
Special requirement for backup/restore local fs on Linux	No	Backup utility must be run with user extended attribute enabled
Special requirement for backup/restore remote fs on Linux	No	No
On Linux, backup local fs and restore to remote fs	Allowed	Not allowed, the restored files cannot be accessed with I/O error
On Linux, backup remote fs and restore to local fs	Allowed	Not allowed, the restored files cannot be accessed with I/O error

Container Compatibility

The CBC-CS1 key is compatible with current Docker and OpenShift support.

Using the AES-CBC-CS1 Encryption Mode in CM

When you create a key in CTE, you enable Encryption Mode by selecting CTE Key Properties. See *Creating a New Key* in the [Managing Policies](#) chapter in the [CTE Administrator Guide](#).

Exceptions and Caveats

Note the following when using AES-CBC-CS1 keys.

Ensure User Extended Attributes are Enabled on RHEL 6

On RHEL6, EXT3/EXT4 are not mounted with user extended attributes enabled, by default. If a GuardPoint is on EXT3/EXT4, then remount EXT3/EXT4 with `user_xattr` as an option. Otherwise, guarding fails with the error "Extended attribute not enabled for GuardPoint."

Guarding Existing Files Without Data Transformation

You must convert an existing file with clear text through offline data transformation or LDT. If you do not transform the file, then after you guard using an AES-CBC key, the file displays garbled characters.

If you use an AES-CBC-CS1 key, access to the file is blocked with an I/O error.

Best Practices for AES-CBC-CS1 Keys and Host Groups

In a host group, do not deploy policies associated with AES-CBC and AES-CBC-CS1 keys unless all hosts are running VTE for Linux version 6.1.0 or CTE version 7.0.0 or later.

CTE and systemd

CipherTrust Transparent Encryption (CTE) for Linux is integrated with the `systemd` framework. To ensure that applications start after the CTE agent starts at startup, you must modify `systemd`. This is also true when the CTE agent is started and stopped manually.

This section contains the following topics:

- Overview of CTE and `systemd`
- CTE Agent Control Changes on `systemd`
- CTE Configuration Changes Required on `systemd`
- SystemD Protection
- Manually Stopping an Application or Service

Overview of CTE and systemd

You can use `systemd` to configure dependent applications to start up or shut down in the proper order when CTE starts up or shuts down on a live system. If applications start before CTE starts, those applications may not be guarded. This applies to cases when you manually start or stop the system, such as when you upgrade CTE.

`systemd` replaces `init` in Linux as a system and service manager. Linux inherited `init` from the UNIX System V `init`. `systemd` is a collection of daemons, libraries, and utilities to provide central management and configuration for certain Linux distributions (see [Linux Distributions that Support CTE and systemd](#)). In addition to

providing enhanced features and performance, **systemd** is backwards compatible with System V and Linux Standard Base **init** scripts.

Linux Distributions that Support CTE and systemd

The entries in the following table are Linux distributions that are compatible with CTE. The table shows which distributions implement **systemd**, and those that do not. See the *Compatibility Matrix for CTE Agent with CipherTrust Manager* or the *Compatibility Matrix for CTE Agent with Data Security Manager* for the Linux distributions and kernels supported with your CTE version and key manager.

Distributions that support systemd	**Distributions that do not support systemd
RHEL 8	SLES
SLES 12	
SLES 15	
Ubuntu 20	
Ubuntu 22	

CTE Agent Control Changes on systemd

The commands to start, stop, restart, and check CTE status on **systemd** are shown in the following table:

Command	Command syntax for distributions that support systemd
Start	<code>/etc/vormetric/secfs start</code>
Restart	<code>/etc/vormetric/secfs restart</code>
Stop	<code>/etc/vormetric/secfs stop</code>
Check status	<code>/etc/vormetric/secfs status</code>

The normal states of CTE services on a system with one or more active GuardPoints is the following:

- **secfs-fs**: active (exited) state

Example

To check the status of CTE, type:

```
/etc/vormetric/secfs status
```

Result secfs-fs service: active (running) since Tue 2022-09-27 09:51:04 CDT; 1h 3min ago

CTE Configuration Changes Required on systemd

The following table is a high-level overview of the required changes in **systemd** unit configuration files to control the applications that must be in sync with CTE during system startup and shutdown.

Typical applications that require `systemd` changes include `postgres`, `httpd`, `mongodb`, `mysqld` and `mariadb`. For example, `mongodb` requires that CTE to be running before `mongodb` starts.

Caution

Configuring the dependencies as recommended here mean that whenever you stop CTE or if CTE stops unexpectedly, the dependent applications will automatically stop shortly before CTE stops. Be sure you understand the implications of this behavior on your production environment.

Task	For more information
Compile a list of your applications that use GuardPoints.	See the application examples above.
Shut down the applications that use GuardPoints.	Adding Dependencies to systemd Unit Configuration Files
Add the following lines to the <code>[Unit]</code> section of the <code>systemd</code> unit configuration file for each application: <code>After=secfs-fs-barrier.service</code> <code>Bindsto=secfs-fs-barrier.service</code>	Adding Dependencies to systemd Unit Configuration Files
To the <code>Before=</code> line in the <code>[Unit]</code> section of the <code>secfs-fs-barrier.service</code> file, add the following: <code>saslauthd.service</code> An entry for each application you added to the <code>systemd</code> unit configuration file.	Adding Applications to the secfs-fs-barrier.service File
Add the following lines to the <code>[Unit]</code> section of the <code>saslauthd.service</code> configuration file: <code>Bindsto=secfs-fs-barrier.service</code> <code>After=secfs-fs-barrier.service</code>	Adding Dependencies to the saslauthd.service File
Force the system to read the changed <code>systemd</code> configuration files by typing <code>systemctl daemon-reload</code> .	Adding Dependencies to the saslauthd.service File
Restart the applications that you shut down to make these changes.	Adding Dependencies to the saslauthd.service File

About systemd Dependency Changes for Unit Configuration Files

The previous table describes the effect of the required unit configuration file changes that are described in the following sections. See the [systemd documentation](#) for more information about the `After=` and `Bindsto=` unit configuration options.

Caution

In some cases, the unit configuration file for an application other than CTE may be overwritten when the application is upgraded. After upgrading an application, verify that changes to that

application's unit configuration file are still in place. Changes to the `secfs-fs-barrier.service` file are retained after you upgrade CTE.

The `secfs-fs-barrier.service` service ensures that CTE services and dependent applications start after CTE services and stop before CTE services as needed during system startup, shutdown, and when starting and stopping services on a live system. This special service manages the dependencies between applications and the `secfs-fs`, `secfs-init`, `secfsd`, and `vmd` services that make up the CTE agent:

File and Change	Purpose
File: Application-specific unit configuration file Add this line to <code>[Unit]</code> section: <code>After=secfs-fs-barrier.service</code>	In conjunction with the <code>Bindsto=</code> option, this option ensures that the application starts after the CTE agent on system startup.
File: Application-specific unit configuration file Add this line to <code>[Unit]</code> section: <code>Bindsto=secfs-fs-barrier.service</code>	If the CTE agent shuts down, the application also shuts down.
File: <code>secfs-fs-barrier.service</code> Add each application to the existing <code>Before=</code> line in the <code>[Unit]</code> section. Add <code>saslauthd.service</code> to the existing <code>Before=</code> line in the <code>[Unit]</code> section.	Ensure that the <code>secfs-fs-barrier.service</code> starts before the application services mentioned in the <code>Before=</code>

Location of Application Unit Configuration Files

To configure the proper startup order of services, modify the unit configuration file for applications that require CTE to be running. You must also modify the `secfs-fs-barrier.service` file. The location of these files varies between Linux distributions as described in the following table.

Distribution	Location of systemd unit configuration files
RHEL 8 SLES 12 SLES 15	<code>/usr/lib/systemd/ system/<application_name>.service</code>
Ubuntu 20 Ubuntu 22	<code>/lib/systemd/ system/<application_name>.service</code>

Adding Dependencies to systemd Unit Configuration Files

If your system supports `systemd` (see [Linux Distributions that Support CTE and systemd](#)), before you can safely reboot your protected host or use the files in the GuardPoint, you must perform the following steps to set the proper CTE dependencies for your applications.

1. Compile a list of your applications that use GuardPoints.
2. Prepare users of those applications for the interruption in service required to make these changes.
3. Shut down each of the affected applications.

- For each application, log in as root and open the unit configuration file for that application using a text editor such as `vi`. See the table above to determine the location of the `systemd` unit file.

For example, the unit configuration file for a hypothetical `exampled` application would be located in `/usr/lib/systemd/system/exampled.service`.

- Locate the `[Unit]` area in the file and add the following two lines at the end of the `[Unit]` section:

```
After=secfs-fs-barrier.service
BindsTo=secfs-fs-barrier.service
```

For example, the `exampled` application unit configuration file might have the following existing `[Unit]` section:

```
[Unit]
Description=Example server
After=syslog.target
After=network.target
```

In this case, you would add the two new lines after `After=network.target`.

- Save and close the unit configuration file.
- Repeat steps 3–6 for each application.

Continue to [Adding Applications to the secfs-fs-barrier.service File](#) to make necessary changes to `secfs-fs-barrier.service`.

Adding Applications to the secfs-fs-barrier.service File

After editing the `systemd` unit configuration file for each dependent application, you must also add each application to the `secfs-fs-barrier.service` file that is installed as part of CTE. The `secfs-fs-barrier.service` file ensures that CTE starts before dependent applications during boot and CTE stops before dependent applications when the system is shut down.

- As a root user, open the `secfs-fs-barrier.service` file in a text editor such as `vi`.

For example, the `secfs-fs-barrier.service` file is located in `/usr/lib/systemd/system/secfs-fs-barrier.service`.

- Add `saslauthd.service` along with the names of the unit configuration files that you edited in the last section to the end of the `"Before="` clause.

For example, the `secfs-fs-barrier.service` file might contain the following before editing:

```
Before=postgresql.service httpd.service mongodb.service mongod.service
mysqld.service mariadb.service nails.service
```

To add an entry for `saslauthd.service` and two custom application services called

`example1.service` and `example2.service`, you would edit the `Before=` line to look like this:

```
Before=postgresql.service httpd.service mongodb.service mongod.service
mysqld.service mariadb.service nails.service saslauthd.service
example1.service example2.service
```

3. Save and close the `secfs-fs-barrier.service` file.

In the future, CTE will start before each application listed in the `Before=` line and those applications will stop before CTE stops.

Drop-in Files for systemd

As an alternative to adding applications to the barrier file, you can use drop-in files to configure the `secfs-fs-barrier.service` file for dependency management using `systemd`. This eliminates the need to modify the service file for configuring dependencies.

All drop-in directory files with the suffix `.conf` are merged in alphanumeric order and parsed after the main unit file has been parsed. Each drop-in file must contain appropriate section headers. `Systemd` reads the `.conf` files in the following order.

1. The instance `.d/` subdirectory
2. The template `.d/` subdirectory

The drop-in `.d/` directories for system services can be placed in the following directories:

- `/etc/systemd/system`
- `/usr/lib/systemd/system` (Ubuntu only)
- `/run/systemd/system`

Drop-in files in `/etc/` take precedence over those in the `/run/` directory which, in turn, take precedence over those in the `/usr/lib/` directory. Drop-in files in any of those directories take precedence over unit files wherever they are located. Multiple drop-in files with different names are applied in lexicographic order, regardless of which directories they reside in.

Following is an example of a drop-in file (`dependencies.conf`) for the `secfs-fs-barrier.service`:

```
cat /usr/lib/systemd/system/sec-fs-barrier.service.d/dependencies.conf
[Unit]
Before=mfetpd.service mfeespd.service
```

The above example displays a drop-in file which adds two McAfee related services in the `Before=` clause of the `secfs-fs-barrier.service` file without modifying the service file itself. Eventually, `systemd` detects the drop-in files and links them to the `secfs-fs-barrier.service` file.

Adding Dependencies to the ``saslauthd.service`` File

The `saslauthd` process handles plaintext authentication requests on behalf of the SASL library. It isolates all code

requiring superuser privileges into a single process, and it can be used to provide proxy authentication services to clients that do not understand SASL based authentication.

The `saslauthd` service must start after the `secfs-fs-barrier` service:

1. As a root user, open the `saslauthd.service` file in a text editor such as `vi`.

For example, the `saslauthd.service` file is located in `/usr/lib/systemd/system/saslauthd.service`.

2. Locate the `[Unit]` area in the file and add the following two lines at the end of the `[Unit]` section:

```
After=secfs-fs-barrier.service
Bindsto=secfs-fs-barrier.service
```

For example, the `saslauthd.service` file might have the following existing `[Unit]` section:

```
[Unit]
After=syslog.target
After=network.target
```

In this case, you would add the two new lines after `After=network.target`.

3. Save and close the `saslauthd.service` file.
4. To force the system to re-read the `systemd` configuration files that you changed in this section and the previous section, type `systemctl daemon-reload`.
5. Start each application that you shut down to make the configuration changes.

SystemD Protection

In RedHat 7 and subsequent versions, a lot of system functionality has been moved to `/etc/systemd/` which was previously not protected in CipherTrust Transparent Encryption. CipherTrust Transparent Encryption now gives you the option to protect it, meaning that no one can modify or delete files.

To protect the `systemD` directory:

1. Log on to CipherTrust Manager.
2. Click **Transparent Encryption**.
3. Click on the desired client name to open it.
4. In the **Advanced Security Configuration**, click **View/Edit Settings** link.

Advanced Security Configuration ✕

This screen lists the security configuration parameters that can be updated after CTE client registration. Every parameter has the fixed set of values, as given below.

PTRACE_PROTECTION ☒ Enabled_For_Authenticators ☐ Enabled_For_All
Enable/Disable ptrace capability for installed binaries. ☐ Disabled_For_All

SYSTEMD_PROTECTION ☐ Enabled ☒ Disabled
Enable/Disable systemd config protection.

Cancel Save

5. Select enabled or disabled and click **save**.
6. If you need to add a process to the directory:
 - a. Disable protection.
 - b. Add the file to the `/etc/systemd/` directory.
 - c. Re-enable protection.

Manually Stopping Application or Service

Manually Stop 3rd Party Applications on a Live System

The applications must already be configured as dependencies in the unit configuration files using the `BindsTo` clause (required). For more information, see [Adding Dependencies to systemd Unit Configuration Files](#).

Use the following commands to stop CTE on a live system with dependent applications running.

```
systemctl stop secfs-fs
/etc/vormetric/secfs stop
```

Response

```
Stopping the CipherTrust Transparent Encryption Agent.
Stopping Live Data Transform processes (if any).
WARNING: Following dependent services will be stopped in order to stop secfs serv
ices.
isecesp.service
isectpd.service
mysql.service
These services are required to start manually.
Successfully stopped the Encryption Expert CTE Agent.
```

Warning

- The 3rd party application services using the **BindsTo** clause that automatically stop must be restarted manually after an upgrade.
- Only GuardPoints that are busy due to 3rd party applications are freed using the new use case. Any GuardPoint due to other I/O operations must be stopped manually.

Utilities for CTE Management

Thales provides a variety of utilities that augment the standard Linux utilities. This combination of tools helps administrators manage CTE. The following utilities are described in this section:

- Agent Health Utility
- Agentinfo Utility (Java version)
- Backup Utility
- Check_host Utility
- Displaying Information for Nested File Systems with the DF tool
- Fsfreeze and xfs_freeze (CTE only)
- Protecting Files with Client Settings (CTE only)
- Restricting Access Overrides with Client Settings
- Register_host Utility
- Secfsd Utility
- Using Advanced Encryption Set New Instructions (AES-NI)
- User Cache Lookup Improvements

- Vmutils
- VMD
- Vmsec

Agent Health Utility

The `agenthealth` utility validates:

- Super-user privilege
- CTE Agent installation
- CTE registration to CipherTrust Manager Server
- CTE processes/ modules that are running
- Available disk resources
- Current GuardPoints
- Tests if the agent can reach the GuardPoints
- CTE log directory resource status
- This directory contains pending CTE log files for upload. This utility reports the size and number of pending files for upload. These text files are logs that contain vmd/SecFS information. They are regenerated whenever secfs restarts. If the number of files is unexpectedly large, this can indicate a problem.

The Agent Health check script

By default, the `agenthealth` script is installed in `/opt/vormetric/DataSecurityExpert/agent/vmd/bin`.

To run the `agenthealth` check script, type:

```
./opt/vormetric/DataSecurityExpert/agent/vmd/bin/agenthealth
```

System Response

```
Checking for super-user privilege ..... OK
CipherTrust Agent installation ..... OK
CipherTrust policy directory ..... OK
Registration to server ..... OK
Kernel modules are loaded ..... OK
VMD is running ..... OK
SECFSD is running ..... OK
dsm4209.sjinternal.com is resolvable ..... OK
dsm4209.sjinternal.com port 8446 is reachable .... OK
```

```

dsm4209.sjinternal.com port 8447 is reachable .... OK
Can communicate to at least one server ..... OK
VMD is listening on port 7024 ..... OK
Time of last update from server ..... 2021-07-07 15:47:08.290
Checking available disk space ..... OK
Checking logging space ..... OK
    Log directory is "/var/log/vormetric"
    File system for log data is "/", 48G free (5% full)
    Log directory contains 9 of maximum 200 files (4% full)
    Log directory contains 1 of maximum 100 Mbytes used (1% full)
Testing access to /media ..... OK
Testing access to /usr/data/sub1 ..... OK
[root@agt4206 bin]#

```

Agent Health Return Codes

Previously, the agent health return codes were only available in `/var/log/vormetric/agenthealth.log`. Now, the following options are also available through the help pages:

Help

This agent health script checks various facets of the CipherTrust agent to make sure that everything is functioning properly. Results are also logged to `/var/log/vormetric/agenthealth.log`.

Syntax

```
./opt/vormetric/DataSecurityExpert/agent/vmd/bin/agenthealth --help
```

Return Codes

Use the return code option to get a list of the return codes and what they mean. The codes are returned if the Agent is not running.

Syntax

```
./opt/vormetric/DataSecurityExpert/agent/vmd/bin/agenthealth --return_codes
```

Response

Return Code	Definition
EPERM	User is not root.
ENOENT	One of the programs used in this script does not exist. See <code>/var/log/vormetric/agenthealth.log</code> for which program is missing.
ENOPKG	Agent software is not properly installed. Agent configuration directory is missing or corrupt. See <code>/var/log/vormetric/agenthealth.log</code> for more details.
EPROTO	Agent is not registered to a key manager. Register the

Return Code	Definition
	agent to a key manager and try again. Try the wait option if the agent has never started correctly after registration. See <code>/var/log/vormetric/agenthealth.log</code> for more details.
EIO	Kernel modules are not loaded. To load a kernel module, type: <code>/etc/vormetric/secfs start</code>
ESRCH	VMD is not running. To start vmd manually, type: <code>/usr/bin/vmd</code>
SECFSD	Secfsd is not running. To start the secfsd manually, type <code>/usr/bin/secfsd</code>
EHOSTUNREACH	Unable to reach the Key Manager. Check network connectivity.
ECONNREFUSED	VMD is not listening. VMD did not finish initialization. See <code>/var/log/vormetric/vmd.log</code>
EWOULDBLOCK	VMD is attempting to connect to the Key Manager but has exceeded the designated wait time. Check <code>/var/log/vormetric/vmd.log</code> to fix any issues and retry.

Wait Time

Use `--w` to set a maximum wait time in seconds. The minimum is 10 seconds to test for the VMD to Key Manager initial contact. The default setting is 0, which means that there is no wait. Maximum is 1200 seconds.

Syntax

```
[root@agt4206 bin]# ./opt/vormetric/DataSecurityExpert/agent/vmd/bin/agenthealth
--w <value>
```

Example

```
[root@agt4206 bin]# ./opt/vormetric/DataSecurityExpert/agent/vmd/bin//agenthealth
--w 60
```

Response

```
Checking for super-user privilege ..... OK
CipherTrust Agent installation ..... OK
CipherTrust policy directory ..... OK
Registration to server ..... OK
Kernel modules are loaded ..... OK
VMD is running ..... OK
SECFSD is running ..... OK
dsm148.i.vormetric.com is resolvable ..... OK
dsm148.i.vormetric.com port 8446 is reachable .... OK
dsm148.i.vormetric.com port 8447 is reachable .... OK
Can communicate to at least one server ..... OK
```

```
VMD is listening on port 7024 ..... OK
Time of last update from server ..... 2021-08-18 10:34:56.665
Checking available disk space ..... OK
Checking logging space ..... OK
Log directory is "/var/log/vormetric"
File system for log data is "/", 29G free (23% full)
Log directory contains 1 of maximum 200 files (0% full)
Log directory contains 0 of maximum 100 Mbytes used (0% full)
```

If the customer did not use the wait time options, the output would look similar to the following:

```
/opt/vormetric/DataSecurityExpert/agent/vmd/bin/agenthealth
Checking for super-user privilege ..... OK
CipherTrust Agent installation ..... OK
CipherTrust policy directory ..... OK
Registration to server ..... OK
Kernel modules are loaded ..... OK
VMD is running ..... OK
SECFSD is running ..... OK
Can communicate to at least one server ..... FAILED
For more information consult the log file /var/log/vormetric/agenthealth.log
```

agentinfo Utility (Java version)

The **agentinfo** utility collects system and CTE configuration data. The **agentinfo** utility is used to take a configuration snapshot of the system that you will send to Thales Customer Support to debug an issue, (This section describes the Java version.)

The **agentinfo** utility is a Java Script file. You can open it in a text editor to see specific functions.

The **agentinfo** utility displays status information on the screen and outputs the results to a compressed tar file. The compressed tar file name format is **ai.<os_name_ver>.qa.com.tar.gz** and it is located in the current working directory.

To create an **agentinfo** file, type:

```
/opt/vormetric/DataSecurityExpert/agent/vmd/bin/agentinfo
```

Backup Utility

When a backup is performed, certain files and directories may be protected against access. Therefore, those files and directories are not written to the backup repository. These include files located in Data Transformation GuardPoints or files in GuardPoints with appropriate policies. Additionally, the following files are locked by default by CTE agent:

```
/opt/vormetric/DataSecurityExpert/agent/secfs/.sec/.access
/opt/vormetric/DataSecurityExpert/agent/secfs/.sec/etc/*
/opt/vormetric/DataSecurityExpert/agent/secfs/.sec/pem/*
```

The following describes how to bypass the issue for multiple scenarios:

Agent is installed in the default location

1. Stop SecFS, type:

```
/etc/vormetric/secfs stop           //Linux  
  
/etc/rc.d/rc2.d/S99secfs stop      //AIX
```

2. Run the backup application with the desired arguments.
3. Restart SecFS, type:

```
/etc/vormetric/ start
```

Using a backup image to install to other agents or restore to a different system

Note

When the image is used to reinstall the system, the agent will automatically start at system boot and will attempt to connect to the key manager to which it was originally registered.

To prevent multiple systems with the same agent ID, you must uninstall CTE from the system before running the backup application. The restore/install from the backup will not have an agent running.

1. Uninstall the agent, type

```
/opt/vormetric/DataSecurityExpert/agent/secfs/bin/uninstallsfs
```

2. Run the backup application with the desired arguments.
3. Re-install CTE agent.

Performing a backup while the agent is running

Before running the backup application, add the files that are protected by the agent to the exclusion rules to exclude them from the backup:

```
/opt/vormetric/DataSecurityExpert/agent/secfs/.sec/.access  
/opt/vormetric/DataSecurityExpert/agent/secfs/.sec/etc/*  
/opt/vormetric/DataSecurityExpert/agent/secfs/.sec/pem/*
```

The GuardPoint policy may implement access restrictions which would also cause the backup application to

generate error messages. These GuardPoint/directories will also need to be added to the exclusion rule method to exclude them from the backup. Alternatively, you can temporarily unguard them while the backup application is running.

If the CTE agent reports a status of incomplete in the backup application and does not start properly, or partially starts but generates error messages at system boot time, then uninstall and reinstall the agent. The restore/clone image contains everything needed to uninstall the agent. Use the following command to perform this operation:

```
/opt/vormetric/DataSecurityExpert/agent/secfs/bin/uninstallsfs
```

Backing up Databases after Encryption

After encrypting a database, CipherTrust Transparent Encryption cannot make a backup of the database. Both scheduled and manual backup fail. The problem was the user's policy. A policy used in this scenario must follow a few rules.

With a CBC_CS1 key, a guarded file is modified to have a 4096 byte header holding key information. When an **Apply Key** effect is specified, the CipherTrust Transparent Encryption code adjusts the length and file offset for this header. Without an **Apply Key** effect, the size and access of the offset include the CBC_CS1 header.

Thales recommends that you modify the first rule of your policy. Remove the action entry for `f_rd_att` from the first rule and add a new rule before it:

```
**action**: f_rd_att

**effect**: Permit, Apply Key
```

Policy processing starts with the first rule and continues until a matching rule is found. The effect for the matching rule is then applied.

For the `f_rd_att` action, this results in the secfs code including the CBC_CS1 key header and adjusts the file size value. Without the Apply Key effect, the file size includes the CBC_CS1 header size and the file appears as 4096 bytes larger than its real size.

check_host Utility

If a CTE software installation fails during the certificate generation and exchange stage, use the `check_host` utility to list the network addresses for the host. The utility checks network interfaces, `/etc/hosts`, DNS, and so on, to compare, test, and evaluate possible addresses for the host, and weights them based upon their network efficiency. FQDNs are the most preferred and stand-alone IP addresses are the least preferred. Some applications, such as silent-mode installation, use `check_host` to determine the best host address to submit to the CipherTrust Manager during registration.

Run the `check_host` utility on a system that is hosting CTE to display available network host names, FQDNs, and IP numbers for the host.

Type:

```
/opt/vormetric/DataSecurityExpert/agent/vmd/bin/check_host
```

check_host Syntax

```
check_host [[-h | -i | -a ] [-s name]] |
-l name:port[,name:port] | -r name
```

Syntax	Description
-h	Print the best host name for this machine
-i	Print the best IP address
-a	Print all the host names and IP addresses
-s	The name of the server (optional hint)
-r	The name of the server for name resolution checks
-l	The name and port of the server for listening checks

Displaying Information for Nested File Systems with the DF tool

When a file system mounts on top of another file system, the command `df -a` does not display the attributes for the covered file system.

On Linux environments, this is the expected behavior for any file system that is overlayed by another file system.

The secfs driver properly handles the call, which is made by the `statfs` system call, which is issued by the `df` tool. When the system call returns, its structures are correctly populated with the details of the nested file system. On examining the source of the `df` tool, it is found that when the `-a` switch is on, it nullifies the stats which are received for overlayed mounts. When the `-a` option is not enforced, the stats are maintained.

Issue the `df` command for a specific mount point, for example `df /xfs/nested-xfs` (where `/xfs` is a secfs GuardPoint). It works correctly.

fsfreeze and xfs_freeze

Users can freeze, snapshot, and unfreeze a file system with an SecFS GuardPoint using `fsfreeze|xfs_freeze` for both XFS and EXT3/4.

SecFS supports freezing with `fsfreeze|xfs_freeze` or by any other program issuing the same type of requests. Freezing SecFS results in freezing the underlying file system, as well as the primary file system.

Restrictions

There are restrictions for using `fsfreeze|xfs_freeze` support with CTE.

Platform Restrictions

The following platform restrictions occur with CTE and `fsfreeze|xfs_freeze`:

- CTE supports the `fsfreeze|xfs_freeze` utility for freezing SECFS GuardPoints on all Linux distributions for kernels ≥ 3.0 for Redhat, SLES, and Ubuntu platforms on EXT3/EXT4/XFS file systems. (Earlier Kernels

do not contain the proper freeze_super VFS code).

Target Restrictions

The expected target of the `fsfreeze|xfs_freeze` command is the path of the GuardPoint.

For example, if `/dev/sdb` is mounted as ext4 on `/data` and CTE contains the GuardPoint: `/data/protected`, then the target of `fsfreeze` must be `/data/protected`, not `/data`.

Valid:

```
fsfreeze -f /data/protected
```

Not valid:

```
fsfreeze -f /data
```

File System Restrictions

The following file system restrictions occur with CTE and `fsfreeze|xfs_freeze`:

- If multiple GuardPoints exist on the same file system, you only need to freeze one.

For example, if `/dev/sdb` is mounted as ext4 on `/data` and the CTE GuardPoints are `/data/protected1` and `/data/protected2`, then issuing:

```
fsfreeze -f /data/protected1
```

freezes `/data/protected1`, `/data/protected2` and the underlying ext4 file system.

Caution

Do not unguard a GuardPoint, or restart the CTE Agent, while the file system is frozen. The only action permitted on a frozen file system is taking a snapshot or backing up.

- If you try to freeze `/data/protected2` after freezing `/data/protected1`, it returns as busy
- If you are not permitted to freeze one GuardPoint, then you cannot freeze any GuardPoints

LDT Restrictions

- You cannot freeze a file system while it is undergoing an LDT rekey operation. If it detects a rekey, the freeze returns as busy
- You cannot start an LDT rekey on a frozen file system

Offline Data Transformation Restrictions

Do **NOT** use `fsfreeze` | `xfs_freeze` while an offline transform policy is in effect.

Protecting Files with Client Settings

When any file is now marked as protected (`|protect|`) in the client settings, that file is protected from being modified or deleted, (even from a root process).

Note

The file is not guarded and it can be external to a GuardPoint.

Previously, the only files that were protected were the following:

```
/etc/passwd
/etc/group
/etc/security/passwd
/etc/ssh/sshd_config
/etc/ssh/sshrd
/opt/testfile
```

If the file marked as `|protect|` does not exist, then CipherTrust Transparent Encryption creates a 0-length file in its place. This provides an efficient means to identify and implement file protection. When the agent is stopped or uninstalled, these 0-length files are deleted and then re-created if the agent is restarted. Additionally, an audit record is generated when a file operation is denied.

The `|protect|` status is displayed using `secfsd -status auth`.

Restricting Access Overrides with Client Settings

CipherTrust Transparent Encryption host/client settings are the means by which an administrator configures user authorization. Users with root privileges, on Linux or AIX systems, have the unfettered ability to override all file access and execution permissions imposed by the system.

CipherTrust Transparent Encryption access control allows you to restrict privileges of users, groups, application processes and binaries, including root users and setuid programs. By default, CipherTrust Transparent Encryption agent **DOES NOT** trust any process as authenticated. Any attempt to access a resource, by any process, will therefore be flagged with a "User Not Authenticated" notification. The CipherTrust Transparent Encryption agent must be instructed to trust the authenticator process progeny. For example, `/usr/sbin/sshd` is a process that can be trusted to authenticate the user to the system and to CipherTrust Transparent Encryption.

In some setups, when editing a host, system administrators can use the **host settings > |authenticator|** feature with **su** to change identities and gain access to restricted data. You can instruct CipherTrust Transparent Encryption to not trust any authentication attempt performed by certain identities by assigning restricted users to a user shell that CipherTrust Transparent Encryption can block from authenticating other processes.

Any executable path that is marked with a `|path_no_trust|` host setting marks the process, and all child processes, as not trusted. Non-trusted processes are treated as "User Not Authenticated" to prevent access on user-based policies.

CipherTrust Transparent Encryption prevents overrides from other host settings authenticators, using the `|path_no_trust|` status. If a user runs the `su` command from a non-trusted shell, that new shell is still marked as `|path_no_trust|`, even if `|authenticator|/usr/bin/su` is specified in the host-settings. The `|path_no_trust|` feature overrides any and all authenticators under host settings.

Note

Using `|trust|*` before a `|path_no_trust|` host setting no longer disables the `|path_no_trust|` host setting.

For example, the following host setting denies authentication for users accessing through `sshd`:

```
|trust|*
|path_no_trust|/usr/sbin/sshd
```

To restrict access overrides:

1. In the CipherTrust Manager products page, click **Transparent Encryption > Clients**.
2. Click on an existing Client name to edit the host.
3. Click **Client Settings** tab.
4. Add the following to the settings:

```
|path_no_trust|<path of the binary>
```

Example:

```
|path_no_trust|/bin/ksh
```

The above example indicates that no process under the `kshell` executable will be authenticated.

5. Click **Apply**.

register_host Utility

Use the `register_host` utility to create certificate requests, exchange certificates between the CipherTrust Manager and the host, and to register CTE on the CipherTrust Manager. After the host is registered, you can configure CTE, apply GuardPoints, or perform database backups. Run the `register_host` utility in text mode on a terminal window.

Caution

The default host registration timeout is 10 minutes. If the host is unable to reach the CipherTrust Manager within the allotted period because of an extremely slow network connection, set the **REGISTER_HOST_TIMEOUT** environment variable to extend the registration timeout. The variable value is an integer expressed in seconds. You might also have to extend the default TCP timeout.

secfsd Utility

The **secfsd** utility displays the following attributes of CTE:

- GuardPoints defined in the **GuardPoints*
- Authentication parameters defined in the *Host Settings* tab
- Lock status set by enabling **FS Agent Locked** and **System Locked**
- Web destination and SSL certificate for uploading log entries
- Policies applied in the **GuardPoints** tab
- Status of required processes (**secfsd** and **vmd**)
- Version of **secfs**

The **secfsd** utility is also used to mount GuardPoints for **Directory (Manual Guard)**. Normally, CTE automatically mounts the **secfs** file system when you apply a GuardPoint to a directory. On Linux, the **secfsd** utility is located in `<install_dir>/secfs/.sec/bin` and a symbolic link to this file is placed in `/usr/bin/secfsd`.

secfsd syntax

Command	Description
<code>-help</code>	display secfsd options

Status Options

Command	Description
<code>-status guard [-v -tree]</code>	list all GuardPoints
<code>-status keys</code>	show current encryption key state
<code>-status auth</code>	list authentication settings
<code>-status lockstat</code>	show CTE lock status
<code>-status logger</code>	list logging details

Command	Description
<code>-status policy</code>	list configured policies
<code>-status pslist</code>	list protected processes
<code>-status devmap</code>	list guarded devices

Manual GuardPoint options

Command	Description
<code>-guard path [container ID]</code>	manually guard path
<code>-unguard path [container ID]</code>	manually unguard path

Version option

Command	Description
<code>-version</code>	list version of kernel module <code>secfs2</code>

** Encryption Mode option information**

Command	Description
<code>crypto</code>	Displays the encryption modes that are supported.

** Configuration Mode option information**

Command	Description
<code>config <config_param> <value></code>	Displays the encryption modes that are supported.

secfsd Examples

Display GuardPoint Information

To display the GuardPoint paths, applied policies, policy type, and guard status, use the `secfsd -status guard` command. For example:

```
secfsd -status guard
```

GuardPoint	Policy	Type	ConfigState	Status	Reason
-----	-----	----	-----	-----	-----
/opt/apl/lib	allow AllOps_fs	local	guarded	guarded	N/A
/dev/sdb	watchaccess_rd	rawdevice	guarded	guarded	N/A
/dev/sdc	watchaccess_rd	manualrawdevice	guarded	guarded	N/A
/dev/sdd	watchaccess_rd	manualrawdevice	unguarded	not guarded	Inactiv
e					
/opt/apl/tmp	MSSQL00123	manual	unguarded	not guarded	Inactiv
e					

Column	Description
GuardPoint	Full path of the GuardPoint.
Policy	Name of the policy applied to the GuardPoint.
Type	Can be local, automount, manual, raw device, or manual raw device. Configured in the GuardPoints tab.
ConfigState	Guard status of the GuardPoint, as recognized by the key manager. It can be guarded or unguarded.
Status	Current guard status, as recognized by CTE. State can vary.
Reason	Additional information about the status, if any.

Note

- Config State and Status can vary. As an example, if you apply a GuardPoint and someone is currently working in the GuardPoint, the policy cannot be applied at that time. In this case, the ConfigState is guarded and the Status is not guarded.
- When the user removes an auto-mounted GuardPoint from CipherTrust Manager, the CTE Agent is only deleted after the configured `autoFs` timeout expires. This timeout does not start until the GuardPoint is free.
The timeout can be changed in the `auto.master` file on the host.

Display GuardPoint Information in a Different Format

To display the same information in a block format, use the `secfsd -status guard -v` command. For example:

```
secfsd -status guard -v

GuardPoint: 1
  Policy:      allowAllOps_fs
  Directory:   /opt/apps/apps1/tmp
  Type:        local
  ConfigState: guarded
  Status:      guarded
  Reason:      N/A
GuardPoint: 2
  Policy:      allowAllRootUsers_fs
  Directory:   /opt/apps/apps1/lib
  Type:        local
  ConfigState: guarded
  Status:      guarded
  Reason:      N/A
```

Display Host Settings

To display the SHA2 hash signature for each protected host setting, use the `secfsd -status auth`

command. For example:

```
secfsd -status auth

|authenticator|/bin/su 3E765375897E04C39AB17D4C755F50A35195535B6747DBA28DF9BD4AA6
72DFF9
|authenticator|/usr/sbin/sshd 98FC599D459EDEA52A60AB394B394803B5DAB96B53148DC6087
32DDA6777FA1A
|authenticator|/usr/sbin/in.rlogind 5C9A0EDD8BF54AE513F039476D21B3032507CF957AA0C
B28C368EB8AB6E684FB
|authenticator|/bin/login 0D2EE0B995A30AE382B4B1CA5104715FC8902F457D283BDABAAD857
B09259956
|authenticator|/usr/bin/gdm-binary 363780522E3CCF9ABF559F059E437743F9F97BBBB0EE85
769007A464AD696BD1
|authenticator|/usr/bin/kdm BAD41BBCDD2787C7A33B5144F12ACF7ABC8AAA15DA9FDC09ECF93
53BFCE614B5
```

Display Key Status

To display the status of CTE keys, use the `secfsd -status keys` command. For example:

```
secfsd -status keys
Encryption keys are available
```

Display Lock Status

To display the status of CTE locks, use the `secfsd -status lockstat` command. For example:

```
secfsd -status lockstat
FS Agent Lock: false
System Lock: false
```

The value is **true** if the lock is applied. The value is **false** if the lock is not applied. **System Lock** corresponds to **System Locked** in the *Host* window. **FS Agent Lock** corresponds to **FS Agent Locked** in the *Host* window.

Note

Before you upgrade, remove CTE software, or change operating system files, the status of FS Agent Lock and System Lock must be false.

Agent Security Configuration Protection

The Agent lock directory, `/opt/vormetric/DataSecurityExpert/agent/secfs/.sec` contains secfs secret files, configuration files, host setting signatures, etc. Thales recommends protecting the directory whenever secfs is online.

Applying improved directory protection ensures that only CTE applications (`vmd`, `secfsd`, `voradmin`, etc.) can modify the `.sec` directory and the files in it. All users, including root, are denied read/write access to the files. They also do not have permissions to modify `conf` and `bin` directories, using other tools.

A new command has been created to protect the directory: `voradmin secfs config`

Syntax

```
voradmin secfs config <configuration_parameter> <value>
```

Example

```
voradmin secfs config pagecache_writeback 1
```

Previously, you would have had to use the following command to achieve the same results as the example above:

```
echo 1 > /opt/vormetric/DataSecurityExpert/agent/secfs/.sec/conf/pagecache_writeback
```

Note

When CTE is upgraded to v7.2.0 from the previous release, it may display 'Permission Denied' warnings which display when files are removed from subdirectories of the `.sec` directory. You can ignore these warnings. They are harmless.

Display CTE Log Status

To display the status of CTE log service, use the `secfsd -status logger` command. For example:

```
secfsd -status logger
```

Upload URL: `https://vmSSA06:8444/upload/logupload,https://vmSSA07:8444/upload/logupload, \`
`https://vmSSA05:8444/upload/logupload` Logger Certificate directory: `/opt/vormetric/DataSecurityExpert/agent/vmd/pem`

This command sequence returns the URL to which the log service sends log data. It also returns the directory that contains the CTE certificate. CTE uses the certificate to authenticate CTE when it uploads the log data to the CipherTrust Manager.

Display Applied Policies

To display the policies that are applied to CTE, use the `secfsd -status policy` command. For example:

```
secfsd -status policy
```

```
Policy: enc-audit  
Type: ONLINE
```

Display CTE Process Information

To display CTE processes, use the `secfsd -status pslist` command. This command shows the process number associated with each CTE process. To show the details about a specific CTE process, use the `ps -fp <process #>` command, where `<process #>` is the process number from the `secfsd -status pslist` command.

For example:

```
secfsd -status pslist
Protected pid list:      739    731

ps -fp 739
  UID      PID    PPID    C   STIME          TTY   TIME    CMD
  root      739     1      0   11:04:56      -    0:00 /opt/vormetric/ \
        DataSecurityExpert/agent/vmd/bin/vmd
```

Display CTE Version Information

To display CTE version information, use the `secfsd -version` command. For example:

```
secfsd -version
version: <Release.build-number>
```

Display CTE Crypto Information

To display CTE support information for encryption modes, use the `voradmin secfs crypto` command. For example:

```
voradmin secfs crypto
AES CBC, CBC_CS1, XTS modes are supported
Encryption key protection is supported
```

Manually Enable a GuardPoint in CipherTrust Manager

To manually enable a GuardPoint on an AIX host:

1. Click **CTE > Clients > <clientName> GuardPoints**
2. Click **Create GuardPoint**.
3. In the Policy field, select a policy.
4. Set Type to **Manual Directory**.
5. Click **Browse** and enter the GuardPoint path.
6. Click **Create**.
7. Log onto the system hosting CTE as the root user.

8. To manually enable the GuardPoint, use the `secfsd -guard <path>` command. For example:

```
secfsd -guard /opt/apps/etcsecfsd: Path is Guarded
```

9. To verify the change, use the `secfsd -status guard` command. For example:

```
secfsd -status guard
```

GuardPoint	Policy	Type	ConfigState	Status	Reason
-----	-----	----	-----	-----	-----
/opt/apps/etc	allowAllOps_fs	manual	guarded	guarded	N/A

Secfsd Raw and Block Devices

CTE only creates block devices. To display them, use the `ls -l /dev/secvm/dev` command. For example:

```
ls -l /dev/secvm/dev
```

```
brw----- 1 root    system    38,  1 Jan 29 16:37 hdisk1
brw----- 1 root    system    38,  2 Jan 29 16:37 hdisk2
crw----- 1 root    system    38,  3 Jan 29 16:37 rhdisk1
crw----- 1 root    system    38,  4 Jan 29 16:37 rhdisk2
```

Note

- Access controls on SECVm devices are supported with **only** Direct IO.
- CipherTrust Transparent Encryption **does not** support access controls on SECVm devices when using buffered I/O.
- Buffered I/O on SECVm devices are only supported with a wide-open (applyKey/permit) policy.

Using Advanced Encryption Set New Instructions (AES-NI)

To verify AES-NI hardware support, type:

```
vmsec check_hwenc
```

Unlike the `-c algo` command above, CTE does not have to be running for this command to execute. This command displays one of the following messages to stdout:

```
"AES-NI hardware encryption is supported on this system."
"AES-NI hardware encryption is not supported on this system. "
```

User Cache Lookup Improvements

CTE has added a feature to improve the performance of the user cache lookup function, which contains information such as username and group name(s), plus timestamps and other supporting flags. It is mainly used during LDAP authentication. This feature improves lookup performance by allowing user-configurable values for lookup retries and user information refresh times. Performance can be impacted if authentication/ user lookups and timeout/ retries take a significant amount of time. Previously, these values were hard-coded. Now they are user-configurable.

The configuration options for this feature contain three new configuration parameters:

Initial cache miss

Initial check of access when no user information cache entry exists.

- **Default value:** 60 seconds
- **Default minimum:** 2 seconds
- **Default maximum:** 3600 seconds (1 hour)

To set this value, type:

```
voradmin secfs config usrinf_miss_timeout <seconds>
```

Cache expiration timeout

Used when user information cache entry has not been used for the duration needed to trigger a refresh.

- **Default value:** 300 seconds (5 minutes)
- **Default minimum:** 60 seconds
- **Default maximum:** 86400 seconds (1 day)

To set this value, type:

```
voradmin secfs config usrinf_expiry_timeout <seconds>
```

Cache stale timeout

When a cache entry has not been updated for the duration of the timeout, the entry will be considered inactive and removed.

- **Default value:** 300 seconds (5 minutes)
- **Default minimum:** 60 seconds
- **Default maximum:** 86400 seconds (1 day)

To set this value, type:

```
voradmin secfs config usrinf_stale_timeout <seconds>
```

Usage

CTE uses the default values initially. If network errors occur and LDAP failure is observed (in system logs, look for timeout errors), then you have two options:

- If the network errors can be corrected in a short time, then the timeout values can remain unchanged.
- If not, set the expiration and stale timeout to large values. Then, reduce the initial timeout incrementally until the problem resolves.

Note

CTE must be restarted when a new timeout value is set, in order for the value to take effect.

Keep the new value until the problem is resolved. Then, once the network problems have been fixed, reset the timeout values back to the initial values.

vmutil

Usage

```
vmutil <options> <operations>
```

Options

Option	Function	Description
-a	--agent <name>	Specify agent type (vmd or pkcs11)
-d	--extdir <string>	Specify location of external certificate and key set
-e	--error <string>	Specify one or more errors for state report
-h	--help	Display help and exit
-l	--loglevel <level>	Specify log output level (debug, info, warn, error or fatal)
-f	--force enabled	Force option for delete host operation
-v	--version	Display program version and exit

Operations

Operation	Description
certexpiry	Report the certificate expiration date for this agent
deletehost	Delete this client from the server
renewcerts	Renew certificate set for this agent
reportstate	Report agent state and error conditions to server
unregister	Unregister this agent/client from the server
updatecerts	Update external certificate and key set for this agent/client

vmd utility

The **vmd** utility displays CTE software version information.

The **vmd** utility is located in `/opt/vormetric/DataSecurityExpert/agent/vmd/bin` and a symbolic link to this file is placed in `/usr/bin/vmd`.

Syntax

vmd [OPTIONS...]

-h show utility syntax

-v display CTE version

-f runs **vmd** in the foreground

Display the Installed Version

To display the installed CTE version, type:

```
vmd -v
Version 6
<Release.build-number>
2022-02-04
Copyright (c) 2009-2025, Thales.. All rights reserved.
```

vmsec Utility

The **vmsec** utility allows you to manage security aspects of CTE on the host. On Linux hosts, the **vmsec** utility is located in:

```
/opt/vormetric/DataSecurityExpert/agent/vmd/bin/vmsec
```

vmsec Syntax

Syntax	Description
<code>checkinstall</code>	Show vmd kernel status
<code>challenge</code>	Enter the dynamic host password
<code>vmdconfig</code>	Display the vmd configuration
<code>check_hwenc</code>	Display kernel configuration
<code>hwok</code>	Report status of hardware signature
<code>passwd [-p <password>]</code>	Enter the static host password
<code>version</code>	Display CTE version

vmsec Examples

- Display CTE Challenge String
- Display CTE Status
- Entering a Password
- Display Kernel Status
- Display CTE Build Information
- Display Contents of Conf files

Display CTE Challenge String

To display a CTE password challenge string and enter the response string when the CipherTrust Manager is not network accessible, use the `vmsec challenge` command. This command displays a challenge string that you can send to your key manager administrator, who will then send you back the correct response information.

For example:

```
vmsec challenge
Contact a Security Server administrator for a response.
Your host name is "Host120" Your challenge is: HPTQ-ZYLK
Response -> IHFY-W7WG-PDA0-QKKQ
```

Contact your key manager administrator and give them the challenge string. The administrator will give you the response string. Enter the response string in the **Response** field and press **Enter**. You have 15 minutes to enter the response string.

Tip

If you are using CipherTrust Manager, the ability to change the contact string will be added in a future release. For CipherTrust Manager, the contact string says "Contact your CM administrator".

Display CTE Status

This utility shows you if CTE is configured and running. If it is not running, you might need to start it manually. To display CTE status, use the `vmsec checkinstall` command. For example:

```
vmsec checkinstall
The kernel component is installed and running.
```

Entering a Password

To enter the CTE static host password, use the `vmsec passwd` command. For example:

```
vmsec passwd
Please enter password:
OK passwd
```

To enter CTE static host password on the command line so you can specify it in a batch script, specify the password using the `-p` option. For example:

```
vmsec passwd -p myPass123
OK passwd
```

Display Kernel Status

To display the kernel status, use the `vmsec status` command. For example:

```
vmsec status
FILE_FORMAT=2
FILE_GENERATED=08/27/2019 18:54:10
SA_QOS_STATUS=0
SA_HOST_CPU_UTIL=0

Display CTE Build Information

To see the CTE build version, use the `vmsec version` command. For example:

```
vmsec version
Version 7
7.8.0.128
2025-03-17 15:15:23 (PDT)
Copyright (c) 2009-2025, Thales. All rights reserved.
```

Display Contents of Conf files

To display the contents of the `agent.conf` and `.agent.conf.defaults` files, use the `vmsec vmdconfig` command. For example:

```
vmsec vmdconfig
appender_syslogdest Syslog_Appender_0=127.0.0.1
VMSDK_AGENT_CONFIG_FILE=/opt/vormetric/DataSecurityExpert/agent/vmd/etc/agent.conf

- Alerts and Errors on Linux

Introduction to in-Place Data Transformation (IDT)

CTE offers in-Place Data Transformation (IDT) Capable Device GuardPoints on Linux. IDT-Capable GuardPoints allow you to guard devices by transforming the plain-text data to cipher-text on the host device. The data transformation process is called in-Place Data Transformation (IDT). The term “IDT-Capable” refers to the data transformation capability available on IDT-Capable GuardPoints.

IDT is not the same as the legacy offline data transformation. IDT is a block level data transformation with built-in resiliency to recover from system crashes during the data transformation process. IDT uses the CTE Private Region to manage the entire transformation process (For details, see [The CTE Private Region and IDT Device Header](#)).

IDT partitions the data on a device in segments of 1 MB in size and transforms one or multiple segments, up to 60 segments, in parallel. The IDT process preserves existing data in a segment during transformation in the CTE Private Region, and then transforms the data in-place. IDT also maintains the segments undergoing transformation in the CTE Private Region. In the event of system crash, IDT will recover the segments undergoing transformation at the time of crash and then resume the transformation process.

Another advantage of IDT over legacy offline data transformation is that IDT does not require a separate policy for data transformation. Instead, IDT allows you to initialize each device as either a “new device” with no existing data or as an “existing device” with existing data that needs to be transformed. You can then apply any IDT policy to any combination of new and existing devices and IDT will immediately guard the new devices while starting the IDT transformation process on the existing devices. New devices are immediately available for use while existing devices are inaccessible until the IDT process completes and all data has been converted from plain-text to cipher-text.

Requirements for IDT-Capable GuardPoints

- IDT-Capable GuardPoints are available for Linux with CTE 6.3.1 or subsequent versions. All versions of CipherTrust Manager work with IDT-Capable GuardPoints.
- The host server must use the Advanced Encryption Standard instruction set (AES-NI).
- The policy assigned to the IDT-Capable GuardPoint must be an **in-Place Data Transformation** policy and use an XTS/CBC-CS1 AES 256 encryption key.
- In order to create an IDT-Capable GuardPoint on a raw device, the device must be either:
 - Exported from an external storage system to the host device.
 - On a locally-attached disk.
- Devices protected by an IDT-Capable GuardPoint cannot currently be initialized/added as physical volumes for use by LVM. When LVM support is added, it will be announced in the CTE Release Notes.
- Existing devices divided into one or more logical partitions cannot be guarded as IDT-Capable Device GuardPoints. Logical partitions in such devices cannot be accessed or separately guarded after guarding the device.

For example, the logical partition `/dev/sda1` or `/dev/sda2` inside `/dev/sda` cannot be accessed after

guarding `/dev/sda` as IDT-Capable GuardPoint. Using `/dev/secvm/dev/sda1` is invalid as `/dev/secvm/dev/sda1` is not a GuardPoint and cannot be guarded, and, as such, would not provide access to clear-text data on `/dev/sda1`. However, you can guard individual partitions, such as `/dev/sda1` or `/dev/sda2`, as IDT-Capable GuardPoints without guarding the entire `/dev/sda` device.

- IDT-Capable GuardPoints requires XTS-AES mode of the AES algorithm for encryption.
- CTE only supports IDT on servers with microprocessors integrated with Advanced Encryption Standard instruction set (AES-NI).

The CTE Private Region and IDT Device Header

IDT-Capable GuardPoints require a small amount of disk space in the standard CTE Private Region. The reserved space is where CTE stores metadata information to identify IDT-Capable GuardPoints and to perform all data transformation and rekey operations in a resilient manner to avoid data loss or integrity issues due to system failures. The IDT-specific reserved space within the CTE Private Region is known as the IDT Device Header. By default, when you initialize a device as an IDT-Capable GuardPoint, CTE reserves 63 MB of space starting at the first sector on the device for the CTE Private Region.

CTE writes the IDT Device Header into the CTE Private Region when the device is guarded for the first time. If there is existing data on the device, the data at the start of the device is relocated to the available free space on the device and CTE creates the CTE Private Region starting at the first sector. For details, see [Initialize a Linux Device with Existing Data](#).

CTE Private Region Location

Normally, CTE requires that the CTE Private Region be embedded at the beginning of the device. IDT, however, allows you to specify that the CTE Private Region for an IDT-Capable GuardPoint should be located in a central CTE metadata directory on the host called `/vte/vte-metadata-dir` (default: `/opt/vte/vte-metadata-dir`). If you use this option, CTE stores the CTE Private Region and IDT Device Header for the device in this directory. The location of the CTE Private Region for a device is determined when you first initialize the device as an IDT-Capable GuardPoint. For details, see [Initializing an IDT-Capable Device](#).

Warning

Access to the CTE metadata directory is local to the CTE protected host. Devices whose access is shared across multiple CTE protected hosts in a cluster *must* be configured with the CTE Private Region embedded in those devices. Using a centralized metadata directory for shared devices will lead data corruption.

The location of the CTE Private Region does not affect CTE's functionality, but there are some considerations if you choose to use the centralized metadata directory `/vte/vte-metadata-dir`:

- Thales recommends that you keep the metadata for the device on the device if at all possible. You should only use the centralized metadata directory if the device cannot be expanded to accommodate the CTE Private Region.
- The centralized CTE metadata directory must be guarded by the Administrator to prevent accidental

modification or deletion of the CTE metadata. If the CTE metadata directory is not guarded, any attempt to configure or enable an IDT-Capable GuardPoint using the centralized metadata directory will be rejected. The policy associated with the metadata directory must:

- Deny all users (including the root user) the ability to modify or remove any files in the metadata directory.
- Use the key rule `clear_key` so that the metadata is stored in clear text.
- You must back up this directory whenever you back up a device that uses the directory. You will not be able to restore a protected device without access to its corresponding metadata in `/vte/vte-metadata-dir`.
- Devices with existing data do not need to be resized to accommodate the CTE Private Region, so there are no disk size discrepancies between system utilities such as `fdisk` and any other applications. However, Thales still recommends that you do not shrink an IDT-Capable GuardPoint even if the CTE Private Region is not embedded on the device.

Device Size

If you embed the CTE Private Region on the device itself, after configuring and guarding the IDT-Capable GuardPoint on the device, the device size reported to applications is the size of the device minus the space reserved for the CTE Private Region. This can lead to a discrepancy between the disk size reported by some applications versus the size reported by system utilities such as `fdisk`.

Warning

Do not shrink IDT-Capable GuardPoints. Due to the relocation of user data from the CTE Private Region, if you shrink the device, you may corrupt data on the device.

The IDT Device Header contains both the available device size and the size of the CTE Private Region. To view the IDT Device Header, use the `voradmin idt status <device-name>` command. The **Exported Disk Size** field shows the disk size available for use by other applications. The **Private Region Size** field shows the disk size reserved for CTE. For example:

```
voradmin idt status /dev/sdc2
IDT Header on /dev/secvm/dev/sdc2
Version:                1
Change:                 0
Private Region Size:    129024 sectors
Exported Device Size:   9627648 sectors
Key UUID:               9cc3c8e4-7ea7-310f-85c7-6f911de1ab52
Mount Path:             None
```

The `voradmin idt status` command also reports the UUID of the XTS/CBC-CS1 AES 256 key applied to the device.

IDT-Capable GuardPoint Encryption Keys

IDT-Capable GuardPoints must be encrypted using XTS/CBC-CS1 AES 256 keys. An XTS/CBC-CS1 AES 256

type key is a 512-bit key composed of two components:

- The first 256 bits of the key is the AES 256 encryption key component.
- The second 256 bits is the tweak component.
- Create XTS keys on CM in the Keys menu.
- For CM, refer to [“Creating a New Key”](#) for more information.

The Key Manager (CipherTrust Manager) generates a UUID, along with other relevant attributes, for each newly-added key. It then provides the key and its attributes to the CTE protected host when the policy containing the key is pushed to the host device. CTE stores the key and its attributes, including the key's UUID, in the IDT Device Header. The first time a device is guarded as an IDT-Capable GuardPoint, CTE writes the IDT Header on the device before data transformation takes place, if data transformation is required.

Key Attributes - Example

The following describes the parameters you should specify to add a new XTS/CBC-CS1 AES 256 key named `IDT_DEMO_KEY_1`. Note the algorithm and encryption mode specified for the key.

- Algorithm: **AES**
- Size: **256**
- Encryption Mode: **XTS/CBC-CS1**

Note the UUID of the key. This UUID is stored in the IDT Device Header on all devices encrypted with this key, allowing you to verify which key is being used on each device.

Policy Requirements for IDT-Capable GuardPoints

IDT-Capable GuardPoints require a policy of type **in-Place Data Transformation** with a single key rule specifying the key names for **Current Key** and **New Key**. The **Current Key** name is `clear_key` or an XTS/CBC-CS1 AES 256 key name, depending on whether the data on the device has already been encrypted.

- If there is no existing data on the device or if the existing data on the device has not yet been encrypted, specify `clear_key` for **Current Key**. In the **New Key** field, specify the name of the XTS/CBC-CS1 AES 256 key that you want to use to encrypt the data on the device.
- If the existing data on the device has already been encrypted, specify the name of the key used to encrypt the data in the **Current Key** field and the name of the new XTS/CBC-CS1 AES 256 key you want to use to rekey the data in the **New Key** field. When the policy is pushed to the host, CTE will rekey the data on the device using the key specified in **New Key**. In other words, the **New Key** field specifies the XTS/CBC-CS1 AES 256 production key name to apply to the device.

In all cases, the **New Key** field specifies the XTS/CBC-CS1 AES 256 production key name that you want to use to encrypt the data on the device. After you guard an existing device with an in-Place Data Transformation policy, CTE transforms the existing data using the New Key. When the process is finished, the New Key becomes the Current Key for that device, and all data will be encrypted or decrypted with that key. The IDT Device Header contains the UUID of the key currently being used to encrypt/decrypt data on the device. To view the current key UUID, use the `voradmin idt status <device-name>` command.

You may add security rules to restrict certain user/process access to protected devices. For suggestions, see [Use Cases Involving IDT-Capable GuardPoints.md](#){:target="_blank"}.

A simple IDT policy requires:

- **Policy type:** in-Place Data Transformation
- **Rule:** Simple security rule that permits access to all users and programs
- **Current key:** `clear_key`
- **New key:** an IDT_KEY for encrypting the data on any device associated with the policy

Guarding an IDT-Capable Device on Linux

In order to guard an IDT-Capable device, you need to:

1. Make sure the devices you intend to guard meet the requirements for IDT-Capable GuardPoints. For details, see [Requirements for IDT-Capable GuardPoints](#).
2. Install the CTE Agent and register the host with the Key Manager if it is not already registered. IDT does not require any special registration options or licenses.
3. Initialize the device using the `voradmin idt config [new|xform]` command to specify whether there is any existing data on this device that needs to be encrypted and to configure the location of the CTE Private Region. For details, see [Initializing an IDT-Capable Device](#).
4. Log on to the Key Manager to apply an IDT-Capable GuardPoint to the device. For details, see [Guard the Linux Device with an IDT-Capable GuardPoint](#).

Warning

For devices with shared access across multiple CTE Protected hosts in a cluster, you must designate one and only one of the nodes in the cluster as the node on which you plan to initialize and guard the device for the first time. The designated node must be the only one that accesses the device until the entire initial data transformation process has completed. This requires guarding each shared device at the designated host level rather than at the host group level if you are using a host group to manage the CTE Protected nodes in your cluster. DO NOT initialize or guard any device on multiple nodes in the cluster simultaneously, because multiple nodes attempting to transform the same data can corrupt the data on the entire device.

Initializing an IDT-Capable Device

When you initialize an IDT-Capable storage device, the process specifies:

- Whether there is existing data on the device that needs to be encrypted.
- Where you want to store the CTE Private Region, which contains the IDT Device Header along with metadata

that identifies the IDT-Capable device as a guarded device. You can embed the CTE Private Region on the device itself or in the central CTE metadata directory on the host. (For details, see [The CTE Private Region and IDT Device Header](#).)

How you initialize the device depends on whether it is a new device or an existing device that already has data that needs to be transformed into cipher-text. For details, see:

- [Initialize a New Linux Device](#)
- [Initialize a Linux Device with Existing Data](#)

Initialize a New Linux Device

Run the `voradmin idt config new` command to initialize a new device. The `new` option specifies that the device does not hold user data so no initial data transformation is required. For a shared device that is accessed from multiple protected hosts, you must initialize the device only once and on only one protected host.

Note

To configure devices with multiple IO paths for Linux, see [Changing the Encryption Key on Linux IDT-Capable Devices](#).

1. Log into the device as `root`.
2. Run the `voradmin idt config [-external] new [-c <n>] <device-name>` command, where:
 - `-external` is an optional parameter that tells CTE you want to use the centralized CTE metadata directory instead of embedding the CTE Private Region on the device itself. If you use this option, you must have configured and guarded the centralized CTE metadata directory as described in [CTE Private Region Location](#).
 - `new` (required) indicates that the device contains no data (it is a new disk). As soon as you push the IDT policy, the device will be available as a guarded IDT-Capable GuardPoint.
 - `-c <n>` (optional). If you use this option, CTE sets the number of data transformation jobs to run in parallel to the number specified in `<n>`. `<n>` can be an integer between 1 and 60 (default: 8).

Each data transformation job transforms 1MB worth of data and requires CPU resources in addition to three I/O operations as part of data transformation. Each job reads 1MB of data from the device, preserves the data in the CTE Private Region, rekeys the data to cipher-text, and writes the transformed data to the device. If you increase the number of parallel jobs, the data transformation process will complete faster but there will be an increased performance impact on the system. Only increase the `-c` option if you are certain that the system resources are available to handle the additional load.

The value for the `-c` option you specify here remains in effect for all subsequent data transformations (such as any data rekeys) until you specify a new value.

- `<device-name>` (required). Specifies the device name. For example, `/dev/sdc2`.

For example, if you want to initialize a new Linux disk named `/dev/sdc2` using 10 parallel data transformation jobs with the CTE Private Region embedded on the device, you would specify:

```
voradmin idt config new -c 10 /dev/sdc2
```

If you want to initialize a new Linux disk named `/dev/sdc2` using the default number of parallel data transformations but with the CTE Private Region in the centralized CTE metadata directory, you would specify:

```
voradmin idt config -external new /dev/sdc2
```

3. To verify that the disk has been initialized, run the `voradmin idt status` command.

```
voradmin idt status /dev/sdc2
Device /dev/sdc2 is configured to guard as IDT-Capable GuardPoint
```

4. At this point the Administrator can protect the device as an IDT-Capable GuardPoint through the Key Manager. For details, see [Guard the Linux Device with an IDT-Capable GuardPoint](#).

Note

The initialization process prepares the device to be guarded but does not actually guard it. You need to assign an IDT-Capable GuardPoint to the device in the Key Manager before the device is actually protected.

Initialize a Linux Device with Existing Data

If the device has existing data, you need to use the `voradmin idt config xform` command to initialize the disk for CTE. Unless you are using the centralized CTE metadata directory, this command examines the current disk size and computes the size required to hold the existing data plus the CTE Private Region at the beginning of the device. After the CTE initialization is complete, you then need to resize the device before you can guard it with an IDT-Capable GuardPoint.

Warning

If access to the device is shared access across multiple CTE Protected hosts in a cluster, be sure to initialize the device on one and only one of the CTE hosts.

The following procedure describes how to initialize the device for CTE. Note that the existing data is not altered in any way until after you perform this procedure and you guard the data with an IDT-Capable GuardPoint. CTE does *not* begin transforming the data from clear-text to cipher-text until the IDT-Capable GuardPoint has been

applied and the encryption key has been pushed to the device through the GuardPoint Policy.

1. Log into the device as `root`.
2. Run the `voradmin idt config [-external] xform [-c <n>] <device-name>` command, where:
 - `-external` is an optional parameter that tells CTE you want to use the centralized CTE metadata directory instead of embedding the CTE Private Region on the device itself. If you use this option, you will not have to resize the device but you must have configured and guarded the centralized CTE metadata directory as described in [CTE Private Region Location](#).
 - `xform` (required) indicates that the device contains existing data. CTE will transform all existing data on the device from clear-text to cipher-text as soon as you guard the device. The device will be inaccessible until the transformation is complete, and the device must remain offline during the entire transformation process. No user access will be permitted until all data has been transformed.
 - `-c <n>` (optional). If you use this option on Linux, CTE sets the number of data transformation jobs to run in parallel to the number specified in `<n>`. `<n>` can be an integer between 1 and 60 (default: 8).

Each data transformation job transforms 1MB worth of data and requires CPU resources in addition to three I/O operations as part of data transformation. Each job reads 1MB of data from the device, preserves the data in the CTE Private Region, rekeys the data to cipher-text, and writes the transformed data to the device. If you increase the number of parallel jobs, the data transformation process will complete faster but there will be an increased performance impact on the system. Only increase the `-c` option if you are certain that the system resources are available to handle the additional load.

The value for the `-c` option you specify here remains in effect for all subsequent data transformations (such as any data rekeys) until you specify a new value.

- `<device-name>` (required). Specifies the device name. For example, `/dev/sdc3`.

For example, if you want to initialize an existing Linux disk named `/dev/sdc3` using 10 parallel data transformation jobs with the CTE Private Region embedded on the device, you would specify:

```
voradmin idt config xform -c 10 /dev/sdc3
Device /dev/sdc3 must be resized to at least 9893888 sectors (4831 MBs) before
guarding as IDT-Capable GuardPoint
```

In this case you must manually resize the Linux disk by at least 9893888 sectors before you can guard it. After you guard the disk, you can expand it again later but you cannot shrink it unless you remove the GuardPoint.

If you want to initialize the same device using the centralized CTE metadata directory, you would specify:

```
voradmin idt config xform -external -c 10 /dev/sdc3
```

Note that you do not get a message about resizing the device because the CTE Private Region will not be embedded on the device.

3. To verify that the disk has been initialized, run the `voradmin idt status` command.

```
voradmin idt status /dev/sdc3  
Device /dev/sdh is configured to guard as an IDT-Capable GuardPoint
```

4. If you are embedding the CTE Private Region on the device, at this point, you need to resize the device using your standard disk management tools before you can guard it. Make sure you increase the device size by at least the amount shown in the `voradmin idt config xform` message.

You cannot assign an IDT-Capable GuardPoint to the device until it has been resized. If you do not resize the device, the GuardPoint assignment will fail.

5. After the device has been resized or the centralized CTE metadata directory has been configured and guarded, the Administrator can protect the device as an IDT-Capable GuardPoint through the Key Manager as described in [Guard the Linux Device with an IDT-Capable GuardPoint](#).

Note

The initialization process prepares the device to be guarded but does not actually guard it. You need to assign an IDT-Capable GuardPoint to the device in the Key Manager before the device is actually protected. In addition, the initialization process is only kept in memory until the device is guarded or rebooted. If the device is rebooted before you guard it, you will need to perform the initialization procedure again.

Guard the Linux Device with an IDT-Capable GuardPoint

After the device has been initialized, you can guard the device as an IDT-Capable GuardPoint from the Key Manager. For existing devices, as soon as the GuardPoint configuration has been pushed to the host and the status changes to guarded, CTE begins transforming the data on the disk using the encryption key associated with the GuardPoint Policy.

Warning

If access to the device is shared access across multiple CTE Protected hosts in a cluster, be sure to guard the device on one and only one of the CTE hosts.

Note

For details about how to create a GuardPoint in CM, see, “[Managing GuardPoints](#)”, [CTE Administration Guide](#).

To see the data transformation progress, use the `voradmin idt xform status <device-name>` command, as described in [Viewing Device Status and the IDT Device Header](#).

After the device is initialized and guarded, the protected device must be accessed through the CTE device pathname. This pathname corresponds to the secvm device. For example, the Linux device pathname `/dev/sdc2` becomes `/dev/secvm/dev/sdc2` as soon as the process is complete.

Note

- Be sure to use the secvm device name when using file system management tools such as `mkfs` and `fsck`.
- Do not use the device mapper names corresponding to IDT-Capable GuardPoints for GuardPoint administration on protected hosts.

Data Relocation and Transformation on Existing Linux Devices

When you add an IDT-Capable GuardPoint to a device that has been initialized with the `voradmin idt xform` command and you opted to embedded the CTE Private Region on the device, CTE first relocates existing data in the region of the device designated as CTE Private Region. The data is relocated to the end of the device, into the new space allocated when you resized the device. The relocation occurs once when the device is guarded for the first time. No relocation is necessary for subsequent rekeys on the device.

Relocation of data is transparent to applications accessing data through the IDT-Capable GuardPoint. CTE will map application I/O requests over the private region to the relocated region. After guarding the device, you can grow the device size further if necessary. However, you cannot shrink the device size.

IDT does not require a separate policy for data transformation. If you initialized the device with the `xform` option, CTE starts the IDT process when transformation is required. During the IDT process, access to the device is blocked until the IDT process completes and all the data on the device has been encrypted.

```
voradmin idt status xform /dev/sdc3
Status:          In-Process
                Relocation Zone 9764864 (relocated = 1)
                SegSpc 27, Xformation Range: 3217 ... 4799, SegIDs: 4795 4796 4791 4792 4
797 4798 4799
                KeyID:          2793      Key Name:      IDT_DEMO_KEY_1
                Old KeyID:       0         Old Key Name:  clear_key

# dd if=/dev/secvm/dev/sdc3 of=/dev/null bs=512 count=1
dd: failed to open 'dev/secvm/dev/sdc3': Resource temporarily unavailable
```

```
# voradmin idt status xform /dev/sdc3
Status:          Complete
                Relocation Zone 9764864 (relocated = 1)
                SegSpc 27, Xformation Range: 3217 ... 20189, SegIDs: none
                KeyID:          2793      Key Name:      IDT_DEMO_KEY_1
                Old KeyID:       0         Old Key Name: clear_key

# dd if=/dev/secvm/dev/sdc3 of=/dev/null bs=512 count=1
1+0 records in
1+0 records out
512 bytes (512 B) copied, 0.000989039 s, 518 kB/s
```

Thin-Provisioned Devices

IDT skips transforming thin-provisioned regions of a device. Data returned to IDT as sequence of clear-text zeros, in sector size granularity, is indication of possible sparse or un-allocated regions of the device that do not have to be transformed.

IDT Recovery From Crash

IDT is fault tolerant in the event of system crashes. IDT keeps track of the transformation process over the entire device. In the event of a crash, IDT will automatically resume transformation from the point of failure as soon the GuardPoint is enabled after system startup.

If you find the transformation status set to **In-Progress** when the GuardPoint is not enabled, the **In-Progress** state reflects an earlier system crash after which the GuardPoint has not been enabled to recover from the interruption in the IDT process.

Example of Creating an IDT-Capable GuardPoint on an Existing Linux Device

The following example shows the process of initializing an existing Linux device using `voradmin idt config xform` and guarding it as an IDT-Capable GuardPoint from the viewpoint of the Linux root user. In this example, all files in `/bin/*` are copied to a temporary location outside the device, then compared with the corresponding files on the device after the device has been resized and encrypted. The comparison proves that the file system is unchanged after the encryption process has completed.

First, we verify that the device is not protected, then we check the current size of the disk and create the copy of the files in `/bin/*`. After that, we run the `voradmin idt config xform` command to initialize the device.

```
voradmin idt status /dev/sdc1
Device /dev/sdc1 is not configured as IDT-Capable
# fdisk -l /dev/sdc1
Disk /dev/sdc1: 21.1 GiB, 21103640576 bytes, 41218048 sectors
Units: sectors of 1 * 512 = 512 bytes
Sector size (logical/physical): 512 bytes / 512 bytes
I/O size (minimum/optimal): 512 bytes / 4194304 bytes
# mkfs.xfs /dev/sdc1
meta-data=/dev/sdc1          isize=256    agcount=4, agsize=1288064 blks
                        =               sectsz=512   attr=2, projid32bit=1
                        =               crc=0        finobt=0, sparse=0
data        =               bsize=4096   blocks=5152256, imaxpct=25
                        =               sunit=0     swidth=0 blks
```

```

naming    =version 2                bsize=4096    ascii-ci=0 ftype=1
log        =internal log            bsize=4096    blocks=2560, version=2
          =                        sectsz=512    sunit=0 blks, lazy-count=1
realtime  =none                    extsz=4096    blocks=0, rtextents=0
# mount -t xfs /dev/sdc1 /xfs
# cp /bin/* xfs
# voradmin idt config xform /dev/sdc1
Device /dev/sdc1 must be resized to at least 41347072 sectors (40378 MBs) before
guarding as IDT-Capable GuardPoint

```

At this point, you need to resize the device using your device management tools. You must increase the size by at least 41347072 sectors (40378 MBs). After the device has been resized, you can verify the new size:

```

fdisk -l /dev/sdc1
Disk /dev/sdc1: 21.2 GiB, 21169700864 bytes, 41347072 sectors
Units: sectors of 1 * 512 = 512 bytes
Sector size (logical/physical): 512 bytes / 512 bytes
I/O size (minimum/optimal): 512 bytes / 4194304 bytes

```

After the device has been resized, the Administrator can guard the device with the desired in-Place Data Transformation policy. If the Administrator chooses Auto Guard, data transformation begins as soon as the policy is pushed to the host. If the Administrator chooses Manual Guard, data transformation does not begin until the Linux root user initiates it with the `secfsd -guard` command. Once data transformation begins, the Linux root user can check the progress using the `voradmin idt status xform` command.

```

secfsd -guard /dev/sdc1
secfsd: Path is guarded
# voradmin idt status xform /dev/sdc1
      Status:          In-Process
      Relocation Zone  9764864 (relocated = 1)
      SegSpc 27, Xformation Range: 3217 ... 4799, SegIDs: 4795 4796 4791 4792 4
797 4798 4799
      KeyID:           2793      Key Name:      IDT_DEMO_KEY_1
      Old KeyID:       0         Old Key Name: clear_key

```

After the status has changed to completed, you can compare the current version of the files in `/bin/*` with the ones you copied earlier.

```

voradmin idt status xform /dev/sdc1
      Status:          Complete
      Relocation Zone  9764864 (relocated = 1)
      SegSpc 27, Xformation Range: 3217 ... 20189, SegIDs: none
      KeyID:           2793      Key Name:      IDT_DEMO_KEY_1
      Old KeyID:       0         Old Key Name: clear_key
# voradmin idt status /dev/sdc1
IDT Header on /dev/secvm/dev/sdc1
      Version:          1
      Change:           0
      Private Region Size: 129024 sectors
      Exported Device Size: 41218048 sectors
      Key UUID:         9cc3c8e4-7ea7-310f-85c7-6f911de1ab52
      Mount Path:       None
# mount -t xfs /dev/secvm/dev/sdc1 /xfs
# for file in `ls /bin/sfx`; do cmp /bin/$file /xfs/$file; done

```

```
# umount /xfs
```

Changing the Encryption Key on Linux IDT-Capable Devices

To meet various compliance requirements, you may want to change the key that CTE has used to encrypt IDT-Capable GuardPoints. Thales refers to this changing of encryption keys as “Key rotation” or “Rekey”. Unlike the Live Data Transformation product offered by Thales for file systems on traditional storage devices, to change the encryption key on an IDT-Capable GuardPoint, the device must be taken offline. The data on the device will be inaccessible during the key rotation process.

For CipherTrust Manager, see [Key Version Modify Request](#) for more information.

Warning

For devices with shared access across multiple CTE Protected hosts in a cluster, you must designate one and only one of the nodes in the cluster as the node on which you plan to initialize and guard the device for rekey. The designated node must be the only one that accesses the device until the entire rekey process has completed. This requires guarding each shared device at the designated host level rather than at the host group level if you are using a host group to manage the CTE Protected nodes in your cluster. **DO NOT** initialize or guard any device on multiple nodes in the cluster simultaneously, because multiple nodes attempting to transform the same data can corrupt the data on the entire device.

1. Log on to the Key Manager.
2. Make sure that you know what Policy you want to associate with the GuardPoint or create a new **in-Place Data Transformation** policy if needed. The key rule must specify the current XTS/CBC-CS1 AES 256 key that the GuardPoint is currently using as well as the new XTS/CBC-CS1 AES 256 key that you want to use to transform the protected data.

You can either create a new in-Place Data Transformation policy or you can change the keys assigned to an existing in-Place Data Transformation policy. If you use an existing policy however, the new key you specify cannot have been previously used to encrypt the IDT-Capable GuardPoint. If you want to rekey the GuardPoint using a previously-used key, you must create a new policy in order to do so.

Include both the current key and the new key in the policy to ensure that both keys will be available during the rekey process, even if the key information stored in the CTE Private Region becomes unavailable.

Do not push this policy to the host yet.

3. Shut down any applications accessing the GuardPoint you are planning to rekey. If the GuardPoint is mounted as a file system, you must also unmount the file system.
4. Once the data can no longer being accessed, you can unguard the GuardPoint on the Key Manager.
 - a. If the GuardPoint is a manual device GuardPoint, you must first unguard it using the `secfsd -unguard` command on the CTE host before you unguard it on the Key Manager. If it is an automatic GuardPoint, you can skip this step and simply unguard the GuardPoint in the Key Manager.

The following example checks the guard status of `/dev/sdc1` and gets the current key name, then unguards the device.

```
secfsd -status guard
GuardPoint  Policy                Type                ConfigState  Status  Reason
-----
-----
/dev/sdc2    IDT_DEMO_POLICY_1  rawdevice          guarded      guarded  N/A
/dev/sdc3    IDT_DEMO_POLICY_1  rawdevice          guarded      guarded  N/A
/dev/sdc1    IDT_DEMO_POLICY_1  manualrawdevice    guarded      guarded  N/A
# voradmin idt status xform /dev/sdc1
      Status:      Complete
      Relocation Zone 0 (relocated = 0)
      SegSpc 27, Xformation Range: 4294967295 ... 4294967295, SegIDs: none
      KeyID:      2793      Key Name:      IDT_DEMO_KEY_1
      Old KeyID:   0        Old Key Name:  clear_key
# secfsd -unguard /dev/sdc1
secfsd: Path is not guarded
# secfsd -status guard
GuardPoint  Policy                Type                ConfigState  Status  Reason
-----
-----
/dev/sdc2    IDT_DEMO_POLICY_1  rawdevice          guarded      guarded  N/A
/dev/sdc3    IDT_DEMO_POLICY_1  rawdevice          guarded      guarded  N/A
/dev/sdc1    IDT_DEMO_POLICY_1  manualrawdevice    unguarded    not guarded  Inactive
```

- b. Return to the Key Manager, select the GuardPoint in the GuardPoints table, and click **Unguard** to unguard the device in the Key Manager.

Wait until the GuardPoint has been removed from the Key Manager.

5. Return to the device and run the `voradmin idt rekey` command. After you run the `voradmin` command, the IDT Device Header is temporarily removed from the device.

```
voradmin idt rekey /dev/sdc1
Enter YES to prepare device /dev/sdc3 for rekey -> YES
# voradmin idt status /dev/sdc1
Device /dev/sdc1 is configured to guard as IDT-Capable GuardPoint
```

Note

For manual GuardPoints, you must unguard the device both using `secfsd -unguard` and the Key Manager before you can use the `voradmin idt rekey` command.

6. In the Key Manager, guard the device with the new **in-Place Data Transformation** policy you created earlier. If you selected a Manual GuardPoint, use `secfsd -guard` to activate the new policy and start the data transformation to the new key.

During the IDT process, user access to the GuardPoint is blocked until IDT completes the transformation process.

The following example shows how to use `secfsd -guard` on manual GuardPoint `/dev/sdc1`, and the status messages that occur during the rekey process. If you are using an automatic GuardPoint, you do not need to use the `secfsd -guard` command. Instead, the rekey process starts as soon as you push the new policy from the Key Manager.

```
secfsd -guard /dev/sdc1
secfsd: Path is guarded
# secfsd -status guard
```

GuardPoint	Policy	Type	ConfigState	Status	Reason
/dev/sdc2	IDT_DEMO_POLICY_1	rawdevice	guarded	guarded	N/A
/dev/sdc3	IDT_DEMO_POLICY_1	rawdevice	guarded	guarded	N/A
/dev/sdc1	IDT_DEMO_POLICY_2	manualrawdevice	guarded	guarded	Data transformation in progress

```
# voradmin idt status xform /dev/sdc1
      Status:                In-Progress
      Relocation Zone 0 (relocated = 0)
      SegSpc 27, Xformation Range: 3987 ... 3993, SegIDs: 3991 3987 3988 399
2 3989 3990 3993
      KeyID:                2921      Key Name:      IDT_DEMO_KEY_2
      Old KeyID:            2793      Old Key Name: IDT_DEMO_KEY_1
```

7. After the `xform` status shows as completed, you can restart all application workloads on the guarded device.

```
voradmin idt status xform /dev/sdc1
      Status:                Complete
      Relocation Zone 0 (relocated = 0)
      SegSpc 27, Xformation Range: 4768 ... 4768, SegIDs: none
      KeyID:                2921      Key Name:      IDT_DEMO_KEY_2
      Old KeyID:            2793      Old Key Name: IDT_DEMO_KEY_1
```

```
# secfsd -status guard
GuardPoint  Policy                Type                ConfigState  Status  Reason
-----
/dev/sdc2   IDT_DEMO_POLICY_1  rawdevice          guarded     guarded  N/A
/dev/sdc3   IDT_DEMO_POLICY_1  rawdevice          guarded     guarded  N/A
/dev/sdc1   IDT_DEMO_POLICY_2  manualrawdevice    guarded     guarded  N/A
```

Guarding an IDT-Capable Device with Multiple IO Paths on Linux

Each individual IO path from a server node to a storage controller is treated as a separate device on the host. DM-Multipath on a Linux host provides a management framework to group the individual IO paths to the same LUN into a single multipath device. If you use DM-Multipath to manage devices on the protected host, the individual devices that correspond to each IO path to the LUN cannot be configured for guarding as IDT-Capable, as those devices are under control of DM-Multipath. To guard such devices, you must guard the device mapper generated by DM-Multipath (multipathd) under the `/dev/mapper` directory.

Note

IDT is the only feature of CTE that exclusively supports guarding of a device mapper generated device under DM-Multipath framework.

The following example illustrates the procedure for guarding a device mapper generated device with the alias name `/dev/mapper/mpathA`.

1. Create an **in-Place Data Transformation** policy using an XTS/CBC-CS1 AES 256 key as the key rule.
2. On the host, prepare the device to be configured as IDT-Capable using the `voradmin idt config [-external] new|xform [-c n] <mapper-alias-name>` command.

For example, if the disk is a new disk with no existing data, you would enter:

```
voradmin idt config new /dev/mapper/mpathA
```

If the disk has existing data that you want to encrypt, you would enter:

```
voradmin idt config xform /dev/mapper/mpathA
```

3. Guard `/dev/mapper/mpathA` as Device GuardPoint using the policy created above. Be sure to check the **in-Place Data Transformation** check box.
4. For Manual Guard configuration, enable the GuardPoint using the `secfsd` command as follows:

```
secfsd -guard /dev/mapper/mpathA
```

5. For Auto Guard, wait for the `/dev/mapper/mpathA` device to be guarded on the protected host.
6. Once the device is guarded, provide the pathname of the secvm device to applications and/or file system operations. For example, `/dev/secvm/dev/mapper/mpathA`.

Viewing Device Status and the IDT Device Header

After you guard a device, you can view the status of that device using the `voradmin idt [xform] status <device-name>` command, where:

- `xform` (optional). If you specify this option, CTE shows the status of any data transformation processes happening on the device. If you do not specify this option, CTE displays the IDT Device Header for the device.
- `<device-name>` (required). The standard Linux name of the device whose status you want to view. (For example, `/dev/sdc2`.)

For example, if you want to view the IDT Device Header for the Linux device `/dev/sdc2`, you would enter:

```
voradmin idt status /dev/sdc2
IDT Header on /dev/secvm/dev/sdc2
      Version:                1
      Change:                 0
Private Region Size:         129024 sectors
Exported Device Size:        9627648 sectors
      Key UUID:               9cc3c8e4-7ea7-310f-85c7-6f911de1ab52
      Mount Path:             None
```

If you want to view the data transformation status on `/dev/sdc2`, you would enter:

```
voradmin idt status xform /dev/sdc3
      Status:                 In-Process
      Relocation Zone 9764864 (relocated = 1)
      SegSpc 27, Xformation Range: 3217 ... 4799, SegIDs: 4795 4796 4791 4792 4
797 4798 4799
      KeyID:                   2793      Key Name:      IDT_DEMO_KEY_1
      Old KeyID:               0         Old Key Name:  clear_key
```

The **Status** field displays **In-Progress** if a data transformation process is running, and **Completed** if the process has finished.

Linux System and IDT-Capable GuardPoint Administration

Note

For details about how to create a GuardPoint in CM, see the chapter, “Managing GuardPoints”, CTE Administration Guide.

Voradmin IDT Commands on Linux

The `voradmin` command is a command line utility for management of CTE specific configuration and status reporting. The `voradmin` command also supports configuration management related IDT-Capable GuardPoints (IDT).

For details about the Linux `voradmin idt` command options, see the man page for the `voradmin` command.

File System Mount Points on Linux

You can create and mount a file system on an IDT-Capable GuardPoint. CTE imposes one restriction on the mount point pathname selected for a device. Once you mount the device on a pathname, you cannot change the mount point to a different pathname. This restriction is enforced to allow the file system mount point to be guarded using a separate policy to enforce access control rules on the mounted file system namespace.

The following example shows the mount point of the IDT-Capable GuardPoint as the `/xfs` directory. The example also shows a failed attempt to mount the file system on a different directory pathname.

```
voradmin idt status /dev/sdc1
IDT Header on /dev/secvm/dev/sdc1
    Version:                1
    Change:                 0
Private Region Size:      129024 sectors
Exported Device Size:     9627648 sectors
    Key UUID:              9cc3c8e4-7ea7-310f-85c7-6f911de1ab52
Mount Path:               /xfs
# umount /xfs
# mkdir /other-xfs
# mount -t xfs /dev/secvm/dev/sdc2 /other-xfs
mount: permission denied
# mount -t xfs /dev/secvm/dev/sdc2 /xfs
```

Auto Mount Options for File System Devices on Linux

IDT-Capable GuardPoints containing file systems can also be added to the `/etc/fstab` configuration file for auto mount at startup or unmount at shutdown. An entry can be for a GuardPoint configured for either Auto Guard or Manual Guard. For more information about Auto and Manual Guard options, see [Guard the Linux Device with an IDT-Capable GuardPoint](#).

Use the device path corresponding to an IDT-Capable GuardPoint device when specifying `fstab` entries, such as `/dev/secvm/dev/sdh`. Do not use the native device pathnames, such as `/dev/sdh`, or device mapper device names. You must also include several settings in the `fstab` entry for each IDT-Capable GuardPoint, as shown in the following table:

Option	Description
<code>x-systemd.requires= secvm-barrier.service</code>	Ensure that the IDT-Capable GuardPoint is enabled before the device is mounted at startup and disabled after the device is unmounted at shutdown. The <code>secvm-barrier.service</code> service is a proxy for all the services that make up CTE.
<code>nofail</code>	The system boot will proceed without waiting for the IDT-Capable device if it can't be mounted successfully.

Option	Description
<code>x-systemd.wanted-by=<idt device>.device</code>	Required for Linux distributions running <code>systemd</code> 242 or later. Instructs <code>systemd</code> to add a <code>wants=</code> dependency on the IDT-Capable device to ensure that, when the device becomes available, this mount operation is executed. <code><idt device>.device</code> is the name of the device specified in <code>fstab</code> with the <code>/</code> replaced with <code>-</code> . For example, <code>/dev/secvm/dev/sdb</code> becomes <code>dev-secvm-dev-sdb.device</code> .

This is an example of an entry in `/etc/fstab` for an IDT-Capable GuardPoint with an xfs file system that is mounted on `/xfs`:

```
/dev/secvm/dev/sdh /xfs xfs x-systemd.requires=secvm-barrier.service, \
x-systemd.wanted-by=dev-secvm-dev-sdh.device,nofail 0 0
```

For information about configuring `systemd` for CTE, see [CTE and `systemd`].

Linux System Utilities for Signing

The following table includes recommendations on the system and file system specific utilities for inclusion in the signature set to allow or deny root execution.

EXT Utilities	Deny/Allow	XFS	Deny/Allow	Generic Utilities	Deny/Allow
<code>badblock</code>	Allow	<code>fsck.xfs</code>	Allow	<code>mount</code>	Allow
<code>debugfs</code>	Deny	<code>mkfs.xfs</code>	Allow	<code>umount</code>	Allow
<code>e2freefrag</code>	Allow	<code>xfs_repair</code>	Allow	<code>dmsetup</code>	Allow
<code>e2fsck</code>	Allow	<code>xfs_admin</code>	Allow		
<code>e2image</code>	Allow	<code>xfs_bmap</code>	Allow		
<code>e2label</code>	Allow	<code>xfs_check</code>	Allow		
<code>e2undo</code>	Allow	<code>xfs_copy</code>	Deny		
<code>filefrag</code>	Allow	<code>xfs_db</code>	Deny		
<code>fsck.ext2</code>	Allow	<code>xfs_estimate</code>	Allow		
<code>fsck.ext3</code>	Allow	<code>xfs_freeze</code>	Allow		
<code>fsck.ext4</code>	Allow	<code>xfs_fsr</code>	Allow		
<code>logsave</code>	Allow	<code>xfs_growfs</code>	Allow		
<code>mke2fs</code>	Allow	<code>xfs_info</code>	Allow		
<code>mkfs.ext2</code>	Allow	<code>xfs_logprint</code>	Allow		
<code>mkfs.ext3</code>	Allow	<code>xfs_mdrestor</code>	Allow		

EXT Utilities	Deny/Allow	XFS	Deny/Allow	Generic Utilities	Deny/Allow
		e			
mkfs.ext4	Allow	xfs_metadump	Allow		
resize2fs	Allow	xfs_mkfile	Deny		
tune2fs	Allow	xfs_ncheck	Allow		

Resizing Guarded IDT Devices

Devices configured as IDT-Capable can be resized using the system-provided resizing utilities. If you are using a file system on the GuardPoint, you can mount the file system after resizing the device and then grow the file system to the new size using the appropriate utility such as `xfs_growfs` or `resize2fs`.

Warning

Do not shrink IDT-Capable GuardPoints. Due to relocation of user data from the CTE Private Region, if you shrink the device, you may corrupt data on the device.

1. Stop applications from accessing the IDT-Capable GuardPoint.
 - Unmount the file system if the device is mounted.
 - Unguard the IDT-Capable GuardPoint if using Auto Guard or on the host with the `secfsd unguard <device-name>` command if using Manual Guard.
2. Use the native disk management tools to resize the device.
3. After resizing the device, check the size of the device with the `fdisk -l` or similar command. Note that you cannot use the `voradmin idt status` command to verify the new size of the device at this point because the size information is not updated in CTE until the IDT-Capable GuardPoint is re-enabled.
4. If the reported size does not match what you expect, you may need to rescan your storage devices using the command appropriate for the device's connection type.
5. Once the expected size is achieved, enable the IDT-Capable GuardPoint and restart your applications.

Resizing Guarded IDT Devices

Devices configured for in-Place Data Transformation can be resized using the system-provided resizing utilities. If you are using a file system on the GuardPoint, you can mount the file system after resizing the device and then grow the file system to the new size using the appropriate utility such as `xfs_growfs` or `resize2fs`.

Warning

Do not shrink IDT GuardPoints. Due to relocation of user data from CTE private region, if you shrink the device, you may corrupt data on the device.

1. Stop applications from accessing the GuardPoint.
 - Unmount the file system if the device is mounted.
 - Disable GuardPoints: auto-guard if it is enabled on the CipherTrust Manager, or manual-guard if it is enabled on the protected host.
2. Use the native disk management tools to resize the device.
3. After resizing the device, check the size of the device. For Linux, you can use the `fdisk -l` command.
4. If the reported size does not match what you expect, you may need to rescan your storage devices using the command appropriate for the device's connection type.
5. Once the expected size is achieved, enable the GuardPoint and restart your applications.

Examples

The following example show the administrative steps to grow an XFS file system mounted on an ES GuardPoint. The example shows a device of size 41,347,072 sectors resized to 43,395,072 sectors.

```
# fdisk -l /dev/sdh

Disk /dev/sdh: 21.2 GB, 21169700864 bytes, 41347072 sectors
Units = sectors of 1 * 512 = 512 bytes
Sector size (logical/physical): 512 bytes / 512 bytes
I/O size (minimum/optimal): 512 bytes / 4194304 bytes

# xfs_info /dev/secvm/dev/sdh
meta-data=/dev/secvm/dev/sdh      isize=512    agcount=4, agsize=1288064 blks
                                     sectsz=512    attr=2, projid32bit=1
                                     crc=1        finobt=0  spinodes=0
data      =                       bsize=4096    blocks=5152256, inampt=25
                                     sunit=0      swidth=0 blks
naming    =version 2              bsize=4096    ascii-ci=0 ftype=1
log       =internal              bsize=4096    blocks=2560, version=2
                                     sectsz=512   sunit=0 blks, lazy-count=1
realtime  =none                  extsz=4096    blocks=0, rtextents=0

# voradmin idt status /dev/sdh
ESG Header on /dev/secvm/dev/sdh
  Version:      1
  Change:      0
  Notifications: None
  Storage Status: None
  Private Region Size: 129024 sectors
  Exported Device Size: 41218048 sectors
  Key UUID:     81e415ed-4a1e-3a2f-b829-5893dd2fd0b0
  Mount Path:   N/A (GuardPoint not enabled)

# umount /xfs
# secfsd -unguard /dev/sdh
secfsd: Path is not guarded
```

In this example we resize the device on the storage array to 43395072 sectors. Notice that the `voradmin` command reports the old device size until the device is guarded.

```
# fdisk -l /dev/sdh

Disk /dev/sdh: 22.2 GB, 22218276864 bytes, 43395072 sectors
Units = sectors of 1 * 512 = 512 bytes
Sector size (logical/physical): 512 bytes / 512 bytes
I/O size (minimum/optimal): 512 bytes / 4194304 bytes

# voradmin idt status /dev/sdh
ESG Header on /dev/secvm/dev/sdh
  Version: 1
  Change: 0
  Notifications: None
  Storage Status: None
  Private Region Size: 129024 sectors
  Exported Device Size: 41218048 sectors
  Key UUID: b1e4450d-0a5e-3a8f-b829-5893dd2fd0b0
  Mount Path: N/A (GuardPoint not enabled)

# secfsd -guard /dev/sdh
secfsd: Path is guarded

# voradmin idt status /dev/sdh
ESG Header on /dev/secvm/dev/sdh
  Version: 1
  Change: 0
  Notifications: None
  Storage Status: None
  Private Region Size: 129024 sectors
  Exported Device Size: 43264048 sectors
  Key UUID: b1e4450d-0a5e-3a8f-b829-5893dd2fd0b0
  Mount Path: /xfs
```

The final step shown in below is to mount and resize the XFS file system to include the extended space into the file system.

```
# mount -t xfs /dev/secvm/dev/sdh /xfs
# xfs_growfs /xfs
meta-data=/dev/secvm/dev/sdh      isize=512    agcount=4, agsize=1288064 blks
                                     sectsz=512    attr=2, projid32bit=1
                                     crc=1        finobt=0  spinodes=0
data      =                       bsize=4096    blocks=5152256, maxpct=25
                                     sunit=0      swidth=0 blks
naming    =version 2              bsize=4096  ascii-ci=0 ftype=1
log       =internal              bsize=4096  blocks=2560, version=2
                                     sectsz=512   sunit=0 blks, lazy-count=1
realtime  =none                  extsz=4096    blocks=0, rtextents=0
data blocks changed from 5152256 to 5408256
# xfs_info /dev/secvm/dev/sdh
meta-data=/dev/secvm/dev/sdh      isize=512    agcount=5, agsize=1288064 blks
                                     sectsz=512    attr=2, projid32bit=1
                                     crc=1        finobt=0  spinodes=0
data      =                       bsize=4096    blocks=5408256, maxpct=25
                                     sunit=0      swidth=0 blks
naming    =version 2              bsize=4096  ascii-ci=0 ftype=1
log       =internal              bsize=4096  blocks=2560, version=2
                                     sectsz=512   sunit=0 blks, lazy-count=1
realtime  =none                  extsz=4096    blocks=0, rtextents=0
```

Alerts and Errors on Linux

This section lists the alerts and errors that may be encountered during system operations.

Encryption key on device has not been made available

This alert may appear as the reason for a GuardPoint not to have been enabled. The message appears in the output of `secfsd -status guard` command. The status indicates that the encryption key specified in the policy for the GuardPoint has not been made available to the protected host.

Solution: Check the host's connectivity with the Key Manager.

Specified policy disagrees with metadata set on the Guard Path

This alert may appear as the reason for a GuardPoint not to have been enabled. The message appears in the output of `secfsd -status guard` command. The status indicates that the key specified in the policy for the GuardPoint does not match with the key stored in the IDT Device Header.

Solution: Un-guard the device and check the name and UUID of the key in the IDT Device Header using `voradmin idt status <device-name>` and `voradmin idt status xform <device-name>` commands and compare the name and UUID with the key name specified in the policy. Correct the discrepancy and re-guard the device.

Device has not been configured for IDT-Capable

This alert may appear as the reason for a GuardPoint not to have been enabled. The message appears in the output of `secfsd -status guard` command. The status indicates that the device has been properly guarded as an IDT-Capable GuardPoint on the Key Manager but the device has not been initialized for guarding as IDT-Capable.

Solution: The most probable cause of this error is that you did not initialize the device for guarding as IDT-Capable on protected host. It's also possible that the guarded device has already configured for guarding as Ean IDT-Capable GuardPoint. If the device needs to be initialized for guarding as IDT-Capable, see [Initializing an IDT-Capable Device](#).

Device not resized for guarding as IDT-Capable

This message appears in the output of `secfsd -status guard` command and indicates that the IDT-Capable GuardPoint was not successfully enabled. The status indicates that the newly guarded IDT-Capable GuardPoint, which has been initialized with `xform` option of `voradmin`, has not been resized to accommodate storage space for the CTE Private Region.

Solution: Unguard the IDT-Capable GuardPoint, resize the LUN and verify that the host sees the expanded size, then guard the IDT-Capable GuardPoint from the Key Manager.

Data transformation failed

This message appears in the output of `secfsd -status guard` command and indicates that the IDT-Capable GuardPoint was not successfully guarded. The status indicates that the protected host encountered an error while transforming the data on the device during IDT.

Solution: Consult with the system and/or storage admin to check on the health of the LUN in the storage array. You may contact Thales Support for troubleshooting and recovery if there has not been a report of any error on the LUN.

Data transformation in progress

This message appears in the output of `secfsd -status guard` command and indicates that the IDT-Capable GuardPoint was not successfully enabled. The status indicates that the protected host is transforming the data on the device.

Solution: You must wait for data transformation to complete. Check the status of transformation by running `voradmin idt status xform <device name>`. Access to the device is blocked until transformation completes.

Device <device-name> is configured to guard as IDT-Capable GuardPoint

This error message is reported by the `voradmin` command when initializing a device as an IDT-Capable GuardPoint that has already been initialized for guarding as an IDT-Capable GuardPoint.

Solution: The device has already been initialized for guarding as IDT-Capable and is probably waiting to be guarded as an IDT-Capable GuardPoint through the Key Manager. Alternatively, if you want to remove the IDT-Capable configuration, use the `voradmin idt delete <device-name>` command.

Device <device-name> is configured as IDT-Capable GuardPoint

This error message is reported by the `voradmin` command when initializing a device that is already being guarded as an IDT-Capable GuardPoint.

Solution: The device is already guarded by an IDT-Capable GuardPoint.

GuardPoint for device <device-name> still guarded on Key Manager

This error message is reported by the `voradmin` command when attempting to initialize a device for rekey or removing the device as IDT-Capable.

Solution: Unguard the IDT-Capable GuardPoint, wait for the protected host to process the update, and then rerun the `voradmin` command.

Failed to open device <device-name>, error Device or resource busy

This message occurs when `voradmin` detects that the target device is busy.

Solution: The device may already be in use by other application. Rerun the `voradmin` command when the device is no longer in use.

Device <device-name> is not configured as IDT-Capable

This error message is reported by the `voradmin` command when attempting to delete a device as an IDT-Capable GuardPoint.

Solution: This message indicates that the target device has been not initialized for guarding as IDT-Capable. The message may also be reported if the specified device has been initialized for guarding as IDT-Capable but it has not been guarded yet. In this case, it removes the preparation made by `voradmin`. You can remove the IDT-Capable configuration status on the device by running `voradmin idt delete <device-name>`. You may see the same error message again, and if you do, you can ignore it.

Abort! Error: Could not stop secfs, secvm device(s) busy

This error occurs during CTE shutdown when there is a busy CTE protected device.

Solution: Verify that all applications directly accessing `secvm` protected GuardPoints have been shut down. Ensure that all file systems on top of a `secvm` protected devices are under the control of `systemd` and have been unmounted before attempting to shut down the agent.

Abort! Error: Could not unmount file systems

This error occurs during CTE shutdown when a file system under the control of `systemd` fails to unmount.

Solution: Verify that file systems on top of an IDT-Capable GuardPoint devices are not busy and then rerun the agent shut down command.

A dependency job for idt.mount failed. See 'journalctl -xe' for details

This error occurs during CTE startup when system fails to mount a file system. This error message is typically accompanied by a long timeout during the CTE startup process.

Solution: Check that the underlying device is available and that the IDT-Capable GuardPoint was successfully applied on the device. Once the device is available, the file system will automatically finish mounting.

ESG/IDT-ALERT: IO error on header for [GuardPoint]

This is an alert message to the Key Manager. It occurs when CTE encounters a general error when attempting to access the private region on an IDT-Capable device.

Solution: An I/O error attempting to read or write to the device may have been caused by errors on the host or storage array. Consult with the system and/or storage admin to check on the health of the LUN in the storage array. You may contact Thales Support for troubleshooting and recovery if there has been no report of errors on the LUN.

ESG/IDT-ALERT: Data transformation failure on [GuardPoint]

This is an alert message to the Key Manager. It occurs when protected host encounters an error transforming the data on device during IDT process.

Solution: Contact Thales Support for troubleshooting and recovery.

ESG/IDT-INFO: Data transformation complete on [GuardPoint]

This message is a notification to the Key Manager admin that the protected host has completed the data transformation of the specified IDT-Capable GuardPoint.

ESG/IDT-ALERT: Failed to resize <device-name>

This alert is a notification to the Key Manager admin that the protected host has failed to update the change to the device size in the IDT Device Header on the device.

Solution: Contact Thales Support for troubleshooting and recovery.

FSADM-ALERT: ESG/IDT required Signature Set for system utilities may have to be resigned

This alert is a notification to the Key Manager admin that the recent system upgrade to the protected host may have updated the binary files listed in the signature set for restricting root access.

Solution: Upon this notification you must immediately re-sign the affected or all the binary files to prevent them from accessing protected data.

File System is not automatically mounted after IDT completes

An IDT-Capable device with a file system that has been configured to automatically mount may fail to automatically mount while the device undergoes data transformation through IDT. Following is a sample log message in the kernel ring buffer that reports a failed attempt to access a device during IDT. You can ignore this message.

```
Vormetric SecVM: secvm_map during IDT (dc 00000000c3537611)
```

When access to a device is to mount the file system, the kernel ring buffer may also report a second error message indicating that a file system failed to mount due to data corruption. You can ignore this message. This occurs because the mount command is issued after the device has been guarded but before data transformation through IDT is complete. While IDT is in progress, the device cannot be used, so any attempt to mount the file system will fail.

Solution: Manually mount the file system after IDT is complete.

Upgrading CTE on Linux

This chapter describes how to upgrade an existing CipherTrust Transparent Encryption (CTE) client and contains the following sections:

Upgrading CTE

This section describes the generic instructions for interactively upgrading CTE. If there are any changes to this procedure for the current release of CTE, those changes will be documented in the CTE Release Notes.

If you want to schedule an upgrade to occur the next time the system boots, see [Scheduled Upgrade Feature](#).

1. Stop any application accessing files in the GuardPoint.
2. Log on to the host where you will upgrade CTE. You must have root access.
3. Copy or mount the installation file onto the host system.
4. Start the upgrade by executing the install program for the release to which you want to upgrade. If you want to automatically accept the CTE License Agreement, you can include the `-y` parameter.

For example, the following command upgrades the product to version `<Release.build-number>` after the user manually reviews and accepts the CTE License Agreement:

```
./vee-fs-7.8.0.75-rh8-x86_64.bin
```

The following command upgrades the product to version `<Release.build-number>` but automatically accepts the CTE License Agreement:

```
./vee-fs-7.8.0.75-rh8-x86_64.bin -y
```

5. Follow the prompts. During an upgrade, the following message displays. Enter Y at the prompt:

```
Upgrade detected: this product will be stopped and restarted.  
Do you wish to proceed with the upgrade? (Y/N) [Y]: Y  
Installation success.  
You will not do the registration steps since CTE is already registered with th  
e Key Manager.
```

6. To verify that the upgrade was successful, use the `vmd -v` command:

```
vmd -v  
Version 6, Service Pack 2  
<Release.build-number>  
2022-02-04  
Copyright (c) 2009-2022, Thales. All rights reserved.
```

Scheduled Upgrade Feature

- Warnings for CTE for Linux
- Using the Scheduled Upgrade Feature
- Performing a Manual Upgrade When an Upgrade is Already Scheduled

Note

Scheduled upgrade on reboot is not supported on HDFS nodes.

Warnings for CTE for Linux

- Prior to upgrading your system, perform a backup or take a snapshot of your system.
- As with prior CTE versions, Key Manager connectivity is required during upgrade.
- Yum updates, or OS patches, should be done prior to CTE upgrade on reboot.
- If you upgrade from a compatible kernel to an incompatible kernel, the `secfs` module will fail to load on the next reboot.
- You may see the following behavior if the upgrade on reboot fails due to a crash, or a power failure, (this is similar to a failure during a normal upgrade).
 - If a crash, or power failure, occurs before the upgrade executes, the upgrade will not take place, and the

currently installed CTE version continues to run after the reboot. Restart the system to upgrade successfully.

- If a crash, or power failure, occurs during the upgrade, CTE may enter an inconsistent state. Perform a restore from your backup, or roll back to the snapshot that you just took. Then, start the upgrade again.
- If a crash, or power failure, occurs after a successful upgrade, then the new version will run on the next reboot. No user intervention is required in this case.
- During reboot or shutdown, all applications and services dependent on CTE services must be stopped before a scheduled update takes place. Failure to stop these services can result in an aborted scheduled upgrade during the system reboot. Examples of situations that may cause an aborted upgrade are applications with open files in a CTE GuardPoint, or a third party anti-virus software doing periodic scans.

For examples of how to set up CTE start/stop dependencies with other programs, see [CTE and systemd](#).

Using the Scheduled Upgrade Feature

The following procedure describes how to use voradmin to schedule an upgrade that will be applied the next time the machine reboots.

1. If you want to check which version of CTE for Linux you currently have installed, use the `vmd -v` command:

```
vmd -v
Version 6, Service Pack 2
7.0.0.47
2022-02-04
Copyright (c) 2009-2022, Thales. All rights reserved.
```

2. To schedule an upgrade on reboot, use the following commands:

```
voradmin upgrade schedule <path_to_CTE_installer_binary> y [-t <custom_extraction_path>]
```

where:

- `<path to CTE installer>` is the full path to the CTE installation file for the release to which you want to upgrade. For example, `./vee-fs-7.8.0.75-129-rh8-x86_64.bin`.
- `-y` is an optional parameter that automatically accepts the CTE License Agreement. If you do not specify this parameter, the installer displays the CTE License Agreement and you must manually accept it before the upgrade can be scheduled.
- `[-t <custom_extraction_path>]` is an optional parameter that specifies the path to a custom binary extraction path directory in which you want CTE to store the temporary files it needs during the upgrade. The default is `/var/tmp/`, but in some systems, `/var/tmp/` is restricted and not available for use.

Exceptions: Do not use the `-t` option on protected paths, GuardPoint paths, or paths which do not have sufficient permissions to copy/extract the target binary.

For example, if you are upgrading to version 7.2.0.xx and you want to automatically accept the license agreement and use a custom directory, you would type:

```
voradmin upgrade schedule ./vee-fs-7.2.0-98-rh8-x86_64 -y -t /my_custom_dir
```

Note

The `[-t]` option is only supported by CTE v7.2 and subsequent versions.

3. If you want to verify that the upgrade was successfully scheduled, use the `voradmin upgrade show` command:

```
voradmin upgrade show
Upgrade on reboot is currently scheduled.
Current CTE version is 7.0.0.47, upgrade on reboot scheduled for CTE 7.1.0.66.
```

4. Reboot the machine, then log in and verify that the upgrade was successful.

```
vmd -v
Version 6, Service Pack 2
7.1.0.66
2022-02-04
Copyright (c) 2009-2022, Thales. All rights reserved.
```

Note

Appropriate logs will be logged in syslog.

Performing a Manual Upgrade When an Upgrade is Already Scheduled

If an administrator runs a manual upgrade after an upgrade has already been scheduled, the installer displays the following warning:

```
WARNING: upgrade on reboot is already scheduled for 7.1.0.66.

Do you want to cancel scheduled upgrade on reboot ? (Y/N) [Y] :
```

If the administrator does *not* cancel the scheduled upgrade, the scheduled upgrade takes precedence and the manual upgrade fails with the message:

```
Already scheduled upgrade on reboot remains intact.

Installation failure.
```

If the administrator wants to proceed with the manual upgrade immediately, they must enter Y at the prompt to cancel the scheduled upgrade:

```
WARNING: upgrade on reboot is already scheduled for 7.1.0.66.

Do you want to cancel scheduled upgrade on reboot ? (Y/N) [Y] : Y

WARNING: upgrade on reboot is cancelled for 7.1.0.66. Proceeding with manual upgr
ade.

Upgrade detected: this product will be stopped and restarted.

Do you wish to proceed with the upgrade? (Y/N) [Y]: Y

.....

Upgrade success.
```

To verify that the upgrade succeeded, the administrator can use the `vmd -v` command:

```
vmd -v
Version 6, Service Pack 2
7.1.0.66
2022-02-04
Copyright (c) 2009-2022, Thales. All rights reserved.
```

To cancel an existing scheduled upgrade on reboot:

```
voradmin upgrade cancel
Successfully cancelled upgrade on reboot
```

Upgrading CTE agents in an LDT Communication Group from 7.4.0 to 7.5.0 and post 7.5.0

When upgrading the CTE agent version on all nodes of an LDT Communication Group, you must stop CTE on all of the nodes to be upgraded before upgrading them.

1. Unguard the GuardPoints on the nodes to be upgraded:
 - a. Go to the CipherTrust Manager UI.
 - b. In the GuardPoint window, click the ellipsis on the right side of a GuardPoint and select disable to disable the GuardPoint.
 - c. Repeat the steps for all of the GuardPoints on the nodes to be upgraded.

2. Stop the CTE service on all of the nodes to ensure that all of the GuardPoints are unguarded.

For **Windows**:

- a. Go to **Control Panel > Services (local)**.
- b. Select **secfsd**.
- c. Select **Stop the Service**.

For **Linux**, type:

```
/etc/vormetric/secfs stop
```

3. Upgrade CTE on all of the nodes.
4. If your setup contains **manual directory** type GuardPoints, then you must run `secfsd -guard <gp>` to guard the GuardPoints again after the upgrade.
5. Verify that the GuardPoints are guarded on all of the nodes. Type:

```
# secfsd -status guard
```

Uninstalling CTE from Linux

Considerations

- The CTE Agent must be removed from the Linux host before the host is removed from the key manager with which it is registered.
- Database applications like DB2 and Oracle can lock the user space while they run. If the uninstall fails because a GuardPoint is in use, determine which applications are using the files in the GuardPoint and stop them. Then run the uninstall again.
- Commands like `fuser` and `lsof` might not reveal an active GuardPoint because they detect active usage, not locked states. Although it may appear that a GuardPoint is inactive, it may be in a locked state. Under this condition, software removal may fail with an error similar to the following:

```
/home: device is busy.
```

Procedure

1. Stop any application from accessing files in the GuardPoint.
2. In the key manager with which this host is registered, do the following:

- Decrypt any data you want to use after uninstall. After the CTE Agent software is removed, access to data is no longer controlled. If data was encrypted, it will remain encrypted. If decrypted or copied out of the GuardPoint, the data is visible as clear text.

This decryption must be done on *every* GuardPoint on the host if you want to access all existing data on the host.

- Make sure the Agent and System locks have been disabled for the host.
- Thales recommends that you remove all GuardPoints from the host before you uninstall the CTE Agent.

Do not remove the host from the key manager yet.

3. Log on to the host as `root`.
4. Change the directory to an unguarded location (for example, `/.`).

Caution

Do not change (`cd`) into the `/opt/vormetric` directory or into any directory below `/opt/vormetric`. If you run the uninstaller from `/opt/vormetric` or any of its subdirectories, the package removal utility may fail and return the following message:

You are not allowed to uninstall from the `/opt/vormetric` directory or any of its sub-directories.
Agent uninstallation was unsuccessful.

5. Start the uninstall. Type:

```
/opt/vormetric/DataSecurityExpert/agent/vmd/bin/uninstall
Would you like to uninstall the vee-fs package? (Y/N) [Y]: Y
.....
Success!
```

6. Remove the host record from the key manager.

Migrating Agents from CTE-U to CTE

Note

This process **only** works on NFS. It is **not** supported on a Local File System.

Assumptions

- CTE-U agents are installed on a client and registered to a CipherTrust Manager.
- GuardPoints are setup and encrypting data on the CTE-U Agent.

Migrating

When you have a CTE-U agent that is already registered with CipherTrust Manager, and you want to change it from CTE-U to CTE, you **must** perform the following steps in order:

1. Unguard the GuardPoints on the client from CipherTrust Manager.
 - a. Go to the CipherTrust Manager UI.
 - b. In the GuardPoint window, click the ellipsis on the right side of a GuardPoint and select **disable** to disable the GuardPoint.
 - c. Repeat the steps for all of the GuardPoints on the nodes to be upgraded.
2. Uninstall the CTE-U software from the agent.
3. Unenroll the client from CipherTrust Manager.
4. Delete the entry from CipherTrust Manager.
5. Add the client back into CipherTrust Manager.
6. Install and Register the new Agent.
7. Create a new LDT policy.

Note

Make sure that the policy uses the same key in CTE-U and in CTE.

8. Create new LDT GuardPoints and apply the LDT policy to the new GuardPoints on the CTE agent.

CipherTrust Transparent Encryption

Version: v7.8.0 (latest)

CTE Agent Linux and Windows Quick Start Guide

CTE protects data at rest, residing on Direct Attached Storage (DAS), Network Attached Storage (NAS), Storage Area Networks (SAN) or in the Cloud. This can be a mapped drive or mounted disk, as well as through Universal Naming Convention paths.

CTE secures data with little impact to application performance. It requires no changes to your existing infrastructure and supports separation of duties between data owners, system administrators, and security administrators.

This section describes how to install CTE on Linux and Windows systems using the standard, interactive installation script for Linux and interactive installer for Windows. After successful installation, register that system with CipherTrust Manager and then create your policies, encryption keys, and GuardPoints using the CipherTrust Manager.

This section contains the following topics:

- [Protecting Data with CTE](#)
- [Using and Renewing Certificates](#)
- [Installation Prerequisites](#)
- [Installing and Registering CTE](#)
- [Guarding a Directory with CipherTrust Manager](#)
- [Guarding a Directory with Ransomware Protection](#)

Installation Prerequisites

The following prerequisites must be met for CTE to install and register to CipherTrust Manager properly:

- CipherTrust Manager installed and configured. See [CipherTrust Manager Documentation](#) for more information.
- CipherTrust Manager must contain a Client Profile. See [Changing the Profile](#) for more information.
- CipherTrust Manager must contain a registration token. See [Creating a Registration Token](#).
- Optionally, the name of the host group you want this client to be a part of.
- CipherTrust Manager must contain an LDT Communication Group if you will use LDT to guard data over CIFS/ NFS shares using LDT policies. See [Managing LDT Communication Groups](#) for more information.

Minimum Hardware Requirements for CTE

The following requirements are the minimum for CTE. When you add LDT, or third-party applications, you need to add more storage and RAM. Refer to the [LDT guide](#) for LDT requirements and the third-party software for their requirements.

Component	CPU	CPU Cores	RAM	Storage (Free Space)
CTE-Windows	Intel/AMD x64 with AES-NI support	4 cores	8 GB	1GB
CTE-Linux	Intel/AMD x64 with AES-NI support	4 cores	8 GB	1GB
CTE-AIX	IBM PowerPC8 or higher	4 cores	8 GB	1GB

Port Configuration Requirements

The following port information applies to both Windows and Linux systems.

Communication through a Firewall

If a protected client must communicate with CipherTrust Manager through a firewall, see the CipherTrust Manager documentation to determine which of the ports must be opened through the firewall.

Communication with CipherTrust Manager

The default port for http communication between CipherTrust Manager and the CTE Agent is **443**. If this port is already in use, you can set the port to a different number during the CTE Agent installation.

Communication for LDT over CIFS/NFS

All nodes that intend to use **LDT over CIFS/NFS** GuardPoint must have the following ports open:

- 7024
- 7025

Note

When you are registering a CipherTrust Transparent Encryption client with CipherTrust Manager, you can manually include a destination port number, (Default: 443). If you enter a port value, using the syntax **<hostname or IP address>:<port number>** then CipherTrust Transparent Encryption **does not** perform a port scan. CipherTrust Transparent Encryption uses the port number provided to verify the target server type using a TLS operation.

If you do not enter a port number, CipherTrust Transparent Encryption performs a port scan to check which ports are listening, including port 443.

Linux

Recommendations and Considerations

- The host on which you want to install CTE *must* support AES-NI hardware encryption. If it does not, any attempt to install or upgrade CTE to release 7.0.0, or any subsequent version, will fail.
- Thales recommends that you install CTE in the default location.
- Do not install CTE on network-mounted volumes such as NFS.
- Make the Installation root directory `/opt` a real directory. If `/opt` is a symlink, you **must** use the `-d` option to specify the installation directory, which must be a real directory.

For example:

```
./vee-fs-7.8.0.75-rh8-x86_64.bin -d /home/hello/
```

Network Setup Requirements

- The IP addresses, routing configurations, and DNS addresses must allow connectivity of the CipherTrust Manager to all clients where you install CTE.
- If the host is a virtual machine, the VM must be deployed and running.

Windows

Recommendations and Considerations

- The host on which you want to install CTE *must* support AES-NI hardware encryption. If it does not, any attempt to install or upgrade CTE to release 7.0.0, or any subsequent version, will fail.
- The IP addresses, routing configurations, and DNS addresses must allow connectivity of the Windows system on which you plan to install CTE to the CipherTrust Manager. After the Windows system is registered as a client with the CipherTrust Manager, the client must be able to poll the CipherTrust Manager in case there are any changes to the encryption keys, policies, or GuardPoints.
- CipherTrust Transparent Encryption must also allow for connectivity of the CipherTrust Manager to all of the clients where you install CTE, as well as communication between different CTE clients that plan to enable LDT over NFS/CIFS.
- If the system is a virtual machine, the VM must be deployed and running.

Installing and Registering CTE

During the installation, you are asked a series of questions. After the installation, you are prompted to immediately register the CTE with a key manager. CTE must be registered with a key manager before you can protect any of the devices on the host.

Select the type of installation you want to do:

- Installation and Registration on Linux
- Installation and Registration on Linux with UEFI Secure Boot
- Windows Installation
- Windows Registration

Installation and Registration on Linux

1. Log on to the host where you will install the CTE Agent as `root`. You cannot install the CTE Agent without `root` access.
2. Copy or mount the installation file to the host system. If necessary, make the file executable with the `chmod` command.
3. Install the CTE Agent. A typical installation uses the following syntax:

```
./vee-fs-<release>-<build>-<system>.bin
```

For example:

```
./vee-fs-7.8.0.88-rh8-x86_64.bin
```

To install the CTE Agent in a custom directory, use the `-d <custom-dir>` option. For example:

```
./vee-fs-7.8.0.88-rh8-x86_64.bin -d /home/my-cte-dir/
```

Note

- If possible, Thales recommends that you use the default directory `/opt/vormetric`.
- Custom directories are **only available** for RHEL and SLES.
- Custom directories are **not available** for COS (Cloud Object Storage).

To view all installer options, use the `-h` parameter. For example:

```
./vee-fs-7.8.0.88-rh8-x86_64.bin -h
```

4. The Thales License Agreement displays. When prompted, type **Y** and press Enter to accept.

The install script installs the CTE Agent software in either `/opt/vormetric` or your custom installation directory and then prompts you about registering the CTE Agent with a key manager.

Welcome to the CipherTrust Transparent Encryption File System Agent Registration Program.

```
Agent Type: CipherTrust Transparent Encryption File System Agent
Agent Version: <Release.build-number>
```

```
In order to register with a CipherTrust Manager you need a valid registration token from the CM.
```

```
Do you want to continue with agent registration?(Y/N) [Y]:
```

5. Type **N** and press Enter to end the installation procedure without registering the CTE Agent with a key manager.
6. Enter **Y** to continue with the registration process. The install script prompts you to enter the host name or IP address of the CipherTrust Manager with which you want to register CTE. For example:

CTE for CipherTrust Manager

```
Do you want to continue with agent registration? (Y/N) [Y]: Y
```

```
Please enter the primary key manager host name: 10.3.200.141
```

```
You entered the host name 10.3.200.141
```

```
Is this host name correct? (Y/N) [Y]: Y
```

CTE for CDSPaaS

```
Do you want to continue with agent registration? (Y/N) [Y]: Y
```

```
Enter the primary key manager host name of the service:
```

```
You entered the host name us1.ciphertrust.dpondemand.io
```

```
Is this host name correct? (Y/N) [Y]: Y
```

Host names:

- **Europe:** `ciphertrust.dpondemand.io`
- **North America:** `us1.ciphertrust.dpondemand.io`

Note

The default communication port is 443. If you want to specify a different communication port, enter it with the primary key manager host name in the format: `<hostName>:<port#>`. For example, `10.3.200.141:8445`.

7. Enter the client host name when prompted.

```
Please enter the host name of this machine, or select from the following list.
```

```
[1] sys31186.qa.com
```

```
[2] 10.3.31.186
```

```
Enter a number, or type a different host name or IP address in manually:
```

```
What is the name of this machine? [1]: 2
```

```
You selected "10.3.31.186".
```

8. Enter the CipherTrust Manager registration token, profile name, host group and host description. If you omit the profile name, CipherTrust Manager associates the default client profile with this client.

```
Please enter the registration token: 12345
```

```
Please enter the profile name for this host: My-Profile
```

```
Please enter the host group name for this host, if any:
```

```
Please enter a description for this host: RHEL7 system West Coast Datacenter
```

```
Token : 12345
```

```
Profile name : My-Profile
```

```
Host Group : (none)
```

```
Host description : RHEL7 system West Coast Datacenter
```

```
Are the above values correct? (Y/N) [Y]: Y
```

9. At the hardware association prompt, select whether you want to enable the hardware association feature to prevent cloning. The default is Y (enabled):

It is possible to associate this installation with the hardware of this machine. If selected, the agent will not contact the key manager or use any cryptographic keys if any of this machine's hardware is changed. This

can be rectified by running this registration program again. Do you want to enable this functionality? (Y/N) [Y]:
Y

10. Type Y to support Filesystem encryption and to choose other features. Type N if you only want to support Ransomware Protection. If you type N, then LDT and COS are not supported.

```
Do you want this host to have Filesystem encryption support enabled on the server? (Y/N) [Y]:
```

11. At the LDT prompt, specify that you want this client to use CTE-LDT by typing Y and pressing Enter:

```
Do you want this host to have LDT support enabled on the server? (Y/N) [N]: Y
```

12. If you are planning to create GuardPoints on NFS shares, enter the name of the LDT Communication Group that this node will join.

```
Enter the LDT Communication Group name: LCG1
```

Warning

The registration token, profile name, client group name and LDT Communication Group name are case-sensitive. If any of these are entered incorrectly, the client registration will not succeed. If the registration fails, click Back in the installer and verify that the case is correct for all entries on this page.

13. The installation checks for Confidential Computing adapter types. If it finds one, it states:

```
The following confidential computing adapter types have been identified.
1. Intel Trust Domain Extensions (tdx)
Do you want this host to have confidential computing enabled? (Y/N) [N]:
```

Type Y to enable Confidential Computing.

14. At the Cloud Object Storage (COS) prompt, specify whether you want this client to use CTE COS.

```
Do you want to configure this host for Cloud Object Storage? (Y/N) [N]:
```

15. Specify if you want to enable Ransomware Protection.

```
Do you want this host to have Ransomware Protection support enabled on the server?
```

```
ver? (Y/N) [N]:
```

16. CTE finishes the installation and registration process.

```
Generating key pair for the kernel component...done.
Extracting SECFS key
Generating EC certificate signing request for the vmd...done.
Signing certificate...done.
Enrolling agent with service on 10.3.200.141...done.
Successfully registered the CipherTrust Transparent Encryption CTE Agent with
the CipherTrust Manager on 10.3.200.141.

Installation success.
```

17. In CipherTrust Manager, change the client password using the manual password creation method. This password allows users to access encrypted data if the client is ever disconnected from the CipherTrust Manager. For details on changing the password, see the CipherTrust Manager documentation.

Installation and Registration on Linux with UEFI Secure Boot

If you want to install the CTE Agent software on a Linux system that has UEFI Secure Boot enabled, you must first download the appropriate Thales public certificate for your version of CipherTrust Transparent Encryption, and add that certificate to the MOK (Machine Owner Key) list.

Note

- The Thales public certificate is valid for three years from the date of issuance. Six months before the current public certificate is set to expire, Thales will release an advisory, along with the new certificate, that will become valid after the six month grace period expires. All future builds of CipherTrust Transparent Encryption will be built with the new certificate.

Warning

- You can only use the new certificate if the CTE build has been signed with the new certificate. If you are using an older version of CipherTrust Transparent Encryption that was signed with a previous certificate, then you **must** use that certificate with CipherTrust Transparent Encryption.

Public Certificate Naming Convention

The Thales public certificate name is `CTE_Secure_Boot_Cert_MM-DD-YYYY.der`:

Example

```
CTE_Secure_Boot_Cert_05-15-2023.der
```

Getting the Current Public Certificate

There are two options for getting the certificate:

Option 1: Install the DER file

1. Download the CipherTrust Transparent Encryption binaries to your local system.
2. Use the `-e` option to extract the public certificate from the downloaded binary:

```
./<cte-binary-name>.bin -e
```

Example

```
./vee-fs-7.8.0.75-95-rh8-x86_64.bin -e
```

3. Add the certificate to the MOK list.

Option 2: Convert the PEM file to DER

1. Download the certificate from the Thales public directory [CTE_Secure_Boot Repository](#)

```
curl -O https://packages.vormetric.com/pub/CTE_Secure_Boot/<certificate_name>.pem
```

Example

```
curl -O https://packages.vormetric.com/pub/CTE_Secure_Boot/CTE_Secure_Boot_Cert_05-15-2023.pem
```

Note

You can also download it from the [Thales Customer Support Portal: KB0027431](#).

2. Convert the certificate from a PEM file to a DER file using the following command:

```
openssl x509 -inform PEM -outform DER -in <certificate_name>.pem -out <certificate_name>.der
```

Example

```
openssl x509 -inform PEM -outform DER -in CTE_Secure_Boot_Cert_05-15-2023.pem  
-out CTE_Secure_Boot_Cert_05-15-2023.der
```

3. Add the certificate to the MOK list.

Adding the Certificate to the MOK List

Note

During this procedure, you **must** reboot the Linux host and then respond to a system prompt as soon as the host restarts.

1. Log into the host as **root**.
2. Add the certificate to the MOK list:

```
mokutil --import <cert-name>
```

Example

```
mokutil --import CTE_Secure_Boot_Cert_05-15-2023.der
```

3. Enter and confirm a password for this request when prompted.
4. Reboot the host and follow the instructions on the console when the host is back online. You will need to enter the password you created in the previous step when prompted. For detailed information, refer to the specific instructions from each linux distribution.

Note

If you do not respond to the system prompt to update the MOK when the host restarts, the prompt will time out and you will need to run the **mokutil** command again.

5. When prompted, reboot the host again.

6. After the host has rebooted for the second time, verify that the certificate has been properly added to the MOK list:

```
mokutil --test-key <cert-name>
```

Example

```
mokutil --test-key CTE_Secure_Boot_Cert_05-15-2023.der
```

Response

```
CTE_Secure_Boot_Cert_05-15-2023.der is already enrolled.
```

Windows Installation

1. Log on to the host as a Windows user with System Administrator privileges.
2. Copy the CTE installation file onto the Windows system.
3. Double-click the installation file. The InstallShield Wizard for CipherTrust Transparent Encryption opens.
4. Verify the version of CTE you are installing and click **Next**.
5. On the **License Agreement** page, accept the License Agreement and click **Next**.
6. Click **Next** to accept the default folder. When you are done, click **Next**.

Note

- Thales recommends that you install CTE in the default installation directory, `C:\Program Files\Vormetric\DataSecurityExpert\agent\`
- You **must** install the CTE Agent on the same drive as Windows. For example, if Windows is installed on the **C:** drive, you must install the CTE Agent on the **C:** drive.

7. On the **Ready to Install** page, click **Install**. When the installation is finished, the **Install Shield Wizard Completed** window opens.
8. On the **InstallShield Wizard Completed** page, make sure the **Register CipherTrust Transparent Encryption now** option is selected and click **Finish**. The installer opens the [Register CipherTrust Transparent Encryption](#) wizard.

Windows Registration

The following procedure describes how to register the CTE Agent after installation is complete.

Use the `register_host` utility to create certificate requests, exchange certificates between the CipherTrust Manager and the host, to enable ransomware detection, and to register CTE on the CipherTrust Manager. After the host is registered, if you selected to enable file system encryption, you can configure CTE, apply GuardPoints, or perform database backups. If you selected ransomware protection, you can apply the protection to volumes. Run the `register_host` utility in text mode on a terminal window.

Caution

The default host registration timeout is 10 minutes. If the host is unable to reach the CipherTrust Manager within the allotted period because of an extremely slow network connection, set the `REGISTER_HOST_TIMEOUT` environment variable to extend the registration timeout. The variable value is an integer expressed in seconds. You might also have to extend the default TCP timeout.

1. Log on to the host as a Windows user with administrative privileges.
2. Launch the CTE Registration Wizard using one of the following methods:
 - In the system tray, right click the CipherTrust Lock icon and select **Register Host**.
 - Run `...\register_host.exe -vmd -silent`.
3. Reboot the system. CTE automatically displays the registration wizard if CTE is not already registered.
4. In the Register Host dialog box, verify the host's machine name and click **Next**.

Note

For CipherTrust Data Security Platform Services, the host names of the services are:

- **Europe:** `ciphertrust.dpondemand.io`
- **North America:** `us1.ciphertrust.dpondemand.io`

5. On the **Gathering agent information** page, select one or both of the following options and click **Next**.
 - **File System:** Allows you to protect and encrypt CTE files with policies
 - **Ransomware Protection:** Protects volumes from ransomware
6. On the **Gathering Key Manager information** page, enter the FQDN or IP address of the primary CipherTrust Manager.

The default communication port is 443. If you want to specify a different communication port, enter it with the primary key manager host name in the format: **<hostName>:<port#>**. For example:10.3.200.141:8445

When you are done, click **Next**. CTE communicates with the selected CipherTrust Manager to validate what features have been licensed and are available to the CTE Agent.

7. On the **Gathering host information** page:

File System

- Specify the host name or IP address of the client. You can select the host name from the drop-down list or type it in the field.
- To prevent cloning, select **Enable Hardware Association**. For details, see [Hardware Association Feature](#).
- If you want to have CipherTrust Transparent Encryption - Live Data Transformation available on the client, select **Enable LDT Feature**. For details on LDT, [CTE Agent Live Data Transformation](#).
- If you want the node to be an [Windows AccessOnly](#) node, select **Enable LDT AccessOnly Feature**.

Ransomware

- Specify the host name or IP address of the client. You can select the host name from the drop-down list or type it in the field.
- To prevent cloning, select **Enable Hardware Association**. For details, see [Hardware Association Feature](#).

When you are done, click **Next**.

8. On the **Gathering registration information** page, enter the following:

File System

- **Registration token:** The registration token for the CipherTrust Manager with which you want to register this host.
- **Profile name:** The name of the profile that you want to associate with this host. This name must match exactly the name of the profile in the CipherTrust Manager. If you do not specify a profile name, the CipherTrust Manager associates the default client profile with this client.
- **Host group** (optional): The name of the client group to which the client will be added.
- **Host description** (optional): A user-defined description of the client. This description will be displayed in the CipherTrust Manager.
- **LDT Communication Group:** If you are planning on using LDT over CIFS/NFS on a CipherTrust Manager, enter the name of the LDT Communications Group that this node will join. See [Adding Clients to an LDT Communication Group](#) for more information.

Ransomware

- **Registration token:** The registration token for the CipherTrust Manager with which you want to register this host.
- **Profile name:** The name of the profile that you want to associate with this host. This name must match exactly the name of the profile in the CipherTrust Manager. If you do not specify a profile name, the CipherTrust Manager associates the default client profile with this client.
- **Host group** (optional): The name of the client group to which the client will be added.
- **Host description** (optional): A user-defined description of the client. This description will be displayed in the CipherTrust Manager.

Warning

The registration information is case-sensitive. If any of it is entered incorrectly, the client registration will not succeed. If the registration fails, click **Back** in the installer and verify that the case is correct for all entries on this page.

When you are done, click **Register**. CTE contacts the CipherTrust Manager and attempts to register the client with the specified options. The Register Host dialog box displays a message with the results of the registration request.

If the registration completed successfully, click **Finish**.

9. Restart the client to complete the installation process on the client.
10. After the host has rebooted, you can verify the installation by checking CTE processes:
 - a. In the system tray of the protected host, right-click the CipherTrust Lock icon.
 - b. Select **Status**. Review the information in the **Status** window to confirm that the correct CTE version is installed and registered.
 - If you are using CipherTrust Manager version 2.2 or later, you can now use CipherTrust Manager to administer CTE on the client.

If you are using CipherTrust Manager version 2.1 or earlier, change the client password using the manual password creation method. This password allows users to access encrypted data if the client is ever disconnected from the CipherTrust Manager. For details on changing the password, see the CipherTrust Manager documentation.

Guarding a Directory with CipherTrust Manager

After you register a client with a CipherTrust Manager, you can create as many GuardPoints on the client as you need. These GuardPoints can protect an entire device or individual directories.

Note

In Windows, for guarding using LDT on a local drive, or on a CIFS/Share drive, refer to the [CTE-Live Data Transformation with CipherTrust Manager](#) guide.

In order to guard a device or directory, you need to use the CipherTrust Manager Console to:

1. [Access the CipherTrust Manager domain](#) in which the client is registered.
2. [Identify or Create an Encryption Key](#) that CTE will use to encrypt the data on the device or directory.
3. [Create a Standard Policy](#) for the device or directory that specifies the access controls and the encryption keys to use for the device or directory.
4. [Create and Assign a GuardPoint](#) to the device or directory.

Access the CipherTrust Manager Domain

1. In a web browser, navigate to the URL of the CipherTrust Manager Console you want to use and log in with CipherTrust Manager Administrator credentials.
2. If the client you want to protect is registered to the default domain (root), proceed to [Create an Encryption Key](#). If you need to change to a different domain, do the following:
 - a. In the top menu bar, click the user name **root/admin** on the right-hand side.
 - b. Select **Switch Domains**, then select the domain in which the client is registered.
 - c. The logged in user now shows the new domain name/user name.

Identify or Create an Encryption Key

1. From the Products page in the CipherTrust Manager Console, click **Keys** in the left hand pane.

Tip

To navigate to the Products page from anywhere in the CipherTrust Manager Console, click the App Switcher icon in the top left corner.

2. Above the Key table, click **Add Key**.
3. In the **Key Name** field, add a name for the key. This name must be unique. For example, Simple-Key.
4. In the **Key Usage** section, make sure **Encrypt** and **Decrypt** are selected.
5. Click **Add Key**. CipherTrust Manager displays the properties for the new key.
6. In the general options area, enable the **Exportable** option.

You can also enable the **Deletable** option in this section if you want a CipherTrust Manager Administrator to be able to delete the key.

ID	2e58c582..51136313	Owner	Global	Object Type	Symmetric Key
UUID	e3ad9c3e..70d47711	Created	05 Mar 2021, 05:13	Algorithm	AES
MUID	e3ad9c3e..7b333c9f	Last Modified	05 Mar 2021, 05:13	Size	256
KeyID	N/A	Exportable	☒	Deletable	☐

7. In the **Key Access** section, do the following:

a. In the Search Groups box, type **CTE**.

If no groups display, make sure that the **Added Only** option is **disabled**.

b. Click the **Read** and **Export** option for both the CTE Admins and CTE Clients groups.

c. When you are done, click **Update**.

8. Click the **CTE** tab and set the following properties:

- **CTE Versioned:** Specify whether the key is versioned.

For a standard policy, and for CTE-U, you should clear this check box. If you do not, the key will not appear in the keys list when you add the key rule to the standard policy.

Note

CTE-U **only** supports standard and offline policies. It **does not** support LDT.

- **Persistent on Client:** Specify whether the key is stored in persistent memory on the client.

Unselected

The keys are only stored on the disk inside the CipherTrust Manager. When required, they are downloaded to CipherTrust Transparent Encryption, but only cached in kernel memory and while encrypted. This is the default mode. The Agent continues to work even if communication to CipherTrust Manager is not active. Note that this mode requires a stable connection between CipherTrust Manager and the CipherTrust Transparent Encryption agent in case the agent is restarted, or the server is rebooted to retrieve the keys and policies from CM.

- **Selected**

In this mode, the keys are further encrypted with a derived key generated using a FIPS-approved derivation function and stored in the local protected directory which can be accessed only by CTE services and utilities. If the connection between CipherTrust Manager and CTE agent is not available, keys are recovered for service through the challenge/response mechanism.

- **Encryption Mode:** Encryption mode of the key. The options are:

- XTS/CBC-CS1
- CBC

For CTE-U, select CBC-CS1. CBC keys are supported due to legacy key requirements, but they are not recommended for CipherTrust Transparent Encryption UserSpace.

9. When you are done, click **Update**.

For creating keys through the API, see [Creating Keys](#) for more information.

Create a Standard Policy

1. In the Applications page of the CipherTrust Manager Console, select the **Transparent Encryption** application.
2. In the sidebar on the Clients page, click **Policies**.
3. Click **Create Policy**. CipherTrust Manager displays the Create Policy Wizard.
4. On the General Info page, set the following options:

Field	Description
Name	A unique name for the policy. Make sure you use a name that is descriptive and easy to remember so that you can find it quickly when you want to associate it with a GuardPoint.. This example uses "Simple-Policy".
Policy Type	The type of policy you want to create.. In this example, we will create a Standard policy.
Description	A user-defined description to help you identify the policy later.. For example: Standard policy for new GuardPoints
Learn Mode	Learn Mode provides a temporary method for disabling the blocking behavior of CTE/LDT policies. While useful for quality assurance, troubleshooting,

Field	Description
	and mitigating deployment risk, Learn Mode is not intended to be enabled permanently for a policy in production. This prevents the policy Deny rules from functioning as designed in the policy rule set.. Ensure that the policy is properly configured for use in Learn Mode. Any Security Rule that contains a Deny effect must have Apply Key applied as well. This is to prevent data from being written in mixed states, resulting in the loss of access or data corruption. Apply Key will have no effect when combined with a Deny rule unless the policy is in Learn Mode.
Data Transformation	If you select Standard as the policy type, also select the Data Transformation option to tell CTE that you want to change the current encryption key used on the data in the GuardPoint, or that you want to encrypt clear-text data for the first time.. This option is only displayed for Standard policies.

When you are done, click **Next**.

- On the Security Rules page, define the security rules that you want to use.

CipherTrust Manager automatically adds a default security access rule with an action of **key_op** and the effects **Permit** and **Apply Key**. This rule permits key operations on all resources, without denying user or application access to resources. This allows it to perform a rekey operation whenever the encryption key rotates to a new version.

To add additional security rules, click **Create Security Rule** and enter the requested information. For details about adding security rules, see the CipherTrust Manager documentation.

When you are done, click **Next**.

- On the Create Key Rule page, click **Create Key Rule** and enter the following information:

Field	Description
Resource Set	If you want to select a resource set for this key rule, click Select and either choose an existing resource set or create a new one. Resource sets let you specify which directories or files will either be encrypted with the key or will be excluded from encryption with this key.

Field	Description
Current Key Name	Click Select to choose an existing key or create a new one. If the data has not yet been encrypted, select clear_key. Otherwise select the name of the non-versioned key that is currently being used to encrypt the data. In this example, select clear_key.
Transformation Key Name	Click Select to choose an existing versioned key or to create a new one. CTE uses the versioned key specified in this field to encrypt the data in the GuardPoint. If the data is currently encrypted, CTE decrypts it using the key specified in the Current Key Name field and re-encrypts it using the key specified in this field.

When you are done, click **Next**.

- On the Data Transformation page, click **Create Data Transformation Rule** and enter the following information:

Field	Description
Resource Set	If you want to select a resource set for this key rule, click Select and either choose an existing resource set or create a new one. Resource sets let you specify which directories or files will either be encrypted with the key or will be excluded from encryption with this key.
Transformation Key Name	Click Select to choose an existing key or to create a new one. CTE uses the key specified in this field to encrypt the data in the GuardPoint. If the data is currently encrypted, CTE decrypts it using the key specified in the Current Key Name field and re-encrypts it using the key specified in this field. For this example, select the key Simple-Key you created in Create an Encryption Key.

When you are done, click **Next**.

- Click **Next**.
- On the confirmation page, review the information for the policy and click **Save**.

Security Rule Ordering for Policies

If you want to enforce restrictions when guarding NFS/CIFS shares using an LDT or standard policy with a **CBC-CS1** key, note the following:

CipherTrust Transparent Encryption embeds the LDT and/or IV (initialization vector) attributes in the first 4K of files for NFS/CIFS shares guarded with an LDT or standard policy with a **CBC-CS1** key. Embedding CipherTrust Transparent Encryption attributes increases the actual file size by 4K. CTE hides that extra 4K when reporting the file size to users, or processes, that access the file with the Apply Key effect.

If you need the actual file size, or read/write access on the embedded header, for backup/restore processes for example, then you need a rule that permits access without Apply Key.

LDT Policies

Example 1: Permits Backup and Restore

A policy that allows backup and restore of encrypted data, clear-text access to certain processes, and denies access to all others:

Order	Resource Set	User Set	ProcessSet	Action	Effect	Browsing	
1				key_op	permit:applykey	No	
2			backup	all_ops	permit:audit	Yes	
3			authorized-processes	all_ops	permit:audit:applykey	Yes	
4				all_ops	deny:audit	Yes	

Rule	Purpose
1	Default LDT rule required for LDT policies.
2	Allows for processes in the backup Process Set to access the real file size and backup the CipherTrust Transparent Encryption attributes along with the encrypted file data.
3	Allows for processes in the authorized-processes Process Set to access the clear-text data, but it hides the additional 4K from the CipherTrust Transparent Encryption attribute.
4	Denies all other processes access to the data.

Example 2: Permits access to certain Processes

A policy that only allows certain processes clear-text access but allows all others to see the OS file attributes.

Order	Resource Set	User Set	ProcessSet	Action	Effect	Browsing	
1				key_op	permit:applykey	No	
2			authorized-processes	all_ops	permit:audit:applykey	Yes	
3				f_md_audit_md_read_r...	permit:audit	Yes	
4				all_ops	deny:audit	Yes	

Rule	Purpose
1	Default LDT rule required for LDT policies.
2	Allows for processes in the authorized-processes Process Set to access the clear-text data.
3	Allows for processes not in the authorized-processes Process Set to read the OS file and directory attributes. Note: Processes that match this rule obtain the file size with the 4K header. If a process that is not in the authorized-processes Process Set needs the file size without the header, then the Apply Key must be present in the Effect or you will need an additional rule granting Apply Key to that specific process. That rule must be defined before this rule.
4	Denies processes not in the authorized-processes

Rule	Purpose
	Process Set from reading any data from the files.

Standard Policies

Example 1: Permits access to certain Processes

A policy that allows backup and restore of encrypted data, clear-text access to certain processes, and denies access to all others:

Order	Resource Set	User Set	ProcessSet	Action	Effect	Browsing	
1			backup	all_ops	permit,audit	Yes	...
2			authorized-processes	all_ops	permit,audit,applykey	Yes	...
3				all_ops	deny,audit	Yes	...

Rule	Purpose
1	Allows for processes in the backup Process Set to access the real file size and backup the CipherTrust Transparent Encryption attributes along with the encrypted file data.
2	Allows for processes in the authorized-processes Process Set to access the clear-text data, but it hides the additional 4K from the CipherTrust Transparent Encryption attribute.
3	Denies all other processes access to the data.

Example 2: Permits access to certain Processes

A policy that only allows certain processes clear-text access but allows all others to see the OS file attributes.

Order	Resource Set	User Set	ProcessSet	Action	Effect	Browsing	
1			authorized-processes	all_ops	permit,audit,applykey	Yes	...
2				f_rd_attr_rd_sec,d_r...	permit,audit	Yes	...
3				all_ops	deny,audit	Yes	...

Rule	Purpose
1	Allows for processes in the authorized-processes Process Set to access the clear-text data.
2	Allows for processes not in the authorized-processes Process Set to read the OS file and directory attributes. Note: Processes that match this rule obtain the file

Rule	Purpose
	size with the 4K header. If a process that is not in the authorized-processes Process Set needs the file size without the header, then the Apply Key must be present in the Effect or you will need an additional rule granting Apply Key to that specific process. That rule must be defined before this rule.
3	Denies processes not in the authorized-processes Process Set from reading any data from the files.

For more information, see [Adding Security Rules](#) in the CipherTrust Manager documentation.

Using Auto Mount with Standard Policies

For CTE v7.8.0 and previous versions, Auto Mount is supported with standard policies, with CBC/CBS-CS1 keys, on both NFS and local file systems. For v7.8.0 and subsequent versions, Auto Mount will be supported with LDT.

Auto Mount is an option provided for guarding a GuardPoint. When selected, you specify the mount point, so it enables automatic guarding of the GuardPoint when accessed at that mount point, rather than immediately after policy deployment.

A GuardPoint configured with a standard policy using auto mount must use GuardPoint type: Auto Directory. The Auto Mount option is not supported with GuardPoint type: manual. When you select GuardPoint type: Auto Directory in a Linux policy, the Auto Mount option displays.

Note

For GuardPoint type: Auto raw, see [File System Mount Points on Linux](#).

Create GuardPoint[?]

Policy *

VMFSODT43-NONLDT-CONFORM-CS1

Select

☒ Enter/Browse Path☐ Upload CSV

/oxf-fs1

Browse

i To apply the same GuardPoint settings to multiple paths, type paths in the Path field or specify them using the Browse button. A maximum of 200 GuardPaths can be specified.

Auto Mount

Multifactor Authentication:

Cancel

Create

Behavior of Auto Mount GuardPoints

After you push a policy on a CTE agent, if you check the status, you'll find that the auto mount GuardPoint is not yet guarded because the guard operation is not yet triggered:

```
secfsd -status guard
```

Example Response

```
GuardPoint Policy Type ConfigState Status Reason
-----
/nfs-oxf-fs1/test VMFSODT40-AUTOMOUNT-POL auto mount guarded not guarded Inactive
```

In the CTE CLI, Auto Mount is controlled by `autofs`. When `autofs` is enabled, accessing the GuardPoint

triggers the guard operation. To trigger **autofs**, type one of the following:

```
systemctl start autofs
systemd.auto mount
```

Example

```
ls /nfs-oxf-fs1/test
secfsd -status guard
```

Example Response

```

${gp} Policy Type ConfigState Status Reason
-----
/nfs-oxf-fs1/test VMFS0DT40-AUTOMOUNT-POL auto mount guarded guarded N/A

```

Note

When adding the auto mount GuardPoint, the mount point should be unmounted. If the mount point is mounted with auto mount, then you must manually **unmount** the mount point so that the next time the mount point is accessed, secfsd will guard the GuardPoint.

Limitations

- CTE does not support nested GuardPoints with auto mount enabled
- The GuardPoint path must be at the same level as the mount point when enabling auto mount on an **autofs** mount point. This ensures that auto mount unguards when the **autofs** mount point times out. If the GuardPoint path is set at any level deeper than the configured **autofs** mount point, the **autofs** mount point will never timeout because the GuardPoint will continue to keep the mount point in a busy state.

Create and Assign a GuardPoint

- Stop all applications that are accessing the directory you want to protect. In this example, we are going to protect the following directories with the same policy and encryption key:

Linux	Windows
/dir/hr/files /dir/accounting/files /dir/shared/hr /dir/shared/accounting	- C:\HR Files\ - C:\Accounting Files\ - C:\Shared Resources\HR\ - C:\Shared Resources\Accounting\

Tip

If you want to encrypt data without taking the device offline, you must use CipherTrust Transparent Encryption - Live Data Transformation.

2. In the Applications page of the CipherTrust Manager Console, select the **CTE** application.
3. In the Clients table, click on the name of the client you want to protect.
4. Above the GuardPoints table, click **Create GuardPoint**.
5. In the Create GuardPoint page:
 - a. In the **Policy** field, select the policy you created earlier.
 - b. In the Type field, select the type of device. You can guard a directory or a raw/block device. For this example, select **Auto Directory**.
 - c. In the **Path** field, enter the directories you want to protect with this policy or click Browse to select them from a explorer window.

If you want to enter multiple paths, put each path on its own line. For example:

Linux:

Windows:

d. Click **Create**.

e. If you want to use the same policy and GuardPoint type on another path, click **Yes** when prompted. Otherwise, click **No**. For this example, click No.

The CipherTrust Manager pushes the GuardPoint configuration to the client.

6. Type the following to transform the data:

```
# dataxform --rekey --print_stat --preserve_modified_time --gp <pathToGP>
```

When the data transformation has finished, applications can resume accessing the now-protected data. (See the “CTE Data Transformation Guide” for more information.)

Using and Renewing Certificates

Certificates are used to verify the identity of a remote peer when agents communicate with CipherTrust Manager. CipherTrust Transparent Encryption and CipherTrust Manager can use internally generated or externally generated certificates.

Automatic Renewal of Client Certificates

The default lifespan of these certificates is set in CipherTrust Manager in the Registration Token section. For the automatic agent certificate renewal process to work, you must have current (not expired) and valid client certificates installed.

The system automatically renews any certificate that is **60** days or closer to expiration. VMD extracts the expiration date from the existing certificate *.pem files. If the current date is later than this renewal date, then the renewal date is the current day.

Note

- The renewal process is transparent and requires no intervention by the administrator. If multiple client agents require renewal at the same time, the clients stagger the renewal process to avoid network congestion. This staggering could introduce a delay of up to 48 hours in the renewal process.
- Certificate renewal will cause VMD to restart. When an agent restarts, or a certificate is renewed, the agent sends a system notification and a log entry.

Updating Client Certificates

You must regenerate client certificates when you:

- Configure an agent to access a new initial CipherTrust Manager
- When CipherTrust Manager updates its certificates
- Delete and reinstall agent software
- Regenerate the CA signer certificate of CipherTrust Manager

Since you are updating client certificates, the client already has certificates and the client is already registered with the initial CipherTrust Manager. The certificates on the local client will be deleted and regenerated automatically. However, you must unregister the client on the CipherTrust Manager before proceeding.

- If you are upgrading agent certificates with the same CipherTrust Manager, there is no need to disable GuardPoints.
- If you are upgrading the agent certificates with a different CipherTrust Manager, disable all configured GuardPoints for the client before proceeding. After certificate upgrade completes, assign the GuardPoints from the new CipherTrust Manager.

To update client certificates:

1. [Unenroll the client](#)
2. [Install and Register the new Agent](#)

Validating Certificates with a Local CA Certificate

Note

This feature is not compatible when using CipherTrust Transparent Encryption with CipherTrust Data Security Platform Services (CDSPaaS).

Ensure that registration by the CTE agent is serviced only by the expected key manager by providing a copy of the CA certificate that will be used to authenticate the TLS communications with the key manager.

- [Validating CipherTrust Manager and CipherTrust Transparent Encryption for Windows with a Local CA Certificate](#)
- [Validating CipherTrust Manager and CipherTrust Transparent Encryption for AIX with a Local CA Certificate](#)
- [Validating CipherTrust Manager and CipherTrust Transparent Encryption for Linux with a Local CA Certificate](#)

Replacing Certificates

Note

This feature is not compatible when using CipherTrust Transparent Encryption with CipherTrust Data Security Platform Services (CDSPaaS).

When replacing CA certificates which have signed CTE clients, see [Certificate Renewals](#) for the proper process.

External CA Certificates

Note

This feature is not compatible when using CipherTrust Transparent Encryption with CipherTrust Data Security Platform Services (CDSPaaS).

External certificates are used for communication between CTE and CM. Install the external certificate before registering CipherTrust Transparent Encryption with CipherTrust Manager.

- [AIX External Certificates](#)
- [Linux External Certificates](#)
- [Windows External Certificates](#)

Protecting Data with CTE

How to Protect Data with CTE

CTE uses policies created in the associated key manager to protect data. You can create policies to specify file encryption, data access, and auditing on specific directories and drives on your protected hosts. Each GuardPoint must have one and only one associated policy, but each policy can be associated with any number of GuardPoints.

Policies specify:

- Whether or not the resting files are encrypted.
- Who can access decrypted files and when.
- What level of file access auditing is applied when generating fine-grained audit trails.

A Security Administrator accesses CipherTrust Manager through a web browser. You must have administrator privileges to create policies using CipherTrust Manager. The CTE Agent then implements the policies once they are pushed to the protected host.

CTE can only enforce security and key selection rules on files inside a guarded directory. If a GuardPoint is disabled, access to data in the directory goes undetected and ungoverned. Disabling a GuardPoint and then allowing unrestricted access to that GuardPoint can result in data corruption.

How to Protect Data from Ransomware with CTE

Note

- Ransomware Protection for **Windows** is compatible with CipherTrust Manager **v2.12** and subsequent versions. It is only supported in CipherTrust Transparent Encryption v7.4.0 for **Windows** and subsequent versions.
- Ransomware Protection for **Linux** is compatible with CipherTrust Manager **v2.17** and subsequent versions. It is only supported in CipherTrust Transparent Encryption v7.8.0 for **Linux** and subsequent versions.

CipherTrust Transparent Encryption with Ransomware Protection protects data on servers and endpoints from ransomware attacks by auditing, monitoring and blocking malicious processes. Users can strengthen their security posture with CipherTrust Transparent Encryption access and encryption policies, multi-factor authentication, and Ransomware Protection for complete control of their data.

CTE Ransomware Protection is not an EDR (Endpoint Detection and Response) or XDR (Extended Detection & Response) solution which tries to prevent end-points from getting infected or track the lateral movement of the ransomware. However, CipherTrust Transparent Encryption with Ransomware Protection works well in conjunction with XDR and EDR solutions. CTE Ransomware Protection solutions performs real-time data analysis on sensitive data, calculates the entropy value of data, and determines whether the application is writing encrypted or unencrypted data. This analysis is performed using the CTE ML (Machine Learning) model and a score is assigned to the process. Based on this score, CTE either alerts the process behavior to the user or blocks process access to the data.

Warning

Ransomware Protection requires the `vmarfs.sys` driver. If you are using Ransomware Protection and you switch to the `vmfiltr.sys` driver, then you will disable Ransomware Protection.

Note

CipherTrust Transparent Encryption Ransomware Protection requires a [Flex Utility license](#) to enable Ransomware Protection within CipherTrust Manager.

Guarding a Directory with Ransomware Protection

Note

- Ransomware Protection for **Windows** is compatible with CipherTrust Manager **v2.12** and subsequent versions.
- Ransomware Protection for **Linux** is compatible with CipherTrust Manager **v2.17** and subsequent versions.

Setting Ransomware Protection GuardPoints

Steps to create GuardPoints on individual clients and client groups are similar. GuardPoints can be created on the GuardPoints tab of individual clients and client groups.

To create a Ransomware Protection GuardPoint:

1. In CipherTrust Manager, open the **Transparent Encryption** application.
2. Select the client or client group on which you want to create a GuardPoint.
 - Click an Ransomware Protection-enabled client under the **Client Name** column (**Clients > Clients**). These are the clients with either Ransomware Protection, or CTE Ransomware Protection, protection mode.
 - Click a client group under the **Client Group Name** column (**Clients > Client Groups**).
3. On the **GuardPoints** tab, click **Create GuardPoint**:

Note

Once Ransomware Protection is enabled during CTE registration, Ransomware Protection is applied to all GuardPoints.

Ransomware Protection is supported in 2 Protection Modes:

- **RWP:** In CipherTrust Manager, when creating a GuardPoint, you cannot assign a policy and type is automatically set to Ransomware Protection Only.
- **CTE-RWP:** On clients with **CTE RWP** mode, you can create a Ransomware Protection GuardPoint set to Ransomware Protection Only, as well as other types of GuardPoints that use policies as shown below. In Linux, Ransomware Protection is also available for other GuardPoints if the GuardPoints are set on a directory.

Status	Policy Name	Protected Path	Type	Client Group	Enabled	LSP Progress	Multi-step Authentication
+	Active	C:\Users\jdoe\Documents	Anti-Credential		Yes	100%	
+	Active	C:\Users\jdoe\Documents*.pdf	Ransomware Protection Only		Yes	100%	

4. Specify the **Path** to be protected. This is a mandatory field. Options to specify the GuardPoint paths are:

- **Enter/Browse Path:** Select this option, and enter the path by either typing or clicking the **Browse** button.

Note

- For **CTE Windows**, Ransomware Protection GuardPoints are applied at the volume level. Even if you specify the path of a folder or a file, the GuardPoint will be applied at the volume level.
- For **CTE Linux**, Ransomware Protection is applied at GuardPoint level.
- If you specify a network share, all of the network shares to be mounted subsequently will be protected.
- A CTE client administrator can configure protection of all existing GuardPoints, and those to be added to the client subsequently.
- A maximum of 200 GuardPaths can be specified using the **Enter/Browse Path** option.

Browse Method

- Click **Browse** to select the path by browsing the client file system. This method prevents typographical errors and verifies client availability. This is the recommended method to specify individual paths. Note that the client must be registered with CipherTrust Manager in order to browse its file system.
- In the **Enter Path** field, specify the path. Alternatively, in the **Select Path** field, select the path from the on-screen file system browser, and click **Select Path**.
- Click **Add**.

Manual Method

Alternatively, if you know the path, manually enter path in the given text box. Enter one path per line.

- **Upload CSV:** Select this option and click **Browse** to upload the CSV file containing the list of one or more paths. This is the recommended method to specify a large number of paths in one step.

Note

If a manually entered path does not yet exist, check that you entered the path correctly. The CipherTrust Manager does not parse manually entered paths for correct syntax.

5. Click **Create**. A message appears prompting to confirm the reuse of these GuardPoint settings on another path.
 - Click **Yes** to use the same settings on another path. The Use Settings on Another Path dialog box is displayed. Perform the following steps:
 - a. In the **Enter Path** field, specify the path. Alternatively, in the **Select Path** field, select the path from the on-screen file system browser, and click **Select Path**.
 - b. Click **Add Path**. The newly added path appears under the Paths list on the left. Similarly, add as many paths as required.
 - c. Click **OK**.
 - Click **No** if you do not want to use the same settings on another path.
6. Check the GuardPoint status, type:

```
secfsd -status guard
```

CTE Agent Linux Integration Guides

This document covers the following information:

- Confidential Computing: Integrating Intel® Tiber™ Trust Services and Intel TDX, with Microsoft Azure or Google Cloud Platform
- Integrating File Activity Monitoring (FAM) with CTE Linux
- Installing CTE on Hadoop
- Using CTE with Oracle
- Integrating and Configuring EDB
- Integration with Pacemaker
- Using CTE with SQL Server on Linux on Red Hat 8
- Configuring Support for SAP HANA
- Using CTE with GlusterFS
- NetApp Snapshot Directory
- Using CTE with Quantum StorNext
- Using CTE with McAfee Endpoint Security for Linux Threat Prevention
- Using CTE with Trend Micro Deep Security Software
- Using CTE and Data Activity Monitoring (DAM) Simultaneously
- CTE for Cloud Object Storage
- CTE with Teradata Database Appliances

Solutions Guides

Solutions guides have been moved to the [Use Cases](#) section.

Installing CTE on Hadoop

This section describes how to protect an HDFS cluster with CTE. It contains the following topics:

- Overview
 - Implementing CTE on HDFS
-

-
- Deploy Cloudera Hadoop on CTE
 - HDFS Upgrade with CTE
 - CTE Installation and Configuration
 - Deleting Metadata in HDFS when Migrating Out of LDT

Overview

The Hadoop Distributed File System (HDFS) is a file system that supports large files and directory structures distributed across hundreds, or even thousands, of commodity *DataNode* hosts in a cluster. Previously, CTE could only protect directories and files on the *local file system* rather than the actual HDFS files and directories. Now, CTE can protect *HDFS* files and directories.

A CipherTrust Manager can:

- Define an encryption policy for HDFS files and directories in HDFS name space.
- Selectively encrypt HDFS folders with different keys providing multi-tenancy support.
- Define user-based I/O access control rules for HDFS files in HDFS name space.

At the heart of an HDFS cluster is the *NameNode* that provides the framework to support a traditional hierarchical file and directory organization. The NameNode is a master server that manages the HDFS name space and regulates access to files by clients.

HDFS files are split into one or more data blocks that are distributed across *DataNode* hosts in a cluster. The NameNode maintains the namespace tree and the mapping of data blocks to DataNodes. To deploy CTE, install CTE on all of the NameNode and DataNode hosts in a cluster.

Overview of CTE on HDFS

The following sections list the high-level steps for implementing CTE protection on your HDFS. The process requires that the HDFS Administrator and CipherTrust Manager to work in tandem to complete separate tasks.

You can keep the HDFS cluster alive a active if you enable HDFS data replication and activate the nodes individually. Following are the high-level steps:

HDFS Administrator

1. Compile a list of directories specified by `dfs.datanode.data.dir`. If these directories do not already exist in the NameNode local file system, create them.
2. Pass the directory list to the CipherTrust Manager.
3. Ask CipherTrust Manager to:
 - a. Add the NameNode to the HDFS host/client group.
 - b. Create a GuardPoint for the HDFS host/client group on each of these directories.

Administrator

1. Create an HDFS host/client group to contain the HDFS nodes.
2. Create a host/client group GuardPoint on each of the datanode directories obtained from the previous step.
3. Add the NameNode to the HDFS host/client group.

HDFS Administrator

1. For each DataNode, take the node offline and perform a data transformation.
2. Ask the Administrator to add the DataNode to the host group. (After the DataNode is added to the host group, it can be brought online.)
3. Repeat this process until all of the nodes have been encrypted and added to the HDFS Host Group.
4. Modify the host group policies to protect specific HDFS files and directories, as needed.

Implementing CTE on HDFS

This section describes how to implement CTE protection on your HDFS NameNode or DataNode. If you enable HDFS data replication, protecting one node at a time allows you to maintain the HDFS cluster. When all of the nodes are configured, you can create GuardPoints on specific HDFS files and directories.

These instructions require that the HDFS Administrator and Administrator work in tandem to complete separate tasks.

Note

The instructions below assume that each NameNode and DataNode exist on their own separate host. If you have a NameNode and DataNode on the same host, see [Implementing CTE on HDFS on a Single Host](#).

CTE on HDFS Implementation Assumptions

- You have installed, configured and registered CTE on all of the NameNodes and DataNodes in the Hadoop cluster.
- The HDFS Administrator has knowledge and experience with HDFS and Ambari.
- The CipherTrust Manager Administrator has knowledge and experience with CTE.
- The two can work and communicate in tandem with each other.

Create an Encryption Zone in HDFS Name Space for AWS EMR

HDFS requires the following manual steps if you want to have an encryption zone in the HDFS name space for AWS EMR, (Elastic MapReduce).

1. Add the following properties to `hdfs-site.xml`.

```
dfs.vte.ioctl.lib vorhdfs dfs.vte.rename.check true dfs.vte.ioctl.device <.sec folder name, up to the CTE installation location>
```

Note

The default .sec folder is `/opt/vormetric/DataSecurityExpert/agent/secfs/.sec`

2. Save the file.
3. Restart HDFS NameNode and DataNode services.

Using the Original Information from HDFS

Update or add the following properties to `hdfs-site.xml` if you want CTE to use the original user information from HDFS.

1. Add the following properties to `hdfs-site.xml`.

```
<property>
  <name>dfs.block.access.token.enable</name>
  <value>true</value>
</property>
<property>
  <name>dfs.client.read.shortcircuit</name>
  <value>false</value>
</property>
<property>
  <name>dfs.vte.user.push</name>
  <value>true</value>
</property>
```

2. Save the file.
3. Restart HDFS NameNode and DataNode services.

Create an HDFS Host Group and GuardPoint in CipherTrust Manager

After configuring the NameNodes, the next steps in activating CTE on HDFS is for the security administrator. To create a client group:

1. Open the **Transparent Encryption** application.
2. Click **Clients > Client Groups**.
3. Click **Create Client Group**. The Create Client Group dialog box displays.
4. Enter a unique **Name** for the client group.
5. Select the **Cluster Type**: HDFS
 - a. **NON CLUSTER**: Creates a non-clustered client group.
 - b. **HDFS**: Creates a clustered client group. An HDFS client group is required to apply GuardPoints on CTE clients in an HDFS cluster.
6. (Optional, displayed if a profile already exists) From the Client Profile drop-down list, select the desired client profile. The default profile is DefaultClientProfile.
7. (Optional) Provide Description to identify the client group. The maximum length can be 256 characters.
8. Click **Create**. The client group is created.
9. Add the NameNode obtained from the HDFS Admin to the HDFS Client Group.

Note

Thales highly recommends using Auto Guard for HDFS. You can use manual guards, but this might result in data corruption if some nodes in a running cluster are guarded, while others are not.

Notes for HDFS Cluster Policies

The following screenshot depicts a valid HDFS policy. You can build a similar policy for your system:

The policy uses the following rules:

- For the user set hdfs-dev-user, the action is all_ops, the effect is Audit, Apply Key, Permit
- For other users the action is READ, the effect is Permit
- For the resource set hdfs-data-1, the key is hdfs-key-1
- For the resource set hdfs-data-2, the key is hdfs-key-2

Create Policy

1 General Info

2 Security Rules

3 Key Rules

4 Confirmation

Review the provided policy details.

1 General Info

Name: hdfs-dev-enc

Policy Type: Standard

Description:

2 Security Rules

Resource Set	User Set	Process Set	Action	Effect	Browsing
	hdfs-dev-user		all_ops	permit,audit,applykey	Yes
			read	permit	Yes

3 Key Rules

Resource Set	Key Name
hdfs-data-1	hdfs-key-1
hdfs-data-2	hdfs-key-2

Back

Save

Additional Settings for HDFS (Linux Clients)

Depending on the Hadoop security authentication mode, additional settings are needed for CTE clients in an HDFS cluster. Add the following settings as appropriate.

!!! note

`/usr/jdk64/jdk1.8.0\_40/bin/java` is the Java executable used to launch the HDFS services. Change the Java jdk path to reflect your end-user environment.

- Sample setup when `hadoop.security.authentication` mode is simple.

```
|authenticator+arg=+class=org.apache.hadoop.hdfs.server.namenode.NameNode|/usr/
jdk64/jdk1.8.0_40/bin/java
      |authenticator+arg=+class=org.apache.hadoop.hdfs.server.datanode.Da
taNode|/usr/jdk64/jdk1.8.0_40/bin/java
```

- Sample setup when `hadoop.security.authentication` mode is Kerberos.

```
|authenticator+arg=+class=org.apache.hadoop.hdfs.server.namenode.NameNode|/usr/
jdk64/jdk1.8.0_40/bin/java
      |authenticator+arg=+class=org.apache.hadoop.hdfs.server.datanode.Se
```

```
cureDataNodeStarter|/usr/lib/bigtop-utils/jsvc
```

Adding a New DataNode to a CTE-protected HDFS

Use the following procedure to add a new DataNode to a CTE-protected HDFS. If not followed, HDFS encrypted files could be exposed in cleartext.

Note

If you already have CTE installed on the cluster nodes before Ambari installs the Hadoop software, see [Install CTE on the Cluster Nodes before Ambari Installs Hadoop](#).

1. Install the HDFS client on the host. This option is available in Ambari when adding a new DataNode to the cluster.
2. Add the new node to the CipherTrust Manager database and make sure that host/client settings of the new node is the same as existing nodes in the cluster. See the *CTE Installation for Hadoop chapter in the CTE Installation and Configuration Guide*.
3. Install CTE on the new node, register to CipherTrust Manager, and run `config-hadoop.sh` to prepare the libraries. See the *Configuring Hadoop to use CTE* section in the *CTE Installation and Configuration Guide*.
4. Make sure that the data directories (specified in `dfs.datanode.data.dir` property) exist on the new node. They must have the same permission and ownership as the other existing nodes in the cluster. If necessary, create them.
5. Add the host/client to the HDFS Host Group that is guarding the cluster. This is important: Do not rely on the DataNode to create the data directories as the data replication can occur before the GuardPoints are in effect.
6. Add the DataNode service to the new node. Again this option is available through Ambari.
7. If using Kerberos, check that the keytab files are created correctly.
8. Start the DataNode service on the new node.
9. Execute some `hdfs dfs` shell commands to ensure that encryption/decryption of data works correctly.

Install CTE on the Cluster Nodes before Ambari Installs Hadoop

If CTE is already installed on the cluster nodes before Ambari installs the Hadoop software, Ambari can mistakenly pick up the `.sec` directory in configuration steps to store the HDFS data. Make sure the following properties do not contain the `.sec` directory:

- DataNode data directory

-
- NameNode data directory
 - Secondary NameNode checkpoint directory
 - Zookeeper directory
 - `yarn.nodemanager.local-dirs`
 - `yarn.nodemanager.log-dirs`
 - `yarn.timeline-service.leveldb-timeline-store.path`
 - `yarn.timeline-service.leveldb-state-store.path`

Note

This list is not exhaustive. Depending on the Hadoop ecosystem packages installed, there can be others.

Configure NameNodes

For both HDFS and Cloudera, you must configure the namenodes.

Configure the Ambari Hadoop NameNodes

The first step to implementing CTE on HDFS is for the **HDFS Administrator** to compile a list of the DataNode HDFS local file system directories, and create them on the NameNode local file systems. After this, the Administrator must add the NameNodes to an HDFS Host Group:

1. Compile a list of directories specified by `dfs.datanode.data.dir`. Obtain this from `hdfs-site.xml` or using Ambari go to:

HDFS > Configs > Settings > DataNode > DataNode directories

2. If these directories do not already exist in the NameNode local file system, create them on each NameNode in your Hadoop cluster.
3. Pass the following information to the Administrator:
 - The directory list and instructions to create a GuardPoint for the HDFS Host Group on each of these directories.
 - Instructions to add the NameNodes IP addresses or host names to the HDFS Host Group.

Create and Configure the Cloudera Hadoop Namenodes and Datanodes

Create the role groups CTE on Cloudera Manager:

1. Create a new role group for the Thales-namenode.
 - a. **Group Name:** thales-namenode
 - b. **Role Type:** NameNode
 - c. **Copy from:** NameNode Default Group
2. Move the name nodes to the group Thales-namenode.

3. Create a new role group for the Thales-datanode.
 - a. **Group Name:** thales-datanode
 - b. **Role Type:** DataNode
 - c. **Copy from:** DataNode Default Group
4. Move the data nodes to the group thales-datanode.

Configure the Thales-namenode group

1. In the **NameNode Environment Advanced Configuration Snippet (Safety Valve)** dialog, in the thales-namenode field:

```
HADOOP_OPTS="-javaagent:/etc/vormetric/hadoop/jar/vormetric-hdfs-agent.jar=voragent"
```

2. In the **NameNode Advanced Configuration Snippet (Safety Valve)** for hdfs-site.xml, add the following values:

```
<property><name>dfs.vte.ioctl.device</name><value>/opt/vormetric/DataSecurityExpert/agent/secfs/.sec</value></property>
<property><name>dfs.vte.ioctl.lib</name><value>vorhdfs</value></property>
<property><name>dfs.vte.rename.check</name><value>true</value></property>
<property><name>dfs.block.access.token.enable</name><value>true</value></property>
```

Configure the Thales-datanode group

1. In the **DataNode Environment Advanced Configuration Snippet (Safety Valve)** dialog, in the thales-namenode field:

```
HADOOP_OPTS="-javaagent:/etc/vormetric/hadoop/jar/vormetric-hdfs-agent.jar=voragent"
```

2. In the **DataNode Advanced Configuration Snippet (Safety Valve)** for hdfs-site.xml, add the following values:

```
<property><name>dfs.vte.ioctl.device</name><value>/opt/vormetric/DataSecurityExpert/agent/secfs/.sec</value></property>
<property><name>dfs.vte.ioctl.lib</name><value>vorhdfs</value></property>
<property><name>dfs.vte.user.push</name><value>true</value></property>
```

```
<property><name>dfs.block.access.token.enable</name><value>true</value></property>
```

Take a DataNode Offline and Perform Data Transformation

The next step in activating CTE on HDFS is to switch a DataNode to offline and transform (encrypt) its sensitive data. Once the data is transformed, the HDFS Admin can add the DataNode to the HDFS Host/Client Group. Then they can switch the DataNode back to online. Most of these procedures are completed by the **HDFS Administrator** although one is done by the Administrator.

1. **HDFS Administrator:** Switch a DataNode to offline.
2. **HDFS Administrator:** Encrypt the files in the directories specified by `dfs.datanode.data.dir` (see [Configure NameNodes](#)).
3. **Administrator:** Create encryption keys and a data transformation policy to transform the data.

**** CipherTrust Manager****

The screenshot shows the 'Create Policy' interface with five steps: General Info, Security Rules, Key Rules, Data Transformation, and Confirmation. The 'Data Transformation' step is active, showing a table of transformation rules.

General Info

Name: hdfs-dev-did
Policy Type: Standard
Description:

Security Rules

Resource Set	User Set	Process Set	Action	Effect	Browsing
*			key_op	permit,applykey	Yes

Key Rules

Resource Set	Current Key Name
hdfs-data-1	clear_key
hdfs-data-2	clear_key

Data Transformation Rules

Resource Set	Transformation Key Name
hdfs-data-1	hdfs-key-1
hdfs-data-2	hdfs-key-2

Back Save

4. **Administrator:** After encrypting the data in those directories, add the DataNode host to the HDFS client group.

5. **HDFS Admin:** After the DataNode is added to the HDFS client group, activate the DataNode online.
6. Repeat this procedure for all of the DataNodes in your HDFS cluster.

For more information, see the [CipherTrust Manager documentation](#).

Implementing CTE on HDFS on a Single Host

It is possible, though not recommended, that an HDFS NameNode and DataNode exist as separate processes on the same host. If this is your deployment, use the following CTE deployment guidelines:

1. Configure the HDFS NameNodes (see [Configure NameNodes](#)):

Note

The directories specified by `dfs.datanode.data.dir` already exist on the local file system so you do not have to create them.

2. Pass the following information to the Administrator:
 - The `dfs.datanode.data.dir` directory list and instructions to create a GuardPoint for the HDFS Host Group on each of these directories.
 - Instructions to add the NameNodes IP addresses, or host names, to the HDFS Host Group.
3. Create an HDFS host/client group and host/client group GuardPoint:
 - a. Administrator must create an HDFS Host Group to contain the HDFS nodes.
 - b. The Administrator must create a GuardPoint for the Host Group on each of the directories specified by `dfs.datanode.data.dir`
4. Take the DataNode offline and perform a data transformation.
5. Add the NameNode/DataNode host/client to the host/client group.

Deploy Cloudera Hadoop on CTE

Deploying Cloudera Hadoop (CDP) on CTE consists of multiple steps that are documented in various locations. The following is the order that you should follow when installing CDP on CTE and links to the relevant documentation.

1. Deploy CDP 7 (Hadoop 3.1.1) cluster on RHEL 7.8 or RHEL 8.5, see the [CDP Private Cloud Base Installation Guide](#)
2. Configure Hadoop configuration for CTE, see [Configure NameNodes](#)

3. Cipher Trust Manager configuration, see [CipherTrust Manager Documentation](#)
4. CTE Installation and registration, see [CipherTrust Transparent Encryption \(CTE\) Documentation Set](#)
5. LDT, see [CTE Live Data Transformation with CipherTrust Manager](#)

HDFS Upgrade with CTE

To upgrade Hadoop, configure CTE to integrate with the new HDFS instance.

Upgrading one node at a time

Once CTE is installed and configured on the node:

1. Make sure that HDFS services are shut down on the node.
2. Upgrade **Hadoop**.
3. Type:

```
/opt/vormetric/DataSecurityExpert/agent/secfs/hadoop/bin/config-hadoop.sh -i -y
```

4. Start HDFS services on the node.

Upgrade CTE with LDT in an HDFS Cluster

If you are using LDT with HDFS cluster, follow these steps when upgrading CTE, in order to maintain your LDT GuardPoints.

1. Suspend rekey on all data nodes.
2. Shutdown your name nodes/data nodes.
3. Upgrade CTE in the name node first.

Note

Always upgrade name nodes before data nodes.

4. After CTE upgrade succeeds, type:

```
config-hadoop.sh -i -y
```

5. On the Ambari admin console, start the name node.
6. Verify that the CipherTrust java process successfully launched in the name node. (You should not see an error message.) Type:

```
ps -ef | grep java | grep vormetric
```

7. Check the CipherTrust Manager status. It should show LDT rekeyed status.
8. Check the name node status. It should display the GuardPoint status and match the state before upgrade. Type:

```
secfsd -status guard
```

GuardPoint	Policy	Type	ConfigState	Status	Reason
-----	-----	----	-----	-----	-----
/hadoop/hdfs/data	LDT_HDFS_Sanity	local	guarded	guarded	N/A

9. Repeat the above steps for all of the data nodes in the HDFS cluster.

Rolling Upgrades

Hortonworks Data Platform has introduced rolling upgrades to automate the Hadoop upgrade process (<http://bit.ly/2pQrFo3>). The upgrade process is controlled by the Upgrade Pack (<http://bit.ly/2rkutvF>) that is predefined and certified by Hortonworks.

To integrate CTE with the upgrade, you need to temporarily change the Ambari scripts before performing the rolling upgrades and then restore the scripts after the upgrades.

1. On Ambari server machine, type:

```
cd /var/lib/ambari-server/resources/common-services/HDFS/2.1.0.2.0/package/scripts
```

2. Copy the utils.py file, type:

```
cp utils.py utils.py.org
```

3. Using a text editor, add the following commands to `utils.py`:

```
if action == "start":
    if name == "namenode" or name == "datanode":
        Execute(format("secfs/hadoop/bin/c onfig-hadoop.sh
        -i -h {hadoop_bin}/../ -j <java home> -p hdp -d", not_if=service_is_up,
        user=params.root_user)
```

```
# For Redhat 6.x, uncomment the following command
# Execute(format("/etc/init.d/secfs secfsd restart"),
not_if=service_is_up, user=params.root_user)
# For Redhat 7.x, uncomment the following command
# Execute(format("/secfs restart"), not_if=service_is_up,
user=params.root_user)
before
Execute(daemon_cmd, not_if=service_is_up, environment=hadoop_env_exports
The Java home of your HDFS instance should be used to replace <java home>:
if action == "start":  if name == "namenode" or name == "datanode":
Execute(format("secfs/hadoop/bin/config-hadoop.sh -i -h {hadoop_bin}
../ -j <java home> -p hdp -d"), not_if=service_is_up,
user=params.root_user)
# For Redhat 6.x, uncomment the following command
# Execute(format("/etc/init.d/secfs secfsd restart"),
not_if=service_is_up, user=params.root_user)
# For Redhat 7.x, uncomment the following command
# Execute(format("/secfs restart"), not_if=service_is_up,
user=params.root_user)
Execute(daemon_cmd,
    not_if=service_is_up,
    environment=hadoop_env_exports)
```

4. Type:

```
ambari-server restart
```

5. Perform rolling upgrades.
6. During the upgrade process, many of the intermediate service status checks can fail. Skip over them by clicking on **Proceed to Upgrade**.
7. Click **Finalize** to complete the upgrade. If the active NameNode fails to activate due to the incompatible HDFS layout version, manually start the NameNode with '**-upgrade**' option to correct the layout version file.

```
/var/lib/ambari-server/ambari-sudo.sh su hdfs -l -s /bin/bash -c 'ulimit -c u
nlimited ; /usr/hdp/current/hadoop-client/sbin/hadoop-daemon.sh --config /usr/
hdp/current/hadoop-client/conf start namenode -upgrade'
```

8. If there are excessive under-replicated blocks, run the following command to isolate them and manually start the replication:

```
su - <$hdfs_user>
```

```
# hdfs fsck / | grep 'Under replicated' | awk -F':' '{print $1}' >> /tmp/under_replicated_files
# for hdfsfile in `cat /tmp/under_replicated_files`; do echo "Fixing $hdfsfile"; hadoop fs -setrep 3 $hdfsfile; done
```

9. Restart the HDFS services. Wait for the replication to complete and the NameNodes to exit safe mode.
10. When Hbase is restarted after upgrades, it tries to rename from: `/apps/hbase/data/.tmp/data/hbase/namespace` to: `/apps/hbase/data/data/hbase/namespace`, which may cause key conflict if the GuardPoint is set incorrectly (for example, `/apps/hbase/data/data` is guarded, but not `/apps/hbase/data/.tmp`). This results in Hbase shutting down.

Before re-starting Hbase, make sure that the GuardPoint policies on the Hbase files are set correctly to cover all Hbase-related files. A broader GuardPoint (`/apps/hbase/data` instead of just `/apps/hbase/data/data` and other folders) could fix this issue.

11. Check cluster upgrade by verifying the `hadoop version`.
12. Run a few map reduce jobs and Hbase commands to make sure that the entire Hadoop stack is working properly.
13. Rename `utils.py.org` to `utils.py`

Configure the Hadoop Cluster for CTE

Configure the Hadoop cluster to use CTE before installing and configuring CTE on the nodes. Use Ambari to perform this configuration.

Create a CipherTrust Configuration Group

The CipherTrust Configuration Group will eventually contain all of the hosts in your Hadoop cluster. At first you create an empty group. Later you populate it with the hosts on which you will install and configure agents.

1. On Ambari, go to **HDFS > Configs > Manage Config Groups**.
2. Add a new configuration group: *CipherTrust*.
3. Make the group, *CipherTrust*, the current group.

Update the Hadoop-env Template with CTE Settings

1. Go to **HDFS > Configs > Advanced > Advanced hadoop-env > hadoop-env template**.
2. Copy and paste the original **hadoop-env** templates into the Thales template and add the following two export lines to specify that the CTE Java agent is instrumented into NameNode and DataNode.

```

hadoop-env template
for jarFile in `ls /usr/share/java/*mysql* 2>/dev/null`
do
    JAVA_JDBC_LIBS=$(JAVA_JDBC_LIBS) $jarFile
done

# Add libraries required by oracle connector
for jarFile in `ls /usr/share/java/*ojdbc* 2>/dev/null`
do
    JAVA_JDBC_LIBS=$(JAVA_JDBC_LIBS) $jarFile
done

export HADOOP_CLASSPATH=$(HADOOP_CLASSPATH) ${JAVA_JDBC_LIBS}

# Setting path to hdfs command line
export HADOOP_LIBEXEC_DIR=${hadoop_libexec_dir}

# Mostly required for hadoop 2.0
export JAVA_LIBRARY_PATH=${JAVA_LIBRARY_PATH}

export HADOOP_OPTS="-Dhdp.version=$HDP_VERSION $HADOOP_OPTS"

do
    JAVA_JDBC_LIBS=$(JAVA_JDBC_LIBS) $jarFile
done

export HADOOP_CLASSPATH=$(HADOOP_CLASSPATH) ${JAVA_JDBC_LIBS}

# Setting path to hdfs command line
export HADOOP_LIBEXEC_DIR=${hadoop_libexec_dir}

# Mostly required for hadoop 2.0
export JAVA_LIBRARY_PATH=${JAVA_LIBRARY_PATH}

export HADOOP_OPTS="-Dhdp.version=$HDP_VERSION $HADOOP_OPTS"

#-----vormetric-----
export HADOOP_NAMENODE_OPTS="-javaagent:/etc/vormetric/hadoop/jar/vormetric-hdfs-agent.jar=voragent ${HADOOP_NAMENODE_OPTS}"
export HADOOP_DATANODE_OPTS="-javaagent:/etc/vormetric/hadoop/jar/vormetric-hdfs-agent.jar=voragent ${HADOOP_DATANODE_OPTS}"
#-----vormetric-----

```

```

export HADOOP_NAMENODE_OPTS="-javaagent:/etc/vormetric/hadoop/jar/vormetric-hdfs-agent.jar=voragent ${HADOOP_NAMENODE_OPTS}"
export HADOOP_DATANODE_OPTS="-javaagent:/etc/vormetric/hadoop/jar/vormetric-hdfs-agent.jar=voragent ${HADOOP_DATANODE_OPTS}"

```

Modify the HDFS IOCTL

1. Go to **HDFS > Configs > Advanced > Custom hdfs-site**.
2. In the **dfs.vte.ioctl.lib** field, type: `vorhdfs`
3. In the **dfs.vte.ioctl.device** field, type:

```
/opt/vormetric/DataSecurityExpert/agent/secfs/.sec
```

Change the HDFS File Rename Check

1. Go to **HDFS > Configs > Advanced > Custom hdfs-site**.
2. Set **dfs.vte.rename.check** to **true**

User Information Push

You only need this configuration if you want to use the original user information with HDFS operation for IO access check.

Note

It has a performance cost.

1. Go to **HDFS > Configs > Advanced > Advanced hdfs-site** and uncheck **HDFS Short-circuit read**.
2. Set **dfs.block.access.token.enable** to **true**.
3. Go to **HDFS > Configs > Advanced > Custom hdfs-site** and set **dfs.vte.user.push** to **true**.

Uninstalling CTE for the Hadoop Cluster

This section explains how to remove CTE and restore the environment back to the non-CTE cluster environment. Thales recommends uninstalling the agent from HDFS nodes one by one, starting from the DataNode. Uninstall the agent from the NameNode last.

1. Shut down one DataNode.
2. Perform the normal agent uninstall procedure.
3. Go to Ambari, remove the DataNode host from the CipherTrust Configuration Group.
4. Start the DataNode.
5. Delete the CipherTrust Configuration Group from Ambari when agent is uninstalled from all DataNodes.
6. Repeat these steps for each DataNode.
7. Repeat these steps for each NameNode.

CTE Installation and Configuration

After configuring the Hadoop cluster for CTE:

1. Install and register CTE on the HDFS nodes.
 - You can do this to all the nodes at once, but the HDFS is unavailable during CTE installation and configuration.
 - You can also do this one node at a time. If you install and register CTE nodes one at a time, you must start from NameNode, then DataNode, and always keep NameNode service up once NameNodes are configured.
2. In either case, add the FQDN of the node to the CipherTrust Configuration Group, then proceed with agent installation and configuration. See [Installing and Configuring CTE on an HDFS Node](#).
 - Modify the Host Group. See [Modifying host settings for HDFS hosts on the CipherTrust Manager](#).
 - Configure CTE by running `config-hadoop.sh` on the HDFS node. See [Configuring Hadoop to Use CTE](#).
 - Review the SecFS configuration variables that support the HDFS name cache. [HDFS Name Cache](#).

Installing and Configuring CTE on an HDFS Node

1. Using Ambari, add the FQDN of the node to the CipherTrust Configuration Group. See [Create a CipherTrust Configuration Group](#).
2. Install, configure, and register CTE.
3. Modify the host settings for each node. See [Modifying host settings for HDFS hosts on the CipherTrust Manager](#).

Modifying host settings for HDFS hosts on the CipherTrust Manager

The Hadoop service can start as root and then downgrade to an unprivileged user. If the unprivileged user is not authenticated by password, CTE flags the user as fake. CTE cannot allow a user to access a resource protected by a user rule when the user is faked, even if the user matches the permit rule. Because of this, modify the CipherTrust Manager host/client setting as follows:

- On Ambari, go to **HDFS > Configs > Advanced > Advanced core-site** and find out if `hadoop.security.authentication` mode is set to **simple** (no authentication) or **Kerberos**.

Modifying host settings for alternate versions of Java

Sometimes, you may have more than one version of Java installed on your systems. This can create issues while using Hadoop, which uses Java to launch different services.

CipherTrust Transparent Encryption expects the following version of Java to be installed on a system:

```
/usr/lib/jvm/java-1.8.0-openjdk-1.8.0.252.b09-2.el7_8.x86_64/jre/bin/java
```

If you have a different version of java installed on any of your systems, then you must perform a simple modification and add authenticators to the Host settings section in CipherTrust Manager for that version of Java as well. See the following section for more information.

Simple Modification

To use a **simple** modification, ask the Administrator to add the following lines to the host/client group:

```
`/usr/jdk64/jdk1.8.0_40/bin/java` is the Java executable used to launch the HDFS services. Change the Java jdk path to reflect your end-user environment.
```

```
|authenticator+arg+=+class=org.apache.hadoop.hdfs.server.namenode.NameNode|
|usr/jdk64/jdk1.8.0_40/bin/java
|authenticator+arg+=+class=org.apache.hadoop.hdfs.server.datanode.DataNode|
|usr/jdk64/jdk1.8.0_40/bin/java
```

The entire host/client settings will look like this:

```
|authenticator|usr/sbin/sshd
|authenticator|usr/sbin/in.rlogind
|authenticator|bin/login/
|authenticator|usr/bin/gdm-binary
|authenticator|usr/bin/kdm
|authenticator|usr/sbin/vsftpd

|authenticator+arg+=+class=org.apache.hadoop.hdfs.server.namenode.NameNode|usr/jdk
64/jdk1.8.0_40/bin/java
|authenticator+arg+=+class=org.apache.hadoop.hdfs.server.datanode.DataNode|usr/jd
k64/jdk1.8.0_40/bin/java
```

Modifying Host Group for HDFS NameNodes HA on CipherTrust Manager

To enable high availability (HA) for your HDFS NameNodes, ask the Administrator to add the following lines to the host/client group.

```
`/usr/jdk64/jdk1.8.0_40/bin/java` is the Java executable used to launch the HDFS services. Change the Java `jdk` path to reflect your end-user environment.
```

```
|authenticator+arg+class=org.apache.hadoop.hdfs.qjournal.server.JournalNode|us
r/jdk64/jdk1.8.0_40/bin/java
|authenticator+arg+class=org.apache.hadoop.yarn.server.applicationhistoryservic
e.ApplicationHistoryServer|usr/jdk64/jdk1.8.0_40/bin/java
|trust+arg+=+class=org.apache.hadoop.hdfs.tools.DFSZKFailoverController|usr/jdk6
4/jdk1.8.0_40/bin/java
```

The entire host/client group for HA (in this example, with Kerberos) will look like this:

```
|authenticator|/usr/sbin/sshd
|authenticator|/usr/sbin/in.rlogind
|authenticator|/bin/login/
|authenticator|/usr/bin/gdm-binary
|authenticator|/usr/bin/kdm
|authenticator|/usr/sbin/vsftpd

|authenticator+arg+class=org.apache.hadoop.hdfs.server.namenode.NameNode|/usr/jdk
64/jdk1.8.0_40/bin/java
|authenticator+arg+=+class=org.apache.hadoop.hdfs.server.datanode.SecureDataNodeSt
arter|/usr/lib/bigtop-utils/jsvc
|trust+arg+class=org.apache.hadoop.hdfs.qjournal.server.JournalNode|/usr/jdk64/jd
k1.8.0_40/bin/java
|trust+arg+=+class=org.apache.hadoop.yarn.server.applicationhistoryservice.Applica
tionHistoryServer| \
/usr/jdk64/jdk1.8.0_40/bin/java
|trust+arg+=+class=org.apache.hadoop.hdfs.tools.DFSZKFailoverController|/usr/jdk6
4/jdk1.8.0_40/bin/java
```

Configuring Hadoop to Use CTE

1. On the HDFS node, type:

```
/opt/vormetric/DataSecurityExpert/agent/secfs/hadoop/bin/config-hadoop.sh -i.
```

HDFS prompts you for the following information:

- **Hadoop product name:** (i.e. *hdp*)
- **Hadoop product version:** (i.e. *2.6.0.2.2.0.0-2041*)
- **Path to JAVA_HOME used by Hadoop:** (i.e. */usr/jdk64/jdk1.8.0_40*)

Note

Alternatively, you can use the automated installation option:

```
/opt/vormetric/DataSecurityExpert/agent/secfs/hadoop/bin/config-hadoop.sh -i -p hdp -v
2.6.0.2.2.0.0-2041 -j /usr/jdk64/jdk1.8.0_40 2.
```

2. Verify the configuration the using the -S option:

```
/opt/vormetric/DataSecurityExpert/agent/secfs/hadoop/ bin/config-hadoop.sh -s

Vormetric-Hadoop Configuration Status
PRODUCT_NAME=hdp- PRODUCT_VERSION=3.0.0.0-2557 HADOOP_HOME=/usr/hdp/current/ha
```

```

doop-client/sbin/./- HADOOP_VERSION=2.7.1 HADOOP_PRODUCT_VERSION=
2.7.1.2.3.0.0-2557- HADOOP_VERSION_MAJOR=2.7 LIBVORHDFS_S0=/usr/hdp/current/hadoopclient/sbin/./lib/native/libvorhdfs.so LIBHDFS_S0=/etc/vormetric/hadoop/lib/libhdfs.so VORMETRIC_HADOOP=/etc/vormetric/hadoop-
#-----vormetric-----

Looks ok

```

Verify secfsd is Running with Hadoop Environment

Use a text editor to view the `/etc/init/secfsd-upstart.conf` file. The file should contain env entries, type:

```
cat /etc/init/secfsd-upstart.conf
```

HDFS Name Cache

Obtaining the HDFS file name from the NameNode is network intensive, so the map from HDFS block file name to HDFS file name is cached in a hash table. The following secfs configuration variables are used to support the hash cache. They are provided in case you need to tune the memory management of the name cache for better performance.

- **hdfs_cache_entry:** Default is 1,024,000, which could cover up to 125TB HDFS data because the default HDFS block size is up to 128MB (128MB * 1024000 = 125TB).
- **hdfs_cache_bucket:** Default is 10240.
- **hdfs_cache_timeout:** Default to 30 minutes.

- **hdfs_cache_interval**: Default wake up interval for a worker thread to update the cache entry whose timeout has expired is 10 seconds.

On Linux, you can configure each secfs configuration variable using the voradmin commands:

For example, to configure the variable, type:

```
voradmin secfs config hdfs_cache_interval 30
```

Note

Because HDFS rename is a metadata operation inside the HDFS NameNode and does not call into the local file system, the hash cache might contain expired data. The HDFS NameNode is coded to prevent renamed data from crossing a key boundary to prevent data corruption. However, other access checks based on the HDFS file name may give incorrect information if the name is expired. Understand this risk before using this feature.

Enabling CTE on HDFS

To enable CTE on your HDFS:

1. Restart CTE agent on the node.

- For Redhat 6.x, type:

```
/etc/init.d/secfs restart
```

- For Redhat 7.x or 8.x, type:

```
/etc/vormetric/secfs restart
```

2. Restart the Hadoop Services in the cluster.

You can now create GuardPoints to protect your entire HDFS.

Deleting Metadata in HDFS when Migrating Out of LDT

In an HDFS deployment, if you migrate from an LDT to a non-LDT environment, the administrator must delete the LDT mdstore file.

In the following example:

`/hadoop/hdfs` is the mount point

`/hadoop/hdfs/data` is the GuardPoint

To manage the migration:

1. In the CipherTrust Manager, click **Client > Client Groups**.
2. Click **<host/client group name>**. The Edit host/client group window opens.
3. Click **GuardPoints**.
4. Select the appropriate HDFS directory with an LDT GuardPoint, and click **Unguard**.
5. Using the Ambari admin console, shutdown all NameNode/DataNode one by one. Ensure that no HDFS GuardPoints are busy.
6. Ensure that no GuardPoints are configured on any HDFS node in the cluster, type:

```
secfsd -status guard
No GuardPoints configured
```

7. On the node running secfs, type:

```
voradmin ldt attr delete <guard path>
# voradmin ldt attr delete /hadoop/hdfs/data
LDT metadata has been removed from all files in GuardPoint /hadoop/hdfs/data
```

8. On the system, verify that the metadata store has been removed from the secfs mount points, type:

```
voradmin ldt rmstore <mount_point>
# voradmin ldt rmstore /hadoop/hdfs
Enter YES if /hadoop/hdfs does not include any GuardPoints associated with an
LDT policy ->YES
MDS file /hadoop/hdfs/::vorm:mds:: has been removed.
```

9. Verify that the metadata store has been removed from the secfs mount points, type:

```
ls -altr <mount_point>
# ls -altr /hadoop/hdfs
You should not see `/hadoop/hdfs/::vorm:mds::` listed.
```

10. Repeat the above steps for each node in the HDFS cluster.

Integrating File Activity Monitoring (FAM) with CTE Linux

Note

This feature is not compatible when using CipherTrust Transparent Encryption with CipherTrust Data Security Platform Services (CDSPaaS).

Software Requirements

Software	Minimum Version Required
CipherTrust Transparent Encryption	7.8.0.75
CipherTrust Manager	2.19 or subsequent versions

Overview of FAM on CTE agents

File Activity Monitoring (FAM) catalogs, monitors, and secures unstructured data (files). Unstructured data refers to any data that is not stored in databases. You can find these files locally, on the network, or in the cloud. FAM provides insights into data location, ownership, access history, permissions, protection, sharing, and sensitivity, enabling informed decisions about data protection.

For more information on FAM, see the [Introduction to the File Activity Monitoring User Guide](#)

CTE agents enabled with both File System Encryption and FAM capabilities can perform file system monitoring and audit file operations, as per the requirements of the Data Security Fabric (DSF) policies.

Scope of FAM on CTE host

Enabling FAM will also monitor activity on files outside of CTE GuardPoints.

Note

FAM will **not** monitor activity on RWP-enhanced files with CTE Ransomware Protection feature enabled

File Monitoring

The CTE agents monitor and audit user and application access to all files. Monitoring is not limited to files inside of CTE GuardPoints. Files outside of CTE GuardPoints are also monitored, except for those in the following directories:

Linux

/dev

```

/roc
/sys
/media
/opt/vormetric
/CTE-custom-install-location

```

Windows

```

\BOOT
\Windows
\Program Files*
\Users\*\APPDATA\ROAMING\MICROSOFT\WINDOWSAPPDATA\ROAMING\MICROSOFT\WINDOWS*
\Users\*\APPDATA\LOCAL\MICROSOFT\*
\Users\*\APPDATA\LOCAL\TEMP\*
\Users\*\APPDATA\LOCAL\PACKAGES\*
\Users\*\APPDATA\LOCAL\GOOGLE\CHROME\*
\PROGRAMDATA\MICROSOFT\*
\PROGRAMDATA\DELL\*

```

Also excluded from monitoring:

- VSS volumes
- DFSR private folders
- CSV volumes
- File operations performed by:
 - CTE internal processes
 - Thales Data Discovery and Classification processes
 - CTE-managed internal system operations
 - Metadata files

FAM Policies vs CTE Policies

FAM policies, which are similar to CTE policies with respect to security rules, allow you to monitor activity on specific data locations and/or by specific users. FAM policies only allow audit rules to specify/filter the content to be monitored. They do not impact access to the file.

Note

FAM policies are associated with the entire client, as compared to CTE policies which are limited to a particular GuardPoint path.

Performance Impact of FAM on CTE

File activity monitoring and audits consume system resources. This can potentially affect the performance of system and critical applications running on CTE agents. You can reduce the performance impact on the DSF management console by modifying the monitoring rules of the FAM policy applied to the CTE agent. For example:

- File operations, such as reading file attributes, are operations that are performed very frequently by applications and system utilities.
- If the CTE GuardPoint has policy rules with audit enabled, then with FAM also enabled, there may be additional overhead/performance impact due to the additional FAM policy evaluation and logging. However, the policy has no impact on file access/permissions.

Adjustments in the FAM policy to reduce, or eliminate highly frequent operations, can decrease the impact of FAM. Consult the FAM documentation for information on adjusting the FAM policy.

Enabling FAM on CTE Agent

You can enable FAM on CTE agent during CTE registration, or through the API.

Enable during Registration

After installing CTE, you enable FAM when registering, or re-registering, to CipherTrust Manager. During registration, you are prompted with the following two questions:

```
Do you want this host to have Filesystem encryption support enabled on the server? (Y/N) [Y]: Y

Do you want this host to have File Activity Monitoring support enabled? (Y/N) [N]: Y
```

Make sure that you answer **Y** to both questions.

Restart Secfs

For CipherTrust Manager v2.19 on **Linux**, post registration, you **must** restart **secfs**. This is **not** required for CipherTrust Manager v2.20 and subsequent versions. To restart secfs:

1. Type:

```
/etc/vormetric/secfs stop
```

2. Type:

```
/etc/vormetric/secfs start
```

Enable through the CM API

You can enable FAM on CTE, post registration:

- As part of the CTE upgrade on reboot process.
- Through the CM API available for CM 2.20 and subsequent versions. See the API documentation available through the CipherTrust Manager software.
- Through the DSF management console. Refer to DSF documentation for more information.

Disabling FAM on CTE

- For CipherTrust Manager v2.19, you cannot completely disable FAM once enabled. However, you can remove the FAM policy associated with the client to temporarily disable FAM audit logging/monitoring.
- For CipherTrust Manager v2.20, you can disable FAM on CTE agent through the DSF management console or through the CM API. Refer to DSF documentation for disabling FAM on CTE agents.

Voradmin Support for FAM

The `voradmin` utility allows you to gather statistics and administer CTE on a host/client. It has slightly different syntax and command capabilities depending on whether the host/client is running in Linux or Windows. The `voradmin` command provides minimal support for FAM administration on CTE agents. You can check the state of FAM and the FAM policy name applied to the CTE host.

The following command reports the state of FAM, the FAM policy name applied to the CTE host, and the DSF GW configuration for forwarding FAM audits to the DSF GWs.

```
voradmin fam show config
```

FAM Output when policy not applied

Example

```
# voradmin fam show config
```

Response

```
FAM_STATE   : DISABLED
FAM_POLICY  : Not Applied
```

FAM Output when policy applied

Example

```
# voradmin fam show config
```

Response

```
FAM_STATE    : ACTIVE
FAM_POLICY   : fam-all-ops-policy
```

Limitation

- File path names included in the FAM audits that are generated from file operations performed inside Linux containers, or namespaces, under **chroot** enforcement, are relative to the directory created by the **chroot**, or container, as the root directory.
- CTE enforces a limit of 128 characters in the FAM policy names. FAM audits resulting from policies exceeding this limit, will have the policy name trimmed to the this limit.

Using CTE with Oracle

This section describes how to install and configure CTE on Oracle RAC ASM, how to use an ASM Filter Driver Linux. It contains the following topics:

- [Oracle RAC ASM and ASMLib](#)
- [Oracle RAC ASMLib Multi-Disk Online Method](#)
- [About Oracle RAC ASM Raw Devices](#)
- [Oracle RAC ASM Multi-Disk Online Method](#)
- [Oracle RAC ASM Multi-Disk Offline Method \(Backup/Restore\)](#)
- [Surviving the Reboot and Failover Testing](#)
- [Using CTE with Oracle ASM Filter Driver](#)
- [Basic Troubleshooting Techniques](#)
- [Using Oracle with CipherTrust Transparent Encryption UserSpace](#)

Basic Troubleshooting Techniques

The following are some of the most common configuration issues that prevent the Oracle ASM configuration from working properly.

If you encountering errors similar to:

- ORA-15075: disk(s) are not visible cluster-wide
- ORA-15032: not all alterations performed

This could be the result of improper settings for the I/O layer, meaning that your disks are not properly configured.

Perform the following tasks to verify that the settings are correct:

1. On the CipherTrust Manager, in the Host Group that was created for the RAC cluster, verify that the host group for this configuration does **NOT** have the Cluster Group option set (this option is only for GPFS, which is not supported with CTE).
2. Ensure that the GuardPoints for the block devices are set at the Host Group level. This ensures that each node receives identical GuardPoints.
3. Verify that the GuardPoints are active on all nodes. When the GuardPoints are set, go to each node and verify that they are set and guarded, using the WebUI or the `secfsd -status guard1` command. If they do not guard correctly:
 - Verify that the udev rules are set correctly, as described in [Modify the UDEV Rules](#)
 - Make sure the device names are the same across all nodes.
4. From ASM, make sure that the `asm_diskstring` parameter is modified to include the CTE devices and that the proper pathname is used, see [Altering ASM_DISKSTRING on ASM](#).

Verifying Database Encryption

Option 1

The best way to verify the state of the data, without impacting anything in the existing environment, is to use the Oracle `kfed` command. You can run this command against the native path of the existing GuardPoints and make sure it returns with valid header information. If it returns valid information with the GuardPoint in place, then this confirms that the data is properly encrypted. If it returns with invalid header information, then that indicates that the data is either clear, double encrypted, or not in the expected encrypted state. The syntax for running this command would look similar to the following but will vary based on your environment.

```
/app/oracle/grid/product/19.0.0/grid/bin/kfed read /dev/rdisk/<diskName>
```

If the location is properly encrypted, following is an example of the viewable output:

```
/app/oracle/grid/product/19.0.0/grid/bin/kfed read /dev/rdisk/<diskName>
```

System Response:

```
kfbh.endian:          1 ; 0x000: 0x01
kfbh.hard:             242 ; 0x001: 0xf2
kfbh.type:            124 ; 0x002: *** Unknown Enum ***
kfbh.datfmt:          66 ; 0x003: 0x42
kfbh.block.blk:       1088904227 ; 0x004: blk=1088904227
kfbh.block.obj:       1558192170 ; 0x008: file=8234
kfbh.check:           3321251423 ; 0x00c: 0xc5f6465f
kfbh.fcn.base:        932956641 ; 0x010: 0x379bc9e1
kfbh.fcn.wrap:        3040493590 ; 0x014: 0xb53a4016
kfbh.spare1:          3806015223 ; 0x018: 0xe2db2ef7
kfbh.spare2:          3794962182 ; 0x01c: 0xe2328706
```

```

KFED-00322: Invalid content encountered during block traversal: [kfbtTraverseBloc
k][Invalid OSM block type][][124]

```

Option 2

The second option to verify the state of the data is to use the `dd` command. This requires you to specify some blocks and write it out to a file. After this completes, read the file using the `strings` command. You can do this while the device is in use. In the example below some sectors are skipped and it only dumps 10000 counts.

For example:

```
dd if=/dev/mapper/asm_data2p1 of=/tmp/dd2.out skip=1047 count=10000
```

Option 3

The third option to verify the state of the data without impacting the existing environment is to use the `strings` command.

Note

The `strings` command cannot read a busy or large device.

You can run this command against the native path (`/dev/<deviceName>`) of the existing GuardPoints (`/dev/secvm/dev/<deviceName>`). The new path to SecVM would be similar to `/dev/secvm/dev/<deviceName>`. By executing the `strings` command against the native path `strings /dev/<devicename> | more`, this does not go through the SecVM device and therefore is not be decrypted. If it is encrypted the output should contain illegible text.

Using CTE LDT with Oracle

Oracle compatibility with LDT

Oracle is compatible with LDT with the following changes:

You must run Oracle with the following file system IO option, when mounted on NFS:

- DirectIO

Note

LDT is not supported on raw devices such as ASM.

Oracle RAC ASM and ASMLib

This section describes how to install and configure CipherTrust Transparent Encryption on an Oracle RAC ASM and ASMLib.

Using CipherTrust Transparent Encryption with an Oracle RAC ASM

You can apply CipherTrust Transparent Encryption when the Oracle DB is active or inactive. If you choose to use it while the Oracle DB is active, it eliminates any downtime. You can apply CipherTrust Transparent Encryption during low volume traffic time frames. If you choose to use this option, then use the **rebalance** function of ASM. This allows you to:

1. Migrate data off of a disk so that it can be dropped/removed from a **Diskgroup**.
2. Apply CipherTrust Transparent Encryption protection.
3. Add the disk back into the diskgroup.

Caution

You **must** drop the related ASM diskgroup first, before dropping the disk. If, for example, you drop an ASM disk before dropping an ASM diskgroup, and then add it back to the diskgroup without cleanly wiping the disk, the ASM diskname will be corrupted. To avoid this problem, clear out the disk before you add it back into the diskgroup. Example: `dd if=/dev/zero of=/dev/secvm/dev/mapper/asmdg-asmlv002 bs=32k`

ASMLib

ASMLib is an optional support library for the Automatic Storage Management feature of the Oracle Database. If the customer is using ASMLib, then management is performed through an Oracle ASM command line. Using this can be simpler than the setup required for standard ASM. The commands and details of the procedure differ as well.

Important ASM Commands and Concepts

Rebalancing Disks

When you drop/remove a disk from the diskgroup, it is important to apply the proper value for the power setting for rebalance and to use the **WAIT** command.

Example ASM Command:

```
SQL> ALTER DISKGROUP <DiskGroupName> DROP DISK <diskName> REBALANCE POWER 8 WAIT;
```

- The rebalance command moves the data off of the disk that you are removing from the diskgroup, distributing the data across the remaining DISKS.
- The power setting is a number from 1 to 11. It determines how much processing power is dedicated to the rebalance, versus normal operations. Unless the encrypting occurs during heavy traffic volume, the minimum value you should use is 6. Otherwise, consult the customer's DBA for the proper setting. An appropriate value to start with is 8.

Mapping Raw Devices

You can map raw devices for this configuration using:

- **Multipath I/O**

This is typically evident when the path for the mapped devices is set to: `/dev/mapper/<device-name>`.

- **Raw devices**

Some customers use raw devices to map a name like raw3 to a specific device name. You usually find this mapping in a file called: `/etc/sysconfig/rawdevices`.

Note

It is important to understand how the device names are used and if they are the same across all of the RAC nodes.

- **EMC PowerPath**

If using EMC PowerPath then the device names are similar to the following: `/dev/emcpowerXXXX`.

When browsing the CipherTrust Manager through the local host, you cannot find Power Path devices. You must manually input the paths. The guarded disk names are prepended with: `/dev/secvm`.

Checking Rebalance Status

The `wait` command is very important when ASM performs a rebalance. When you specify `wait`, the command prompt does not display until all of the data is rebalanced and migrated off of the disk. If you do not specify `wait`, the command prompt returns immediately, and you must issue the following ASM command to check the status of the rebalance:

```
SQL> select * from v$asm_operation;
```

This command returns information about the:

- State
- Current power level
- Current amount rebalanced
- Estimated work until completion
- Rate
- Estimated minutes
- Any error codes

Note

It is highly recommended that you always specify the `wait` command when performing a **Drop Disk** with Rebalance. If it is not specified, ASM may prematurely release the disk, thereby allowing CTE to place a GuardPoint on the disk before the rebalance completes. This action may corrupt the data.

Oracle cautions against this issue:

Caution

The `ALTER DISKGROUP...DROP DISK` statement returns before the drop and rebalance operations complete. Do not reuse, remove, or disconnect the dropped disk until the `HEADER_STATUS` column in the `V$ASM_DISK` view for this disk changes to `FORMER`. You can query the `V$ASM_OPERATION` view to determine the amount of time remaining for the drop/rebalance operation to complete. For more information, refer to the Oracle Database SQL Language Reference and the Oracle Database Reference.

Determining Best Method for Encrypting Disks

A diskgroup can contain one or multiple disks. You must determine if the diskgroup contains enough disks and free space for encryption. If the diskgroup contains only one disk, or multiple disks but not enough free space,

then you must use the **Offline** (backup/restore) method for encryption.

If the diskgroup contains more than one, you can use the **Online** (rebalancing) method. During rebalancing, additional disks allow for migrating data from the original disk so that it can be encrypted, added back into the diskgroup, and then migrated back to the source disk. Therefore, if the customer does not want to permanently add extra disks, they can add disks temporarily, just for rebalancing.

In general, once you have completed the initial setup for the operating system with which you are working, for both ASM or ASMLib, the high-level process is the same for applying CTE protection to raw devices and using them.

Online Method (No Application / Database Downtime)

Typically, when using the online method, follow these steps:

1. Make an ASM disk available for protection by either removing a disk from an existing diskgroup, or allocating a new disk.
2. Apply CTE encryption to the disk.
3. Add each protected disk to the diskgroup.
4. Restart the nodes and the failover test.
5. Repeat the previous steps for each disk in the diskgroup.

Offline Method (Backup the DB)

Typically, when using the offline method, follow these steps:

1. Backup the database.
2. Make an ASM disk available for protection by either removing a disk from an existing diskgroup, or allocating a new disk.
3. Stop the Oracle database.
4. Delete the diskgroup.
5. Apply CTE encryption to the disk.
6. Recreate the diskgroup.
7. Add the protected disk to the diskgroup.
8. Restart the nodes and the failover test.
9. Repeat the previous steps for each disk in the diskgroup.

General Prerequisites

Setup

- Verify that you have a current backup of the database
- Install and register CTE agents on all RAC node Hosts
- Create a **Host Group** and add all RAC node hosts as members
- Create an encryption key for the Oracle RAC Database / Application
- Create an Oracle policy using the proper encryption key

Note

If the raw device mappings for the disk(s) are **not** identical across all nodes in the RAC, then you cannot use a Host Group for managing the GuardPoint within the CipherTrust Manager. You **must** apply the GuardPoint to each Host individually. This is typically not optimal, as a Host Group is the most effective and consistent way to manage GuardPoints for Oracle RAC environments.

Altering ASM_DISKSTRING on ASM

ASM uses the `asm_diskstring` setting to identify the path where ASM will attempt to locate available disks to use. If you are using device names when adding the disk, you must modify the string to include the path to SecVM.

1. To retrieve the `ASM_DISKSTRING` setting, type:

```
SQL> SHOW PARAMETER ASM_DISKSTRING
```

2. To modify the setting, type:

```
SQL> ALTER SYSTEM SET ASM_DISKSTRING='/dev/mapper/*', '/dev/secvm/dev/mapper/*';
```

Where the path added is the path to SecVM.

ASMLib manages the binding, not ASM. ASMLib creates ASMLib devices on the SecVM devices and presents it to ASM. ASM automatically recognizes the new device. This creates the need to alter diskstrings for ASM. In addition, Oracle ASM sees a new device created using ASMLib and Raw, by default.

For example:

Using Oracle ASMLib to bind the device:

```
oracleasm createdisk <devicename> /dev/secvm/dev/<blockdev>
```

Using the raw command to bind the device:

```
raw /dev/raw/rawN /dev/secvm/dev/<blockdev>
```

Specific Prerequisites

Establishing a Starting Point

In many production environments, you may find that it has been a very long time since the RAC nodes have had the services restarted or have been completely rebooted. This can result in a lack of understanding of the actual state of the RAC cluster and its ability to survive a reboot on its own, prior to installing CTE.

Restarts can uncover issues in the RAC environment that are unrelated to CTE. To avoid issues after a CTE installation, Thales recommends that you restart each RAC node **AFTER** CTE is installed and **PRIOR** to establishing any GuardPoints. This may not be feasible in a single node configuration. However, by doing so, CTE is installed but inactive, and you can ensure that the platform is in a workable state prior to getting started.

The Importance of Device Mapping

It is important to use device naming and mapping in a multi-node RAC configuration. Verify the device names to ensure that the disks are mapped to the same disks on each RAC node before applying any GuardPoints. Thales recommends that RAC nodes use the same device names across all nodes. If they do not match, then problems can occur.

If the RAC nodes use the same device names, use a Host Group to create GuardPoints. If they do not match, do not use a Host Group to create GuardPoints. Set them up independently on each Host.

Important Note about Raw Devices on UNIX

In general, raw devices are created as either character or block mode devices. Any I/O performed on character devices is non-buffered, while I/O on block devices is buffered and performed in defined block sizes (that is, 4K bytes).

While the Oracle documentation for using ASM with raw devices indicates that you can use either character or block devices, **CTE REQUIRES a block device for guarding**.

Note

- Attempting to apply a GuardPoint on a character device that does not have a corresponding block device may result in a GuardPoint that never encrypts data. The status of the GuardPoint never shows as guarded.
- The WebUI does not support browsing for the character devices. You would need to manually paste the name into the WebUI.

Block Device Support

CipherTrust Transparent Encryption UserSpace block device support requires that the underlying kernel supports I/O direct mode for loop devices (`LOOP_SET_DIRECT_IO`) in order to properly flush and retrieve data from a disk. This support was not added in the kernel loop driver until **kernel 4.10**. Any distribution with a kernel level lower than that may improperly cache data and therefore, should not be used in a multi-node setup sharing block devices because stale data may be returned to the application.

Oracle RAC ASMLib Multi-Disk Online Method

The online method describes how to remove, protect and add disks to a diskgroup.

Assumptions

Using the Online Method assumes that there is enough free space in the diskgroup so that you can drop/remove, protect and then add the disk back into the diskgroup.

Note

During the initial investigation, you may want to ensure that you have the correct raw device name for each disk that you plan on protecting. Before making any changes to the ASM configuration, obtain the definitive device names for each disk by running the following from the command prompt:

```
oracleasm querydisk -p <diskName>
```

To add the disk to the diskgroup using the online method and make it ready for use:

1. Open a terminal session on both RAC Nodes.
2. On **RAC Node 1**, perform the following:
 - a. On the ASM, type the following to remove a disk for the diskgroup.

```
SQL> ALTER DISKGROUP <diskGroupName> DROP DISK <diskName> REBALANCE POWER 1  
1 WAIT;
```

- b. Delete the disk from ASM, type:

```
oracleasm deletedisk <diskName>
```

- c. Verify that the disk is deleted from the ASM and therefore, it is not listed, type:

```
oracleasm listdisks
```

Note

If you are planning to apply a GuardPoint to a raw device that is currently in an ASM diskgroup, you must remove and delete the disk from the diskgroup before you apply the GuardPoint. ASMLib will not see the guarded disk if you skip this step. When deleting the disk, make sure that the deletion completes before continuing.

About Oracle RAC ASM Raw Devices

When Not Using ASMLib

Before starting the CTE implementation, investigate how the customer is using raw devices for their ASM configuration.

Devices using Raw Bindings

Typically, a device that uses a raw binding looks like the following to ASM:

```
/dev/raw/raw1
```

If the device is mapped this way, you must locate where the mapping is performed. Typically, you can find this in the following configuration file:

```
/etc/sysconfig/rawdevices
```

The underlying binding could be to either a **standard device** name or a **multipath** I/O device name. Either way, you must find where the bind commands are run so that you can modify them for SecVM.

Note

If raw bindings are in use, then typically no changes are needed for the `asm_diskstring`. Because the binding to the actual device is created through the `bind` command, locate where the binding occurs and change the binding to SecVM.

Multipath I/O Devices

Devices using multipath I/O are typically found with the name:

```
/dev/mapper/mpath1
```

Generally, when using multipath I/O, you create SecVM on the multipath device name.

Note

- **CTE:** If you use multipath I/O devices in the ASM configuration to add its disk, you must modify the `asm_diskstring` parameter to include the `/dev/secvm/dev/*` path.
- **CTE-U:** If you use multipath I/O devices in the ASM configuration to add its disk, you must modify the `asm_diskstring` parameter to include the `/dev/secvm/*` path.

Standard Devices

In many cases the ASM configuration may be using plain device names, like the following:

`/dev/sda1`

Note

- **CTE:** If you use standard device names in the ASM configuration to add a disk, you must modify the `ASM_DISKSTRING` parameter to include the `/dev/secvm/dev/*` path.
- **CTE-U:** If you use standard device names in the ASM configuration to add a disk, you must modify the `ASM_DISKSTRING` parameter to include the `/dev/secvm/*` path.

Consistent Naming of Devices across RAC Nodes

As previously stated, if the raw device mappings for the disk(s) are **NOT** identical across all nodes in the RAC, then you **CANNOT** use a Host Group and you **MUST** apply the GuardPoints to each Host individually. This is typically NOT optimal, as a Host Group is the most effective way to manage an Oracle RAC environment.

Oracle RAC ASM Multi-Disk Online Method

Performing encryption with the online rebalancing method requires sufficient free space to allow the drop of the largest ASM disk.

Checking for Space

In the Oracle system, use the following commands to check for available disk space:

1. Check total free space in the disk group:

```
SELECT name, free_mb, total_mb, free_mb/total_mb*100 as percentage FROM v$asm_diskgroup;
```

```

NAME                                FREE_MB  TOTAL_MB  PERCENTAGE
-----
DATA                                7        2109    .331910858

```

2. Check individual ASM disk size and usage:

```

select a.name DiskGroup, b.disk_number Disk#, b.name DiskName, b.total_mb, b.free_mb, b.path, b.header_status FROM v$asm_disk b, v$asm_diskgroup a where a.group_number (+) =b.group_number order by b.group_number, b.disk_number, b.name

```

```

DISKGROUP  DISK#  DISKNAME          TOTAL_MB  FREE_MB  PATH
HEADER_STATUS
-----
DATA        0      DATA_0000        1874      1273    /dev/oracleasm/disks/D
ATA3        MEMBER
DATA        1      DATA_0001        1992      608     /dev/oracleasm/disks/D
ATA4        MEMBER
DATA        3      DATA_0003        117       0       /dev/oracleasm/disks/D
ATA2        MEMBER
            0      DATA_ENC_0000    109       28      /dev/oracleasm/disks/D
ATA1_ENC    MEMBER

```

Adding a Disk to the Diskgroup

Using the Online Method assumes that there is enough free space in the diskgroup so that you can drop/remove a disk, protect it with CTE, and then add it back into the diskgroup.

To add the disk to the diskgroup:

1. Open a terminal session on both RAC Nodes.
2. On **RAC Node 1**, on the ASM, remove the disk from the disk group, type.

```
ALTER DISKGROUP <diskGroupName> DROP DISK <diskName> REBALANCE POWER 11 WAIT;
```

3. On the CipherTrust Manager, in the Host Group, apply a GuardPoint to the Raw Device: `<rawDevice1Name>`.
4. From **RAC Node 1**, to display the status of the guarded disks, type:

```
secfsd -status guard
```

- On both **RAC Node 1 and 2** type:

```
chown oracle:oinstall /dev/secvm/<rawDevice1Name>
chmod 660 /dev/secvm/<rawDevice1Name>
```

- From **RAC Node, on the ASM**, add the protected disk to the disk group:

```
ALTER DISKGROUP <diskGroupName> ADD DISK /dev/secvm/<rawDevice1Name> NAME <disk1Name>;
```

The disk is now added to the diskgroup and ready for use.

- The system is now ready for a reboot and failover test. For details, see [Surviving the Reboot and Failover Testing](#).

Troubleshooting

Occasionally, settings do not persist when the system is rebooted. To ensure they do persist, edit the `/etc/rc.local` file and add the following lines:

```
Echo "Changing Permission for secvm devices"
chown oracle:oinstall /dev/secvm/dev/<rawDevice1Name>
chmod 660 /dev/secvm/dev/<rawDevice1Name>
```

Oracle RAC ASM Multi-Disk Offline Method (Backup/Restore)

Using the Offline Method assumes that there is not enough free space in the diskgroup.

- Open a terminal session on both RAC Nodes.
- On RAC Node 1, on the ASM, type the following to remove the disk group.

```
DROP DISKGROUP <diskGroupName> FORCE INCLUDING CONTENTS;
```

Note

Make sure that the disk is removed before guarding the raw devices.

- On the CipherTrust Manager, in the Host Group, apply GuardPoints to the three raw devices:

```
<rawDeviceName1>
```

```
<rawDeviceName2>
<rawDeviceName3>
```

4. On **RAC Node 1**, to display the status of the guarded disks, type:

```
secfsd -status guard
```

5. On both **RAC Node 1** and **2**, type:

CTE

```
chown oracle:oinstall /dev/secvm/<rawDeviceName1>
chmod 660 /dev/secvm/<rawDeviceName1>
chown oracle:oinstall /dev/secvm/<rawDeviceName2>
chmod 660 /dev/secvm/<rawDeviceName2>
chown oracle:oinstall /dev/secvm/<rawDeviceName3>
chmod 660 /dev/secvm/<rawDeviceName3>
```

CTE-U

```
chown oracle:oinstall <rawDeviceName1>
chmod 660 <rawDeviceName1>
chown oracle:oinstall <rawDeviceName2>
chmod 660 <rawDeviceName2>
chown oracle:oinstall <rawDeviceName3>
chmod 660 /dev/<rawDeviceName3>
```

6. From **RAC Node 1, on the ASM**, add the protected disk to the disk group, type:

```
ALTER DISKGROUP <diskGroupName> ADD DISK /dev/secvm/<rawDeviceName1> NAME <diskName1>;
ALTER DISKGROUP <diskGroupName> ADD DISK /dev/secvm/<rawDeviceName2> NAME <diskName2>;
ALTER DISKGROUP <diskGroupName> ADD DISK /dev/secvm/<rawDeviceName3> NAME <diskName3>;
```

The disks are now added to the diskgroup and ready for use.

7. On **RAC Node 1**, restore the database.
8. The system is now ready for a reboot and failover test. Go to the section [Surviving the Reboot and Failover Testing](#).

Troubleshooting

Occasionally, settings do not persist when the system is rebooted. To ensure they do persist, edit the `/etc/rc.local` file and add the following lines:

```
"Changing Permission for secvm devices"
chown oracle:oinstall /dev/secvm/dev/<rawDeviceName1>
chmod 660 /dev/secvm/dev/<rawDeviceName1>
chown oracle:oinstall /dev/secvm/dev/<rawDeviceName2>
chmod 660 /dev/secvm/dev/<rawDeviceName2>
chown oracle:oinstall /dev/secvm/dev/<rawDeviceName3>
chmod 660 /dev/secvm/dev/<rawDeviceName3>
```

Surviving the Reboot and Failover Testing

Preparing for Failover Testing with ASMLib

When using ASMLib with the `createdisk` command, there is no requirement to make additional changes in `rc.local` or other areas for mapping device names or to use `chmod` or `chown` for SecVM. This is because it is managed for you by the `createdisk` function and you can verify this by running the following command:

```
ls -l /dev/oracleasm/disks
```

CTE Load Order and Startup Scripts

The last change is to ensure that CTE starts before ASM starts in the startup scripts.

Failover Testing

Confirm that everything is functional:

- Ensure that the GuardPoints are all operational.
- Ensure that you receive valid results when you query the database.
- Verify that the load order ensures that CTE starts before ASM.

Once verified, you can start the failover testing for each RAC Node.

1. Reboot the RAC Node 1 and monitor the startup.
2. Once the restart is clean, reboot RAC Node 2 and monitor the startup.

Issues with Device Mapper and Invalid Guard Path

If CTE is unable to apply a GuardPoint on a raw device, the logs may generate an error similar to the following:

```
[SecFS, 0] EVENT: Failed to guard /dev/mapper/devicename (reason: Invalid Guard Path flags 0x2 gypped 0x4 status 0x11) - Will retry later
```

If you receive this error, use the setup command to check the status of the disks, type:

```
setup info <deviceName>
```

Before attempting to establish a GuardPoint, look closely at the open count value and ensure that it is 0 on all nodes.

Using CTE with Oracle ASM Filter Driver

This chapter describes how to configure CTE on Oracle Standalone and RAC ASM Filter Driver for Linux. It contains the following topics:

- How to enable CTE for Oracle ASMFD
- How to configure CTE and create a guarded Oracle ASMFD
- How to convert a baseline ASMFD disk group to a guarded ASMFD disk group
- How to uninstall/ upgrade CTE with an active ASMFD Setup

About Oracle ASM Filter Driver

Oracle ASM Filter Driver (Oracle ASMFD) is a kernel module that resides in the I/O path of the Oracle ASM disks. Oracle ASM uses the filter driver to validate write I/O requests to Oracle ASM disks.

The Oracle ASMFD simplifies the configuration and management of disk devices by eliminating the need to rebind disk devices used with Oracle ASM each time the system is restarted.

The Oracle ASM Filter Driver rejects any I/O requests that are invalid. This action eliminates accidental overwrites of Oracle ASM disks that would cause corruption in the disks and files within the disk group.

Audience

Users must be a Senior Oracle DBA administrator who is comfortable setting up a baseline ASMFD environment.

Prerequisites

The following setup allows CTE to correctly load the guarded ASMFD disks correctly after CTE is installed, upgraded, or restarted:

1. Ensure that the ASM \$ORACLE_BASE variable is assigned a value in `/root/.bash_profile`, if Oracle is already installed.
2. Ensure that a line starting with **+ASM** exists in the `/etc/oratab`.

Note

This line is added by Oracle when Oracle is configured with ASM.

Enable Oracle ASMFD for CTE

To enable Oracle ASMFD:

1. Log in as the root user and stop the Oracle Grid Infrastructure for a standalone server, type:

```
$GRID_HOME/bin/crsctl stop has
```

2. Configure Disk Discovery for AFD. Modify the following files by adding the content of `/dev/secvm/dev/sd*` to the OS files in `/etc/oracleafd.conf` and `/etc/afd.conf` with `afd_filtering` enabled, type:

```
cat /etc/afd.conf
afd_diskstring='/dev/sd*,/dev/secvm/dev/sd*'
afd_filtering=enable

cat /etc/oracleafd.conf
afd_diskstring='/dev/sd*,/dev/secvm/dev/sd*'
afd_filtering=enable
```

- a. To prevent the file from changing back to `afd_diskstring='/dev/sd*'` make it read only, type:

```
chmod 444 /etc/oracleafd.conf /etc/afd.conf
```

3. Restart ACFS before proceeding, type:

```
acfsload stop
acfsload start
```

4. Restart the Oracle Grid Infrastructure, type:

```
$GRID_HOME/bin/crsctl start has
```

5. Verify that `/dev/secvm/dev/sd*` is part of the SQL output and the state is enabled as a grid, type:

```
SELECT SYS_CONTEXT('SYS_ASMFD_PROPERTIES', 'AFD_DISKSTRING') FROM DUAL;
```

Expected Response

```
SYS_CONTEXT( 'SYS_ASMFD_PROPERTIES', 'AFD_DISKSTRING' )
-----
/dev/sd*, /dev/secvm/dev/sd*
```

Note

If using Oracle RAC (Real Application Clusters), repeat the previous steps for all of the nodes in the related RAC cluster.

Configure CTE and create a guarded Oracle ASMFD

To configure CTE and create a Guarded Oracle ASMFD:

1. Create a raw device disk, for example:

```
/dev/sdc
```

2. Partition the targeted raw device, for example:

```
/dev/sdc1
```

3. Guard the partitioned raw device, that you just created, using CTE.
4. Create an ASMFD disk on the guarded partitioned raw device, type:

```
$GRID_HOME/bin asmcmd afd_label '<disk_label>' '<guarded_raw_partition>'
```

Example:

```
$GRID_HOME/bin asmcmd afd_label 'DISK1' '/dev/secvm/dev/sdc1'
```

5. Verify that the new disk was created, type:

```
$GRID_HOME/bin asmcmd afd_alsdk
```

The disk should display in the list of disks, similar to the following:

```
Label  Filtering  Path
```

```
=====
DISK1  ENABLED  /dev/secvm/dev/sdc1
```

6. If using Oracle RAC (Real Application Clusters), repeat the previous steps for all of the nodes in the RAC cluster.
7. Now you can use the Oracle Grid ASM Configuration Assistant GUI to create the targeted guarded ASMFD disk group on the above created guarded ASMFD disk, DISK1. See the Oracle GRID documentation for more information.

Convert a baseline ASMFD disk group to a CTE guarded ASMFD disk group using the Offline method

We will use the following example scenario in this section:

Objective:

- Convert the baseline ASMFD disk group **DATA1**, to a CTE guarded ASMFD disk group.
- Current configured baseline **DATA1** disk group consists of ASMFD disk **DISK1** on a raw partitioned device /dev/sdc1.

To convert:

1. If the targeted raw disk partition to be guarded does not yet exist, create it. For example: /dev/sdd1.

Note

The capacity of /dev/sdd1 must be large enough to transfer all of the data from ASMFD disk DISK1 on /dev/sdc1.

2. Using CTE, guard the raw partitioned device.
3. Create an ASMFD disk on the guarded raw partition:

```
$GRID_HOME/bin asmcmd afd_label '<disk_label>' '<guardedRawPartition>'
```

Example

```
$GRID_HOME/bin asmcmd afd_label 'DISK2' '/dev/secvm/dev/sdd1'
```

4. Ensure that there are current backups of all of the database(s) residing on the ASMFD disk group DATA.

5. Shutdown all databases residing on ASMFD disk group DATA1.
6. In the ASM database, run the following SQL command with the rebalance option to add a guarded ASMFD disk DISK2 to ASMFD disk group DATA1, type:

```
ALTER DISKGROUP <ASMFD diskgroup name> ADD DISK 'AFD:<ASMFD disk name>' REBALANCE POWER 11 WAIT;
```

Example

```
ALTER DISKGROUP DATA1 ADD DISK 'AFD:DISK2' REBALANCE POWER 11 WAIT;
```

7. Verify the results, type:

```
col PATH for a15 col DG_NAME for a15 col DG_STATE for a10 col FAILGROUP for a10 select dg.name
dg_name, dg.state dg_state, dg.type, d.disk_number dsk_no,d.path, d.mount_status, d.FAILGROUP, d.state
from v$asm_diskgroup dg, v$asm_disk d where dg.group_number=d.group_number and dg.name = 'DATA1'
```

System Response:

DG_NAME	DG_STATE	TYPE	DSK_NO	PATH	MOUNT_S	FAILGROUP	STATE
DATA1	MOUNTED	EXTERN	0	AFD:DISK1	CACHED	DISK1	NORMAL
DATA1	MOUNTED	EXTERN	0	AFD:DISK2	CACHED	DISK2	NORMAL

8. Run the following SQL command, in the ASM database, to transfer all data from ASMFD disk DISK1 to ASMFD disk DISK 2 and then drop ASMFD disk DISK1 from ASMFD disk group DATA1, type:

```
ALTER DISKGROUP DROP DISK 'AFD: REBALANCE POWER WAIT;
```

Example:

```
ALTER DISKGROUP DATA1 DROP DISK 'AFD:DISK1' REBALANCE POWER 11 WAIT;
```

Verify the results:

```
col PATH for a15 col DG_NAME for a15 col DG_STATE for a10 col FAILGROUP for a10 select dg.name
dg_name, dg.state dg_state, dg.type, d.disk_number dsk_no,d.path, d.mount_status, d.FAILGROUP, d.state
from v$asm_diskgroup dg, v$asm_disk d where dg.group_number=d.group_number where dg.name =
'DATA1'
```

System response

DG_NAME	DG_STATE	TYPE	DSK_NO	PATH	MOUNT_S	FAILGROUP	STATE

```

-----
-----
DATA1          MOUNTED      EXTERN      0      AFD:DISK2    CACHED      DISK2      NORMAL

```

At this point, all data in the ASMFD disk group DATA1 has been transferred from the baseline ASMFD disk DISK1, to the guarded ASMFD disk DISK2. At this time, the databases that are residing in ASMFD disk group DATA1 can now be restarted.

Convert a baseline ASMFD disk group to a CTE guarded ASMFD disk group using the Online method

We will use the following example scenario in this section:

- Number of RAC nodes: 2
- Name of Diskgroup: DATA1
- Number of disks: 3

Name of baseline disks assigned to raw device:

- DISK1: /dev/sdb1
- DISK2: /dev/sdc1
- DISK3: /dev/sdd1

ASMFD disk group **DATA1** was created from baseline ASMFD disks DISK1, DISK2, and DISK3.

```

DG_NAME      DG_STATE  TYPE      DSK_NO  PATH          MOUNT_S  FAILGROUP  S
-----
DATA1        MOUNTED   EXTERN    0      AFD:DISK1     CACHED   DISK1      N
DATA1        MOUNTED   EXTERN    0      AFD:DISK2     CACHED   DISK2      N
DATA1        MOUNTED   EXTERN    0      AFD:DISK3     CACHED   DISK3      N

```

Objective:

- Convert all of the database data on ASMFD disk group DATA1 from baseline to a CTE guarded ASMFD disk group.

Note

The combined capacity of /dev/sdc1 on DISK2 and /dev/sdd1 on DISK3 must be large enough to

hold all of the data transferring from ASMFD disk DISK1 on /dev/sdb1.

To convert:

From RAC Node 1:

1. Connect locally, as the system administrator, to an Oracle ASM instance using OS authentication, type:

```
sqlplus 'as sysasm'
```

2. At the ASM prompt, drop the ASMFD disk DATA1 from the disk group DISK1, type:

```
ALTER DISKGROUP DATA1 DROP DISK DISK1 REBALANCE POWER 11 WAIT;
```

3. Verify that the ASMFD DISK2 is no longer part of the ASMFD disk group DATA1, type:

```
sqlplus 'as sysasm' col PATH for a15 col DG_NAME for a15 col DG_STATE for a10 col FAILGROUP for a10
select dg.name dg_name, dg.state dg_state, dg.type, d.disk_number dsk_no,d.path, d.mount_status,
d.FAILGROUP, d.state from v$asm_diskgroup dg, v$asm_disk d where dg.group_number=d.group_number
and dg.name = 'DATA1';
```

System Response

DG_NAME	DG_STATE	TYPE	DSK_NO	PATH	MOUNT_S	FAILGROUP
DATA1	MOUNTED	EXTERN	0	AFD:DISK2	CACHED	DISK2
NORMAL						
DATA1	MOUNTED	EXTERN	0	AFD:DISK3	CACHED	DISK3
NORMAL						

Note

Depending on the size of your data, DISK1 might take some time to no longer show in the above query.

4. From the OS command prompt, drop ASMFD disk DISK1:

```
$GRID_HOME/bin asmcmd afd_unlabel DISK1
```

- From the command prompt, verify DISK1 is no longer visible on both RAC Node 1 and 2.

```
$GRID_HOME/bin asmcmd afd_lslbl
```

- Using CTE, guard the DISK1 raw partitioned device `/dev/sdb1`.
- From the command prompt, recreate ASMFD disk DISK1, with the guarded raw device `/dev/sdb1`.

CTE

```
$GRID_HOME/bin asmcmd afd_label 'DISK1' '/dev/secvm/dev/sdb1'
```

CTE-U

```
$GRID_HOME/bin asmcmd afd_label 'DISK1' '/dev/secvmsdb1'
```

- From the command prompt, verify that DISK1 is now visible on both RAC Node 1 and 2 with the newly guarded path:

```
$GRID_HOME/bin asmcmd afd_lslbl
```

- From the ASM prompt, add the guarded ASMFD disk DISK1 back to the ASMFD disk group DATA1, type:

```
sqlplus 'as sysasm'
ALTER DISKGROUP DATA1 ADD DISK 'AFD:DISK1' REBALANCE POWER 11 WAIT;
```

- Verify that ASMFD disk DISK1 is now part of ASMFD diskgroup DATA1, type:

```
sqlplus 'as sysasm' col PATH for a15 col DG_NAME for a15 col DG_STATE for a10 col FAILGROUP for a10
select dg.name dg_name, dg.state dg_state, dg.type, d.disk_number dsk_no,d.path, d.mount_status,
d.FAILGROUP, d.state from v$asm_diskgroup dg, v$asm_disk d where dg.group_number=d.group_number
and dg.name = 'DATA1';
```

System Response

DG_NAME	DG_STATE	TYPE	DSK_NO	PATH	MOUNT_S	FAILGROUP
DATA1	MOUNTED	EXTERN	0	AFD:DISK1	CACHED	DISK1
NORMAL						
DATA1	MOUNTED	EXTERN	0	AFD:DISK2	CACHED	DISK2
NORMAL						

DATA1	MOUNTED	EXTERN	0 AFD:DISK3	CACHED	DISK3
NORMAL					

Note

Depending on the size of your data, DISK1 might take some time to display in the above query.

11. Repeat the previous steps for Baseline DISK 2 and DISK 3

Uninstall/ Upgrade CTE with active ASMFD Setup

For an Active ASMFD Standalone Setup

1. Shutdown all databases running on guarded devices.
2. Shutdown the CRS and ACFS, type:

```
crsctl stop resource -all
crsctl stop has
afdload stop
```

3. Perform CTE maintenance, uninstall or upgrade.
4. Restart ACFS and CRS, type:

```
afdload start
crsctl start has
crsctl start resource -all
```

5. Restart related databases.

For an Active ASMFD RAC Setup

To perform CTE maintenance on all ASMFD RAC nodes in a cluster:

1. Shutdown all databases running on guarded devices.
2. Shutdown CRS, ACFS, and AFD on all nodes, type:

```
$GRID_HOME/bin/crsctl stop cluster -all
$GRID_HOME/bin/acfsload stop cluster -all
```

```
$GRID_HOME/bin/afdload stop cluster -all
```

3. Perform CTE maintenance, uninstall, or upgrade on all targeted RAC nodes.
4. Restart AFD, ACFS, and CRS on all nodes, type:

```
$GRID_HOME/bin/afdload start cluster -all
$GRID_HOME/bin/acfsload start cluster -all
$GRID_HOME/bin/crsctl start cluster -all
```

5. Restart related databases.

To perform CTE maintenance on a ASMFD RAC cluster in a rolling fashion:

1. Shutdown all instances running on guarded devices on the targeted RAC node only.
2. Shutdown CRS, ACFS, and AFD on the targeted RAC node only. Type:

```
$GRID_HOME/bin/crsctl stop has
$GRID_HOME/bin/acfsload stop
$GRID_HOME/bin/afdload stop
```

3. Perform CTE maintenance, uninstall, or upgrade on the targeted RAC node only.
4. Restart AFD, ACFS, and CRS on a targeted RAC node only, type:

```
$GRID_HOME/bin/afdload start
$GRID_HOME/bin/acfsload start
$GRID_HOME/bin/crsctl start has
```

5. Restart related instances on the targeted RAC node.

Note

If AFD fails to stop, try the following OS command:

```
modprobe -r oracleafd
```

Using Oracle with CTE-U

When guarding an ASM disk with CipherTrust Transparent Encryption UserSpace, there can be a 10% drop in database performance. This occurs when the underlying device is in Oracle direct mode. This mode avoids

double-caching, which consumes memory, and therefore impacts performance on some workloads.

This issue is affected by the `block_o_direct` parameter. If that parameter is set to `0`, the IO will be reported as complete, (meaning committed to disk) before it actually is. This is a data integrity risk for a database, because the normal mode is to mark as journal complete as soon as the data is safe on a disk. This incorrect reporting could result in a race that could lead to a journal being cleared before the data is on the disk. If a crash occurs during this window, the data would be lost.

In this scenario, data integrity and performance are at odds. You must choose which one to highlight.

1. To set CTE-U for **optimal data integrity**, type the following command:

```
voradmin secfs config block_o_direct 1
```

2. To set CTE-U for **optimal performance**, type the following command:

```
voradmin secfs config block_o_direct 0
```

Note

The commands listed in the steps above will change the `block_o_direct` parameter in CipherTrust Transparent Encryption UserSpace, in the `config.yaml` file located in: `/opt/vormetric/DataSecurityExpert/agent/secfs/.sec/conf/secfs_config.yaml`

Integrating and Configuring EDB

This chapter describes how to configure and integrate Enterprise DB Postgres Advanced Server (EDB) with CTE in Linux. It contains the following sections:

- [Preparing to Create GuardPoints](#)
- [Integration with CTE](#)

Overview

EDB provides database management software to get more functionality from PostgreSQL. EDB offers secure, scalable, advanced and enterprise-class PostgreSQL solutions. Advanced Server extends PostgreSQL with the security and performance features that enterprises need. It's also compatible with Oracle databases.

Prerequisites

Refer to [EDB documentation](#) for information on how to setup and configure EnterpriseDB.

Preparing to Create GuardPoints

Before you can safely reboot your machine, create GuardPoints, and administer any of the services, you must perform the following steps:

1. Stop the EDB service.
2. Open the `/lib/systemd/system/edb-as-13.service` file.
3. Below the `[Unit]` section, add the following line: `Requires=secfs-fs-barrier.service`.
4. Save the file and exit.
5. Open the file: `/lib/systemd/system/secfs-fs-barrier.service`.

Note

If using CTE-U, open the file: `secfs-fuse.service`.

6. At the end of the `[Before]` clause, add `edb-as-13.service`.
7. Save the file and exit.
8. Type: `systemctl daemon-reload`.
9. Type: `systemctl start edb-as-13.service`.
10. Reboot the system.
11. Stop the EDB.
12. Restart SecFS.
13. Start the EDB service again.

Integration with CTE

The following describes how to integrate EDB with CTE using an offline dataxform policy:

1. Enable and start EDB.
2. Create a database with sample data.
3. Install the latest CTE build. Refer to the [CTE Agent Linux Quick Start Guide](#) for more information.
4. Register CTE with a CipherTrust Manager.

5. Stop the EDB service.
6. Guard the EDB data and log directories with a Dataxform policy.

For example, create a policy that transforms from Clear key to AES256.
7. Perform a data transformation on both directories.
8. After Dataxform finishes, guard both directories with a policy using the correct key.

For example, use AES256 on both directories.
9. After the database and log directories are guarded, start the EDB service again.

Integration with Pacemaker

This document covers the following information:

- Using CTE with Pacemaker
- Performing CTE maintenance with LDT GuardPoints and a Pacemaker Setup

Performing CTE maintenance with an LDT GuardPoint in a Pacemaker Setup

Unguard the LDT GuardPoint with Pacemaker setup

1. Stop the SQL server, type:

```
sudo systemctl stop mssql-server
```

2. Delete the existing resource constraints from LDT and the colocation from the Pacemaker setup.

Example

A. If it exists, get the ID of the PCS constraint co-location. In the example below the, ID is: `co-location_set_msmsmt`

```
sudo pcs constraint show --full
.
.
.
Resource Sets:
set mssql_fs mssql_gpfs mssql_gpldt sequential=false (id:co-location_set_msmsmt_set) setoptions score=INFINITY (id:co-location_set_msmsmt)
```

B. Remove the PCS constraint co-location and PCS resource, type:

```
sudo pcs constraint remove co-location_set_msmsmt
sudo pcs resource delete mssql-ldtmgp
```

Expected Result: Current LDT GuardPoint status should be now be: unguarded.

Example

```
secfsd -status guard
```

Response

GuardPoint s	Reason	Policy	Type	ConfigState	Statu
-----	-----	-----	----	-----	
-----	-----				
/var/opt/mssql/LDT		LDT_clear_to_CS1_aes256_onhost	manual	unguarded	not g
uarded	Inactive				

3. Unguard the LDT GuardPoint from the Cluster Host Group in CipherTrust Manager.

Expected Result: The LDT GuardPoint should no longer be displayed when `secfsd -status guard` is executed.

Perform CTE maintenance

Now you can perform CipherTrust Transparent Encryption maintenance tasks that require stopping secfs such as:

- Stop CipherTrust Transparent Encryption
- Upgrade CipherTrust Transparent Encryption
- Uninstall CipherTrust Transparent Encryption
- Create a new baseline database for LDT on the same LDT &{gp}

See [CTE Agent for Linux Advanced Configuration](#) for more information.

Note

Before creating a new baseline database for LDT: Ensure that your target LDT GuardPoint path does not have an `ldt xattr` value on it so that the directory can trigger the initial rekey at the start of guarding. If it does have an `ldt xattr` value from a previous setup, then use the command `voradmin`

```
ldt xattr delete` to remove the old xattr value.
```

Re-Enable LDT GuardPoint with Pacemaker Setup

1. Re-enable the LDT GuardPoint from the Cluster Host Group in CipherTrust Manager. Wait until the GuardPoint is visible again and in the `unguarded` state before moving to the next step below.

Example

```
# secfsd -status guard
```

Response

GuardPoint	Policy	Type	ConfigState	Statu
s Reason				
-----	-----	----	-----	
-----	-----			
/var/opt/mssql/LDT	LDT_clear_to_CS1_aes256_onhost	manual	unguarded	not g
uarded Inactive				

2. Add the resource `mssql-ldtmgp` back into the Pacemaker setting and verify that it has started:

Example

```
sudo pcs resource create mssql-ldtmgp ocf:heartbeat:mgp mgpdir=/var/opt/mssql/LDT --group Apache_Grp-fs
```

The LDT GuardPoint should now be automatically active again in Pacemaker.

```
# secfsd -status guard
```

Response

GuardPoint	Policy	Type	ConfigState	Statu
s Reason				
-----	-----	----	-----	
-----	-----			
/var/opt/mssql/LDT	LDT_clear_to_CS1_aes256_onhost	manual	guarded	guard
ed N/A				

3. Start SQL server, type:

```
sudo systemctl start mssql-server
```

4. Add the LDT resource constraints and co-location back into the Pacemaker setting.

Example

- A. Add failover resource constraints back:

```
sudo pcs constraint order start mssql_gp1dt then start mssql-ldtmgp  
sudo pcs constraint order stop mssql-ldtmgp then stop mssql_gp1dt
```

- B. If constraint co-location was used, add it back:

```
sudo pcs constraint co-location set mssql_fs mssql_gpfs mssql_gp1dt sequentia  
l=false
```

5. Restart Pacemaker so that it can pick up the newly created resource configurations.

- A. Stop SQL server, type:

```
sudo systemctl stop mssql-server
```

- B. Reboot Pacemaker, type:

```
sudo systemctl restart pacemaker
```

- C. Re-start SQL server, type:

```
sudo systemctl start mssql-server
```

Using CTE with Pacemaker

This chapter describes how to configure CTE with Pacemaker and MySQL on Red Hat 7 or Red Hat 8. It contains the following sections:

- Overview
- Considerations and Requirements
- Creating GuardPoints

Overview

Pacemaker is a high-availability cluster resource manager that runs on a set of hosts (a cluster of nodes) in order to preserve integrity and minimize downtime of desired services (resources). Every resource has a resource agent that abstracts the service it provides and present a consistent view to the cluster.

Thales provides a resource agent for CTE that allows CTE to guard nodes running MySQL databases over an NFS share in a Pacemaker environment.

Considerations and Requirements

- System Requirements:
 - Red Hat 7 or Red Hat 8. Other versions of Red Hat are not supported.
 - Pacemaker with Corosync and the MySQL database service configured. Make sure that the Pacemaker properties settings for features such as STONITH and quorum are correct based on your Pacemaker environment.

Note

Other database applications may be used instead of MySQL, but Thales has only tested the CTE resource agent with MySQL.

- The CTE resource agent supports manual GuardPoints on a device or folder. Automatic GuardPoints are not supported.
- The CTE resource agent supports GuardPoints created from Standard or Live Data Transformation policies. It does not support IDT-Capable GuardPoints or CTE-Efficient StorageGuardPoints.
- If you install Pacemaker after you have installed CTE, you must copy the CTE resource agent to the `ofc` directory.

```
cp /opt/vormetric/DataSecurityExpert/agent/secfs/systemd/pacemaker_ra_mgp //CTE-U
cp /opt/vormetric/DataSecurityExpert/agent/secfs/.sec/bin/pacemaker_ra_mgp //CTE
```

- Upgrades to the CTE resource agent will require using Pacemaker to put each node into maintenance mode while the upgrade is performed.

Creating GuardPoints

1. Install the CTE Agent on each node in the Pacemaker cluster, and register that node in the same domain in your key manager. For details, see [Getting Started with CTE for Linux](#).

2. In your key manager, do the following:

- Create a manual GuardPoint for the MySQL data directory `/var/lib/mysql/` on all of the nodes in the cluster. You can use either a Standard or a Live Data Transformation policy to create the GuardPoint, but you must use the same policy on the GuardPoint for each node.
- Create any other manual GuardPoints you want to use. Each GuardPoint must be created on all nodes in the cluster and each set of GuardPoints must use the same policy.

For example, if you have three nodes in the cluster and you want to add a Standard GuardPoint for `/hr/shared/files` and a Live Data Transformation GuardPoint for `/dir/accounting/data`, on each of the three nodes in the cluster you would create:

- A Standard or Live Data Transformation GuardPoint for `/var/lib/mysql/`.
- A Standard GuardPoint for `/hr/shared/files`.
- A Live Data Transformation GuardPoint for `/dir/accounting/data`.

3. Select one of the nodes in your cluster and log into that node as `root`.

4. On the selected node, add a Pacemaker resource for the manual GuardPoint using the following command:

```
pcs resource create mysql-mgp ocf:heartbeat:mgp mgpdir=/var/lib/mysql \
[start_services=true] [stop_services=false]
```

where:

- `start_services=true` is an optional command that tells the resource agent to start the CTE services before enabling any manual GuardPoints. The options are `true` or `false`, and the default is `true`.
- `stop_services=false` is an optional command that tells the resource agent to stop the CTE services after disabling any manual GuardPoints. The options are `true` or `false`, and the default is `false`.

5. Create the required resource groups, colocation settings, and constraints.

Warning

If the resource groups and colocation constraints are not configured properly, the PCS cluster could run resources on multiple nodes. If the ordering constraints are not set properly, the cluster could fail to start because the system tries to mount the GuardPoint before the file system has been mounted or tries to unmount the file system before the GuardPoint has been disabled. Make sure that the following resource groups and constraints are set properly.

To do so:

- a. Create a MySQL file system group (`mysql-fsg`) that contains `mysql-fs` and `mysql-mgp` using the following command:

```
pcs resource group add mysql-fsg mysql-fs mysql-mgp
```

- b. Create a MySQL service group (`mysql-sg`) that contains `mysql-server` and `mysql-vip` using the following command:

```
pcs resource group add mysql-sg mysql-vip mysql-server
```

- c. Configure the colocation and ordering constraints so that:

- `mysql-sg` and `mysql-fsg` are colocated.
- `mysql-fs` starts before `mysql-mgp`.
- `mysql-mgp` stops before `mysql-fs`.
- `mysql-fsg` starts before `mysql-sg`.

To do so, use the following commands:

```
pcs constraint colocation add mysql-sg with mysql-fsg
pcs constraint order start mysql-fs then start mysql-mgp
pcs constraint order stop mysql-mgp then stop mysql-fs
pcs constraint order start mysql-fsg then start mysql-sg
```

6. To check the status of the cluster after the configuration is complete, use the `pcs status` command.

Using CTE with SQL Server on Linux on Red Hat 8

Considerations and Requirements

- **System Requirements:**
 - **SQL Server 2019:** Other versions of SQL Server are not supported with CipherTrust Transparent Encryption.
 - **Red Hat 8:** Other versions of Red Hat are not supported with CipherTrust Transparent Encryption.

Note

Other database applications may be used instead of MySQL, but Thales has only tested this feature with MySQL.

- CipherTrust Transparent Encryption agent supports manual GuardPoints on a device or folder for both standalone and cluster SQL Server database. Automatic GuardPoints are supported on a standalone SQL Server database. Automatic GuardPoints are supported on a standalone SQL Server database but not for cluster SQL Server databases.
- The CipherTrust Transparent Encryption resource agent supports GuardPoints created from standard or Live Data Transformation policies. It does not support IDT-Capable GuardPoints or in-place Device GuardPoint GuardPoints.

Create a CTE guarded standalone SQL Server database

1. Configure the target database data and log directory location as mssql, type:

```
sudo /opt/mssql/bin/mssql-conf set <filelocation.defaultdatadir> /u01/app/mssql/data
sudo /opt/mssql/bin/mssql-conf set <filelocation.defaultlogdir> /u01/app/mssql/log
sudo systemctl restart mssql-server
```

2. Guard targeted directory with standard encryption policy using CS1 or CBC keys of either 128aes or 256aes encryption.

Example

Policy Type: **Standard**

Rule	Value
** Security Rules**	
Action	all_ops
Effect	permit, audit, applykey
** Key Selection Rule**	
Key	aes128 or 256 with CS1 or CBC

```
secfsd -status guard
```

Response

GP Reason	Policy	Type	ConfigState	Status
-----	-----	----	-----	-----

```

      /u01/app/mssql/data      encrypt_cs1_aes128_all  local  guarded  guarde
d  N/A
      /u01/app/mssql/data      encrypt_cbc_aes256_all  local  guarded  guarde
d  N/A

```

3. Create a target SQL Server database on a guarded directory as mssql, type:

```

sqlcmd -S localhost -U SA -P '<password>'
CREATE DATABASE <targetdb>
go

```

4. Verify that data and log files are residing in the newly designated directory:

```

use <targetdb>
SELECT filename from sysfiles
GO

```

Expected results: Should see data/log file in a guarded directory:

```

/u01/app/mssql/data/testdb.mdf
/u01/app/mssql/log/testdb_log.ldf

```

Convert a baseline SQL Server database to a CTE GuardPoint using Dataxform

1. Shutdown the SQL Server service, type:

```

sudo systemctl stop mssql-server
systemctl status mssql-server

```

2. Create an online policy using CS1 or CBC keys of either 128aes or 256aes encryption.

Example of aes256

Policy Name: dxf_clear_to_cbc_aes250_onhost

Policy Type: Standard

Rule	Value
** Security Rules**	
Action	key_ops

Rule	Value
Effect	permit, applykey
** Key Selection Rule**	
Key	clear_key
Data Transformation	
Key	cbc_aes256_onhost

3. Add the GuardPoint with the policy `dxfclear_to_aes256_onhost` to the targeted baseline database data/log directory, type:

```
secfsd -status guard
```

Response

```
GuardPoint      Policy                                     Type  ConfigState  Statu
s      Reason
-----
-----
/u01/app/mssql/log    dxfclear_to_cbc_aes250_onhost  local  guarded      guard
ed N/A
/u01/app/mssql/data   dxfclear_to_cbc_aes250_onhost  local  guarded      guard
ed N/A
```

4. Run the `dataxform` command with the above policy as the root user.

```
dataxform --rekey --cleanup_on_success --gp /u01/app/mssql/dataxform/data
dataxform --rekey --cleanup_on_success --gp /u01/app/mssql/dataxform/log
```

Example

```
dataxform --rekey --eanup_on_success --gp /u01/app/mssql/dataxform/data
```

Response

```
Checking if `/u01/app/mssql/dataxform/data` is a guard point with a rekey poli
cy applied
`/u01/app/mssql/dataxform/data` is a guard point with a rekey policy applied
About to perform the requested data transform operation
-- Be sure to back up your data
```

```
-- Please do not attempt to terminate the application
Do you wish to continue (y/n)?y
.
.
.
Data transform for guard point /data1/oracle/oradata/xformdb finished
About to remove the data transformation status files
Do you wish to continue (y/n)?y
Removal of data transformation status files completed
```

5. Unguard GuardPoints `/u01/app/mssql/dataxform/data` and `/u01/app/mssql/dataxform/data` from policy `dxfc_clear_to_aes256_onhost`.
6. Guard these GuardPoints again with a standard policy which encrypts using the same open aes256 key policy as `dxfc_clear_to_cbc_aes256_onhost`.

```
secfsd -status guard
```

Response

GuardPoint son	Policy	Type	ConfigState	Status	Rea
-----	-----	----	-----	-----	
/u01/app/mssql/data	encrypt_cbc_aes256_all	local	guarded	guarded	N/A
/u01/app/mssql/log	encrypt_cbc_aes256_all	local	guarded	guarded	N/A

7. Start the database and then test to see if the data is accessible, type:

```
sudo systemctl start mssql-server
sqlcmd -S localhost -U SA -P '<password>'
use <targetdb>
SELECT filename from sysfiles
go
```

Expected results: You should be able to log into your targeted transformed database and query system files.

1. Enable the LDT setting in CipherTrust Manager using one of the following methods:
 - Install agent to your targeted database host with LDT enabled [Configuring CTE with CipherTrust Manager](#).
 - Enable LDT on an existing CipherTrust Transparent Encryption installed host using the [CM GUI](#).
2. Create a targeted new baseline in the SQL Server database:

Example

```
sudo /opt/mssql/bin/mssql-conf set filelocation.defaultdatadir /var/opt/mssql/LDT/data
sudo /opt/mssql/bin/mssql-conf set filelocation.defaultlogdir /var/opt/mssql/LDT/data
sudo systemctl restart mssql-server
systemctl status mssql-server
sqlcmd -S localhost -U SA -P '<password>'
CREATE DATABASE `<targetdb>`
SELECT Name from sys.Databases
go
```

3. Create an LDT encryption policy using CS1 or CBC keys of either 128aes or 256aes.

Example

Field	Value
Name	LDT_clear_to_CS1_aes256_onhost_key
Expiration Date	<target date>
Algorithm	AES256 or AES128
Encryption Mode	CBC_CS1 or CBC
Key Type	Cache on Host
Automatic Key Rotation	Selected
Key Version Life Span (days)	<target #>

4. Create an online LDT policy using the key created in the previous step.

Example for CBC_CS1 with AES256

Policy Name: LDT_clear_to_CS1_aes256_onhost

Security Rules

Rule	Action
Order 1	
Action	key_op
Effect	Permit, Apply Key
Browsing	No

Rule	Action
Order 2	
Action	all_ops
Effect	Permit, Audit, Apply Key
Browsing	Yes

Rule	Action
Order 3	
Action	all_ops
Effect	Deny, Audit
Browsing	Yes

Key Selection Rule:

Key	Description
Order 1	
Current Key	clear_key
Transformation Key	LDT_clear_to_CS1_aes256_onhost_key
Exclusion Rule	No

5. Stop the SQL Server, type:

```
sudo systemctl stop mssql-server
systemctl status mssql-server
```

6. Guard the new LDT baseline database with the LDT policy created in the previous step.

```
secfsd -status guard
```

Response

```
GuardPoint          Policy          Type          Con
figState  Status  Reason
-----
/var/opt/mssql/LDT/data  LDT_clear_to_CS1_aes256_onhost  local  guarded
```

```
guarded N/A
```

Wait for the Rekey Status in CipherTrust Manager to display: **Rekeyed**.

7. Run LDT with the same policy to verify the transformation of the baseline database.

```
voradmin ldt attr get <data/log directory of baseline database>
```

Example:

```
voradmin ldt attr get /var/opt/mssql/LDT/data
```

Response

```
LDT stats: version=6, rekey_status=rekeyed
  Number of times rekeyed:          1 time
  Rekey start time:                 2022/09/02 05:41:26
  Last rekey completion time:       2022/09/02 05:41:28
  Estimated rekey completion time:  N/A
  Policy key version:               0
  Pushed Policy key version:        0
  Policy ID:
    1001
  Data stats:
    total=16.0MB, rekeyed=11.0MB
    truncated=0.0MB, sparse=5.0MB
  File stats:
    total=2, rekeyed=2, failed=0
    passed=0, skipped=0, created=0, removed=0, excluded=0
```

Expected results:

- No errors in output
- rekey_status=rekeyed

Note

Do not start the next step until rekey_status = rekeyed.

8. Restart the SQL Server, type:

```
su - mssql
sudo systemctl start mssql-server
systemctl status mssql-server
```

9. Access the targeted database and query the data, type:

```
sqlcmd -S localhost -U SA -P '<password>'
use <targetdb>
use <targetdb>
SELECT filename from sysfiles
go
```

Expected results: You should be able to log into your targeted database and query system files.

Configuring Support for SAP HANA

This section describes SAP HANA, which provides automatic host-failover support. It contains the following topics:

- [Overview](#)
- [Customizing CTE for SAP HANA in HA Mode](#)
- [Using SAP HANA with LDT](#)
- [Setting Memory Allocation](#)

Overview

SAP HANA provides automatic host-failover support. CTE works with HANA fibre storage systems to enable and disable GuardPoints when a protected host starts, stops, or fails over to standby host.

CipherTrust Transparent Encryption - SAP HANA (CTE-SAP HANA) supports non-shared storage where each HANA node has its own separate storage volumes. CTE-SAP HANA provides customized scripts to support startups, shutdowns, and fail overs.

HANA attaches logical unit number (LUNs) or logical volume management (LVMs) using a Fibre Storage Connector (fcClient) providers. Thales provides hooks that are called by the HANA fcClient providers that manage guarding or unguarding of storage locations.

Note

Thales recommends using host groups to manage configuring in a clustered host environment.

Customizing CTE for SAP HANA in HA Mode

Caution

The following procedure only applies if multiple HANA nodes are configured in a high availability (HA) environment. If you are installing CTE on a single HANA node, do not change the default HANA or CTE settings.

1. Go to the installation directory:

```
cd /opt/vormetric/DataSecurityExpert/agent/secfs/saphana
```

2. If required, edit the appropriate CTE `fcClient` refined script:

Script file	Use
<code>fcClientRefinedVTE.py</code>	fcClient provider for LUN
<code>fcClientLVMRefinedVTE.py</code>	fcClientLVM provider for LVMs

3. Copy the appropriate script file to a shared location that is accessible to all nodes. In a HANA cluster environment, all nodes require access to the CTE scripts.
4. Edit the storage section of the `global.ini` file to indicate the corresponding CTE `fcClient` as the High Availability (HA) provider and to point to the location of the CTE script.

LUN Example

```
[storage]
  ha_provider = fcClientRefinedVTE
  ha_provider_path = /hana/shared/myFcClient
```

If necessary, enable debug tracing:

```
[trace]
  ha_provider = debug
  ha_fcclient = debug
  ha_fcclientrefinedvte = debug
```

LVM Example

```
[storage]
```

```
ha_provider = fcClientLVMRefinedVTE
ha_provider_path = /hana/shared/myFcClient
```

If necessary, enable debug tracing:

```
[trace]
  ha_provider = debug
  ha_fcclientlvm = debug
  ha_fcclientlvmrefinedvte = debug
```

5. Use the same CTE agent with all hosts, including standby hosts.
6. Ensure that `/etc/sudoers` includes the following:

```
<sid>adm ALL=NOPASSWD: /usr/bin/secfsd
```

7. Enable the guard paths at the mount-point level.

For example, individual guards were placed on `/hana/data/HAN/mnt00001`, `/hana/data/HAN/mnt00002`, and so forth.

- a. Use a similar naming practice for log partitions, such as `/hana/log/HAN/mnt00001`, and so forth.
 - b. Place the guard at the mount-point level. The guarded paths must match the corresponding data and log mount paths.
8. Configure GuardPoints as type `manual`. You must enable and disable the GuardPoints immediately after the device is attached, or just prior to detachment.

The reason for manual GuardPoints is that it invokes guarding and unguarding from within the HANA during the startup, shutdown, or failover process. The process resembles that of mounting and unmounting guarded auto-mount points.

9. Configure all GuardPoints so that they are available in the standby host, so that any data and log partitions that fail over from any host can be guarded on the standby.

Thales recommends that you configure all GuardPoints on all hosts, because a failed-over active host can then become the new standby, and will require all available GuardPoints.

Example

The following is an example of the data and log volumes for the host that are mounted.

```
/dev/mapper/VG_HAN_DATA_1-LV_HAN_DATA_1      793971096   3059712  750579916   1%
/hana/data/HAN/mnt00001
```

```

/hana/data/HAN/mnt00001          793971096  3059712  750579916  1% /han
a/data/HAN/mnt00001
/dev/mapper/VG_HAN_LOG_1-LV_HAN_LOG_1  496233160  2461764  468564152  1% /han
a/log/HAN/mnt00001
/hana/log/HAN/mnt00001          496233160  2461764  468564152  1% /han
a/log/HAN/mnt00001

```

Note that partition `mnt00002` is also configured, although not currently mounted by HANA. The `secfsd` status output should show the GuardPoint configuration as follows:

GuardPoint	Policy	Type	ConfigState	Status	Reason
/hana/data/HAN/mnt00001	my-pol	manual	guarded	guarded	N/A
/hana/log/HAN/mnt00001	my-pol	manual	guarded	guarded	N/A
/hana/data/HAN/mnt00002	my-pol	manual	unguarded	not guarded	Inactive
/hana/log/HAN/mnt00002	my-pol	manual	unguarded	not guarded	Inactive

For more information, see [SAP HANA Fiber Channel Storage Connector Admin Guide](#).

Using SAP HANA with LDT

SAP HANA is compatible with LDT with the following changes:

- You must add additional CTE commands to the HANA administrator entry. Using a text editor, edit `/etc/sudoers` and add entries for `/usr/bin/voradmin` and `/usr/bin/vmsec`:

```

hanadm ALL=NOPASSWD: /usr/bin/secfsd,/usr/bin/voradmin,/usr/bin/vmsec,/sbin/mu
ltipath,/sbin/multipathd,/etc/init.d/multipathd,/usr/bin/sg_persist,/bin/moun
t,/bin/umount,/bin/kill,/usr/bin/lsof,/sbin/vgchange,/sbin/vgscan

```

- If you are using an `ext3` file system, you must mount it with extended attributes. Using a text editor, edit the storage section of the `global.ini` file, type:

```

partition_*_data__mountOptions = -o user_xattr
partition_*_log__mountOptions = -o user_xattr

```

Setting Memory Allocation

There is a limitation in memory allocations for SAP HANA with asynchronous direct I/O. When you use CTE in conjunction with applications like SAP HANA that can process large numbers of direct I/O writes through the Linux AIO interface, CTE can allocate more memory than is desirable.

To limit the amount of memory that CTE consumes for AIO buffers, use the following configuration to limit the amount of memory CTE consumed for AIO buffers:

```
max_aio_memory_limit <MB>
```

The MB value specifies how much memory to allocate to temporary DIO buffers.

Note

If you do not specify a value, the default is 0, which has no memory bounding effect.

Set the option by echoing a value into the `/opt/vormetric/DataSecurityExpert/agent//secfs/.sec/conf/` configuration file. For example:

```
echo 1024 > /opt/vormetric/DataSecurityExpert/agent/ secfs/.sec/conf/max_aio_memory_limit
```

This limits the memory consumed by AIO buffers to 1GB.

Note

You **must restart** CTE after changing any values in the configuration directory to make the changes effective.

Using CTE with GlusterFS

This chapter describes how to configure CTE with GlusterFS. It contains the following sections:

- Overview
- Considerations and Requirements
- Configuring GlusterFS for CTE

Overview

GlusterFS is a scalable network file system suitable for data-intensive tasks such as cloud storage and media streaming. The Gluster share can also be mounted as an NFS client.

Thales provides support for GuardPoints in a Gluster environment.

Considerations and Requirements

- Gluster is supported on Red Hat 8 and Red Hat 9. Other versions of Red Hat are not supported.
- Clients must have gluster-fuse installed.
- Encryption keys for GlusterFS GuardPoints must use the CBC or CBC-CS1 encryption mode.

- The following CTE features are not supported in GlusterFS:
 - Auto-mounted file systems.
 - CTE-Live Data Transformation.
 - IDT-Capable GuardPoints.

Note

In a multi-node configuration, Thales has tested only the close-to-open consistency for GlusterFS. Other consistencies offered by GlusterFS are not guaranteed to work with CTE.

Configuring GlusterFS for CTE

1. On the Gluster server, configure the following Gluster volume properties for all configurations:

- `performance.flush-behind` should be off.
- `network.remote-dio` should be disabled.
- `performance.strict-o-direct` should be on.

For example, if the Gluster volume name is `MyGlusterVolume`, you would enter the following commands:

```
gluster vol set MyGlusterVolume performance.flush-behind off
gluster vol set MyGlusterVolume network.remote-dio disable
gluster vol set MyGlusterVolume performance.strict-o-direct on
```

2. If you want to use CBC-CS1 encryption keys, configure the following additional Gluster volume properties on the Gluster server:

- `performance.read-ahead` should be off.
- `performance.cache-size` should be 1GB.
- `performance.write-behind` should be off.
- `performance.client-io-threads` should be on.

For example:

```
gluster vol set MyGlusterVolume performance.read-ahead off
gluster vol set MyGlusterVolume performance.cache-size 1GB
```

```
gluster vol set MyGlusterVolume performance.write-behind off
gluster vol set MyGlusterVolume performance.client-io-threads on
```

3. On the clients, do the following based on your configuration:

- If the kernel version is *earlier* than version 4.0.0, the Gluster share must be mounted with the `use-readdir=no` mount option.

```
mount -t glusterfs -o acl,use-readdir=no MyGlusterVolume /gluster
```

- If you want to use CBC-CS1 encryption keys, the Gluster share must be mounted with the `direct-io-mode=enable` mount option.

```
mount -t glusterfs -o acl,direct-io-mode=enable MyGlusterVolume /gluster
```

- If you are using only CBC encryption keys with kernel versions 4.0.0 and later, no changes need to be made on the clients.

NetApp Snapshot Directory

This section describes SecFS support for NetApp .snapshot directory over NFS. It contains the following topics:

- [Overview](#)
- [Accessing Snapshots](#)
- [Enabling Snapshots](#)
- [Dataxform Considerations](#)

Overview

The NetApp snapshot directory contains ONTAP snapshot data entries for a specific live volume. Each snapshot is a read-only volume that is automatically mounted over NFS.

A snapshot copy is a read-only image of a traditional, or FlexVol volume, or an aggregate, that captures the state of the file system at a specific point in time.

Data ONTAP maintains a configurable snapshot copy schedule that creates and deletes snapshot copies automatically for each volume.

Accessing snapshots

By default, every volume contains a directory named .snapshot through which users can access previous versions of files. Users can gain access to snapshot copies depending on the file-sharing protocol used, NFS or CIFS. You can also prevent access to snapshot copies.

Snapshot files carry the same read permissions as the original file. A user who has permission to read a file in the volume, can also read that file in a snapshot copy. A user without read permission to the volume cannot read that file in a snapshot copy.

Note

Snapshot copies do not have write permissions.

Snapshot directories only display at the mount point, although they actually exist in every directory in the tree. This means that the `.snapshot` directory is accessible by name in each directory, but is only seen in the output of the `ls` command at the mount point. The snapshots are stamped with the date and time.

Enabling Snapshots

The NetApp storage administrator, or the OnTap device, must configure this feature. No configuration is required through CTE. CTE guards the client directory mounting the OnTap data volume over NFS.

Note

The NetApp documentation is located here: [NetApp Product documentation](#)

Dataxform Considerations

You cannot transform snapshot directory entries with Dataxform with a new key, because the snapshots are read only. You must keep previous keys and alter the running security policy accordingly to maintain access to the older snapshot entries alongside any new snapshots taken with the new key.

Also, any snapshots that get created during the data transform process (this may take a long time) have to be discarded/deleted as it may contain a mix of data blocks encrypted with both old and new keys.

Best Practices

Maintaining keys for access to older snapshots can be tedious and cumbersome. Therefore, the simplest and safest practice is to delete all old snapshots once the data is transformed with a new key.

This allows for all new snapshots to be readable with the new key while old keys can be discarded, unless used in other security policies.

Using CTE with Quantum StorNext

This chapter describes how to configure CTE and Quantum StorNext devices to interoperate to allow CTE policies to apply to storage managed by Quantum StorNext.

This section contains the following topics:

- [Overview of using CTE with Quantum StorNext](#)

- CTE and Quantum StorNext compatibility
- Setting up CTE and Quantum StorNext integration
- Stop secfs before upgrading StorNext LAN clients

Overview of using CTE with Quantum StorNext

Quantum StorNext Fibre Channel-connected devices provide shared file access to third party storage for workstation clients and are optimized for simultaneous access to very large files such as video files. The Quantum StorNext file system is known as SNFS or by its older name, CVFS.

You can encrypt and control access to SNFS files with policies by installing CTE Agents on Linux clients that are configured for access to the SNFS file system. Some limitations apply to this integration, such as supported operating systems, supported SNFS features, concurrent read/write access by multiple clients, and GuardPoint settings (see the next section for more information about these limitations).

CTE and Quantum StorNext Compatibility

The following sections list the supported operating systems and CTE settings supported for use with Quantum StorNext file systems. Important unsupported configuration parameters are also listed.

Supported StorNext Server and Client Configurations

The CTE integration with SNFS file systems works only with certain SNFS versions, SNFS storage policies, and client operating systems.

Configuration parameter	Linux
StorNext (SNFS) operating system version	6.x
StorNext metadata controller (MDC) server OS type	Linux MDC supported
StorNext replication policy	Not supported
StorNext deduplication policy	Not supported
StorNext truncation	Supported
StorNext full and partial backup	Supported
StorNext expand file system	Supported
StorNext data migration	Supported
StorNext read-ahead cache	Disable for use with CTE
Client operating systems	Red Hat Enterprise Linux (RHEL) 7.x
StorNext LAN client	DLC
StorNext mount method: locally mounted directory	Supported
StorNext mount method: CIFS	Not supported
StorNext mount method: NFS	Not supported

Supported GuardPoint and Key Settings for SNFS File Systems

When configuring CTE GuardPoints and keys for SNFS, keep in the mind the compatibility limitations listed in the following table.

!! note

Because AES-CBC-CS1 keys are not supported on Windows, do not create a policy on Linux that uses AES-CBC-CS1 keys if access to the same SNFS GuardPoint is required by both Windows and Linux LAN clients.

Configuration element	Linux
Offline data transformation	Supported
Live Data Transformation (LDT)v	Not supported
Key manager compatibility	See the <i>Compatibility Matrix for CTE Agent with Data Security Manager</i> or the <i>Compatibility Matrix for CTE Agent with Data Security Manager</i> for your CTE version
Guard unstructured data	Supported
Guard structured data	Not supported
GuardPoint type: Directory (including entire SNFS volume)	Supported
GuardPoint type: Raw device	Not supported
GuardPoint type: Block device	Not supported
GuardPoint mount option: manual guard	Supported
GuardPoint mount option: auto guard	Supported
GuardPoint mount option: automount	Not supported
AES-CBC key type	Supported
AES-CBC-CS1 key type	Supported

Supported Concurrent Access Read/Write Scenarios

If you want to allow access by multiple clients (users) to CTE-protected SNFS files under the same GuardPoint, just read-only access is supported. StorNext file locking is not implemented in CTE, so there is currently no way to prevent concurrent conflicting writes to the same file. As a result, Thales does not support write access to the same GuardPoint from multiple clients.

To enable read access to the same GuardPoint from multiple clients, ensure that all clients are configured to use the same policy and key.

Configuration parameter	Linux
Read/write access from a single LAN client to a GuardPoint	Supported

Configuration parameter	Linux
Read/write access from two or more LAN clients to the same GuardPoint	Not supported
Read-only access from one, two, or more LAN clients to the same GuardPoint	Supported

Setting up CTE and Quantum StorNext Integration

For the most part, CTE integration with Quantum StorNext is the same as for any standard file system. The next section provides an overview of the steps involved in making CTE work with SNFS. Later sections provide more information about the steps that are new or differ significantly from a typical CTE setup.

Integration Task Overview

The table below provides an overview of the steps involved in setting up SNFS and CTE to work together. As noted in the table, some of these tasks are described in the documentation for your selected key manager. Some of these steps may need to be performed by other staff members at your organization if you have divided the security administration duties as recommended by Thales and you don't have access to the key manager.

Task	Key configuration notes	For more information
Install and configure a Quantum StorNext MDC server for use with CTE	Disable the StorNext read-ahead cache. Only certain StorNext policies, features, and mount types are supported. See Supported StorNext Server and Client Configurations .	See Installing and Configuring a Quantum StorNext MDC Server for Use with CTE .
Install and configure Quantum StorNext clients for use with CTE	Ensure that SNFS starts before secfs. See Ensuring that the StorNext SNFS File System Starts Before secfs . Only certain operating systems are supported. See Supported StorNext Server and Client Configurations .	See Installing and configuring Quantum StorNext DLC Clients for Use with CTE .
Create a domain for one or more SNFS hosts, or add them to an existing domain	No difference from standard CTE agent configuration.	See "Domain Management" in your key manager documentation.
Add the host to the key manager	No difference from standard CTE agent configuration.	See "Configuring Hosts and Host Groups" in your key manager documentation.
Install and register the CTE Agent on the host system	No difference in installation.	See Getting Started with CTE for Linux
Create encryption keys (optional)	No difference from standard CTE agent configuration.	See "Managing Keys" in your key manager documentation. For information about AES-CBC-CS1 keys, see Enhanced Encryption Mode .
Configure host groups containing one or more StorNext LAN clients	No difference from standard CTE agent configuration.	See "Configuring Hosts and Host Groups" in your key manager

Task	Key configuration notes	For more information
(optional)		documentation.
Configure policies (including user, process, and resource sets) to control access or enable encryption	No difference from standard CTE agent configuration.	See “Configuring Policies” in your key manager documentation.
Configure one or more GuardPoints	Some GuardPoint settings are not supported. See Supported GuardPoint and Key Settings for SNFS File Systems .	See “Managing GuardPoints” in your key manager documentation

Installing and Configuring a Quantum StorNext MDC Server for Use with CTE

Install and configure a Quantum StorNext metadata controller (MDC) server using the [Quantum StorNext documentation](#) as a guide. The CTE integration works with Linux StorNext MDCs. Ensure that you configure the StorNext server to work with the settings supported by CTE as listed in [Supported StorNext Server and Client Configurations](#). For example, you must disable the StorNext read-ahead cache and only certain StorNext policies, features, and mount types are supported.

Installing and Configuring Quantum StorNext DLC Clients for Use with CTE

Install and configure Quantum StorNext DLC clients using the [Quantum StorNext documentation](#) as a guide. The CTE integration works with Linux StorNext DLCs.

Ensure that you configure DLC clients to work with the settings supported by CTE as listed in [Supported StorNext Server and Client Configurations](#). For example, only certain operating systems are supported.

Note

Read-only access is supported if multiple StorNext LAN clients will access files in the same GuardPoint. For more information, see [Supported Concurrent Access Read/Write Scenarios](#).

Ensuring that the StorNext SNFS File System Starts Before secfs

For CTE to function properly for Linux SNFS clients, the SNFS service must start before the CTE `secfs` service. Add an entry for the SNFS file system to `/etc/fstab` on each Linux client that has a CTE agent installed on it. Use the following format:

```
/snfs_share /stornext/snfs1 cvfs defaults,diskproxy=client 0 0
```

In this example, `/snfs_share` should be a share that has been exported from the StorNext Server. It should not be a local disk. You may have completed this configuration step as part of the StorNext LAN client installation. See the [Quantum StorNext documentation](#) for more details.

Installing the CTE Agent on Each StorNext LAN client

Install a CTE Agent on each computer that is set up as a StorNext LAN client and for which you want to set policies. For supported operating systems, see the table in [Supported StorNext Server and Client Configurations](#).

Use any installation method supported for your operating system. For details, see [Getting Started with CTE for Linux](#).

Stop secfs Before Upgrading StorNext LAN Clients

Before you upgrade StorNext Linux LAN clients, disable or stop the CTE `secfs` service. To stop the `secfs` service, follow these steps:

1. Log in as root on the computer that contains the LAN client that you want to upgrade.
2. Type the following command: `/etc/vormetric/secfs stop`

After you upgrade the StorNext client, start `secfs` again by logging in as root and running the `/etc/vormetric/secfs start` command.

Using CTE with McAfee Endpoint Security for Linux Threat Prevention

McAfee Endpoint Security for Linux Threat Prevention detects malware such as viruses and handles the malware according to policies that you configure in McAfee ePO. This chapter describes how to configure McAfee and CipherTrust Transparent Encryption to work together.

This section contains the following topics:

- [Supported McAfee Versions and Linux Operating Systems](#)
- [Ensuring the Correct McAfee Service Startup and Shutdown Order](#)
- [Excluding CTE protected directories with McAfee 10.5.x](#)
- [Updating McAfee](#)
- [Virus Scanning Behavior Differences for CIFS and NFS GuardPoints](#)

Supported McAfee Versions and Linux Operating Systems

In general, Thales has verified that CipherTrust Transparent Encryption is compatible with McAfee version 10.6.5 and later on Red Hat Enterprise Linux (RHEL) 7 and RHEL 8. See the most recent *Compatibility Matrix for CipherTrust Transparent Encryption Agent with CipherTrust Manager* or *Compatibility Matrix for CipherTrust Transparent Encryption Agent with Data Security Manager* for details about the versions of McAfee Endpoint Security for Linux Threat Prevention that have been verified to work with CipherTrust Transparent Encryption.

Ensuring the Correct McAfee Service Startup and Shutdown Order

CipherTrust Transparent Encryption services and McAfee services must be started and stopped in the correct order to prevent problems with any data that is guarded by CipherTrust Transparent Encryption. This order is important any time these services need to be started or stopped, such as:

- During the normal startup and shutdown of your Linux host.
- Before enabling a scheduled upgrade of CipherTrust Transparent Encryption.
- Before performing a manual upgrade of CipherTrust Transparent Encryption.
- As needed for maintenance or troubleshooting.

Ensuring the Correct McAfee Service Order in systemd

Configuring the proper startup and shutdown order of CipherTrust Transparent Encryption and McAfee services in `systemd` ensures that the services start in the right order during system startup and shutdown. This is also important if you configure a scheduled upgrade of CipherTrust Transparent Encryption, as CipherTrust Transparent Encryption services will need to be shut down during the upgrade.

The following McAfee services must be configured to start after CipherTrust Transparent Encryption services:

- For McAfee 10.6.6 or later:
 - `mfetpd.service`
 - `mfeespd.service`
- For McAfee 10.6.5 or earlier:
 - `isectpd.service`
 - `isecespd.service`

To configure this behavior, add these services to the `Before=` line in the `secfs-fs-barrier.service` file on your system. The order of these services on the `Before=` line in the `secfs-fs-barrier.service` file does not matter. For more information, see [Location of Application Unit Configuration Files] and [Adding Applications to the `secfs-fs-barrier.service` File].

Starting or Stopping McAfee and CipherTrust Transparent Encryption Manually

When you manually start or stop McAfee and CipherTrust Transparent Encryption, you must do so in the correct order.

To manually stop McAfee and CipherTrust Transparent Encryption:

1. Stop McAfee services using one of the following:

For McAfee 10.6.6 or later:

```
systemctl stop mftpd.service mfeespd.service
```

For McAfee 10.6.5 or earlier:

```
systemctl stop isecesp.service isectpd.service
```

2. Stop CipherTrust Transparent Encryption:

Linux distributions that support <code>systemd</code>	<code>/etc/vormetric/secfs stop</code>
Linux distributions that do not support <code>systemd</code>	<code>service secfs stop</code>

To manually start McAfee and CipherTrust Transparent Encryption:

1. Start CipherTrust Transparent Encryption:

Linux distributions that support <code>systemd</code>	<code>/etc/vormetric/secfs start</code>
Linux distributions that do not support <code>systemd</code>	<code>service secfs start</code>

2. Start McAfee services using one of the following:

For McAfee 10.6.6 or later:

```
systemctl start mftpd.service mfeespd.service
```

For McAfee 10.6.5 or earlier:

```
systemctl start isecesp.service isectpd.service
```

Excluding CTE protected directories with McAfee

Starting with CipherTrust Transparent Encryption v7.2.0, two conflicts exist between McAfee's On-Access Scan and CipherTrust Transparent Encryption when both applications are installed, regardless of installation order. This conflict occurs because McAfee's On-Access Scan tries to scan files in the initial startup (protected) directory, `/opt/vormetric/DataSecurityExpert/agent/secfs/.sec/` whenever those files are accessed by CipherTrust Transparent Encryption's own processes and utilities. Access to a CipherTrust Transparent Encryption protected directory, and its subdirectories, is restricted so that no other process or utility can access them.

The fix is to add the CipherTrust Transparent Encryption protected directories to the McAfee On-Access Scan exclusion list:

1. Change the directory. At the command line, type:

- For **McAfee 10.6.5** or prior versions:

```
#cd /opt/isec/ens/threatprevention/bin/
```

- For **McAfee 10.6.6** or subsequent versions:

```
#cd /opt/McAfee/ens/tp/bin
```

2. Add the exclusion to McAfee's On-Access Scan, type:

```
'--addexclusionrw --excludepaths "/opt/vormetric/DataSecurityExpert/agent/secfs/.sec/" --excludesubfolder'
```

The entire exclusion list command should look like the following:

- **McAfee 10.6.5** or prior versions:

```
./isecav --setoasprofileconfig --profile standard --addexclusionrw --excludepaths "/opt/vormetric/DataSecurityExpert/agent/secfs/.sec/" --excludesubfolder
```

- **McAfee 10.6.6** or subsequent versions:

```
./mfetpcli --setoasprofileconfig --profile standard --addexclusionrw --excludepaths "/opt/vormetric/DataSecurityExpert/agent/secfs/.sec/" --excludesubfolder
```

Note

You only need to run this command once.

Updating McAfee

It is not necessary to shut down CipherTrust Transparent Encryption services when you update McAfee Endpoint Security to a new version. Follow the update procedure described by McAfee. Before updating, ensure that the new version of McAfee is compatible with CipherTrust Transparent Encryption as described in [Supported McAfee Versions and Linux Operating Systems].

Note

When you upgrade McAfee, make sure that the current McAfee services are configured to start *after* the CipherTrust Transparent Encryption services in **systemd**. The McAfee service names depend on the version of McAfee that you are using. For details, see [Ensuring the Correct McAfee Service Order in systemd].

Virus Scanning Behavior Differences for CIFS and NFS GuardPoints

By default, on McAfee Endpoint Security, on-access virus scanning for remotely mounted file systems such as CIFS and NFS, is disabled. However, for GuardPoints configured on CIFS and NFS volumes, this default is ignored. So on-access virus scanning is always on for GuardPoints configured on CIFS and NFS volumes. This means that if a process attempts to save an inCipherTrust Transparent Encryption file to a GuardPoint configured on a CIFS or NFS volume, the inCipherTrust Transparent Encryption file will be discovered immediately, if it matches the McAfee malware detection algorithm and handled according to the appropriate malware policy in McAfee ePO.

Using CTE and Database Activity Monitoring (DAM) Simultaneously

Note

This feature is not compatible when using CipherTrust Transparent Encryption with CipherTrust Data Security Platform Services (CDSPaaS).

Security administrators can protect execution of processes/binaries on CTE agents from a ptrace attachment. This prevents process injection attacks through ptrace system call. Refer to [Blocking ptrace system calls to prevent process injection attacks](#) for more information.

Using Ptrace and DAM

Thales CipherTrust Transparent Encryption and Imperva Database Activity Monitoring (DAM) can operate simultaneously on the same system if the ptrace attachment is not blocked on the system. Choose one of the following two configuration options from the **Advanced Security Configuration** that do not affect DAM agent functionality.

- **Disabled_for_all**
- **Enabled_for_Authenticators (Default setting)**

Disabling ptrace protection for Imperva DAM processes when setting to Enabled for All

During Imperva DAM and Thales CTE integration testing, Thales discovered that when the **ptrace_configuration** option is set to **enabled_for_all** in CTE, the DAM audit logs do not generate. This is because the **enabled_for_all** option blocks ptrace injection for all system binaries. Imperva DAM uses InjectionManager to inject shared libraries into database processes to monitor database activity. Since CTE blocks all ptrace injections in this mode, DAM fails to inject these shared libraries into the database processes. As a result, no logs are generated or sent to the gateway server.

The solution is for CTE to exempt certain applications from ptrace protection using client settings. You need to specify the binary that performs the tracing, and tag it with **|allow_ptrace|** in the client settings in CipherTrust Manager. If the binary is also listed under a host setting, the tag must be combined accordingly. For example, if the binary falls under the Authenticator client setting, the tag in the client settings should be:

```
|Authenticator+allow_ptrace|
```

Ensuring the Correct CTE/DAM Service Startup and Shutdown Order

CipherTrust Transparent Encryption services and DAM services must be started and stopped in the correct order to prevent problems with any data that is guarded by CipherTrust Transparent Encryption. This order is important any time these services need to be started or stopped, such as:

- During the normal startup and shutdown of your Linux host.
- Before enabling a scheduled upgrade of CipherTrust Transparent Encryption.
- Before performing a manual upgrade of CipherTrust Transparent Encryption.
- As needed for maintenance or troubleshooting.

Starting or Stopping DAM and CipherTrust Transparent Encryption Manually

Warning

CTE cannot be stopped while the DAM agent is running.

CTE Commands for Stopping and Starting the Agent

Command	Command syntax for Linux distros that support systemd	Command syntax for Linux distros that DO NOT support systemd
Start	<code>/etc/vormetric/secfs start</code>	<code>service secfs start</code>
Restart	<code>/etc/vormetric/secfs restart</code>	<code>service secfs restart</code>
Stop	<code>/etc/vormetric/secfs stop</code>	<code>service secfs stop</code>
Check status	<code>/etc/vormetric/secfs status</code>	<code>service secfs status</code>

DAM Commands for Stopping and Starting the Agent

Command	Command syntax	Comment
Start	<code><DAM-remote-agent-install-</code>	

Command	Command syntax	Comment
	<code>directory>/ragent/bin/ rainit start</code>	
	<code><DAM-remote-agent- install- directory>/installer/bin/ rainstallerinit start</code>	Required if it exists
Stop	<code><DAM-remote-agent- install- directory>/ragent/bin/ rainit stop</code>	
	<code><DAM-remote-agent- install- directory>/installer/bin/ rainstallerinit stop</code>	Required if it exists

See [Adding Dependencies to systemd Unit Configuration Files](#) for more information.

Ensuring the proper order

Perform the following steps in this exact order:

1. Stop the DAM agent monitoring.
2. Stop CipherTrust Transparent Encryption.
3. Perform the CTE or DAM upgrade or maintenance.
4. Start DAM agent monitoring.
5. Start CipherTrust Transparent Encryption.

Prerequisites

1. [Install CTE v7.8.0](#) on the agent and register it with CipherTrust Manager.
2. Ensure that Imperva DAM is installed and configured correctly on the MX server.

Exempting Applications

1. Update the client settings to include the `allow_ptrace` tag for the InjectionManager binary.

2. In the Client window, click **Advanced Security Configuration** and ensure that **Enabled_For_All** is selected.
3. Restart the MX server agent and database service to apply the updated CTE client settings:
 - a. Stop the DAM agent service.
 - b. Stop the database service.
 - c. Start the database service.
 - d. Start the DAM agent service.

Note

Consult the Imperva documentation for more information.

4. Perform any activity on the database. You should now see this activity reflected in the MX server DB audit logs.

Using CTE with Trend Micro Deep Security Software

Trend Micro's Deep Security software provides comprehensive security in a single solution that is purpose-built for virtual, cloud, and container environments. Thales has verified certain versions of this Trend Deep product for compatibility with CTE on Red Hat Enterprise Linux (RHEL) 7 and RHEL 8.

This section contains the following topics:

- Ensuring Correct Deep Security Service Startup Order
- Updating Deep Security

Ensuring Correct Deep Security Service Startup Order

CTE services and Deep Security services must be started and stopped in the correct order to prevent problems with your data that is guarded by CTE. This order is important any time these services need to be started or stopped, such as:

- During normal startup and shutdown of your Linux host.
- Before enabling a scheduled upgrade of CTE.
- Before performing a manual upgrade of CTE.
- As needed for maintenance or troubleshooting.

Ensuring Correct Deep Security Service Startup Order in systemd

Configuring the proper startup and shutdown order of CTE and Trend Micro's Deep Security services in `systemd` ensures that the services start in the right order during system startup and shutdown. This is also important if you configure a scheduled upgrade of CTE.

The following Deep Security service must be configured to start after CTE services:

`ds_agent.service`

To configure this behavior, add this service to the `Before=` line in the `secfs-fs-barrier.service` file on your system. The order of these services on the `Before=` line in the `secfs-fs-barrier.service` file does not matter. See [Location of Application Unit Configuration Files](#) for the location of the `secfs-fs-barrier.service` file on your system. See [Adding Applications to the secfs-fs-barrier.service File](#) for information about how to add services to the `secfs-fs-barrier.service` file.

Ensuring Correct Deep Security Service Startup Order Manually

Perform the following commands in this order if you need to stop Deep Security and CTE services manually:

1. Stop Deep Security services:

```
systemctl stop ds_agent.service
```

2. Stop CTE:

Linux distributions that support systemd	<code>/etc/vormetric/secfs stop</code>
Linux distributions that do not support systemd	<code>service secfs stop</code>

Perform the following commands in this order if you need to start Deep Security and CTE services manually:

1. Start CTE:

Linux distributions that support systemd	<code>/etc/vormetric/secfs stop</code>
Linux distributions that do not support systemd	<code>service secfs stop</code>

2. Start Deep Security services:

```
systemctl start ds_agent.service
```

Updating Deep Security

It is not necessary to shut down CTE services when you update Trend Micro Deep Security to a new version. Follow the [Update Deep Security software](#) described by Trend Micro.

CTE for Cloud Object Storage

Note

For CipherTrust Transparent Encryption and CipherTrust Transparent Encryption UserSpace, using, configuring and installing Cloud Object Storage works identically. The product names, CTE and CTE-U, are used interchangeably in the following sections.

This section discusses how to configure CTE for Cloud Object Storage buckets. It contains the following topics:

- [COS Overview and Requirements](#)

-
- CTE COS S3 Installation Overview and Requirements
 - Configure the AWS CLI and COS S3
 - Guard an AWS Bucket
 - Using a COS Proxy Root CA Certificate Information
 - Protecting Python Programs with CTE
 - Creating a COS Policy

COS Overview and Requirements

CipherTrust Transparent Encryption for Cloud Object Storage (CTE COS) is an object storage service that you can use to store and protect any amount of data for a range of use cases, such as websites, mobile applications, backup and restore, archive, enterprise applications, IoT devices, and big data analytics. CTE COS provides management features so you can organize your data and configure finely-tuned access controls to meet your specific business, organizational, and compliance requirements.

CTE COS for Amazon Simple Storage Service (CTE COS S3) is an extension to CTE for inline encryption and local host access controls involving applications performing REST-API-based operations to S3 object stores.

CTE COS S3 is not a replacement for AWS IAM access controls which are enforced independently at the AWS server end.

The following diagram shows the high-level CTE COS S3 architecture:

Supported operations

- CTE COS S3 will process only AWS S3 REST https calls issued by applications. The interception is done by a bundled TLS proxy with additional CTE services.
- CTE's traditional access controls and inline encryption are transparently applied during the following operations:
 - Create a bucket
 - Write an object
 - Read an object
 - Delete an object
 - List objects

Limitations

- CTE COS S3 is supported only on RHEL 8 and RHEL 9.
- Only REST API based S3 protocol-aware applications are supported.
- Only locally generated self-signed COS Proxy CA Certificates are supported.
- AWS S3 URL path validations are not currently implemented. CTE COS S3 requires that the user must specify the correct URLs for bucket paths.
- CTE COS S3 permits only AES CBC-CS1 encryption. Encrypted files in protected buckets therefore will prepend the 4K embedded header used in CTE's AES CBC-CS1 encryption. The key manager will enforce usage of AES CBC-CS1 keys within S3 bucket policies.

Multi-part Upload Restrictions

- All upload operations for a multi-part upload must be conducted from the same host.
- Maximum file size upload is 5TB.
- Part sizes during uploads must be identical. The part numbering must be in sequence starting with 1, e.g. 1,2,3,4,... Not 10, 20, 30, etc.
- The part size specified in CTE S3's AWS credential file must match the part size specified within the application.
- Thales recommends that the Content-MD5 header be included in the request message.

System and Software Requirements

- The RHEL 8, or 9 Linux hosts must meet the standard CTE requirements.
- You must have an AWS account
- We recommend that you guard the bucket by restricting it with a CTE COS S3 Role to prevent accidental data corruption from connections outside the control of CTE COS S3. For details, see [Optionally Configure a CTE COS S3 Role for Guarded Buckets](#).
- You must download and install the pre-requisite rpm packages before you install CTE COS S3. For details, see [Install Required Linux Packages](#).
- The CTE Agent must be installed in the default directory on the host. You cannot change the default path if you also enable CTE COS S3.

Client Software Requirements

- Clients must exist on the same host as CTE COS S3. External Client connections will be rejected by the COS Proxy.
- Clients must be AWS S3 protocol aware, and can directly connect to a S3 bucket without the use of an intermediary service, such as the AWS S3 Management Console website.
- Clients must be configured to divert outgoing network connection to a COS proxy (default is localhost:3128 or 127.0.0.1:3128). For more information, see [Configure the AWS CLI Network Proxy](#).
- Clients must use the TLS 1.2 / TLS 1.3 network encryption protocol over TCP/IP to establish connections to the COS proxy.
- Clients must be configured to use the COS CA Root Certificate of the COS proxy to verify and authenticate TLS connections. For more information, see [Configure the AWS CLI to use the COS Root CA Certificate](#).

CTE COS S3 Installation Overview

In order to configure CTE COS S3, you must complete the following tasks.

Note

The AWS CLI is used as a sample application to explain the detailed installation procedure.

1. Install the required packages for CTE COS S3. For details, see [Install Required Linux Packages](#)
2. Install CTE and generate the local COS Proxy CA Certificate. For details, see [Install CTE with COS Service](#)

Note

You can only install the Cloud Object Storage feature during CTE installation. You cannot install it post installation.

3. Configure the client to use the COS Proxy CA Certificate. For details, see [Configure the AWS CLI to use the COS Root CA Certificate](#).
 4. Configure the client to use the COS proxy port. For details, see [Configure the AWS CLI Network Proxy](#).
 5. Configure CTE COS S3 with AWS Credentials. For details, see [Configure CTE COS S3](#).
 6. Optionally configure Role & IAM policies for CTE COS S3 for guarded buckets. For details, see [Optionally Configure a CTE COS S3 Role for Guarded Buckets](#).
-

7. Configure the guarded buckets. For details, see [Guard an AWS Bucket](#).

Install Required Linux Packages

CTE COS S3 requires the following prerequisite packages:

- `boost-regex`
- `boost-system`
- `boost-thread`
- `libcurl`
- `libtool-ltdl`
- `libxml2`
- `epel-release`.
- `cryptopp` // This package must be installed after `epel-release`.
- `log4cpp` // This package must be installed after `epel-release`.

For example:

```
sudo yum install boost-regex boost-system boost-thread libcurl libtool-ltdl libxml2 epel-release
sudo yum install cryptopp log4cpp
```

CTE COS S3 supports both Python2 and Python3. If both versions of Python are available, CTE COS S3 will use Python3. For either Python package, you also need to install the Python modules "`boto3`" and "`future`" after you install the main python package.

Example for Python2

```
sudo yum install python-pip
sudo pip install boto3 future
```

Example for Python3

```
sudo yum install python3 python3-pip
sudo pip3 install boto3 future
```

Install CTE with COS Service

Note

- You can only install the Cloud Object Storage feature during CTE installation. You cannot install it post installation.
- Do *not* change the default CTE installation directory. CTE must be installed in the default location if you enable Cloud Object Storage.

When the installer asks about Cloud Object Storage, type **Y** and follow the prompts as shown.

```
Do you want this host to have Cloud support enabled on the server? (Y/N) [N]: Y

CTE COS CA Cert is located in /opt/vormetric/DataSecurityExpert/agent/squid/etc/cosCA.crt
Clients must be updated to use the new CA Certificate

Generating certificate signing request for the kernel component...done.
Signing certificate...done.
Generating EC certificate signing request for the vmd...done. Signing certificate...done.
Generating EC certificate signing request for the vmd...done.
Signing certificate...done.

The following is the fingerprint of the EC CA certificate. Please verify that it matches the fingerprint shown on the Dashboard page of the Management Console.
If they do not match, it can indicate an unsuccessful setup or an attack.
B0:93:C7:67:07:C9:CB:09:E2:21:F1:5C:8A:C8:79:8F:03:86:21:F2
Do the fingerprints match? (Y/N) [N]: Y

Successfully registered the CipherTrust Transparent Encryption Agent with the primary CipherTrust Data Security Server on security.manager.example.com.
Starting CTE Cloud Service
Installation success.
```

Enable COS on an Agent with no COS Service

To enable COS on a system that has CTE installed but no COS Service:

- Uninstall CTE completely.
- Reinstall CTE and select **Yes** when asked:

```
Do you want to configure this host for Cloud Object Storage? (Y/N) [N]: Y
```

Uninstall COS from an Agent

Currently, the only method for uninstalling COS is as follows:

1. Uninstall CTE completely.
2. Delete the host/client from CM.
3. Re-register the host/client.
4. Reinstall CTE and select **NO** when asked:

```
Do you want to configure this host for Cloud Object Storage? (Y/N) [N]: N
```

Configure the AWS CLI to use the COS Root CA Certificate

You must configure the AWS CLI to use the COS root CA certificate. To do so, edit `~/.aws/config` and add the following line to the AWS cli configuration file:

```
ca_bundle = /opt/vormetric/DataSecurityExpert/agent/squid/etc/cosCA.crt
```

For example:

```
cat ~/.aws/config
[default]
output = json
Region = us-west-1
ca_bundle = /opt/vormetric/DataSecurityExpert/agent/squid/etc/cosCA.crt
```

Configure the AWS CLI Network Proxy

All communications between client applications and the AWS server must be done through the COS proxy and the environment variable `HTTPS_PROXY` or `https_proxy` should be set. If both variables are defined, then the AWS CLI will use `https_proxy`.

For example:

```
export HTTPS_PROXY=localhost:3128
```

Configure CTE COS S3

In order for CTE COS S3 to do transparent encryption and decryption, all requests sent to the AWS S3 server must be generated and signed using valid AWS credentials. In order to retrieve these credentials for CTE COS S3, you can use any of the following methods:

- **The User Supplies the Credentials for the User's AWS Account**

The application can send the long-term credentials from the user's AWS account to CTE COS S3. These credentials do not expire.

For the AWS CLI, the credentials are in the credential file `~/.aws/credentials`. The user credentials consists of an Access Key ID and a Secret Access Key. For details about accessing the user's credentials, see your AWS documentation.

To add the AWS credentials to CTE COS S3, use the `voradmin cos s3 cred add` command:

```
voradmin cos s3 cred add [<aws_key_id> <aws_secret_key>]
```

where:

- `<aws_key_id>` is the AWS secret key ID from the `.aws/credentials` file.
- `<aws_secret_key>` is the AWS secret key from the same file.

For example:

```
voradmin cos s3 cred add AKIA****P KQSm****D
```

The User Supplies Temporary Security Credentials

You can use temporary security credentials, which expire after a short period of time. Usually temporary security credential are obtained through IAM roles and other features of the AWS Security Token Service.

Use the `voradmin cos s3 cred add` command, described above, to add the temporary credential to CTE COS S3.

CTE COS S3 Captures Temporary Credentials

CTE COS S3 can capture a temporary, newly generated, security credential and automatically add it to CTE COS S3 if the application generates the temporary security credential using the AWS Security Token Service with one of the following 3 actions and `HTTPS_PROXY` is set to `localhost:3128`.

- `AssumeRole`
- `AssumeRoleWithSAML`
- `AssumeRoleWithWebIdentity`

No other action is required from the application or user.

CTE COS S3 Retrieves Credentials from EC2 Instance Metadata Service

When CTE COS S3 is installed on AWS EC2 instance with an attached role, CTE COS S3 automatically retrieves the credential from Instance Metadata Service and uses it. However, if CTE COS S3 already has a valid credential given by the user or admin using the `voradmin` command, then that credential will be used instead. For information about setting up an IAM Role, see your AWS EC2 documentation.

No action is required from application or user.

Setting the Default Chunk Size

Note

If a chunk size is configured in the AWS CLI configuration, you must configure the same chunk size for CTE COS S3.

The default chunk size for multi-part uploads is 8 MB. To change the chunk size, use the following command:

```
voradmin cos s3 chunk [<aws_key_id> <aws_secret_key>] [<chunk_size>]
```

where:

- `<aws_key_id>` is the AWS secret key ID from the `.aws/credentials` file.
- `<aws_secret_key>` is the AWS secret key from the same file.
- `<chunk_size>` is the number of MB per chunk that you want to use for multi-part uploads. Enter an integer between 5 and 5120.

The `voradmin` command prompts for any of the optional parameters that you do not specify on the command.

For example, to set a chunk size of 250MB, you would enter:

```
voradmin cos s3 chunk AKIA****P KQSm****D 250
```

Optionally Support other 3rd Party S3 Compatible Storage

CTE COS S3 has a configuration file that lists all supported S3 compatible cloud storages. It is located at:

```
`<installation_directory>/agent/squid/etc/cos.conf`
```

To support a new 3rd party S3 compatible storage:

1. Add a new section to the configuration file with its name and endpoint base url. The following is an example with Wasabi Cloud Storage.

```
[wasabi]
endpoint = wasabisys.com
```

2. Restart CTE COS service using the following command:

```
voradmin cos service stop
voradmin cos service start
```

3. Configure credentials and other needed items following the guideline for the 3rd party S3 compatible storage.

Configure a CTE COS S3 Role for Guarded Buckets

AWS provides the IAM Role feature that contains certain specific permissions. A user can assume the IAM Role and therefore take on those permissions. CTE COS S3 provides a special feature using this IAM Role to prevent access to one or more buckets outside the CTE COS S3 protection as shown in the following diagram:

Note

This step is optional.

Only hosts that are configured with the CTE COS S3 Role can access the protected buckets. All other access attempts from any hosts where the CTE COS S3 Role is not configured, including attempts made through the AWS S3 Console, are blocked for the protected buckets.

This is a one-time configuration process. After the CTE COS S3 Role is configured on a host by the system or security administrator, all authorized users in the host can access the protected buckets.

Prerequisites

To set up a CTE COS S3 Role, you need a delegated IAM user, role, and policy. The delegated IAM user should be created by the AWS Administrator without any specific privileges. The role and policy must be created by a user who has at least the following privileges:

- `iam:ListPolicies`
- `iam:CreatePolicy`
- `iam:GetPolicyVersion`
- `iam:ListRoles`
- `iam:ListRolePolicies`
- `iam:ListAttachedRolePolicies`
- `iam:AttachRolePolicy`
- `iam:UpdateAssumeRolePolicy`
- `iam:CreateRole`
- `iam:GetRole`

Procedure

1. In the IAM Management Console, create a policy that allows access to specific S3 resources. You can leave the policy open to include all S3 resources in the account or include only those buckets that require CTE protection. Make sure you name the policy something that you will remember.

Tip

You can also create the policy as an inline policy after you create the CTE COS S3 Role later in this procedure.

For example, you can create a policy called `VTE_S3_Role_Policy` that allows access to the single S3 bucket `vte-cos-s3-rtb`. To verify that the policy restricts access to that bucket, you can look at the Resource allocation in the Policy summary.

The full JSON for the `VTE_S3_Role_Policy` is:

```
{  
  "Version": "2012-10-17",
```

```

"Statement": [
  {
    "Sid": "VisualEditor1",
    "Effect": "Allow",
    "Action": "s3:*",
    "Resource": [
      "arn:aws:s3::vte-cos-s3-rtb",
      "arn:aws:s3::vte-cos-s3-rtb/*"
    ]
  }
]
}

```

2. Create a new role that you can use for the CTE COS S3 Role. For example, you could call the role VTE_S3_Role.
3. Assign the CTE COS S3 policy you created to the role, or click **Add inline policy** to create a new policy. For example:

4. Create a delegated IAM user for the CTE COS S3 Role. The user does not require any privileges because its only job is to assume the CTE COS S3 Role. The delegated IAM user can either be in the same account as the role or it can be in a different trusted account. For example, you could create a user called VTE_S3_User with no privileges.
5. Set "Trusted Entities" to the delegated IAM user on the **Trust relationships** tab. For example:

- Configure the CTE COS S3 Role with the credentials of the delegated IAM user you created earlier by entering the following command in the command line on the host system:

```
voradmin cos s3 role config [<aws_key_id> <aws_secret_key> <user_arn> <role_arn>]
```

where:

- `<aws_key_id>` is the AWS secret key ID for the delegated IAM user that you created.
- `<aws_secret_key>` is the AWS secret key or the delegated IAM user that you created.
- `<user_arn>` is the Amazon Resource Name for the delegated IAM user that you created.
- `<role_arn>` is the Amazon Resource Name for the delegated IAM Role that you created.

If you omit any of the optional parameters, the **voradmin** command prompts you for that information.

For example, if the AWS account number for the delegated IAM user is 1XXXXXXXXXXXX, the user name is VTE_S3_User, and the CTE COS S3 Role is VTE_S3_Role, you would enter:

```
voradmin cos s3 role config AKIA****P KQSm****D arn:aws:iam::1XXXXXXXXXXXX:user/VT  
E_S3_User arn:aws:iam::1XXXXXXXXXXXX:role/VTE_S3_Role
```

After you configure the user and assign the CTE COS S3 Role, CTE will access the S3 bucket through the delegated IAM user account using temporary credentials that CTE regenerates periodically. These credentials are

maintained entirely by CTE and are never exposed to end users.

Secure an S3 Bucket with the CTE COS S3 Role

When you enable the CTE COS S3 Role for a bucket, the associated bucket policy prevents unauthorized users from accessing the contents of the bucket. To enable the CTE COS S3 Role for a bucket, use the following command:

```
voradmin cos s3 role secure-bucket <key_id> <secret key> <cos name> <region> <bucket_name>
```

where:

- `<aws_key_id>` is the AWS secret key ID for the delegated IAM user that you created.
- `<aws_secret_key>` is the AWS secret key for the delegated IAM user that you created.
- `<cos name>` is the cloud service name from CTS COS configuration file, `<installation directory>/agent/squid/etc/cos.conf`.
- `<region>` is the region where the S3 bucket is located in the targeted cloud storage service.
- `<bucket_name>` is the name of the S3 bucket on which you want to enable the CTE COS S3 Role.

For example, if the bucket name is `vte-cos-s3-rtb`, you would enter:

```
voradmin cos s3 role secure-bucket AKIA****P KQSm****D aws us-west-1 vte-cos-s3-rtb
```

Disable the CTE COS S3 Role for an S3 Bucket

To remove the CTE COS S3 Role restrictions associated with a bucket, use the following command:

```
voradmin cos s3 role release-bucket <key_id> <secret key> <cos name> <region> <bucket_name>
```

where:

- `<aws_key_id>` is the AWS secret key ID for the delegated IAM user that you created.
- `<aws_secret_key>` is the AWS secret key for the delegated IAM user that you created.
- `<cos name>` is the cloud service name from CTS COS configuration file, `/agent/squid/etc/cos.conf`.
- `<region>` is the region where the S3 bucket is located in the targeted cloud storage service.
- `<bucket_name>` is the name of the S3 bucket on which you want to disable the CTE COS S3 Role.

For example, if the bucket name is `vte-cos-s3-rtb`, type:

```
voradmin cos s3 role release-bucket AKIA****P KQSm****D aws us-west-1 vte-cos-s3-rtb
```

Guard an AWS Bucket

To Guard an AWS bucket, you must:

1. Create a CBC_CS1 key. For CM, see [Creating a New Key](#) in the [CM Administrator Guide](#).
2. Create a Cloud Object Storage (COS) policy. See [Creating a COS Policy](#).
3. Apply the policy to the host. For CM, see [Managing GuardPoints](#) in the [CTE Administrator Guide](#).

Using a COS Proxy Root CA Certificate Information

The CTE COS CA Certificate, not to be confused with the Kernel and VMD Kernel Certificates, is used with the COS internal Proxy Certificate Authority and must be used by Clients to validate Certificates received during their TLS connection handshake. The default COS CA Self-Signed root CA is automatically created using a locally generated Public/Private Key with the following parameters:

```
CERT_FIELD_PARAM="/C=OZ/ST=Munchkin-land/L=Emerald City/O=ACME Inc/OU=ACME Deliveries/CN=localhost"

SUBJECT_ALT_NAME_PARAM="DNS.1:localhost,IP.1:127.0.0.1"
```

To view the currently installed Certificate for the COS Proxy CA, use the `voradmin cos ca_cert display` command.

In the context of the internal COS Proxy CA, the FQDN of 'localhost' would be the correct value, as well as the loop-back IP address of 127.0.0.1 This results in the following locally generated Root CA Certificate.

```
Certificate:
Data:
Version: 3 (0x2)
Serial Number:

```

If you want to change the defaults, you can use the silent install option with the `CERT_FIELD_PARAM` and `SUBJECT_ALT_NAME_PARAM` set to the desired values, or you can replace the default Certificate using the `voradmin cos ca_cert` command. For more details, see the `voradmin` manpage.

Protecting Python Programs with CTE

CTE uses SHA-256 to generate binary signatures that can be used to allow certain trust levels for a customer application. Capturing the signature of a binary allows CTE to determine if the application's binary has changed in any way, because those changes might mean the security of the binary has been compromised.

While this mechanism works well for executable binaries to verify an application's validity at run time, this mechanism does *not* work for applications implemented with interpreter languages because CTE can only access

the interpreter's signature to validate the file. The program itself is something that is executed by the interpreter and thus CTE cannot hook into this process. Scripting languages like Python are particularly difficult because many Python programs include other Python files, which means there is no single program signature that defines the execution path.

While CTE cannot use signature sets to protect traditional Python programs, tools like PyInstaller allow for the creation of a self-contained Python executable that CTE can sign and protect.

Benefits of Using PyInstaller with CTE

Using PyInstaller allows the creation of self-contained Python binary packages. These packages contain the Python interpreter, the Python program, and all required modules and libraries. Because each package includes all of the files it needs, it is immune to changes to the Python modules or libraries on the system. This not only allows CTE to sign the binary but it also adds extra protection against an attacker trying to gain access through modifications of the underlying libraries.

Another benefit is that it provides security administrators with a stable process that is reasonably immune to system updates done by a system administrator. Once the application binary has been created and signed, the behavior of the program will not change because of updates made through the OS packaging system or Python's PIP package manager.

Getting PyInstaller

PyInstaller is an OpenSource project. The instructions for installing PyInstaller, as well as the documentation, are available on the [project page](#).

Example Usage

The exact usage of PyInstaller arguments varies based on the details of the Python program being packaged into an executable. This example shows what is needed to generate a self-contained AWS CLI binary with PyInstaller. It uses the `--onefile` flag to generate a single, self-contained binary. It assumes that the pip3 Python package manager is already installed on the system.

Installing PyInstaller

The following command installs PyInstaller in `${HOME}/.local/bin/PyInstaller`:

```
pip3 install --user PyInstaller
```

Installing the Amazon AWS Command Line Utility

The following command installs the AWS utility in `${HOME}/.local/bin/aws`:

```
pip3 install --user awscli
```

Creating a Runtime Hook

The following command creates a runtime hook that changes the Python `botocore` root directory within the packaged binary. This is necessary to make sure that we use the `botocore` packaged by PyInstaller. The hook is save to a file named `change-botocore-root.py`. For more information on runtime hooks, see the

PyInstaller documentation.

```
cat <EOF> ${HOME}/change-botocore-root.py
import sys
import boto3

if getattr(sys, 'frozen', False):
    boto3.BOTO3_ROOT = sys._MEIPASS
EOF
```

In order to get the AWS CLI utility working with PyInstaller, we need to specify some hidden imports as well as add some folders from the `awscli` and `boto3` packages into the executable. For more information about hidden imports and adding files to the executable, see the PyInstaller documentation.

```
${HOME}/.local/bin/PyInstaller --onefile \
--hiddenimport=awscli.handlers \
--hiddenimport=pipes \
--add-data=${HOME}/.local/lib/python3.6/site-packages/awscli/data:data \
--add-data=${HOME}/.local/lib/python3.6/site-packages/boto3/data:data \
--runtime-hook=${HOME}/change-botocore-root.py \
${HOME}/.local/bin/aws
```

The resulting binary will be saved in the current working directory as `dist/aws`.

Enable COS on an Agent with no COS Service

To enable COS on a system that has CTE installed but no COS Service:

1. Uninstall CTE completely.
2. Reinstall CTE and select **Yes** when asked:

```
Do you want to configure this host for Cloud Object Storage? (Y/N) [N]: Y
```

Creating a COS Policy

Prerequisites for a COS Policy

1. Install Required Linux Packages
2. Generate a self-contained AWS CLI binary with PyInstaller

Make sure to:

- a. Install PyInstaller
- b. Install the Amazon AWS Command Line Utility
- c. Create a Runtime Hook

3. Configure a CTE COS S3 Role for Guarded Buckets

User Set

- [Create User Sets by Adding Members Manually](#)

Key Rule

- [Add Key Rules](#)
- For COS keys:
 - **Algorithm:** AES
 - **Object Type:** Symmetric Key
 - **Size:** 256
 - **Encryption Mode:** CBC-CS1
 - **Key Usage:** Encrypt, Decrypt
 - **Exportable:** On

Process Set

- The **Directory** is the directory where you created the binary when you generated a self-contained AWS CLI binary with PyInstaller in step 2 of the prerequisite section above.
- The **File** is the file created during that process.

CTE with Teradata Database Appliances

CipherTrust Transparent Encryption (CTE) offers IDT-Capable GuardPoints on Linux for protecting data on raw devices. The IDT solution offers data encryption, data transformation, and access control on storage devices. The principles behind CTE's IDT-Capable GuardPoints can also be applied to protect Teradata Database Appliances. (For details about IDT, see [CipherTrust In-Place Data Transformation for Linux](#).)

This section contains the following topics:

- [IDT-Capable GuardPoints and Teradata Database Appliances](#)
- [Requirements and Considerations](#)
- [Guarding a Teradata Database Device](#)
- [Changing the Encryption Key on Teradata Devices](#)
- [Access Rules to Apply on the Teradata Database Appliance](#)

-
- [Replication of IDT Metadata Files Across Members of a Clique](#)
 - [Generating IDT-capable Metadata for Teradata Storage Expansion](#)
 - [Best Practices](#)
 - [Uninstalling CTE from the Teradata Cluster](#)
 - [Alerts and Errors](#)

IDT-Capable GuardPoints and Teradata Database Appliances

The Teradata Database Appliance must be protected by an IDT-Capable GuardPoint. The In-Place Data Transformation (CTE-IDT) feature offers capabilities such as initial data transformation and access control on protected raw devices. The transformation capability transforms existing clear-text data on a device to cipher-text, and allows for subsequent re-transformation using another encryption key.

You must be familiar with CTE and CipherTrust Manager support for IDT-Capable GuardPoints before you can configure CTE to work with Teradata. For details about CTE-IDT, see [CipherTrust In-Place Data Transformation for Linux](#).

Requirements and Considerations

Location of the CTE Private Region

The CTE Private Region contains the metadata CTE requires in order to support initial transformation of data on the device and subsequent data transformation to other encryption keys. By default, CTE creates the CTE Private Region at the beginning of the guarded device. If data already exists on the device, CTE requires that the device be expanded by 63 MB to make room for the CTE Private Region. The existing data in the first 63MB of the device is then migrated into the expanded space and the beginning of the device is reserved for the CTE metadata. This data relocation is completely transparent to applications and users.

With a Teradata Database Appliance, however, CTE cannot create the CTE Private Region at the beginning of the Teradata pdisk devices because the disks in the Appliance cannot be expanded. Therefore, for Teradata Databases, CTE stores the metadata in a special directory called the CTE Metadata Directory located at: `/var/opt/teradata/vormetric/vte-metadata-dir`. This directory contains all of the metadata for every Teradata Database device that is protected by CTE.

While this does not affect the functionality of CTE, it does affect the way administrators need to back up the Teradata Database because both the Teradata Database and the metadata directory must be backed up together. You will not be able to restore a Teradata Database without access to the associated metadata in the CTE metadata directory.

Metadata File Access and Teradata Clusters

A Teradata cluster can contain multiple hosts. The members of a cluster that share access to pdisk devices belong to a clique. When you create an IDT-Capable GuardPoint on a pdisk, the metadata for that GuardPoint must be available to all members of the clique. CTE automatically replicates the metadata files across the members of a clique when the metadata is created or changed. For details, see [Replication of IDT Metadata Files Across Members of a Clique](#).

Additional Requirements and Considerations

- The Teradata kernel must be at minimum version 4.4.140-96.54.TDC-default on every node of the Teradata Database Appliance on which you plan to install CTE. Refer to the release notes document for CTE releases for compatibility requirements between the kernel releases from Teradata, and the CTE releases.

Caution

- Be sure the version of the Teradata Database is fully compatible with CTE.
 - The Parallel Upgrade Tool (PUT) component of Teradata Database has been enhanced to discover CTE protected devices. The Parallel Upgrade Tool (PUT) component of Teradata (TDput) must be version TDput-03.09.06.09 or higher. This PUT component must be available in your Teradata Database.
- The Parallel Database Extensions (PDE) component of Teradata (ppde) must be version ppde-16.20.53.07 or higher. This PDE component must be available in your Teradata Database.
- The Teradata I/O Scheduler (tdsched) component must be version 01.04.02.02-1 or higher. This I/O Scheduler component must be available in your Teradata Database.
- Contact your Teradata Customer Support Representative if you are unsure of the availability of this functionality in your Teradata cluster.

- The CTE Agent must be installed in `/opt/teradata/vormetric` on every node in the Teradata cluster. In order to specify this location, use the `-d` option when installing CTE. For example:

```
./vee-fs-7.8.0.75-sles12-x86_64.bin -d /opt/teradata/vormetric
```

Note

The CTE Agent can be installed without stopping the Teradata Database service.

- The CTE metadata directory `/var/opt/teradata/vormetric/vte-metadata-dir` must be guarded by the Administrator to prevent accidental modification or deletion of the CTE metadata files. If the CTE metadata directory is not guarded, any attempt to configure or enable an IDT-Capable GuardPoint on the Teradata appliance will be rejected.

The standard CTE policy associated with the metadata directory must:

- Deny all users (including the root user) the ability to modify or remove any files in the metadata directory.
- Specify the key `clear_key` in the key rule so that the metadata is stored in clear text.

- The following table displays how to set up your policy for guarding the CTE metadata directory:

Security Rules	
Action	Effect
Read	Permit, Audit
all_ops	Deny, Audit
Key Selection Rules	
Key	
clear_key	

- Stop the Teradata Database service when upgrading an existing CTE Agent installation, type:

```
tpareset -x Stopping Database
```

- Stop the Teradata Database service so that CTE can rekey any guarded devices. The service must remain stopped until CTE has finished rekeying all of the guarded devices on the appliance.

Calculate Encryption/Key Rotation Time for Teradata Databases

The Thales Engineering team has a set of scripts which help to calculate the estimated encryption time for CTE on a Teradata database cluster.

Using the **dd** command, the scripts simulate the I/O sequences for encrypting **pdisks** during initial encryption. The scripts perform only read operations for simulation. Two parameters are required for simulation: the amount of data to read from each **pdisk**, and the IDT concurrency level to be applied during simulation. The larger the data size, the more sample performance data will be available for estimation. Thales recommends a minimum of 4GB for data size.

The concurrency level is the IDT concurrency level for encrypting IDT configured devices. You can specify the number of segments to transform concurrently using **-c** option of the **voradmin** command when initializing the device. By default, CTE-IDT transforms 8 segments concurrently, if the concurrency level has not been specified through the voradmin command. You can specify 16 for concurrency level if the backend storage for **pdisks** uses high speed flash drives, otherwise use 8.

Note

When choosing the concurrency level for your system you **must** consider the number of CPU cores, the total IOPS of your storage system, the size of the device to transform, and the duration for the data transformation.

The scripts collect the performance data in log files during execution. The logs are saved in **/tmp/cte_data** and **/tmp/perfmon_cte_dd.log**. The Thales team will need those logs to help you with encryption time estimation.

Obtaining the Scripts and Calculating Encryption Time

1. Download the scripts:
 - `con-pdisks-dd.sh`
 - `con-pdisks-test.sh`
2. Modify the bash variable `PDISKS` in the script: `con-pdisks-dd.sh`

Example

```
PDISKS="list of pdisks assigned to this node ..."  
PDISKS="/dev/sda1 /dev/sda2 /dev/sdb1 /dev/sdb2"
```

3. Divide the disks assigned to the clique, equally amongst the nodes of the clique.
4. Copy all of the scripts to the same directory on each Cluster.
5. Run `cond-pdisks-test.sh` concurrently on all of the nodes with the selected devices.

```
# sh con-pdisks-test.sh `<number of GBs to read from each `pdisk`>` `<concurr  
ency level to be applied when reading `pdisks`>`
```

Example

```
# sh con-pdisks-test.sh 4 16
```

6. Contact [Thales Technical Support](#). They will need the collected data to calculate encryption time.

Note

1. The scripts only perform read operations to generate IO load similar to the IDT encryption process, meaning, there is no write operations. Thales factors in a few parameters to estimate rekey time.
2. Thales recommends executing the scripts when the database is not busy.
3. If there are multiple cliques, and if the user requires estimation for each clique, collect the data for each clique separately.

Guarding a Teradata Database Device

To guard a Teradata Database device:

- Install CTE on the Teradata Database Appliance
- Identify Devices to be Guarded with IDT-Capable GuardPoints
- Select the Initial Configuration Method
- Initialize and Guard the Database Devices Using the Standard Initialization Method
- Automating and Reducing the Duration of Initial Data Transformation
- Automating and Reducing the Duration of Subsequent Data Transformation
- Initialize and Guard the Teradata Database Devices Using the Backup/Restore Method

Note

You must use the **In-Place Data Transformation** policy type when guarding Teradata devices.

Install CTE on the Teradata Database Appliance

CTE must be installed on every node in the Teradata cluster, including any Hot Standby Nodes. When you install CTE on every node in your Teradata cluster and register each node with CipherTrust Manager, the following are required:

- You must have AES-NI key available on the host.
- The Teradata kernel must be at version 4.4.140-96.54.TDC-default, or higher, on the Teradata Database Appliance on which you plan to install CTE. Refer to CTE release notes for compatibility between CTE and the Teradata kernel releases.
- Your version of Teradata Database must be fully compatible with CTE for supporting the pdisk devices protected as IDT-Capable GuardPoints.
- The CTE Agent must be installed in `/opt/teradata/vormetric`. In order to specify this location, use the `-d` option when installing CTE. For example:

```
./vee-fs-7.8.0.75-sles12-x86_64.bin -d /opt/teradata/vormetric
```

Warning

Before you install or upgrade CTE, you must stop the Teradata Database and any other applications that access the database devices directly or through the database service. Failure to stop the applications will result in a failure to install or upgrade CTE.

Caution

Be sure to install the CTE Agent in a file system with sufficient free storage space. The minimum available free space is the number of pdisks in your cluster multiplied by 63MB.

Identify Devices to be Guarded with IDT-Capable GuardPoints

Storage devices in Teradata clusters are known as pdisks. A pdisk is a slice of a LUN exported from the backend storage system attached to the nodes in a cluster. For example, the pdisk named `/dev/pdisk/dsk304` is a symbolic link to the slice on the LUN called `/dev/disk/by-id/`

`tdmp-360080e500043092c0000b46f5c34c018-part3`, as shown below:

```
ls -l /dev/pdisk/dsk304
lrwxrwxrwx 1 root root 70 May 18 12:21 /dev/pdisk/dsk304 -> /dev/disk/by-id/tdm
p-360080e500043092c0000b46f5c34c018-part3
```

CTE guards the devices represented by the pdisks in the Teradata cluster. In the example above, the device that you must configure and guard as an IDT-Capable GuardPoint is `/dev/disk/by-id/tdmp-360080e500043092c0000b46f5c34c018-part3`.

Note

You cannot use the symbolic link name when initializing or guarding the storage devices.

To identify the disks available to the Teradata cluster and require CTE protection, look in `/dev/pdisks` on each node in the cluster. Any symbolic links that point to a Linux device path are the disks that should be initialized.

Caution

Do *not* enter the path name of the pdisk device when initializing it for guarding or in the CipherTrust Manager when you actually guard the device.

Select the Initial Configuration Method

Select the initial configuration method that you want to use. Thales supports two methods for the initial configuration of Teradata Database devices:

- **Standard Initialization Method**

This method configures devices for initial encryption of existing clear-text data on the database devices. The time required to encrypt may take hours or even days, depending on the volume of data, the number of database devices and nodes, and the bandwidth of the storage back-end of database devices. For details, see

Initialize and Guard the Database Devices Using the Standard Initialization Method.

- **Backup/Restore Initialization Method**

This method skips the initial encryption step but requires a full backup of the database and the engagement of Teradata Customer Support to assist you with some configuration steps at the Teradata database level in preparation for the full restore of the database after the database devices are protected. The length of time required for this method depends on the length of time it takes to back up, and then fully restore, your Teradata database. For details about using this method, see [Initialize and Guard the Teradata Database Devices Using the Backup/Restore Method](#).

Initialize and Guard the Database Devices Using the Standard Initialization Method

The following procedure describes how to perform the initial configuration of your database devices using the Standard Initialization Method. This procedure encrypts the existing data in place and does not require you to backup your Teradata database when initially deploying CTE. It may, however, take several hours, or even days, to complete depending on the volume of data, the number of database devices and nodes, and the bandwidth of the storage back-end of database devices.

Warning

For each device, you must designate *one and only one* of the nodes in the cluster as the initial node. This is the node on which you plan to initialize and guard the device for the first time. The designated node must be the only one that guards the device until the entire initial data transformation process has completed. **DO NOT** initialize or guard any device on multiple nodes in the cluster simultaneously, because multiple nodes attempting to transform the same data can corrupt the data on the entire device.

1. Shut down the Teradata Database. You cannot initialize an online database device.
2. For each device, designate one of the nodes in the cluster as the initial node that you will use for the initial data transformation when the device is guarded for the first time.
3. Log into the designated node in the Teradata Database Appliance. Type:

```
voradmin idt config [-external] [new|xform] [-c <n>] <device-name>
```

- **[new|xform]** (required)

Indicates whether data already exists on the device. If the device contains no data, specify **new**. If the device contains data that you want to keep, specify **xform**. Most installations of Teradata Appliance are expected to have pdisks populated with data, therefore, most often you will use the **xform** option. When you use **xform**, CTE will transform all existing data on the device from clear-text to cipher-text as soon as you guard the device on the Appliance. The device will be inaccessible until the transformation is complete, and the device must remain offline to the Teradata Database service during the entire transformation

process. No user access will be permitted until all of the data has been transformed.

- **-external** (required)

You *must* use this option when initializing any Teradata device. With this option, CTE writes the CTE Private Region to a metadata file located in the CTE metadata directory. For details, see [Location of the CTE Private Region](#).

- **-c <n>** (optional)

If you use this option, CTE sets the number of data transformation jobs to run in parallel to the number specified in **<n>**. **<n>** can be an integer between 1 and 60, (default: 8).

Each data transformation job transforms 1MB worth of data and requires CPU resources in addition to three I/O operations as part of data transformation. Each job reads 1MB of data from the device, preserves the data in the CTE private region, rekeys the data to cipher-text, and writes the transformed data to the device. If you increase the number of parallel jobs, the data transformation process will complete faster but there will be an increased performance impact on the system. Only increase the **-c** option if you are certain that the system resources are available to handle the additional load.

The value for the **-c** option you specify here remains in effect for all subsequent data transformations (such as any data rekeys) until you specify a new value.

- **<device-name>** (required)

The name of the Teradata Database device that you want to initialize.

For example:

```
voradmin idt config -external xform -c 20 \  
/dev/disk/by-id/tdmp-360080e500043092c0000b46f5c34c018-part3
```

4. Repeat the **voradmin idt config** command for each device that you want to initialize. If you want to distribute the initial data transformation or subsequent rekey load on all of the disks across all the nodes in the cluster, make sure that you run the **voradmin idt config** command for each device on the node you designated for data transformation, *excluding* the HSN node. The node on which you run the **voradmin idt config** command is the node that performs the data transformation on the device. Do *not* designate the HSN node for data transformation because the devices on the HSN node may be reserved and therefore not available for IO operations.

Guard the Devices as IDT-Capable GuardPoints

Warning

For each device, you must designate a node in the cluster as the initial node on which you plan to initialize and guard the device for the first time. The designated node must be the only one that accesses the device until the entire initial data transformation process has completed. This requires guarding each device at the designated client level rather than at the client group level. DO NOT initialize or guard any device on multiple nodes in the cluster simultaneously, because multiple nodes attempting to transform the same data can corrupt the data on the entire device.

To create an IDT GuardPoint:

1. On the **GuardPoints** tab, click **Create GuardPoint**.
2. Select a **Policy**. This is a mandatory field.
 - a. Click **Select** next to the Policy field.
 - b. Select an *In-place Data Transformation* policy. If no policy exists, create one, as described in [Creating Policies](#).

Name	Type	Version
☐ testcospic	Cloud Object Storage	0
☐ testpolicy	Standard	1
☐ idtpic	Live Data Transformation	0
☒ test-idt-plc	In-place Data Transformation	0

- c. Click **Select**.

Note

When an IDT policy is selected, the **In-place Data Transformation** toggle is displayed on the Create GuardPoint dialog box.

3. Select the **Type** of device to protect. This is a mandatory field. The options for a **In-place Data Transformation** policy are:

Type	Description
Auto Raw or Block Device	Select for IDT policies for raw (block) devices.
Manual Raw or Block Device	Select for IDT policies for raw (block) devices to be guarded manually.

Note

Manual Raw or Block Device are guarded and unguarded (for example, mounted and unmounted) by running the `secfsd -guard` and `secfsd -unguard` commands.

4. Specify the **Path** to be protected. This is a mandatory field. Options to specify the GuardPoint paths are:

- **Enter/Browse Path:** Select this option, and enter the GuardPoint paths by either typing or clicking the **Browse** button.

Note

A maximum of 200 GuardPaths can be specified using the **Enter/Browse Path** option.

- Click **Browse** to select a path by browsing the client file system. This method prevents typographical errors and verifies client availability. This is the recommended method to specify individual paths.

File system of a client that is not registered with the CipherTrust Manager cannot be browsed.

- Alternatively, if you know the path, manually enter full paths of one or more directories in the given text box. Enter one path per line.

Create GuardPoint

/dev/sdb/

Browse

i To apply the same GuardPoint settings to multiple paths, type paths in the Path field or specify them using the Browse button. A maximum of 200 GuardPaths can be specified.

In-place Data Transformation: ☒

Efficient Storage: ☐

5. Make sure the In-place Data Transformation option is selected.
6. Click **Create**. A message appears prompting to confirm the reuse of these GuardPoint settings on another path.
 - Click **Yes** to use the same settings on another path. The Use Settings on Another Path dialog box is displayed. Perform the following steps:
 - a. Specify a new **Path**.
 - b. Click **Add Path**. The newly added path appears under the Paths list on the left. Similarly, add as many paths as required.
 - c. Click **OK**.
 - Click **No** if you do not want to use the same settings on another path.

CipherTrust Manager pushes the policy and the GuardPoint configuration to the node in the cluster. The CTE agent on the node writes the IDT Device Header into the CTE Private Region in the local CipherTrust Transparent Encryption metadata directory on the node.

If this is a new device, the status immediately changes to guarded. If there is existing data on the device, CTE begins transforming the data from clear-text to cipher-text as soon as the GuardPoint configuration is available and the device status changes to guarded. The device will remain inaccessible until this data transformation completes. The length of time required to transform the data depends on the amount of existing data and the number of parallel data transformation jobs specified in the `voradmin idt config` command. To see the data transformation progress, use the `voradmin idt xform status <device-name>` command, as described in [Viewing Device and Data Transformation Status](#).

Devices with existing data are transformed from clear-text to cipher-text using the encryption key specified in the selected policy through the In-Place Data Transformation (CTE-IDT) process. For details on how CTE does data transformation on IDT GuardPoint, see [CipherTrust in-Place Data Transformation for Linux](#).

After the device is initialized and guarded, the protected device must be accessed through the device pathname corresponding to the secvm device. For example, if you guard the Linux device `/dev/disk/by-id/tdmp-360080e500043092c0000b46f5c34c018-part3`, the pathname becomes `/dev/secvm/dev/disk/by-id/tdmp-360080e500043092c0000b46f5c34c018-part3` as soon as the process is complete.

7. After all of the Teradata Database devices have been guarded, disable the guarded IDT-GuardPoints on each designated node and then enable those GuardPoints at the Client Group level on all the nodes in the clique.
8. After guarding your devices and before starting your database, you must change the current configuration of your cluster to reflect the status of the pdisk devices guarded as IDT GuardPoint. See the **Rebuild Vconfig Only** option of the Teradata Parallel Upgrade Tool (PUT) service to apply the guarded status of the pdisk devices into your database configuration. The **Rebuild vconfig** process applies the guarded configuration status of each pdisk and resets the pdisk symbolic link to the CipherTrust Transparent Encryption `secvm` device.

Warning

You must complete this step before starting your database. Failure to do so will result in database failures and potential corruption of your database.

For example, the pdisk `/dev/pdisk/dsk304` is linked to the secvm device after **Rebuild Vconfig Only** commits the guarded status of pdisk on each node:

```
# ls -l /dev/pdisk/dsk304
lrwxrwxrwx 1 root root 70 May 18 12:21 /dev/pdisk/dsk304 -> /dev/secvm/dev/disk/by-id/tdmp-360080e500043092c0000b46f5c34c018-part
```

9. After all of the Teradata Database devices have been guarded in the clique and the **Rebuild Vconfig Only** on TDput has been executed, start the Teradata Database, type:

```
# /etc/init.d/tpa start
```

Viewing Device and Data Transformation Status

After you guard a Teradata Database device, you can view the status of that device using the `voradmin idt status [xform] <device-name>` command, where:

- **xform** (optional)

If you specify this option, CTE shows the status of any data transformation processes happening on the device. If you do not specify this option, CTE displays the IDT Device Header for the device.

- **<device-name>** (required)

The name of the Teradata Database device that you want to initialize. This must be the actual device name and not the symbolic pdisk name.

For example, if you want to view the status of device `/dev/disk/by-id/tdmp-360080e500043092c0000b46f5c34c018-part3`, you would enter:

```
voradmin idt status /dev/disk/by-id/tdmp-360080e500043092c0000b46f5c34c018-part3
```

If you want to check the data transformation progress on the device `/dev/disk/by-id/tdmp-360080e500043092c0000b46f5c34c018-part3`, you would enter:

```
voradmin idt status xform \
/dev/disk/by-id/tdmp-360080e500043092c0000b46f5c34c018-part3
```

The **Status** field displays **In-Progress** if a data transformation process is running, and **Completed** if the process has finished.

Automating and Reducing the Duration of Initial Data Transformation

CTE for Teradata allows Teradata customers to run their database services on top of a high performing encrypted storage infrastructure, solving many security and compliance concerns. Teradata systems are usually mission critical and cannot afford to be offline for significant periods of time. The problem, therefore, is how to convert an existing Teradata system from one that is unencrypted, to one that is encrypted. Thales calls this conversion process rekeying, or data transformation.

The following steps outline the process the Teradata operations team should follow to encrypt the platform while minimizing system downtime and operational disruptions. The process leverages the fact that a Teradata system is composed of multiple disks, which create a redundant platform, and effectively approaches the conversion process by breaking it into smaller, more manageable, and less disruptive steps. Operators should prepare for data transformation and schedule time to complete the transformation process while the Teradata database services are down. The process supports recovery from unexpected IO failure during the transformation process of migrating data from unencrypted to encrypted. This document describes the procedure and execution of the transformation process using a script that orchestrates the entire transformation process across multiple nodes in a clique, and significantly reduces the entire data transformation time.

Warning

Thales recommends that you backup the Teradata database before starting the transformation process.

Use the `cte-pdisk-idt.sh` script to perform the initial rekey using embedded metadata on the Teradata `pdisks` that will be configured for IDT using external metadata. This reduces the time needed to encrypt the `pdisks` because the external metadata is a bottleneck when performing rekey on multiple concurrent devices. The script works by saving the last 63 MB of a device to a file, and then configuring the device as IDT with embedded metadata. The last 63 MB is saved because devices configured for IDT with embedded metadata relocate the first 63 MB to the end of the device to make space for the metadata. Upon completion of rekey, the script then restores the first 63 MB from the end of the device and the last 63 MB for the saved file before converting the device to IDT with external metadata.

Note

- This script **only** works for CTE 7.3.0 or subsequent versions
- This script **only** works for initial rekey.

Getting Help

Recovery from interruption during the preparation step requires manual intervention. Recovery from unexpected failure occurs when the GuardPoints are guarded again. You can then restart the script in the monitor mode to resume monitoring the transformation progress.

In the event that the script is interrupted, or a system crash, contact [Thales Support](#). If possible, include the following information to facilitate recovery:

- Output of the script
- Output of the `secfsd -status guard` command (if the interruption did not crash the system)
- Contents of the `/tmp/pdisks.list` file
- Contents of the `/tmp/monitor-idt.disks` file
- Contents of the `/opt/teradata/vormetric/agent/secfs/.sec/conf/sod_config` file
- Contents of the `/var/opt/teradata/vormetric/vte-metadata-dir` directory (including file sizes)

Prerequisites

- Your policy for the external metadata directory **must** allow read/write access for the `dd`, `mv`, `rm`, and `stat` functions.

- Your policy for the raw device **must** allow read/write access with apply key effect for the **dd** function.

Install and Setup

1. Install the agent in `/opt/teradata/vormetric` and setup the external metadata directory `/var/opt/teradata/vormetric/vte-metadata-dir` on all nodes in the clique.
 - See [Install CTE on the Teradata Database Appliance](#) for more information on installing CTE on Teradata.
2. Copy the `cte-pdisk-idt.sh` script from `/opt/teradata/vormetric/agent/secfs/.sec/bin/` to `/root`.
3. Shutdown Teradata, type:

```
tpareset -x -f 'Setting up CTE'
```

4. Generate a list of disks to encrypt, type:

```
ls -l /dev/pdisk/dsk* | awk '{ print $(NF) }' > /tmp/all_pdisks.list
```

Note

This command generates a file with a list of disks in the format: `/dev/disk/by-id/*`.

5. Divide `/tmp/all_pdisks.list` into separate files based on the number of active (non-HSN) nodes in the clique. For example, if the list contains 300 disks and there are 4 active nodes, there should be 4 files with 75 disks in each.
6. Copy each file as `/tmp/pdisks.list` to the corresponding host that will oversee encrypting those disks. For example, if there are 300 disks in a 4-node clique, each node should have a unique list of 75 disks.
7. Add a manual IDT GuardPoint on each node for the disks in `/tmp/pdisks.list`

Note

The script only toggles the GuardPoints in the `/tmp/pdisks.list` file so it is safe to add manual GuardPoints for all of the devices on all of the nodes. However, automated metadata distribution does not work if the GuardPoint is present on all nodes as it expects the node performing transformation to be the only node with the GuardPoint at this point.

Configure and Initialize

1. To configure the devices for IDT on each node, save the last 63 MB, and start the initial rekey, type:

```
/root/cte-pdisk-idt.sh -m pre -y -f /tmp/pdisks.list
```

2. To monitor transformation with the following and wait for transformation to complete, type:

```
/root/cte-pdisk-idt.sh -m mon
```

3. To finish the setup, type:

```
/root/cte-pdisk-idt.sh -m post -f /tmp/pdisks.list
```

This restores the data to the first and last 63 MB of the device, restores the external metadata, and sets the `pdisk symlinks` to their associated `secvm` device.

4. Verify that identical metadata is present for all devices on all of the nodes, type:

```
ls -l /var/opt/teradata/vormetric/vte-metadata-dir | wc -l
```

If identical metadata is not present on all of the nodes in the same clique, manually synchronize the contents of the external metadata directory.

5. Unguard all of the nodes from the security server and switch to auto-guard GuardPoints.
6. Use the [Teradata PUT tool](#) to update the `pdisk` symbolic links permanently.
7. Start Teradata to verify that the database can start, type:

```
/etc/init.d/tpa start
```

8. Clean up the files created by the script, type:

```
rm -f /tmp/all_pdisks.list /tmp/pdisks.list.done /tmp/cte_pdisk_idt_pre.out
```

Script Help Output

```
/root/cte-pdisk-idt.sh -h
```

Response

```

Usage  /root/cte-pdisk-idt.sh [-h] [-y] [-t #] [-m <mon|pre|post>]
      < [-p </dev/pdisk/dsk#>] </dev/disk/by-id/scsi-...>
      -f <batch_file> >

-f <batch_file> File with list of disks to transform
File should have one entry per line
Format is,
    /dev/disk/by-id/tdmp-xxx
    /dev/disk/by-id/tdmp-yyy
    ...
or
    /dev/pdisk/dsk# -> /dev/disk/by-id/tdmp-xxx
    /dev/pdisk/dsk# -> /dev/disk/by-id/tdmp-yyy
    ...

Format for the latter option can be generated with,

    ls -l /dev/pdisk/dsk* | awk '{ print $(NF - 2), \
$(NF - 1), $NF }'

-m mon      Monitors IDT status on disks undergoing transformation started with the '-m pre' option
-m full     Performs the entire transformation process (default)
-m pre      Performs steps to set up and begin encryption of a device
-m post     Performs steps after device has been encrypted to restore borrowed space

With the 'full' mode, the script will wait while the device undergoes encryption. The 'pre' mode will start encryption and then terminate the script and wait for a user to rerun the script with the 'post' mode after encryption is complete.

-t #        Number of threads to use during IDT (default: 16, range: 1 - 60)
-p          Pdisk to link to after transformation is complete
-y          Skips user prompts
-h          Displays this help

```

Automating and Reducing the Duration of the Subsequent Data Transformations

You can use the `cte-idt-rekey.sh` script to perform subsequent rekey operations using embedded metadata on a set of IDT-Capable devices configured with external metadata. This reduces the time needed to rekey the devices, as the external metadata is a bottleneck when performing rekey on multiple concurrent devices. The script works by converting each device to IDT with embedded metadata before launching rekey. Embedded IDT metadata makes rekey operations significantly faster. The process of converting to embedded metadata is accomplished by:

1. Saving the first 63 MB of the device.
2. Copying the external metadata into the first 63 MB of the device.

3. Renaming the external metadata file to disable the use of external metadata.
4. Upon completion of rekey, the script then copies the first 63 MB out of the new external metadata file, and then restores the original 63 MB of the device that had been the backup, before the device converted it to IDT with the external metadata.

Note

- This script is **only** compatible with CTE v7.8.0.100 and subsequent versions.
- This script **only** works for subsequent rekey operations. Use the script: `cte-pdisk-idt.sh` for the initial data transformation.
- Thales recommends that you backup the data on the devices before starting the transformation process.

Prerequisites

- Your policy for the external metadata directory **must** allow read/write access for the `dd`, `mv`, `rm`, and `stat` binaries.
- Your policy for the raw device **must** allow read/write access with apply key effect for the `dd` binary.

Applying the Script

The following steps describe how to use the script for a set of devices in a clique with one, or multiple, nodes. In a multi-node clique, each node should perform the same steps with a different set of disks so that the work of rekeying all of the disks in the clique is distributed across the members.

Note

Do not run the script on Hot Standby Nodes (HSNs).

1. Copy the `/root/cte-idt-rekey.sh` from `/opt/teradata/vormetric/agent/secfs/.sec/bin` to `/root`.
2. Shutdown **Teradata**.
3. Create a list of the disks on which to perform subsequent rekey operations. The path to the disks **must be the same** as the disks that the GuardPoints are set on.
4. Create a directory, `/var/opt/teradata/vormetric/backup`, for the backups for the first 63 MB to be saved.

5. Apply a GuardPoint to that directory with a standard policy that encrypts the data and allows read/write access.
6. Modify the policy set on the external metadata directory, `/var/opt/teradata/vormetric/vte-metadata-dir`, and the devices, to allow read/write access so that the script can manipulate the external metadata files.
7. Prepare an alternate policy if needed.

If using a new policy to rekey the device, create a new policy with the current key set to the transformation key from the existing policy, and a new XTS key as the transformation key. For example, if the current policy encrypts from clear to XTS-key1; the new policy should encrypt from XTS-key1 to XTS-key2. The new policy must also allow `dd read/write access`. You can remove this access from the policy after all of the steps have been completed.

8. Run the script with the `backup` option and pass in the disk list:

```
/root/cte-idt-rekey.sh backup /<path/to/disks>.list
```

9. Wait for the script to finish the backup on all of the nodes in the clique.
10. Unguard all of the IDT device GuardPoints.
11. Alter the policy to use the new key (unless using a new alternate policy from step 8).
12. Re-guard all of the devices with manual GuardPoints.
13. Run the script with the `rekey` option and pass in the disk list:

```
/root/cte-idt-rekey.sh rekey /<path/to/disks>.list
```

14. Follow the on-screen prompts to enter the number of threads desired for rekey.
15. Wait for the script to finish rekey on all of the nodes in the clique.
16. Ensure that the external metadata files on all of the nodes in the clique are identical to the files on the node that ran the script. Verify this by running the command: `md5sum <file>` for the metadata files on all of the nodes within a clique to verify their consistency. If there is a discrepancy, overwrite the inconsistent metadata file with the file from the node used to rekey the device.
17. Remove the manual GuardPoints set in step 12 and re-guard with autoguard GuardPoints in the same manner as the original configuration.
18. Verify the data and access to the device(s) with the command: `verify_pdisks`.
19. Undo the modifications to the policy on the external metadata directory: `/var/opt/teradata/vormetric/vte-metadata-dir`.

20. Unguard and remove the backup directory `/var/opt/teradata/vormetric/backup`.
21. Start **Teradata**.

Initialize and Guard the Teradata Database Devices Using the Backup/Restore Method

The Standard Initialization Method encrypts the Teradata database devices using In-place data transformation. Because Teradata Appliance models range in both storage and node sizes within a cluster, the time it takes to encrypt the existing data in-place on these large scale models may exceed the desired time frame.

To address this issue on an existing Teradata database, you can configure CTE on Teradata Appliances using the Backup and Restore method to retain existing data. The total time required to configure your Teradata Appliances with CTE using this method depends on how long your backup/restore application takes to restore the database.

To initialize and guard the devices using the selected initialization method, you must:

1. Backup the entire Teradata database, including all meta files, required for a full restore of that database.
2. Install and configure CTE on the Teradata database devices.
3. Work with Teradata Customer Support to initialize a `sysinit` on the Teradata Appliance cluster in preparation for a full database restore.
4. Perform a full restore of the Teradata database from the backup to the CTE protected devices. CTE automatically encrypts the data as it is restored to each protected device.

Prerequisites

Before starting this process, complete the following prerequisites:

- Make sure you have met the requirements described in [Requirements and Considerations](#).
- Create or identify the XTS/CBC-CS1 AES 256 key that you will use for the In-Place Data Transformation policy that you will apply to the IDT-Capable GuardPoints.
- Create a **Standard** policy that will be used to guard the CTE Metadata Directory (`/var/opt/teradata/vormetric/vte-metadata-dir`).
- Create an **In-Place Data Transformation** policy that will be used to guard the Teradata Database Devices. This policy must use an XTS/CBC-CS1 AES 256 key.
- Identify all of the devices that need to be guarded as described in [Identify the Devices to Be Guarded](#).

Procedure

1. Using a Teradata certified backup application, backup your entire Teradata database. The backup needs to include the Data Dictionary, the user database, and everything else that is required for a successful restore of your database. Contact your Teradata Customer Support representative for the requirements for a full backup.

2. After confirming that your backup of the Teradata database completed successfully, shutdown the Teradata database, type:

```
tpareset -x -f "shutting down for CTE installation"
```

3. Install CTE in `/opt/teradata/vormetric` on all nodes in the Teradata cluster and register them to a CipherTrust Manager server as described in [Install CTE on the Teradata Database Appliance](#).

```
./vee-fs-7.8.0.75-sles12-x86_64.bin -d /opt/teradata/vormetric
```

4. Create the CTE metadata directory (`/var/opt/teradata/vormetric/vte-metadata-dir`) on all nodes in the cluster.

```
. pcl -shell "mkdir -p /var/opt/teradata/vormetric/vte-metadata-dir"
```

5. If you are using the Teradata Intelibase model, complete the following step. If you are using the Teradata Inteliflex model, proceed to Step 6.
 - a. Log on to the CipherTrust Manager, click the **Hosts/Clients** tab, and set the GuardPoint to the CTE Metadata Directory (`/var/opt/teradata/vormetric/vte-metadata-dir`) using the Standard policy that was created for the metadata directory on all the nodes in the Teradata cluster.
 - b. On each node, identify the list of disks that will be configured and guarded as "new" devices as described in [Identify the Devices to Be Guarded](#).
 - c. On each node, configure each disk to be guarded as a new IDT-Capable device using the `voradmin idt config -external new` command.

```
voradmin idt config -external new \  
/dev/disk/by-id/tdmp-360080e500043092c0000b46f5c34c018-part3
```

Note

Make sure that you configure each device using the `new` option. This option tells CTE to guard the device without transforming the data.

- d. Log on the CipherTrust Manager, click the **Hosts/Clients** tab, and select one of the host in the clique to set the GuardPoints for all the devices that have been initialized as new IDT-Capable devices using the In-Place Data Transformation policy that you created.

Repeat this step for all other hosts until all initialized devices have been guarded with an In-Place Data

Transformation policy.

6. If you are using the Teradata Inteliflex model, complete the following step. Otherwise, proceed to Step 7.
 - a. Designate one of the nodes in a clique as the node on which you will perform the first-time initialization and guarding procedures for each device. For example, if you have a 4 clique cluster, you must designate a total of 4 nodes, one from each clique.
 - b. Log on to the CipherTrust Manager, click the **Host/Client Groups** tab, and create a host group for each clique. For example, if your Inteliflex cluster has 4 cliques, you would create 4 host groups, one for each clique. For example, cluster-clique-1, cluster-clique-2, cluster-clique-3, and cluster-clique-4.
 - c. On the **Host/Client Groups** tab, click the name of one of the client groups you just created. Click on the **Members** tab and add the designated node from the clique as a member of this client group.

Repeat this step until all designated nodes have been added to the client group that matches their clique. In the previous example, you would have one designated node in each of the 4 client groups that you created.

- d. On the **Host/Client Groups** tab, click the name of one of the host groups that you just created. Click on the **GuardPoints** tab and add a GuardPoint for the CTE Metadata Directory (`/var/opt/teradata/vormetric/vte-metadata-dir`) using the Standard policy that was created for the metadata directory on all the nodes in the Teradata cluster.

Repeat this step for each Host/Client Group you created for your cliques. In the previous example, you would add the metadata directory GuardPoint in each of the 4 host groups that you created.

- e. On the designated node for each clique, identify the list of disks that will be configured and guarded as a “new” IDT device as described in [Identify the Devices to Be Guarded](#).
 - f. Configure each disk device on the designated node to be guarded as a new IDT-Capable device, type:

```
voradmin idt config -external new \
/dev/disk/by-id/tdmp-360080e500043092c0000b46f5c34c018-part3
```

Note

Make sure that you configure each device using the new option. This option tells CTE to guard the device without transforming the data.

- g. For each of the other designated nodes you identified, identify the list of devices to be guarded and configure them using the `voradmin idt config -external new` command.
 - h. Repeat this configuration process until all devices on all designated nodes that you want to guard have
-

been configured as new IDT-Capable devices.

- i. On the **Host/Client Groups** tab, click the name of one of the clientgroups you just created. Click on the **GuardPoints** tab and add a GuardPoint for each device that you initialized as a new IDT-Capable device using an In-Place Data Transformation policy.
- j. Repeat this step on each one of the host groups you created.

The guarded devices will immediately be set as guarded on the designated node through the client group. However, as part of Teradata cluster support, each guarded device will have its metadata file replicated across all nodes in a clique as described in [Replication of IDT Metadata Files Across Members of a Clique](#). You must wait for metadata replication to complete for each clique in a cluster before continuing to the next step. This process takes approximately 1 second per disk that was guarded. So if you guarded 10 disks, you need to wait approximately 10 seconds. Verify that the number of metadata files on each clique matches with the designated node using the following command:

```
pcl -shell "ls /var/opt/teradata/vormetric/vte-metadata-dir | wc -l"
```

The number of metadata files on each node in the clique should also match the number of devices in that clique. For example, if you have a clique with 10 devices in it, then the results of the above `pcl` command should show 10 metadata files on each node in the clique.

- k. After metadata replication is completed on all cliques, log on the Key Manager and click the **Hosts/Client Group** tab, then click the name of one of the client groups you just created. Click the **Members** tab and add the rest of the nodes that belong to that clique to the Host Group. After all the nodes have been added, the Key Manager automatically pushes the existing GuardPoints out to the newly added members.
 - l. Repeat this step for each one of the Host Groups that you created for your cliques.
7. Verify that all of the nodes in a clique show that all of the devices as guarded.

```
pcl -shell "secfsd -status guard"
```

8. Work with Teradata Customer Support to perform a `sysinit` of the Teradata appliances in preparation for the full database restore.
9. Restore your Teradata database from backup.

Changing the Encryption Key on Teradata Devices

To meet various compliance requirements, you may want to change the key that CTE used to encrypt the Teradata Database devices. This process is called “Key rotation” or “Rekey”.

If you want to rekey a Teradata Database device, you can either:

- Follow the process for standard IDT-Capable GuardPoints. For details, see [Changing the Encryption Key on Linux IDT-Capable Devices](#).

- Use the Backup/Restore method as described in [Initialize and Guard the Teradata Database Devices Using the Backup/Restore Method](#). The only differences between the initial configuration described in that section and rekey process are:
 - You do not need to change the policy assigned to the CTE Metadata Directory.
 - You need to create a new In-Place Data Transformation policy, that specifies a key rule with the existing key used to encrypt the Database devices in the **Current Key** field, and the new XTS/CBC-CS1 AES 256 key that you want to use to encrypt the data in the **New Key** field.
 - When you re-guard the designated node in each clique, make sure that you use the new policy so that CTE knows it needs to re-encrypt the data with the new key after you restore the devices from the backup.

Note

Make sure that you stop the Teradata database before you rekey the devices.

Warning

Rekeying a device must be executed only on *one and only one* of the nodes in the cluster. DO NOT prepare the device for rekey or guard the device with the new rekey policy on multiple nodes in the cluster because doing so initiates the data transformation process on the device on multiple nodes. The simultaneous attempts to rekey the data can cause data corruption of all of the data on the entire device.

Access Rules to Apply on the Teradata Database Appliance

This section provides the instructions for creating a sample policy and signature sets specific to a Teradata Database Appliance to deny unprivileged users access to clear-text data on guarded devices. Such a policy requires the inclusion of specific security rules to restrict access to the Teradata Device GuardPoints for specific set of users, groups, and/or processes.

Note

You **must** add binaries to client settings to allow trusted processes to access policies. Failure to do so results in a **User not Authenticated** error which prevents access for user-based policies. For example, when using `tvsa_agent` for a Teradata cluster, you must add `/usr/pde/bin/tvsa_agent` as an authenticator in the client settings.

1. In the CipherTrust Manager, edit the host/client entry for the Teradata Database Appliance.
2. Go to the **Host/Client Settings** tab and add the following entries to the list of binaries:

-
- |authenticator|/usr/pde/bin/pdmain
 - |authenticator|/opt/teradata/sm3g/bin/tdsmagent
 - |authenticator|/usr/pde/bin/pcl
 - |authenticator|/opt/teradata/TDput/bin/putservices
 - |authenticator|/usr/pde/bin/tvam
3. Create a signature set for system processes that require access to guarded devices. The following system processes on the Teradata Database Appliance must be permitted access:

- /usr/lib/systemd/systemd-udevd
- /sbin/dmsetup
- /opt/teradata/vormetric/agent/vmd/bin/get_disks
- /sbin/pvdisplay
- /sbin/lvdisplay
- /usr/sbin/parted

You can include additional processes as needed.

4. Create a signature set for Teradata Database processes that require access to guarded devices. The following directories contain the Teradata binaries that require access:

- /usr/pde/bin/*
- /usr/tdbms/bin/*
- /opt/teradata/gsctools/bin/*
- /opt/teradata/TDput/bin/*

You can include additional processes as needed.

5. Create a system-level process set to associate the system-level processes listed in step 3, with the signature set you created in step 3. In the following example, this process set is called TD-Demo-system-process.

2 Processes

Directory	File	Signature	
/opt/teradata/vormetric/agent/vmd/bin	get_disks	TD-Demo-System-Process	
/sbin/	dmsetup	TD-Demo-System-Process	
/sbin/	lvdisplay	TD-Demo-System-Process	
/sbin/	pwdisplay	TD-Demo-System-Process	
/usr/lib/systemd	systemd-udevd	TD-Demo-System-Process	

6. Create a Teradata Database process set to associate the signature set for the Teradata Database binaries created in step 4.

2 Processes

Directory	File	Signature	
/opt/teradata/TDput/bin/	*	TD-Demo-TD-Binaries	***
/opt/teradata/gsctools/bin/	*	TD-Demo-TD-Binaries	***
/usr/pde/bin/	*	TD-Demo-TD-Binaries	***
/usr/tdbms/bin/	*	TD-Demo-TD-Binaries	***

7. Create the user set for the Teradata trusted group on your appliance.
8. If you have any other trusted groups that you want to include in your security rule, add a user set for each one of those trusted groups. You can add as many user sets to the policy as you need.
9. Create a user set for the root user and any other privileged users you want to add.
10. Verify that you have the complete signature sets, process sets, and user sets as shown in the examples below.
11. Apply the policy to the Teradata Device GuardPoints.

Replication of IDT Metadata Files Across Members of a Clique

For Teradata, metadata for IDT-Capable GuardPoints is stored in external files in the CTE metadata directory. Because the Teradata appliance is a cluster of multiple hosts/clients that share access to the same devices across multiple nodes, a metadata file must be replicated across the nodes that are in the same clique within the cluster, including Hot Standby nodes. Replication is required when the initial data transformation has been completed, and it is required again during subsequent rekeys. The availability of the metadata files on all members of the clique is critical for high availability of Teradata database in the event of a node failure because the data on the device cannot be accessed without the encryption key stored in the metadata.

Upon completion of data transformation on each device, the CTE Agent on that device automatically replicates the metadata file for that device to the other nodes in the clique using the Teradata `pcl` command. CTE uses `pcl` to both determine the other members of the clique and to replicate the metadata to those other members. When the metadata is replicated on the remote nodes, any existing metadata for the recently-transformed device already on those nodes is replaced with the updated metadata files sent by the CTE Agent. This replacement is achieved by sending the updated metadata file to all of the remote nodes through `pcl` and replacing each existing metadata file on the remote nodes with the most recent metadata files.

Specific Issues to Consider

This section describes specific problems that may be encountered during data transformation and metadata replication. Manual user intervention will be required to recover from the reported issues. For troubleshooting and recovery steps, see [Alerts and Errors](#).

General PCL Error

If the `pcl` command fails during the replication process, a message indicating the error will be logged. The messages are tagged with IDT-TD-ALERT. For example:

- IDT-TD-ALERT: Node <node name> did not respond to `pcl` command
- IDT-TD-ALERT: Failed to distribute IDT-Capable metadata file to remote nodes

These errors indicate that the node specified in the first error did not respond to a `pcl` command during metadata distribution. As a result, the metadata distribution must be manually performed across the clique before access to the device is possible.

Offline Node in Clique During Data Transformation

If a node is offline during data transformation and metadata replication process, CTE will log a message that metadata replication to the target node failed. The administrator will be required to manually replicate the metadata file to the offline node when the node comes online. The metadata file must be replicated before the database is brought up.

To do so:

- Run the `voradmin td distribute <device name>` command to distribute the metadata file of each device. The command will copy, or update, the metadata file on the agent that has come online. For example:

```
voradmin td distribute \  
/dev/disk/by-id/tdmp-360080e500043092c0000b46f5c34c018-part3
```

Adding a New Node to a Clique

When you add a new node to an existing clique, the metadata files of all disks shared in the clique must be manually replicated to the newly added node before any of the guarded devices on the new node are enabled. This should be done manually using the `voradmin td distribute` command, as described above, by the Teradata administrator as part of joining the cluster.

Interoperability with Host Groups

For Teradata, when you create a new IDT-Capable GuardPoint using the `voradmin idt config xform` command, or when you subsequently rekey an existing IDT-Capable GuardPoint with the `voradmin idt rekey` command, the device must be initialized and guarded on one and only one of the nodes in the cluster. That means the IDT-Capable GuardPoint cannot be part of a client group when an IDT-Capable GuardPoint is created or rekeyed because membership in a client group means that any data transformation on any member of the client group is initiated for that member on all nodes in the client simultaneously. In the case of a Teradata cluster, multiple nodes simultaneously trying to perform data transformation on a particular device can lead to data corruption of all data on the entire device.

After the device has been guarded, or rekeyed, and the metadata files have been replicated to other members of the Teradata clique, then you can then rejoin the client with the client group.

To configure a new device whose host/client is part of a host/client group:

1. Make sure that there is no GuardPoint for the device at the client group level.
2. Designate one of the nodes in the cluster as the node that you will use to initialize the GuardPoint and for the initial data transformation when the device is guarded for the first time.
3. On the designated node, initialize the device using the `voradmin idt config -external xform <device name>` command. For details, see [Initialize and Guard the Database Devices Using the Standard Initialization Method](#).
4. Guard the device on the designated node using an In-Place Data Transformation policy. For details, see [Guard the Devices as IDT-Capable GuardPoints on CM](#).
5. Wait for the data transformation to complete on the host and for CTE to replicate the metadata to the other members of the clique.
6. You can verify that the metadata file has been distributed to the other nodes in the clique by running `md5sum /var/opt/teradata/vormetric/vte-metadata-dir/vormetric/secvm_<device>_metadata` on each node in the clique.
7. Remove the IDT-Capable GuardPoint you added earlier in this procedure.
8. Guard the device through the client group to make sure that all nodes in the cluster recognize it as guarded.

**** To rekey a new device whose host/client is part of a host/client group:****

1. Unguard the IDT-Capable GuardPoint through the client group and make sure that it has been removed from all nodes in the cluster.
2. Designate one of the nodes in the cluster as the node that you will use to prepare the GuardPoint for rekeying

and to perform the data transformation when the device is guarded with the new policy.

3. On the designated node, prepare the device for rekey using the `voradmin idt rekey <device name>` command.
4. On the other nodes in the clique, make sure that the device metadata has been renamed running `ls /var/opt/teradata/vormetric/vte-metadata-dir/vormetric/secvm_<device>_metadata*` on each of the other nodes. On these other nodes, the metadata file for the device should be renamed to `/var/opt/teradata/vormetric/vte-metadata-dir/vormetric/secvm_<device>_metadata_xforming`.
5. Guard the device on the designated node with the In-Place Data Transformation policy that specifies the new key you want to use for the device.
6. Wait for the data transformation process to complete, and then make sure that the metadata for the device has been updated on the other nodes in the clique and the renamed metadata files have been removed. Each node should have identical copies of `/var/opt/teradata/vormetric/vte-metadata-dir/vormetric/secvm_<device>_metadata` and `/var/opt/teradata/vormetric/vte-metadata-dir/vormetric/secvm_<device>_metadata_xforming` should *not* exist on any node.
7. Remove the IDT-Capable GuardPoint that you created earlier in this procedure on the designated node.
8. Guard the device through the client group to make sure that all nodes in the cluster recognize it as guarded.

Best Practices

- Using a of Host/Client Group to Guard Metadata Directories
- Using a Host/Client Group for Guarding Teradata Devices in a Clique
- Best Practice for Preparation for Initial Data Transformation or Rekey

Using a of Host/Client Group to Guard Metadata Directories

Thales recommends that customers use a host group exclusively for guarding and management of the CTE external metadata directories across all nodes in Teradata cluster. (For details about the CTE metadata directory, see [Location of the CTE Private Region](#).)

By using a Host/Client Group, you can apply the same policy to the external metadata directory (`/var/opt/teradata/vormetric/vte-metadata-dir`) on all of the CTE protected nodes in the cluster.

Using a Host/Client Group for Guarding Teradata Devices in a Clique

Thales recommend that customers use a Host/Client Group to guard and manage the devices shared by all CTE protected nodes in a clique. Each clique in the cluster should be associated with a separate Host/Client Group. When configuring the Host/Client Group, the members for that client group are the nodes that belong within a clique in the cluster.

Example 1: If you have a cluster consisting of 4 cliques where there are 2 nodes sharing disks in each clique, you would create 4 Host/Client Groups, one for each clique. In each Host/Client Group, you would add the 2 nodes that are associated with the clique.

Example 2: If you have a cluster consisting of 1 clique where there are 6 nodes sharing disks in the clique, you want to create 1 client group with all 6 members that belong within that clique.

Below is an example of the Host Groups for a cluster consisting of three cliques and one metadata group:

Select	Name	Cluster Group	Description
☐	TD-cluster1-clique-1		host/client group for cluster1 clique-1
☐	TD-cluster1-clique-2		host/client group for cluster1 clique-2
☐	TD-cluster1-clique-3		host/client group for cluster1 clique-3
☐	TD-cluster1-metadata-dir		host/client group for cluster1 metadata

Best Practice for Preparation for Initial Data Transformation or Rekey

With large amounts of data managed in Teradata clusters, duration of initial data transformation and/or subsequent rekey can be very long and challenging because the database must be stopped during the data transformation process. Although you cannot transform data without shutting down the database, you may be able to reduce the transformation time by distributing the transformation of the guarded devices across multiple nodes in your cluster.

Because multiple nodes in a cluster within a clique share access to the same devices, you can designate a subset of devices to each node within the clique for initial data transformation or subsequent rekey. This requires unguarding all of the IDT-Capable devices in the Host/Client Group associated with the clique, and re-enabling each IDT-Capable GuardPoint on the node designated for the data transformation of that IDT-Capable GuardPoint. The device then remains unguarded on other nodes until the data transformation completes.

After the data transformation completes, you can then enable the guarded devices at the Host/Client Group level. Enabling the guarded device at Host/Client Group level enables the guarded devices on all of the nodes within the clique to share access to the device.

After transforming data and guarding each device on all of the nodes, you can then restart the database.

As described in [Interoperability with Host Groups](#), the metadata file for each device is replicated to the hosts in the cluster that share access to the device. As noted, replication of metadata files is automatic.

Uninstalling CTE from the Teradata Cluster

The following procedure describes how to remove CTE from your Teradata cluster. Note that uninstalling CTE will unprotect the pdisk devices that CTE is protecting/encrypting. Because the data on the pdisks remain encrypted after uninstalling CTE, the entire clear-text data must be restored to the pdisks from backup. Therefore, you must have a full backup of your database to restore to your cluster before you uninstall CTE. See the Teradata Administration Guide or your Teradata Customer Support Representative for information about backing up your database in full.

Note

You must be familiar with CTE operations for protecting Teradata clusters and IDT-Capable GuardPoints.

To uninstall CTE:

1. Make sure you have access to a full database backup so that you can restore your Teradata database after uninstalling CTE.
2. Shut down your Teradata database.
3. Use the `secfsd -status guard` command to view the full list of device GuardPoints guarded by CTE on each node of your cluster. From this information, create a consolidated list of GuardPoints with one entry per device in the consolidated list. Note that the devices accessed by the nodes in the same clique are shared devices on each node. The consolidated list must include all devices that are protected in your cluster.
4. Perform the following steps on the CipherTrust Manager:
 - a. Click on the client group name associated with your Teradata cluster and then click the **GuardPoints** tab.
 - b. Select the device names listed in GuardPoints table. The devices listed in GuardPoints table are the same devices listed in the consolidated list of devices compiled in step 3.
 - c. Unguard the selected device GuardPoints on all nodes in the cluster.
 - d. Wait for device status to change from green circle to red circle in the Status column for all the selected devices.
 - e. Select the same devices.
 - f. Click **Unguard** to remove the selected device GuardPoints on all nodes in the cluster.
5. Perform the following steps on one of the nodes of every clique in your cluster:
 - a. Run the `voradmin idt delete` command to delete the IDT-Capable GuardPoint configuration recorded for each device. This command automatically deletes the GuardPoint configuration across the nodes in the same clique.

```
voradmin idt delete <device name>
```

- b. Repeat the previous step on the other devices in your cluster, if any.
6. Go back to the Key Manager and do the following:
 - a. Select the Metadata Directory GuardPoint in the GuardPoints table of the same host group.

- b. Click **Disable** to disable the Metadata GuardPoint directory on every node in the cluster.
 - c. Select the Metadata Directory GuardPoint in the GuardPoints table again and then click **Unguard** to remove the Metadata Directory GuardPoint on all the nodes in the cluster.
7. On every node in the cluster:
- a. Run the following command to stop CTE service on each node:

```
/etc/vormetric/secfs stop
```

- b. Run the following command to uninstall the CTE Agent on each node:

```
/opt/teradata/vormetric/agent/vmd/bin/uninstall
```

To restore a full backup of the database to your cluster, contact your Teradata Customer Support Representative (CSR) to perform System Initializer and do a full restore.

Alerts and Errors

This section lists the alerts and errors that may be encountered during system operations on Teradata Appliance. Refer to Alerts and Errors listed in the chapter on IDT-Capable Device GuardPoints for additional Alerts and Errors.

General Errors

The errors in this section indicate what step failed during CTE system operations for Teradata clusters and will always be paired with an operation error which indicates which CTE system operation failed. For example:

- IDT-TD-ALERT: Node <node name> did not respond to pcl command
- IDT-TD-ALERT: Failed to complete rekey on remote nodes

This pairing of errors indicates that the steps after data transformation were unsuccessful and that the `voradmin` command `voradmin td rekeyed <device name>` is the one that failed.

For details about the `voradmin td rekeyed` command, see the `voradmin` manpage.

IDT-TD-ALERT: Node <node name> did not respond to pcl command

The node listed did not respond to a pcl command to perform an operation.

Solution: Check if the node is still online and responding. If it is, run the `voradmin` command to repeat the failed operation. This error message will always be accompanied by one of the other IDT-TD-ALERTS which will determine which `voradmin` command to run to correct the error.

IDT-TD-ALERT: Node <node name> failed to perform voradmin task

The node listed failed to perform a `voradmin` command invoked through `pcl`.

Solution: Correct the issue blocking `voradmin` and run the `voradmin` command to repeat the failed operation. This error message will always be accompanied by one of the other IDT-TD-ALERTS which will determine which `voradmin` command to run to correct the error.

IDT-TD-ALERT: Failed to find clique for disk <device>

CTE failed to locate the clique for the device specified.

Solution: Verify that `/usr/lib/tmpfiles.d/pdisk.conf` is properly configured on all nodes in the Teradata cluster.

IDT-TD-ALERT: Failed to move or rename IDT-Capable metadata file on remote nodes

This error can be due to two issues; one, metadata files that have been distributed to the remote nodes cannot be moved into the metadata directory, or two, metadata files on remote nodes cannot be renamed in preparation for rekey.

Solution: For the first issue, rerun `voradmin td distribute <node name> <device name>` command once any other problems have been resolved. For the second issue rerun `voradmin td rekey <device name>` to prepare for rekey again once any other problems have been resolved.

For details about the `voradmin td` commands, see the `voradmin` manpage.

IDT-TD-ALERT: Failed to get GuardPoint status on remote nodes

The GuardPoint for the device is still present on the CipherTrust Manager for remote nodes or CTE failed to ascertain the GuardPoint status for remote nodes.

Solution: Verify that the GuardPoint for the device has been removed from the CipherTrust Manager for remote nodes and then rerun the `voradmin` command. This error message will always be accompanied by one of the other IDT-TD-ALERTS which will determine which `voradmin` command to run to correct the error.

Operation Errors

These errors indicate which CTE system operation failed and what command should be run upon resolution of the issue that caused the error.

IDT-TD-ALERT: Failed to distribute IDT-Capable metadata file to remote nodes

CTE failed to copy the IDT-Capable metadata file from the current node to all nodes in the clique.

Solution: Correct any issues blocking `pcl` or `voradmin` and then run `voradmin td distribute <node name> <device name>` to attempt copying the metadata file over to the remote node.

For details about the `voradmin td distribute` command, see the `voradmin` manpage.

IDT-TD-WARNING: Failed to delete IDT-Capable metadata file on remote nodes

CTE was unable to remove the IDT-Capable metadata file for a device from a remote node.

Solution: Run `voradmin idt delete <device name>` on the remote node after correcting issues impeding voradmin. Members of the clique that have successfully removed the metadata file will not be adversely affected if an attempt to remove an already de-configured device occurs.

IDT-TD-ALERT: Failed to complete rekey on remote nodes

CTE was unable to complete the rekey operation on remote nodes to make the device available for guarding again.

Solution: Correct the issue and run `voradmin td rekeyed <node name> <device name>` to signal the remote node that rekey is complete and provide an updated copy of the metadata file to that remote node.

Generating IDT-capable Metadata for Teradata Storage Expansion

Teradata Disk Expansion with IDT-Capable Devices

You can use the `voradmin td expand` command to configure new disks as IDT-capable devices during Teradata disk expansion.

Note

- Guard each new device using the same policy applied to an existing guarded IDT-Capable device.
- Only use this option on new disks added during Teradata disk expansion.

After the new disk is visible to all members of the clique, perform the following steps to configure the new disk:

1. Configure the new disk using the following command on any node in the clique.

```
voradmin td expand <newDiskName> <existingDiskName>
```

Note

Do not run this command on the same device on multiple nodes.

2. Guard the new device on the CipherTrust Manager on all members of the clique.

For disk expansion that includes the addition of a new node to the clique, perform the following steps:

1. Install CTE on the new node and register the node to the CM, but **DO NOT** add the node to the client group, if using one.
2. On the new node, create the CTE Metadata directory, type:

```
mkdir -p /opt/teradata/vormetric/vte-metadata-dir
```

3. On one of the existing nodes in the clique, run the `voradmin td distribute` option to copy all existing metadata to the new node, type:

```
voradmin td distribute < node1 name, node2 name, etc..> <device>
```

4. On the same node selected in step 3, use the `voradmin td expand` option to configure the new disk as an IDT-Capable device, type.

```
voradmin td expand <newDiskName> <existingDiskName>
```

Note

The `td expand` option must be run on each new disk.

5. On CipherTrust Manager, guard the new disk in the client group. You can verify that the new disk is now guarded on all nodes except the new node.
6. On the CipherTrust Manager, add the new node as a member to the client group. Once the new node is added as a member, CipherTrust Manager will push the security policy to the new node and guard all of the disks with metadata files on the new node.

Confidential Computing: Integrating Intel® Tiber™ Trust Services and Intel TDX, with Microsoft Azure or Google Cloud Platform

Note

This feature is not compatible when using CipherTrust Transparent Encryption with CipherTrust Data Security Platform Services (CDSPaaS).

Confidential Computing is a cloud computing technology that can isolate and protect data on Confidential Virtual Machines (CVMs), or Trusted Domains (TDs), while it is being processed by the application, to protect it from a broad range of software attacks. Confidential Computing ensures that all data operations are executed within a Trusted Execution Environment.

Confidential Computing provisioning requires Intel® Tiber™ Trust Services (ITTS), to attest the CVMs, or TDs, and create a Trusted Execution Environment around them. ITTS is a verifier in a remote attestation application architecture. In Remote Attestation procedures, one peer (the "Attester"), produces cryptographic information about itself ("Evidence") to enable a remote peer (the "Relying Party") to decide whether or not to consider that Attester a trustworthy peer. In this case, CipherTrust Manager is the Relying Party.

When using Confidential Computing, CTE/CTE-U and CipherTrust Manager manage the attestation process to provision confidential computing on VMs running on agents to provide End-To-End Data Protection. The role of the confidential computing model is to gather the evidence and provide it to CipherTrust Manager to have it attested for by ITTS. If attestation fails, Confidential Computing prevents access to the encrypted data that it guards.

Requirements & Specifications

System	Description
Attestation Authority	Intel® Tiber™ Trust Services (ITTS)
Agent requirements	- Cloud Service Provider: Azure Cloud and Google Cloud Note Support available for the following. • Azure: Intel TDX (Trust Domain Extension) • Google Cloud: Intel TDX and Intel TDX with

System	Description
	NVIDIA H100 Operating Systems: - CTE - Ubuntu 24.04 - CTE-U - Ubuntu 24.04 - RHEL 9 & 10 Kernels (for CTE): CC is supported on cloud specific kernels. Cloud specific kernel numbers end in: -azure -gcp - See the CTE Compatibility Portal for more kernel compatibility information.
CipherTrust Manager Minimum Version	2.20
CipherTrust Transparent Encryption Minimum Version	7.8.0
CTE-U Minimum Version	10.5.0

Prerequisites

1. Install CipherTrust Manager v2.20, or a subsequent version, on a [virtual](#) or [physical](#) system.
2. Ensure that the clocks on the CipherTrust Manager, the CTE client, and the Intel server are synchronized. If they are not, see [Network Time Protocol Server Configuration](#) for more information.
3. Obtain a valid account for one of the following environments:
 - Microsoft Azure
 - Google Cloud Platform
4. Obtain an Intel® Tiber™ Trust Services account.
5. Install and configure **Microsoft Authenticator** on your mobile phone.

Note

For the purposes of this documentation, Thales has documented use of Microsoft Authenticator as the Multi-Factor Authentication (MFA) program. You can use any MFA application with the portal. See [How to Add Additional Authentication Methods](#) to set up and use an alternative MFA provider.

Creating Keys and Policies in the Intel Portal

1. Open Microsoft Authenticator on your mobile phone. The login requests an authentication code from Microsoft Authenticator to access the site.
2. Login to the Intel Portal.
3. Create an [Attestation API key](#). You can associate it with either a simple policy, or one with an MRTD (Measurement of Trust Domain) value.
 - a. In the navigation bar on the left, click **Manage Policies**.
 - b. Click **Add a Policy**. Follow the on-screen instructions for creating a policy.

Field Name	Value
Attestation Type	TDX Attestation
Policy Type	Appraisal policy with an MRTD value.

Simple Policy

```
default matches_sgx_policy = false
matches_sgx_policy = true
{
  input.tdx_is_debuggable == false
}
```

- c. To find the TDX MRTD value, on the CipherTrust Transparent Encryption agent, type:

```
sudo tpm2_nvread --offset=560 --size=48 -C o 0x01400001 | xxd -p | tr -d
'\n' | awk '{print}'
```

- d. To find the TDX MRSEAM value, on the CipherTrust Transparent Encryption agent, type:

```
sudo tpm2 nvread --offset=312 --size=48 -C o 0x01400001 | xxd -p | tr -d
```

- e. Add the policy that you created in the previous step to your API key.
4. Create an **Admin API Key**.
 - a. In the navigation bar on the left, click **Admin API Keys**.
 - b. Select the View icon () for the API key that you want to copy.
 - c. Select the Copy icon (). The API key is copied to your system memory.
 - d. Alternatively, to create a new API key, click **Delete/Regenerate API Key**.

- e. Use the API key with the Trust Services CTL CLI utility to manage admins and users.

Reference Information

To learn how to create an Intel Trust Services policy, consult the following Intel documentation:

- [Appraisal Policies](#)
- [Author a custom policy](#)
- [Policy builder tool](#)

Provisioning TDX machines

Select to provision TDX machines for either Microsoft Azure or Google Cloud Platform.

Provision a TDX machine from Microsoft Azure

1. Login to the [Azure Portal](#).
2. Open Microsoft Authenticator to obtain an authorization code.

- Enter that Microsoft Authenticator code in the dialog on the [Azure Portal](#) page.
- From the home page of the Azure portal, click **Create Resource**.
- Click **Virtual Machine** > **Create** and follow the on-screen instructions to create a VM.

Field Name	VM Type	Value
Security Type	TDX	Confidential virtual machine
OS Image	TDX	Ubuntu Server 24.xx LTS (Confidential VM) -x64 Gen 2
VM architecture	TDX	x64
Size	TDX	Standard DC4eds_v5 or larger

Note

Secure boot is enabled by default. You can disable it once **confidential VM security type** is selected. A link appears for configuring the security features. Toggle the option for **Enable secure boot** to disable it.

- Click **Review & Create**.

Validate TDX machine

1. List the contents for `/dev/tpm`, type:

```
ls -l /dev/tpm*
```

Result

```
crw-rw---- 1 tss root  10,   224 Aug 14 22:25 /dev/tpm0
crw-rw---- 1 tss tss  253, 65536 Aug 14 22:25 /dev/tpmrm0
```

2. Verify that Intel TDX is activated, type:

```
grep TDX
```

Result

```
[0.902814] Memory Encryption Features active: Intel TDX
```

3. Verify that the TPM (Trusted Platform Module) is valid, type:

```
grep TPM
```

Result

```
[ 0.000000] efi: ACPI=0xbfffa000 ACPI 2.0=0xbfffa014 SMBIOS=0xbff85000 SMBI
OS 3.0=0xbff83000 TPMFinalLog=0xeb39000 MEMATTR=0xbf414018 MOKvar=0xbf402000

```

Install the Trusted Platform Module tools on your Agent VM

- Download the Trusted Platform Module (TPM) tools, type:

```
apt update
apt install tpm2-tools
apt install libnsl2
apt install libatomic1
```

Provision a TDX machine from Google Cloud Platform

Prerequisites

- Obtain an image of **Ubuntu 24.xx LTS**

Use Google Cloud (GCP) to Grant access to all VM instances in a project

- Grant access to all VM instances in a project, type:

```
gcloud projects add-iam-policy-binding thl-ite-d-itecc \
--member: 'group:gcp-ite-itecc@thalescloud.io' \
--role: 'roles/iap.tunnelResourceAccessor' \
--impersonate-service-account automation@thl-ite-d-itecc.iam.gserviceaccount.co
m\
```

Note

Change the thales-related variables to values appropriate for your network.

Reference Information

- Grant access to all VM instances in a project

Check Network (VPC) and firewall flow

Warning

Your network security rules **must** allow public IP for external connection enabled. Otherwise, CTE agent registration may fail.

Create a GCP TDX VM

1. Install the gcloud SDK.

2. Login in and set up the project ID.
3. Create a network, type:

```
gcloud compute networks create tdx-default-network \
--subnet-mode=auto\
--BGP_ROUTING_MODE: REGIONAL\
--IPV4_RANGE: <for-your-network>\
--GATEWAY_IPV4: <for-your-network>
```

4. Create an SSH connection, type:

```
gcloud compute firewall-rules create allow-ssh --network tdx-default-network
--allow tcp:22
```

5. Create the VM, type:

```
gcloud compute instances create tdxvm-cpl-gcp \
--machine-type c3-standard-4 --zone us-central1-a \
--confidential-compute-type=TDX \
--on-host-maintenance=TERMINATE \
--image-family=ubuntu-2404-lts \
--image-project=tdx-guest-images \
--project cpl-tdx-l-tdxpreview-01 \
--subnet "tdx-default-network"
```

6. Connect to the VM with the gcloud sdk, type:

```
gcloud compute ssh tdxvm-cpl-gcp \
--project=cpl-tdx-l-tdxpreview-01 \
--zone=us-central1-a
```

Note

- This should create an ssh key pair. Make sure that the `/.ssh/google_compute_engine.pub` is in your list of allowed ssh keys in your VM google console. (Metadata → SSH Keys).
- If, after you log in, your prompt does not have color, username and machine name, check if the interpreter is `bash` with `echo $0`. If it is not, change it to `bash` with `sudo chsh -s /bin/bash $USER`.

TDX-GCP

CipherTrust Manager Requirements

Create an Attestation Authority Connection

Provisioning Confidential Computing on agents requires one **admin connection** (connection with administrator privileges) and one **non-admin connection** (connection without administrator privileges). The admin connection is necessary to retrieve the policies from the Attestation Authority. CipherTrust Manager uses the connection details to communicate with Intel® Tiber™ Trust Services (ITTS) for agent attestation when a request is received from the agent.

To create the **Attestation Authority** connections:

1. Log on to CipherTrust Manager.
2. In the left nav-bar, click **Access Management > Connections**.
3. Select **+ Add Connection**.
4. In the **Select Connection Type**, click **More**.
5. From the **Select Connection** dropdown, select **Attestation Authority** and click **Next**.
6. In the **General Info** section, enter the **Name** and **Description** for the connection and click **Next**.
7. In **Configure Connection**, create an Admin User Connection by selecting from the following options. Choose European or US for your URLs based on which URL is valid for your account:

Field Name	Country	Value	Description
URL for API method	US	https://api.trustauthority.intel.com	URL for connecting to the Attestation Authority.
	Europe	https://api.eu.trustauthority.intel.com	
	US: AMD	https://api.pilot.trustauthority.intel.com	Pilot for AMD

		urity.intel.com	
Base URL	US	https://portal.trustauthority.intel.com	Base URL for connecting to the Attestation Authority.
	Europe	https://portal.eu.trustauthority.intel.com	
	US: AMD	https://portal.pilot.trustauthority.intel.com	Pilot for AMD
API Key			Provide either the Admin API key, or the Attestation API key, created in ITTS to establish the connection with the Attestation Authority.
Metadata			Provide meta information in the JSON format.

8. Select **Admin User** to create a connection with administrator privileges. Click **Next**.
9. In **Add Products** section, select the **CTE** checkbox.

Note

CTE-U users should also select CTE.

10. Click **Add Connection**.
11. Repeat these steps to create the Attestation connection. **Do not** select Admin User in step 8.

Note

In CipherTrust Manager, select **Access Management > Connections**, click the ellipsis (...) to View, Edit, or Delete the connections..

Create a Global Client Profile

Create a Client Profile to associate with the Attestation Authority connection.

1. In the CipherTrust Manager dashboard, click **Access Management > Client Profiles > Add Client Profile**.
2. Enter **Profile Name** and **Description**.
3. Select **CA Type**: Local or External.
4. Select the respective Local or External CA in **Select <CA Type> CA**.
5. Enter the **Certificate Duration** (in days) for which the CA certificate remains active.
6. Expand the **CONFIDENTIAL COMPUTING** section and add the following details:

Field Name	Value	Description
Attestation Authority Identifier	Intel® Tiber™ Trust Services (ITTS)	
Attestation Connection	Select a non-admin connection	
Admin Connection	Select an admin connection	Note: Admin and non-admin type connections should belong to the same Attestation Authority.
Policy Type	Appraisal policy	These policies are fetched from the Attestation Authority server. You can select appraisal policies.
Policy Names	<policy_names>	Select one or more policies from the drop-down menu.
Cloud Provider	[Azure Google Cloud]	

7. Click **Add/Update Client Profile**.

Create a Registration Token

Create a registration token on the CipherTrust Manager. You must have administrator privileges to create registration tokens.

1. Log on to the CipherTrust Manager GUI as administrator.
2. In the left pane, click **Access Management > Registration Tokens**.
3. On the right, click **Add Registration Token**. The Create New Registration Token wizard displays.
4. Click **Begin** to start token creation. The Configure Token screen displays.
5. (Optional) Specify a **Name Prefix** for the client name. This prefix is used to construct names for clients whose names are not specified during registration with the CipherTrust Manager using this token.
 - If the name prefix is specified as `ks_client`, client names will be constructed as `ks_client#`; for

example, `ks_client1`, `ks_client2`, `ks_client3`, and so on. However, if a client's name is specified during registration, this name prefix is not used for that client.

- If the name prefix is **not** specified, the CipherTrust Manager will construct a *random* name for clients.

6. Set the **Token lifetime**. You **must** include a time unit with it such as:

Token Lifetime Span	Value
10 m	10 minutes
10 h	10 hours
10 d	10 days
unlimited	Never expires

7. Specify **Client Capacity**. This is the maximum number of clients that can be registered using this registration token. The default capacity is **100** clients.
8. Select **Add Profile** and add the client profile that you just created.
9. Click **Create Token**. The Create Token screen displays the generated registration token in **ASCII** and **Base64** encoding. CipherTrust Manager accepts the registration token in ASCII format only.
10. Click **Copy** next to the token to save the copied token. Use this token when registering and migrating clients.

Install and Register CipherTrust Transparent Encryption with a Confidential Computing VM

Prerequisites

Ubuntu Users Only

Before installing Confidential Computing, you must disable the Ubuntu unattended upgrade feature in order to prevent it from automatically upgrading to a kernel version that CipherTrust Transparent Encryption has yet to support. Once the kernel is upgraded, there does not appear to be a method to downgrade it, or choose a compatible kernel version.

To disable the Ubuntu unattended upgrade feature:

1. Type the following command:

```
dpkg-reconfigure unattended-upgrades
```

2. Choose **No** to the question about automatic updates.
3. Verify that the following configuration file shows **0** values, type:

```
cat /etc/apt/apt.conf.d/auto-upgrades
```

Expected Response

```
APT::Periodic::Update-Package-Lists "0";
APT::Periodic::Unattended-Upgrade "0";
```

Install CipherTrust Transparent Encryption

1. Install CipherTrust Transparent Encryption v7.8.0, or a subsequent version, on the VM to which you installed the TPM tools, type:

```
sudo ./vee-fs-7.8.0-88-ubuntuXX-x86_64.bin -y
```

2. During registration, select to enable Confidential Computing.
3. Log on to the host where you will install the CTE Agent as **root**. You cannot install the CTE Agent without **root** access.
4. Copy or mount the installation file to the host system. If necessary, make the file executable with the **chmod** command.
5. Install the CTE Agent. A typical installation uses the following syntax:

```
./vee-fs-<release>-<build>-<system>.bin
```

For example:

```
./vee-fs-7.8.0.88-rh8-x86_64.bin
```

To install the CTE Agent in a custom directory, use the **-d <custom-dir>** option. For example:

```
./vee-fs-7.8.0.88-rh8-x86_64.bin -d /home/my-cte-dir/
```

Note

- If possible, Thales recommends that you use the default directory **/opt/vormetric**.
- Custom directories are **only available** for RHEL and SLES.

- Custom directories are **not available** for COS (Cloud Object Storage).

To view all installer options, use the `-h` parameter. For example:

```
./vee-fs-7.8.0.88-rh8-x86_64.bin -h
```

6. The Thales License Agreement displays. When prompted, type **Y** and press Enter to accept.

The install script installs the CTE Agent software in either `/opt/vormetric` or your custom installation directory and then prompts you about registering the CTE Agent with a key manager.

Welcome to the CipherTrust Transparent Encryption File System Agent Registration Program.

```
Agent Type: CipherTrust Transparent Encryption File System Agent
Agent Version: <Release.build-number>
```

```
In order to register with a CipherTrust Manager you need a valid registration token from the CM.
```

```
Do you want to continue with agent registration? (Y/N) [Y]:
```

7. Type **N** and press Enter to end the installation procedure without registering the CTE Agent with a key manager.
8. Enter **Y** to continue with the registration process. The install script prompts you to enter the host name or IP address of the CipherTrust Manager with which you want to register CTE. For example:

CTE for CipherTrust Manager

```
Do you want to continue with agent registration? (Y/N) [Y]: Y
```

```
Please enter the primary key manager host name: 10.3.200.141
```

```
You entered the host name 10.3.200.141
```

```
Is this host name correct? (Y/N) [Y]: Y
```

CTE for CDSPaaS

```
Do you want to continue with agent registration? (Y/N) [Y]: Y
```

```
Enter the primary key manager host name of the service:
```

```
You entered the host name us1.ciphertrust.dpondemand.io
```

```
Is this host name correct? (Y/N) [Y]: Y
```

Host names:

- **Europe:** ciphertrust.dpondemand.io
- **North America:** us1.ciphertrust.dpondemand.io

Note

The default communication port is 443. If you want to specify a different communication port, enter it with the primary key manager host name in the format: <hostName>:<port#>. For example, 10.3.200.141:8445.

9. Enter the client host name when prompted.

```
Please enter the host name of this machine, or select from the following list.
```

```
[1] sys31186.qa.com
```

```
[2] 10.3.31.186
```

```
Enter a number, or type a different host name or IP address in manually:
```

```
What is the name of this machine? [1]: 2
```

```
You selected "10.3.31.186".
```

10. Enter the CipherTrust Manager registration token, profile name, host group and host description. If you omit the profile name, CipherTrust Manager associates the default client profile with this client.

```
Please enter the registration token: 12345
```

```
Please enter the profile name for this host: My-Profile
```

```
Please enter the host group name for this host, if any:
```

```
Please enter a description for this host: RHEL7 system West Coast Datacenter
```

```
Token : 12345
```

```
Profile name : My-Profile
```

```
Host Group : (none)
```

```
Host description : RHEL7 system West Coast Datacenter
```

```
Are the above values correct? (Y/N) [Y]: Y
```

11. At the hardware association prompt, select whether you want to enable the hardware association feature to prevent cloning. The default is Y (enabled):

It is possible to associate this installation with the hardware of this machine. If selected, the agent will not contact the key manager or use any cryptographic keys if any of this machine's hardware is changed. This can be rectified by running this registration program again. Do you want to enable this functionality? (Y/N) [Y]: Y

12. Type Y to support Filesystem encryption and to choose other features. Type N if you only want to support Ransomware Protection. If you type N, then LDT and COS are not supported.

```
Do you want this host to have Filesystem encryption support enabled on the server? (Y/N) [Y]:
```

13. At the LDT prompt, specify that you want this client to use CTE-LDT by typing Y and pressing Enter:

```
Do you want this host to have LDT support enabled on the server? (Y/N) [N]: Y
```

14. If you are planning to create GuardPoints on NFS shares, enter the name of the LDT Communication Group that this node will join.

```
Enter the LDT Communication Group name: LCG1
```

Warning

The registration token, profile name, client group name and LDT Communication Group name are case-sensitive. If any of these are entered incorrectly, the client registration will not succeed. If the registration fails, click Back in the installer and verify that the case is correct for all entries on this page.

15. The installation checks for Confidential Computing adapter types. If it finds one, it states:

```
The following confidential computing adapter types have been identified.
1. Intel Trust Domain Extensions (tdx)
Do you want this host to have confidential computing enabled? (Y/N) [N]:
```

Type Y to enable Confidential Computing.

16. At the Cloud Object Storage (COS) prompt, specify whether you want this client to use CTE COS.

```
Do you want to configure this host for Cloud Object Storage? (Y/N) [N]:
```

17. Specify if you want to enable Ransomware Protection.

```
Do you want this host to have Ransomware Protection support enabled on the server? (Y/N) [N]:
```

18. CTE finishes the installation and registration process.

```
Generating key pair for the kernel component...done.
Extracting SECFS key
Generating EC certificate signing request for the vmd...done.
Signing certificate...done.
Enrolling agent with service on 10.3.200.141...done.
Successfully registered the CipherTrust Transparent Encryption CTE Agent with
the CipherTrust Manager on 10.3.200.141.

Installation success.
```

19. In CipherTrust Manager, change the client password using the manual password creation method. This password allows users to access encrypted data if the client is ever disconnected from the CipherTrust Manager. For details on changing the password, see the CipherTrust Manager documentation.

Validate Confidential Computing on the CTE Agent for Attestation

1. Verify that your agent is capable of confidential computing, type:

```
sudo /opt/vormetric/DataSecurityExpert/agent/vmd/bin/vmutil -a vmd cc_check
```

Result if validation succeeds

```
This system is capable of confidential computing.
```

Result if validation fails

```
This system is not capable of confidential computing
```

In the UI, CipherTrust Manager displays the term **warning** in the status column and displays a banner message indicating that the Agent failed attestation.

2. If using a policy with an MRTD value, validate that the MRTD value in the policy and on the Agent are the same, type:

```
sudo tpm2_nvread --offset=560 --size=48 -C o 0x01400001 | xxd -p | tr -d '\n' | awk '{print}'
```

It should be the same value as the MRTD value on this file:

```
cat /opt/vormetric/DataSecurityExpert/agent/vmd/etc/attestation.txt
```

Note

Attestations fail when the TCB status becomes out-of-date. Following is an example from the attestation report:

```
"attester_tcb_status": "OutOfDate"
```

Attestations will continue to fail until Azure rolls out a new paravisor with the updated TCB on the VM (This would also mean new measurements, such as the MRTD values, that you will need to update in the attestation policy).

To temporarily workaround this out-of-date TCB issue, remove the following line from the attestation policy:

```
input.attester_tcb_status = "UpToDate"
```

Confidential Computing Policies

There are no special CTE policies for Confidential Computing. Create standard and LDT policies as usual.

Confidential Computing GuardPoints

There are no special GuardPoints for Confidential Computing. Create GuardPoints as usual.

Integrating with Intel® Tiber™ Trust Services and Intel TDX for Confidential Computing

Caution

This feature is a technical preview for evaluation in non-production environments. Details and functionality are subject to change.

Note

This feature is not compatible when using CipherTrust Transparent Encryption with CipherTrust Data Security Platform Services (CDSPaaS).

Confidential Computing is a cloud computing technology that can isolate and protect data on Confidential Virtual Machines (CVMs), or Trusted Domains (TDs), while it is being processed by the application, to protect it from a broad range of software attacks. Confidential computing ensures that all data operations are executed within a Trusted Execution Environment.

Confidential Computing provisioning requires Intel® Tiber™ Trust Services (ITTS), to attest the CVMs, or TDs, and create a Trusted Execution Environment around them. ITTS is a verifier in a remote attestation application architecture. In Remote Attestation procedures, one peer (the "Attester"), produces cryptographic information about itself ("Evidence") to enable a remote peer (the "Relying Party") to decide whether or not to consider that Attester a trustworthy peer. In this case, CipherTrust Manager is the Relying Party.

CipherTrust Transparent Encryption and CipherTrust Manager manage the attestation process to provision confidential computing on VMs running on CTE agents to provide End-To-End Data Protection. The role for CTE in this confidential computing model is to gather the evidence and provide that to CipherTrust Manager to have it attested for by ITTS. If attestation fails, CTE prevents access to the encrypted data that it guards.

Requirements & Specifications

System	Description
Attestation Authority	Intel® Tiber™ Trust Services (ITTS)
Agent Requirements Minimum versions listed. Subsequent versions also valid.	▪ Cloud Service Provider: Azure version 5.19 ▪ Operating System: Ubuntu 22.04 ▪ Kernel: 6.5.0-1025-azure
CipherTrust Manager Minimum Version	2.18
CipherTrust Transparent Encryption Minimum Version	7.7.0

Prerequisites

1. Install CipherTrust Manager v2.18, or a subsequent version, on a [virtual](#) or [physical](#) system.

Note

Ensure that the clocks on the CipherTrust Manager, the CTE client, and the Intel server are synchronized. If they are not, see [Network Time Protocol Server Configuration](#)

2. Obtain a valid account for [Microsoft Azure](#).
3. Obtain an [Intel® Tiber™ Trust Services](#) account.
4. Install and configure **Microsoft Authenticator** on your mobile phone.

Note

For the purposes of this documentation, we have documented use of Microsoft Authenticator as the Multi-Factor Authentication (MFA) program. You can use any MFA application with the portal. See [How to Add Additional Authentication Methods](#) to set up and use an alternative MFA provider.

Provision a TDX machine from Microsoft Azure

TDX is the remote attestation service.

1. Login to the [Azure Portal](#).
2. Open Microsoft Authenticator to obtain an authorization code.
3. Enter that Microsoft Authenticator code in the dialog on the [Azure Portal](#) page.
4. From the home page of the Azure portal, click **Create Resource**.
5. Click **Virtual Machine** > **Create** and follow the on-screen instructions to create a VM.

Field Name	Value
Security Type	Confidential virtual machine
OS Image	Ubuntu Server 22.04 LTS (Confidential VM) -x64 Gen 2
VM architecture	x64

Field Name	Value
Size	Standard DC4eds_v5 or larger

Note

Secure boot is enabled by default. You can disable it once `confidential VM security type` is selected. A link appears for configuring the security features. Toggle the option for `Enable secure boot` to disable it.

6. Click **Review & Create**.

Validate TDX machine

1. List the contents for `/dev/tpm`, type:

```
ls -l /dev/tpm*
```

Result

```
crw-rw---- 1 tss root 10, 224 Aug 14 22:25 /dev/tpm0
crw-rw---- 1 tss tss 253, 65536 Aug 14 22:25 /dev/tpmrm0
```

2. Verify that Intel TDX is activated, type:

```
grep TDX
```

Result

```
[ 0.902814] Memory Encryption Features active: Intel TDX
```

3. Verify that the TPM (Trusted Platform Module) is valid, type:

```
grep TPM
```

Result

```
[ 0.000000] efi: ACPI=0xbfffa000 ACPI 2.0=0xbfffa014 SMBIOS=0xbff85000 SMBI
OS 3.0=0xbff83000 TPMFinalLog=0xbeb39000 MEMATTR=0xbf414018 MOKvar=0xbf402000
INITRD=0xbea62c18                      RNG=0xbffd201
8                      TPMEventLog=0xb6fb3018
[ 0.070902] ACPI: TPM2 0x00000000BFFD3000 000034 (v03 VRTUAL VTPM 00000
001 MSFT 00000001)
[ 0.094058] ACPI: Reserving TPM2 table memory at [mem 0xbffd3000-0xbffd303
3]
```

Reference Information

- Create a confidential VM with the Azure CLI
- Deploy confidential VM with ARM template
- Create confidential VM in the Azure portal

Install the Trusted Platform Module tools on your Agent VM

1. Download the Trusted Platform Module (TPM) tools, type:

```
git clone https://github.com/tpm2-software/tpm2-tools
```

2. Install the Trusted Platform Module (TPM) tools on the CipherTrust Transparent Encryption agent, type:

```
apt install tpm2-tools
```

Creating Keys and Policies in the Intel Portal

1. Open Microsoft Authenticator on your mobile phone. The login requests an authentication code from Microsoft

Authenticator to access the site.

2. Login to the [Intel Portal](#).
3. Create an [Attestation API key](#). You can associate it with either a simple policy, or one with an MRTD (Measurement of Trust Domain) value.
 - a. In the navigation bar on the left, click **Manage Policies**.
 - b. Click **Add a Policy**. Follow the on-screen instructions for creating a policy.

Field Name	Value
Attestation Type	TDX Attestation
Policy Type	Appraisal policy with an MRTD value.

Simple Policy

```
default matches_sgx_policy = false
matches_sgx_policy = true
{
  input.tdx_is_debuggable == false
}
```

- c. To find the TDX MRTD value, on the CipherTrust Transparent Encryption agent, type:

```
sudo tpm2_nvread --offset=560 --size=48 -C o 0x01400001 | xxd -p | tr -d
'\n' | awk '{print}'
```

- d. To find the TDX MRSEAM value, on the CipherTrust Transparent Encryption agent, type:

```
sudo tpm2 nvread --offset=312 --size=48 -C o 0x01400001 | xxd -p | tr -d
```

- e. Add the policy that you created in the previous step to your API key.
4. Create an **Admin API Key**.
 - a. In the navigation bar on the left, click **Admin API Keys**.
 - b. Select the View icon () for the API key that you want to copy.
 - c. Select the Copy icon (). The API key is copied to your system memory.
 - d. Alternatively, to create a new API key, click **Delete/Regenerate API Key**.

Delete/Re-generate API key

API key "**User-Management-API-2**" will be deleted and a new key will be re-generated. You will not be able to utilize the previous key after deleting.

Are you sure you want to delete and re-generate this key?

CANCEL

YES, RE-GENERATE KEY

- e. Use the API key with the Trust Services CTL CLI utility to manage admins and users.

Reference Information

To learn how to create an Intel Trust Services policy, consult the following Intel documentation:

- [Appraisal Policies](#)
- [Author a custom policy](#)
- [Policy builder tool](#)

CipherTrust Manager Requirements

Create an Attestation Authority Connection

Provisioning Confidential Computing on CTE clients requires one **admin connection** (connection with administrator privileges) and one **non-admin connection** (connection without administrator privileges). The admin connection is necessary to retrieve the policies from the Attestation Authority. CipherTrust Manager uses the connection details to communicate with ITTS for agent attestation when a request is received from the agent.

To create the **Attestation Authority** connections:

1. Log on to CipherTrust Manager.
2. In the left nav-bar, click **Access Management > Connections**.
3. Select **+ Add Connection**.
4. In the **Select Connection Type**, click **More**.
5. From the **Select Connection** dropdown, select **Attestation Authority** and click **Next**.
6. In the **General Info** section, enter the **Name** and **Description** for the connection and click **Next**.

7. In **Configure Connection**, create an Admin User Connection by selecting from the following options. Choose European or US for your URLs based on which URL is valid for your account:

Field Name	Value	Description
URL for API method	https://api.trustauthority.intel.com	URL for connecting to the Attestation Authority.
Base European URL	https://portal.eu.trustauthority.intel.com	Base URL for the Attestation Authority.
Base U.S. URL	https://portal.trustauthority.intel.com	Base URL for the Attestation Authority.
API Key		Provide either the Admin API key or the Attestation API key created in ITTS to establish the connection with the Attestation Authority.
Base API European URL	https://api.eu.trustauthority.intel.com	Base URL for API connection.
Base API U.S. URL	https://api.trustauthority.intel.com	Base URL for API connection.

8. Select **Admin User** to create a connection with administrator privileges. Click **Next**.
9. In **Add Products** section, select the **CTE** checkbox.
10. Click **Add Connection**.
11. Repeat these steps to create the Attestation connection. **Do not** select Admin User in step 8.

Note

In CipherTrust Manager, select **Access Management > Connections**, click the ellipsis (...) to View, Edit, or Delete the connections..

Create a Global Client Profile

Create a Client Profile to associate with the Attestation Authority connection.

1. In the CipherTrust Manager dashboard, click **Access Management > Client Profiles > Add Client Profile**.
2. Enter **Profile Name** and **Description**.
3. Select **CA Type**: Local or External.

4. Select the respective Local or External CA in **Select <CA Type> CA**.
5. Enter the **Certificate Duration** (in days) for which the CA certificate remains active.
6. Expand the **CONFIDENTIAL COMPUTING** section and add the following details:

Field Name	Value	Description
Attestation Authority Identifier	Intel Trust Authority (ITTS)	
Attestation Type	TDX Attestation	
Attestation Connection	Select a non-admin connection	
Admin Connection	Select an admin connection	Note: Admin and non-admin type connections should belong to the same Attestation Authority.
Policy Type	Appraisal policy	These policies are fetched from the Attestation Authority server. You can select appraisal policies.
Policy Names	<policy_names>	Select one or more policies from the drop-down menu.
Cloud Provider	Azure	

7. Click **Add/Update Client Profile**.

Create a Registration Token

Create a registration token on the CipherTrust Manager. You must have administrator privileges to create registration tokens.

1. Log on to the CipherTrust Manager GUI as administrator.
2. In the left pane, click **Access Management > Registration Tokens**.
3. On the right, click **Add Registration Token**. The Create New Registration Token wizard displays.
4. Click **Begin** to start token creation. The Configure Token screen displays.
5. (Optional) Specify a **Name Prefix** for the client name. This prefix is used to construct names for clients whose names are not specified during registration with the CipherTrust Manager using this token.
 - If the name prefix is specified as `ks_client`, client names will be constructed as `ks_client#`; for example, `ks_client1`, `ks_client2`, `ks_client3`, and so on. However, if a client's name is specified during registration, this name prefix is not used for that client.
 - If the name prefix is **not** specified, the CipherTrust Manager will construct a *random* name for clients.

- Set the **Token lifetime**. You **must** include a time unit with it such as:

Token Lifetime Span	Value
10 m	10 minutes
10 h	10 hours
10 d	10 days
unlimited	Never expires

- Specify **Client Capacity**. This is the maximum number of clients that can be registered using this registration token. The default capacity is **100** clients.
- Select **Add Profile** and add the client profile that you just created.
- Click **Create Token**. The Create Token screen displays the generated registration token in **ASCII** and **Base64** encoding. CipherTrust Manager accepts the registration token in ASCII format only.
- Click **Copy** next to the token to save the copied token. Use this token when registering and migrating clients.

Install and Register CipherTrust Transparent Encryption with a Confidential Computing Azure VM

Prerequisites

Ubuntu Users Only

Before installing CipherTrust Transparent Encryption, you must disable the Ubuntu unattended upgrade feature in order to prevent it from automatically upgrading to a kernel version that CipherTrust Transparent Encryption has yet to support. Once the Azure kernel is upgraded, there does not appear to be a method to downgrade it, or choose a compatible kernel version.

To disable the Ubuntu unattended upgrade feature:

- Type the following command:

```
dpkg-reconfigure unattended-upgrades
```

- Choose **No** to the question about automatic updates.
- Verify that the following configuration file shows **0** values, type:

```
cat /etc/apt/apt.conf.d/20auto-upgrades
```

Expected Response

```
APT::Periodic::Update-Package-Lists "0";
APT::Periodic::Unattended-Upgrade "0";
```

Install CipherTrust Transparent Encryption

1. Install CipherTrust Transparent Encryption v7.7.0, or a subsequent version, on the VM to which you installed the TPM tools, type:

```
sudo ./vee-fs-7.7.0-48-ubuntu22-x86_64.bin -y
```

2. During registration, select to enable Confidential Computing.
3. Log on to the host where you will install the CTE Agent as **root**. You cannot install the CTE Agent without **root** access.
4. Copy or mount the installation file to the host system. If necessary, make the file executable with the **chmod** command.
5. Install the CTE Agent. A typical installation uses the following syntax:

```
./vee-fs-<release>-<build>-<system>.bin
```

For example:

```
./vee-fs-7.8.0.88-rh8-x86_64.bin
```

To install the CTE Agent in a custom directory, use the **-d <custom-dir>** option. For example:

```
./vee-fs-7.8.0.88-rh8-x86_64.bin -d /home/my-cte-dir/
```

Note

- If possible, Thales recommends that you use the default directory **/opt/vormetric**.
- Custom directories are **only available** for RHEL and SLES.
- Custom directories are **not available** for COS (Cloud Object Storage).

To view all installer options, use the **-h** parameter. For example:

```
./vee-fs-7.8.0.88-rh8-x86_64.bin -h
```

6. The Thales License Agreement displays. When prompted, type **Y** and press Enter to accept.

The install script installs the CTE Agent software in either `/opt/vormetric` or your custom installation directory and then prompts you about registering the CTE Agent with a key manager.

Welcome to the CipherTrust Transparent Encryption File System Agent Registration Program.

```
Agent Type: CipherTrust Transparent Encryption File System Agent
Agent Version: <Release.build-number>
```

```
In order to register with a CipherTrust Manager you need a valid registration token from the CM.
```

```
Do you want to continue with agent registration? (Y/N) [Y]:
```

7. Type **N** and press Enter to end the installation procedure without registering the CTE Agent with a key manager.
8. Enter **Y** to continue with the registration process. The install script prompts you to enter the host name or IP address of the CipherTrust Manager with which you want to register CTE. For example:

CTE for CipherTrust Manager

```
Do you want to continue with agent registration? (Y/N) [Y]: Y
```

```
Please enter the primary key manager host name: 10.3.200.141
```

```
You entered the host name 10.3.200.141
```

```
Is this host name correct? (Y/N) [Y]: Y
```

CTE for CDSPaaS

```
Do you want to continue with agent registration? (Y/N) [Y]: Y
```

```
Enter the primary key manager host name of the service:
```

```
You entered the host name us1.ciphertrust.dpondemand.io
```

```
Is this host name correct? (Y/N) [Y]: Y
```

Host names:

- **Europe:** `ciphertrust.dpondemand.io`
- **North America:** `us1.ciphertrust.dpondemand.io`

Note

The default communication port is 443. If you want to specify a different communication port, enter it with the primary key manager host name in the format: `<hostName>:<port#>`. For example, `10.3.200.141:8445`.

9. Enter the client host name when prompted.

```
Please enter the host name of this machine, or select from the following list.
```

```
[1] sys31186.qa.com
```

```
[2] 10.3.31.186
```

```
Enter a number, or type a different host name or IP address in manually:
```

```
What is the name of this machine? [1]: 2
```

```
You selected "10.3.31.186".
```

10. Enter the CipherTrust Manager registration token, profile name, host group and host description. If you omit the profile name, CipherTrust Manager associates the default client profile with this client.

```
Please enter the registration token: 12345
```

```
Please enter the profile name for this host: My-Profile
```

```
Please enter the host group name for this host, if any:
```

```
Please enter a description for this host: RHEL7 system West Coast Datacenter
```

```
Token : 12345
```

```
Profile name : My-Profile
```

```
Host Group : (none)
```

```
Host description : RHEL7 system West Coast Datacenter
```

```
Are the above values correct? (Y/N) [Y]: Y
```

11. At the hardware association prompt, select whether you want to enable the hardware association feature to prevent cloning. The default is Y (enabled):

It is possible to associate this installation with the hardware of this machine. If selected, the agent will not contact the key manager or use any cryptographic keys if any of this machine's hardware is changed. This can be rectified by running this registration program again. Do you want to enable this functionality? (Y/N) [Y]:
Y

12. Type Y to support Filesystem encryption and to choose other features. Type N if you only want to support Ransomware Protection. If you type N, then LDT and COS are not supported.

```
Do you want this host to have Filesystem encryption support enabled on the server? (Y/N) [Y]:
```

13. At the LDT prompt, specify that you want this client to use CTE-LDT by typing Y and pressing Enter:

```
Do you want this host to have LDT support enabled on the server? (Y/N) [N]: Y
```

14. If you are planning to create GuardPoints on NFS shares, enter the name of the LDT Communication Group that this node will join.

```
Enter the LDT Communication Group name: LCG1
```

Warning

The registration token, profile name, client group name and LDT Communication Group name are case-sensitive. If any of these are entered incorrectly, the client registration will not succeed. If the registration fails, click Back in the installer and verify that the case is correct for all entries on this page.

15. The installation checks for Confidential Computing adapter types. If it finds one, it states:

```
The following confidential computing adapter types have been identified.
1. Intel Trust Domain Extensions (tdx)
Do you want this host to have confidential computing enabled? (Y/N) [N]:
```

Type Y to enable Confidential Computing.

16. At the Cloud Object Storage (COS) prompt, specify whether you want this client to use CTE COS.

```
Do you want to configure this host for Cloud Object Storage? (Y/N) [N]:
```

17. Specify if you want to enable Ransomware Protection.

```
Do you want this host to have Ransomware Protection support enabled on the server? (Y/N) [N]:
```

18. CTE finishes the installation and registration process.

```
Generating key pair for the kernel component...done.  
Extracting SECFS key  
Generating EC certificate signing request for the vmd...done.  
Signing certificate...done.  
Enrolling agent with service on 10.3.200.141...done.  
Successfully registered the CipherTrust Transparent Encryption CTE Agent with  
the CipherTrust Manager on 10.3.200.141.  
  
Installation success.
```

19. In CipherTrust Manager, change the client password using the manual password creation method. This password allows users to access encrypted data if the client is ever disconnected from the CipherTrust Manager. For details on changing the password, see the CipherTrust Manager documentation.

Validate Confidential Computing on the CTE Agent for Attestation

1. Verify that your CTE agent is capable of confidential computing, type:

```
sudo /opt/vormetric/DataSecurityExpert/agent/vmd/bin/vmutil -a vmd cc_check
```

Result if validation succeeds

```
This system is capable of confidential computing.
```

Result if validation fails

```
This system is not capable of confidential computing
```

In the UI, CipherTrust Manager displays the term **warning** in the status column and displays a banner message indicating that the Agent failed attestation.

2. If using a policy with an MRTD value, validate that the MRTD value in the policy and on the Agent are the same, type:

```
sudo tpm2_nvread --offset=560 --size=48 -C o 0x01400001 | xxd -p | tr -d '\n' | awk '{print}'
```

It should be the same value as the MRTD value on this file:

```
cat /opt/vormetric/DataSecurityExpert/agent/vmd/etc/attestation.txt
```

Note

Attestations fail when the TCB status becomes out-of-date. Following is an example from the attestation report:

```
"attester_tcb_status": "OutOfDate"
```

Attestations will continue to fail until Azure rolls out a new paravisor with the updated TCB on the VM (This would also mean new measurements, such as the MRTD values, that you will need to update in the attestation policy).

To temporarily workaround this out-of-date TCB issue, remove the following line from the attestation policy:

```
input.attester_tcb_status = "UpToDate"
```

Confidential Computing Policies

There are no special CTE policies for Confidential Computing. Create standard and LDT policies as usual.

Confidential Computing GuardPoints

There are no special GuardPoints for Confidential Computing. Create GuardPoints as usual.

CipherTrust Transparent Encryption

CTE Agent Live Data Transformation

- Introduction to LDT
- Getting Started
- Installing LDT
- Using LDT
- LDT Administration
- Using LDT with CIFS/NFS shares
- Troubleshooting LDT

Note

File Name Change

The metadata storage (MDS) file name has changed from `::vorm_mds: :_` to `__vorm_mds__`. GuardPoints will automatically rename the MDS file when guarding with a CTE 7.6.0 agent. LDT NFS GuardPoints will rename once all of the hosts, with the same share guarded, have been upgraded.

Introduction to LDT

This section contains the following topics:

- Overview of LDT
- Versioned Keys in LDT
- LDT Policies
- LDT Runtime Flow
- LDT Administrator Roles
- Resiliency

Overview of LDT

CipherTrust Transparent Encryption - Live Data Transformation (LDT) is an optional, separately licensed feature of CipherTrust Transparent Encryption (CTE). With LDT, after enabling a GuardPoint, a Administrator can encrypt, or rekey, GuardPoint data without blocking user or application access to the data. In LDT, *rekey* means decrypting data with the current cryptographic key and then encrypting it with a new cryptographic key. The concept of rekey,

and how LDT rekeys data, is described in this document.

After enabling GuardPoints, LDT performs *initial* encryption or rekeying in the background, unnoticed by users. The data stays live and available. This accelerates CTE deployments and eliminates the need to block application and user access to data during encryption or rekey operations, which can seriously inconvenience users and affect operational efficiency.

With LDT, the Administrator can create a single LDT policy for both initial encryption and subsequent rekeying. The same policy applies to production access and security rules without restricting user or application access to data. Applications have continuity of access to GuardPoint data during LDT.

Warning

To prevent data loss or corruption, you must stop all applications and users that are accessing files inside a GuardPoint before enabling a Live Data Transformation encryption policy for that GuardPoint. Terminating the applications closes all files that are currently being accessed inside the GuardPoint.

Unlike non-Live Data Transformation policies, however, you do not need to keep the GuardPoint offline while data transformation takes place. Instead, you can restart all applications as soon as the GuardPoint has been applied to the host, and CTE will perform the data encryption in the background. This is the only application service downtime required when using LDT.

Note

While LDT is supported on platforms with SELinux enabled in enforcing mode, you may run into interoperability issues with certain SELinux policies that may be enforcing rules against CTE access. If you experience issues running CTE with SELinux enabled, contact your system administrator for assistance. Thales Technical Support will recommend that you disable or change the mode to permissive mode to rule out SELinux when investigating reported issues.

Use Cases

This section provides a summary of typical uses for LDT. The concepts mentioned in this section are described in more detail throughout the rest of this guide.

1. Encrypt unprotected data.

When protecting files in a directory, you must encrypt them. This process is called *initial* data encryption.

2. Convert non-LDT GuardPoints to LDT GuardPoints.

Use when you have existing GuardPoints that are protected with policies created before you started using LDT.\

3. Rekey process.

Changing the key from one version to another version of the same key provides more security. Using LDT, you can change the encryption keys to more secure keys.

-
4. Transform the encrypted data to clear data.

Versioned Keys in LDT

LDT uses *versioned* keys. Each version of a particular versioned key has the same key name and encryption algorithm, but its own unique cryptographic material. That means that data encrypted with version 3 of a key named **LDT-Key** *cannot* be decrypted by any other version of **LDT-Key**, even though the key name remains the same.

Versioning allows you to add one key to your LDT encryption policy and then use different versions of that same key to periodically re-encrypt your data over time. LDT uses the new key material to transform data to the new key version, as part of the same Live Data Transformation policy that also protects the data. The process of re-encrypting data with a new version of the existing key is called *Key Rotation*.

In CipherTrust Manager, you can create a versioned key and then add that key to one or more Live Data Transformation policies. When you use CipherTrust Manager to create a new version of the key, CipherTrust Manager automatically pushes the new key version to any CTE clients associated with the Live Data Transformation policies that contain the key. As soon as the CTE Agent receives the new key, it begins transforming the data to the new key version in the background.

You can also create a Key Rotation Schedule in CipherTrust Manager that automatically rotates your keys periodically. When the scheduled rekey date is reached, CipherTrust Manager automatically creates a new key version and pushes it to any CTE clients that are associated with any policies that include the key. When CTE receives the new key version, it automatically starts the rekey process on the affected LDT GuardPoints.

Rekey | Key Rotation

In LDT, *rekeying* or *key rotation* means decrypting the data with a previous version of the key and re-encrypting it with a new version of the key. LDT allows users and applications to access data while LDT is rekeying the data. Rotating the key and re-encrypting the GuardPoint data with the new version of the key helps to maintain a high level of data security.

Most often, the rekey happens automatically based the Key Schedule defined in CipherTrust Manager, but you can also generate a new version of the key whenever you want to rekey the GuardPoints associated with that key.

LDT Policies

In LDT, you define a single policy for initial data encryption and subsequent rekeying. The policy specifies:

- **Current key**
Associated with data that you want to protect using LDT. This is either a non-versioned key from an earlier policy, or `clear_key`, which means that the data is not currently encrypted.
- **Transformation key**
The versioned key that LDT applies to transform the data from the key used for initial data transformation. When the transformation key rotates, it transforms the data from a previous version of the transformation key to a new version.

Note

Transformation key and versioned key are used interchangeably throughout this document.

As soon as LDT applies the policy to a GuardPoint and enables protection for it, LDT triggers an initial transformation from the current key to the transformation key.

When the transformation key expires, it generates the next version of the versioned key with new cryptographic material. The CipherTrust Manager then pushes the policy to the hosts. The policy now contains the new version of the key. This initiates a rekey process on the GuardPoint to transform data to the new version of the transformation key specified in the policy.

Users and applications can continue accessing data without any interruption during initial encryption and subsequent key transformations.

Note

During LDT policy creation, you must use the Apply Key effect in your policy. If you do not, then end users can see the clear text data until the file is transformed.

LDT Runtime Flow

This section presents an overview of how LDT works and what to expect when LDT is enabled and running in your environment. All of the tasks mentioned here are described in more detail later in this chapter.

First, the administrator completes LDT setup:

1. Upload the LDT license on the CipherTrust Manager.
2. Register LDT hosts with the CipherTrust Manager and be sure that the hosts are licensed for LDT.
3. Create one or more versioned keys.
4. Optionally create a Key Rotation Schedule or add your new keys to an existing schedule.
5. Define Live Data Transformation policies which use the versioned key(s) and contain rules governing LDT operations.
6. Optionally provide Quality of Service (QoS) settings for the LDT hosts. The QoS settings control the:
 - Window of time in which LDT operations are allowed to run.
 - Percentage of CPU resources that LDT can use, or the amount of data to transform according to the QoS setting per the Administrator.

Note

Configuring the QoS settings is highly recommended as a best practice.

When these items are set up, LDT is ready to transform and encrypt data by applying policies to GuardPoints for live initial transformation and subsequent rekeys, as well as enforcement of security rules.

LDT goes through the following phases after the keys and Live Data Transformation policies are defined:

1. Initial data transformation starts

LDT begins when an Live Data Transformation policy is first applied to a GuardPoint or an LDT key is automatically rotated through a key rotation schedule in CipherTrust Manager. When a client that uses the associated policy contacts CipherTrust Manager, CipherTrust Manager sends the new policy, or the the key rotation notification, to the client. (If the same versioned key is used in multiple policies, *all* of the clients associated with the policies that contain the key are notified when the key changes.)

2. New key version triggers a rekey on the affected GuardPoints

On each host/client , CTE determines which GuardPoints are using the key that has just rotated to a new version. CTE starts an LDT rekey on each of those GuardPoints.

On Windows, you must wait for the current key rotation process to finish before you can launch another rekey request. On Linux, if another rekey is already underway on that GuardPoint, the new rekey is queued for later execution. For details, see [Rotating Encryption Keys While a Rekey is in Progress \(Relaunch\)](#).

3. Scan for files

On each GuardPoint where CTE has started a rekey, LDT determines which files to transform. LDT takes inventory of files encrypted with earlier versions of the rotated key and makes a persistent list of the files for transformation.

The scan phase might be interrupted, such as by a host reboot. In this case, when the host reboots and the GuardPoint is enabled again, the scan operation starts over from the beginning.

4. Rekey/Key Rotation

- a. Each file, from the persistent list of files, is decrypted using the old version of the key. The old key is applied to each file and then re-encrypted using the new version of the key. Note that new files created during the LDT process do not need to be rekeyed, as they inherit the new version of the key. Multiple files and multiple regions of files are rekeyed simultaneously.
- b. The LDT extended attribute of each file is updated. (For more about extended attributes, see [LDT Metadata in Extended Attributes](#).)
- c. You can suspend and resume the LDT rekey operation manually, or through the QoS schedule. This manages the impact LDT has on other applications and processes.

If system errors occur during rekeying, such as IO errors or crashes, LDT can manage and recover from them after the system error is fixed.

5. Finish

When all of the required files in the GuardPoint have been rekeyed, the system and storage resources used by LDT are released, except for the storage required for the extended attributes.

LDT creates a rekey report, listing all of the files that were rekeyed. For more information, see [Obtaining a Rekey Report](#).

Upon completion of rekey, the Rekey Status in the GuardPoint Status window of the CipherTrust Manager Console shows Rekeyed.

LDT Administrator Roles

Using LDT requires coordination and collaboration between several different administrators. Security, system, application performance and backup schedules are critical factors that affect planning. It is very important for the **CipherTrust Manager Administrator** to coordinate with the **system administrator** and the **backup administrators**. The following table describes the roles and responsibilities for these administrators.

LDT Administrators

Role	Responsibility	Actions
CipherTrust Manager Administrator	Administers CipherTrust Manager	Coordinates with system and backup administrators. Creates security policies, key rotation schedules, and rules for LDT. Defines Quality of Service settings for LDT, applications, and backups.
System administrator	Administers servers on which CipherTrust Transparent Encryption (CTE) is deployed	Coordinates with the CipherTrust Manager Administrator to create Quality of Service schedule, taking into consideration the backup schedules.
Backup administrator	Manages data backups for data encrypted by CTE	Coordinates with the CipherTrust Manager Administrator to create Quality of Service schedule, taking into consideration the backup schedules.

Resiliency

CipherTrust Transparent Encryption - Live Data Transformation is resilient to many user actions and system occurrences. Since it is designed to run periodically without intervention, it includes various features to provide this resilience.

Before LDT enables a GuardPoint, it checks for any inconsistencies in files that were undergoing rekey at the time when system operations were interrupted. If it finds any inconsistencies, LDT corrects them before it enables the GuardPoint. It should only take a few seconds to identify and correct any inconsistency. On Windows, this process

is delayed until applications access the affected files.

During rekey, if an issue such as an I/O problem or system crash occurs, the resiliency features of LDT ensures the consistency of user data. Such issues can cause an interruption in the middle of a rekey operation. When system operations resume, LDT corrects the problems and then resumes rekeying.

Getting Started

This section contains the following topics:

- [Using LDT](#)
- [Backup/Restore](#)
- [Restrictions](#)

Using LDT

Note

- If you are new to CTE and LDT, read the CipherTrust Manager documentation first to familiarize yourself with the concepts of GuardPoints and Policies.
- Before installing LDT, see the [Linux Kernel Support](#) to verify that your version of Linux is supported.

The following list contains the steps for successfully setting up and using LDT.

1. Install the LDT License on the CipherTrust Manager.

CipherTrust Transparent Encryption - Live Data Transformation is a separately-licensed feature of CTE. Before you can use it, you have to install the license to activate it. LDT is licensed for a specific number of hosts.

For details about licensing, see the CipherTrust Manager documentation.

2. Install the CTE Agent and select the LDT feature during the install. For more information, see [Installing and Registering the CTE Agent Software on Linux](#) or [Installing and Registering the CTE Agent Software on Windows](#).

If the client is already registered with CipherTrust Manager, you can enable LDT on the client through the CipherTrust Manager Console. For more information, see [Enabling LDT on a Protected Host](#).

3. Create Versioned Keys.

LDT uses *versioned keys*. A versioned key rotates to the next version of the key generating new key material automatically without policy change. LDT encrypts data with keys that use encryption standards like AES-256.

This allows data to be re-encrypted without users having to edit the policy.

For more information, see [Keys in LDT \(Versioned Keys\)](#) and [Creating and Viewing Versioned Keys](#).

4. Optionally create a Key Rotation Schedule that will automatically rotate the versioned keys periodically. For more information, see [Creating a Key Rotation Schedule](#).

5. Create LDT Policies.

LDT uses a single Live Data Transformation policy to address both initial encryption and subsequent rekeying. The same policy applies to production access and security rules without restricting user or application access to data. Applications have continuity of access to GuardPoint data during LDT.

For more information, see [Creating LDT Policies](#).

6. Set QoS Settings.

QoS enables administrators to manage and control LDT impact to application workloads by monitoring and controlling the use of host system resources, such as memory or I/O utilization, during CipherTrust Transparent Encryption - Live Data Transformation. Administrators can also choose schedules for data transformation, or manually pause or resume transformation operations.

For more information, see [Quality of Service](#).

7. Create GuardPoints and apply LDT policies to the GuardPoints.

A GuardPoint is a directory in the file system hierarchy, where its contents have a CipherTrust data protection policy applied to it. The CTE Agent intercepts any attempt to access anything in the GuardPoint and uses the policies obtained from the CipherTrust Manager to grant or deny the access attempt. Typically data copied into a GuardPoint is encrypted, and only authorized users can decrypt and use that GuardPoint data.

For more information, see [Creating an LDT GuardPoint](#).

Backup/Restore

Before you enable a GuardPoint with an LDT Policy, make sure that you back up your data.

For more information, see [Backup Requirements](#) and [Backing Up and Restoring LDT GuardPoints](#).

Restrictions

Remember the following restrictions when using LDT:

- LDT does not support nested GuardPoints, where a GuardPoint is contained inside another GuardPoint.
- LDT does not support nested mount points. (Nested mount points refer to filesystems mounted under another mount point). In this case, the GuardPoint is applied only at the top level.

```
/dev/mapper/testvg2-lv1 on /opt/communities type ext4 (rw,realtime)
/dev/mapper/testvg2-lv2 on /opt/communities/zookeeper-communities type ext4 (r
w,realtime)
/dev/mapper/testvg2-lv5 on /opt/communities/zookeeper-communities/data-logs typ
e ext4 (rw,realtime)
```

- For HA clusters, LDT only supports the Asymmetric (active/passive) configuration. LDT does not support Symmetric (active/active) configuration.
- If you want to create LDT GuardPoints on Linux NFS shares or Windows CIFS shares, you must register the host with CipherTrust Manager and add the host to an LDT communication group.
- LDT does not support Auto Raw or Block Device GuardPoints.

Windows Only Limitations

LDT supports GuardPoints on CIFS network shared directories with the following restrictions:

- If any files are opened exclusively by another application, LDT cannot rekey those files until the other applications have released the lock.
- If a backup is taken at the snapshot level, CTE metadata is also backed up. If a restore operation tries to restore CTE metadata, CTE agent does not allow this operation and the metadata restore fails. Do not restore the CTE metadata, or ignore the error from the restore utility, if the CTE metadata restore fails.
- LDT on a ReFS file system runs slowly because of limited support from the Extended Attributes on the ReFS file system.

Note

Customers running older versions of ReFS.sys on Windows Server 2012 R2 should be aware of the memory growth issue encountered by the Thales engineering team. This issue seems to occur only when LDT is running on a large number of files. As the system memory consumption by REFS file system increases, it can eventually make the system unresponsive. This issue does not occur with the recent versions of ReFS file system drivers available on Windows Server 2016. After consulting with Microsoft, they suggest that all customers migrate to Windows Server 2016 if they are using ReFS file.

Protecting local directories and CIFS shares Simultaneously with LDT policies/dev/mapper/testvg2-lv1 on /opt/communities type ext4 (rw,relatime)

```
/dev/mapper/testvg2-lv2 on /opt/communities/zookeeper-communities type ext4 (rw,relatime) /dev/mapper/
testvg2-lv5 on /opt/communities/zookeeper-communities/data-logs type ext4 (rw,relatime)
```

1. Ensure that CTE Windows is running with the **VMLFS** driver.
2. To check the currently installed drivers, type:

```
fltmc
```

3. If the output table contains `vmlfs`, the driver is set properly. If not, type the following, in an administrative command prompt, to switch to the `VMLFS` driver:

```
voradmin config enable vmlfs
```

Note

- The above command requires all directories to be unguarded before switching the driver
- The system requires a reboot after the driver has been changed

Linux Only Limitations

- LDT does not support Linux auto-mounted file systems.
- LDT support is limited to `ext3`, `ext4`, and `XFS` file systems when `user_xattr` mount option is enabled.
- LDT does not support system hibernation (`pm-hibernate`) on Linux hosts where LDT is in use.
- You cannot use LDT and Docker container on the same host.
- You cannot use LDT and OpenShift container on the same host.
- Mounting an NFS mount point within a standard GuardPoint, or LDT GuardPoint, is not supported.

Installing LDT

This section contains the following topics:

- [System Requirements](#)
- [Installing the LDT License](#)
- [Installing and Registering CTE Agent Software on Linux](#)
- [Installing and Registering CTE Agent Software on Windows](#)
- [Setting the Linux Kernel Time Zone](#)
- [Enabling LDT on a Protected Host](#)

System Requirements

CipherTrust Transparent Encryption - Live Data Transformation (LDT) requires the following environment.

Note

See the latest [Compatibility Matrix for CTE Agent](#) for a list of CTE versions and supported operating systems.

CipherTrust Software Requirements

- CTE Agent version 7.0.0 or higher must be installed on every client that you want to protect.
- The CipherTrust Manager with which these clients are registered must be version 2.0.0 or higher.

LDT License Requirements

- One LDT license is required for *each* protected host.

LDT Client Minimum System Requirements

Product	OS	Required Memory (RAM)	CPU
LDT	All OS	16GB for rekeying up to 4 GuardPoints concurrently.	4
		Additional 4GB for every 4 additional GuardPoints rekeying concurrently.	

Calculating Additional Disk Space Requirements

LDT requires a specific amount of disk space in the file system or NFS/CIFS share for each GuardPoint, over and above the space required for the guarded files themselves. LDT uses the additional space to store LDT metadata.

The typical minimum space requirement for a GuardPoint is the number of files in the GuardPoint multiplied by 4K, plus 256MB. To estimate the amount of free file system disk space required for a GuardPoint, type:

```
voradmin ldt space <guardpoint-name>
```

Backup Requirements

- For **Windows**, GuardPoints in local file systems or CIFS shares, the application can use Volume Shadow Copy service (VSS) or robocopy for backup and restore.

- For **Linux**, GuardPoints in local file systems, the backup application must have the capability to back up user-extended attributes. For example, Thales tested LDT with NetBackup. You can also use other applications that can back up user-extended attributes.

Backup Requirements for Linux GuardPoint backup on NFS

- You can only perform a backup or restore on the NFS client designated as the primary client for the GuardPoint. Use backup clients or tools such as tar, rsync, etc. on this client. You can backup or restore individual files, or subdirectories, within a GuardPoint namespace without an Apply Key Effect. However, this excludes MDS files and all LDT private files under `vorm_ldtprivspace`.
- Performing a backup or restore on a non-primary client is not supported and may lead to data and/or LDT metadata inconsistencies, in target files, in the backup image or in the restored files. Attempts to restore files on a non-primary client will be detected and rejected. Refer to section [Encrypted Backup and Restore](#) for additional information.
- File backup/restore can only be executed when the GuardPoint is rekeyed, or in a subsequent rekeying suspended state. File backup should **not** be executed during initial rekeying state.
- For **Linux**, GuardPoints on NFS shares, the normal procedure is to back up the NAS server that serves the NFS clients rather than backing up the individual NFS clients. Because backups on NAS servers are remote from a CTE perspective, it is extremely important that CTE is *not* performing any data transformation in any GuardPoint while the NAS server is being backed up. This includes both initial data transformation and automatic or manual data rekey.

Warning

Make sure that all live data transformation has completed on all NFS GuardPoints before you back up the NAS servers associated with the NFS shares on which those GuardPoints reside. You must also make sure that no automatic rekey tasks will start while the NAS backup is in progress.

Linux-Specific Requirements

- To use LDT on an ext3 or ext4 file system, the block size **must** be 4K. Run `dumpe2fs` to determine the block size of the ext3 or ext4 file systems before using LDT. This limitation does not apply to XFS file systems or NFS shares. You can use LDT on XFS with a block size of 1K or 2K.

Local File System Requirements

- For LDT to work properly on local file systems, the underlying file system must support and enable user-extended attributes. All of the file systems supported by LDT support these attributes. If you are using LDT with ext3 or ext4 mount points, you must explicitly enable the extended attribute mount option by editing `/etc/fstab` and adding the `user_xattr` mount option. In the other file systems supported by LDT, user extended attributes are enabled by default, so you do not have to explicitly enable them.

Example `/etc/fstab` entry for ext3 on Red Hat or SLES:

```
/dev/sdb1 /disk2 ext3 defaults,user_xattr 0 0
```

Example `/etc/fstab` entry for ext4 on Red Hat or SLES 12 (ext4 is not supported on SLES 11):

```
/dev/sdc1 /disk3 ext4 auto,users,user_xattr,exec 0 0
```

For more information about extended attributes, see [LDT Metadata in Extended Attributes](#).

NFS Share Requirements

- For GuardPoints on NFS shares, LDT embeds file specific LDT metadata in the beginning of each file during the initial data transformation phase. The size of each file becomes larger by 4096 bytes to accommodate this required metadata. Both the metadata and the file size increase are hidden from users and applications as long as the GuardPoint remains enabled.
- If a GuardPoint is disabled, the metadata remains in each file and both the metadata and the file size increase become visible to users and applications.

Note

Thales highly recommends that NFS shared directory be mounted with `sync` option.

Supported Applications in Linux

- For all of the supported operating systems for database applications, see the [Compatibility Matrix for CTE Agent](#).

Replication

- `rsync`
- Hardware/software based replication system

SAP HANA Fibre Channel Systems

- SAP HANA is compatible with LDT. See the [Compatibility Matrix for CTE Agent](#).

Windows-Specific Requirements

CIFS Share Requirements

- For GuardPoints on CIFS shares, LDT embeds file specific LDT metadata in beginning of each file during the

initial data transformation phase. This metadata remains hidden to users and other applications as long as the GuardPoint is enabled.

- If a GuardPoint is disabled, the metadata remains in each file and becomes visible to users and other applications.
- The size of each file becomes larger by 4096 bytes to accommodate the required LDT metadata.

Installing the LDT License

LDT installs with the CTE Agent software, but it is a separately-licensed CTE feature. Before you can use it, you have to install the license on the CipherTrust Manager to activate LDT on any CTE clients. LDT is licensed for a specific number of clients.

1. Obtain an LDT license from Thales. You can purchase LDT along with the CipherTrust Manager software or you can add LDT later.
2. Install the license on the CipherTrust Manager.

For details, see the CipherTrust Manager documentation.

To confirm that the LDT license is in effect:

1. In the CipherTrust Manager Applications Page, open the **Admin Settings** application.
2. Click **Licensing** in the left-hand menu bar.
3. Expand the entry for **CTE - Live Data Transformation** in the License table. CipherTrust Manager shows the total number of client licenses in the **Total Clients** field and the total number of licenses used in the **Used Clients** field.

Installing and Registering the CTE Agent Software on Linux

The following prerequisites must be met for CTE to install and register to CipherTrust Manager properly:

Prerequisites

The following prerequisites must be met for CTE to install and register to CipherTrust Manager properly:

- CipherTrust Manager installed and configured. See [CipherTrust Manager Documentation](#) for more information.
- CipherTrust Manager must contain a Client Profile. See [Changing the Profile](#) for more information.
- CipherTrust Manager must contain a registration token. See [Creating a Registration Token](#).
- Optionally, the name of the host group you want this client to be a part of.
- CipherTrust Manager must contain an LDT Communication Group if you will use LDT to guard data over CIFS/NFS shares using LDT policies. See [Managing LDT Communication Groups](#) for more information.

Minimum Hardware Requirements for CTE

The following requirements are the minimum for CTE. When you add LDT, or third-party applications, you need to add more storage and RAM. Refer to the [LDT guide](#) for LDT requirements and the third-party software for their requirements.

Component	CPU	CPU Cores	RAM	Storage (Free Space)
CTE-Windows	Intel/AMD x64 with AES-NI support	4 cores	8 GB	1GB
CTE-Linux	Intel/AMD x64 with AES-NI support	4 cores	8 GB	1GB
CTE-AIX	IBM PowerPC8 or higher	4 cores	8 GB	1GB

Procedure

1. Log on to the host where you will install the CTE Agent as `root`. You cannot install the CTE Agent without `root` access.
2. Copy or mount the installation file to the host system. If necessary, make the file executable with the `chmod` command.
3. Install the CTE Agent. A typical installation uses the following syntax:

```
./vee-fs-<release>-<build>-<system>.bin
```

For example:

```
./vee-fs-7.8.0.88-rh8-x86_64.bin
```

To install the CTE Agent in a custom directory, use the `-d <custom-dir>` option. For example:

```
./vee-fs-7.8.0.88-rh8-x86_64.bin -d /home/my-cte-dir/
```

Note

- If possible, Thales recommends that you use the default directory `/opt/vormetric`.
- Custom directories are **only available** for RHEL and SLES.
- Custom directories are **not available** for COS (Cloud Object Storage).

To view all installer options, use the `-h` parameter. For example:

```
./vee-fs-7.8.0.88-rh8-x86_64.bin -h
```

4. The Thales License Agreement displays. When prompted, type **Y** and press Enter to accept.

The install script installs the CTE Agent software in either `/opt/vormetric` or your custom installation directory and then prompts you about registering the CTE Agent with a key manager.

Welcome to the CipherTrust Transparent Encryption File System Agent Registration Program.

```
Agent Type: CipherTrust Transparent Encryption File System Agent
Agent Version: <Release.build-number>
```

```
In order to register with a CipherTrust Manager you need a valid registration token from the CM.
```

```
Do you want to continue with agent registration?(Y/N) [Y]:
```

5. Type **N** and press Enter to end the installation procedure without registering the CTE Agent with a key manager.
6. Enter **Y** to continue with the registration process. The install script prompts you to enter the host name or IP address of the CipherTrust Manager with which you want to register CTE. For example:

CTE for CipherTrust Manager

```
Do you want to continue with agent registration? (Y/N) [Y]: Y
```

```
Please enter the primary key manager host name: 10.3.200.141
```

```
You entered the host name 10.3.200.141
```

```
Is this host name correct? (Y/N) [Y]: Y
```

CTE for CDSPaaS

```
Do you want to continue with agent registration? (Y/N) [Y]: Y
```

```
Enter the primary key manager host name of the service:
```

```
You entered the host name us1.ciphertrust.dpondemand.io
```

```
Is this host name correct? (Y/N) [Y]: Y
```

Host names:

- **Europe:** `ciphertrust.dpondemand.io`
- **North America:** `us1.ciphertrust.dpondemand.io`

Note

The default communication port is 443. If you want to specify a different communication port, enter it with the primary key manager host name in the format: `<hostName>:<port#>`. For example, `10.3.200.141:8445`.

7. Enter the client host name when prompted.

```
Please enter the host name of this machine, or select from the following list.
```

```
[1] sys31186.qa.com
```

```
[2] 10.3.31.186
```

```
Enter a number, or type a different host name or IP address in manually:
```

```
What is the name of this machine? [1]: 2
```

```
You selected "10.3.31.186".
```

8. Enter the CipherTrust Manager registration token, profile name, host group and host description. If you omit the profile name, CipherTrust Manager associates the default client profile with this client.

```
Please enter the registration token: 12345
```

```
Please enter the profile name for this host: My-Profile
```

```
Please enter the host group name for this host, if any:
```

```
Please enter a description for this host: RHEL7 system West Coast Datacenter
```

```
Token : 12345
```

```
Profile name : My-Profile
```

```
Host Group : (none)
```

```
Host description : RHEL7 system West Coast Datacenter
```

```
Are the above values correct? (Y/N) [Y]: Y
```

9. At the hardware association prompt, select whether you want to enable the hardware association feature to prevent cloning. The default is Y (enabled):

It is possible to associate this installation with the hardware of this machine. If selected, the agent will not contact the key manager or use any cryptographic keys if any of this machine's hardware is changed. This

can be rectified by running this registration program again. Do you want to enable this functionality? (Y/N) [Y]:
Y

10. Type Y to support Filesystem encryption and to choose other features. Type N if you only want to support Ransomware Protection. If you type N, then LDT and COS are not supported.

```
Do you want this host to have Filesystem encryption support enabled on the server? (Y/N) [Y]:
```

11. At the LDT prompt, specify that you want this client to use CTE-LDT by typing Y and pressing Enter:

```
Do you want this host to have LDT support enabled on the server? (Y/N) [N]: Y
```

12. If you are planning to create GuardPoints on NFS shares, enter the name of the LDT Communication Group that this node will join.

```
Enter the LDT Communication Group name: LCG1
```

Warning

The registration token, profile name, client group name and LDT Communication Group name are case-sensitive. If any of these are entered incorrectly, the client registration will not succeed. If the registration fails, click Back in the installer and verify that the case is correct for all entries on this page.

13. The installation checks for Confidential Computing adapter types. If it finds one, it states:

```
The following confidential computing adapter types have been identified.
1. Intel Trust Domain Extensions (tdx)
Do you want this host to have confidential computing enabled? (Y/N) [N]:
```

Type Y to enable Confidential Computing.

14. At the Cloud Object Storage (COS) prompt, specify whether you want this client to use CTE COS.

```
Do you want to configure this host for Cloud Object Storage? (Y/N) [N]:
```

15. Specify if you want to enable Ransomware Protection.

```
Do you want this host to have Ransomware Protection support enabled on the server?
```

```
ver? (Y/N) [N]:
```

16. CTE finishes the installation and registration process.

```
Generating key pair for the kernel component...done.
Extracting SECFS key
Generating EC certificate signing request for the vmd...done.
Signing certificate...done.
Enrolling agent with service on 10.3.200.141...done.
Successfully registered the CipherTrust Transparent Encryption CTE Agent with
the CipherTrust Manager on 10.3.200.141.

Installation success.
```

17. In CipherTrust Manager, change the client password using the manual password creation method. This password allows users to access encrypted data if the client is ever disconnected from the CipherTrust Manager. For details on changing the password, see the CipherTrust Manager documentation.

Installing and Registering the CTE Agent Software on Windows

The following prerequisites must be met for CTE to install and register to CipherTrust Manager properly:

Prerequisites

The following prerequisites must be met for CTE to install and register to CipherTrust Manager properly:

- CipherTrust Manager installed and configured. See [CipherTrust Manager Documentation](#) for more information.
- CipherTrust Manager must contain a Client Profile. See [Changing the Profile](#) for more information.
- CipherTrust Manager must contain a registration token. See [Creating a Registration Token](#).
- Optionally, the name of the host group you want this client to be a part of.
- CipherTrust Manager must contain an LDT Communication Group if you will use LDT to guard data over CIFS/NFS shares using LDT policies. See [Managing LDT Communication Groups](#) for more information.

Minimum Hardware Requirements for CTE

The following requirements are the minimum for CTE. When you add LDT, or third-party applications, you need to add more storage and RAM. Refer to the [LDT guide](#) for LDT requirements and the third-party software for their requirements.

Component	CPU	CPU Cores	RAM	Storage (Free Space)
CTE-Windows	Intel/AMD x64 with AES-NI support	4 cores	8 GB	1GB
CTE-Linux	Intel/AMD x64 with AES-NI support	4 cores	8 GB	1GB
CTE-AIX	IBM PowerPC8 or higher	4 cores	8 GB	1GB

Installation

1. Log on to the host as a Windows user with System Administrator privileges.
2. Copy the CTE installation file onto the Windows system.
3. Double-click the installation file. The InstallShield Wizard for CipherTrust Transparent Encryption opens.
4. Verify the version of CTE you are installing and click **Next**.
5. On the **License Agreement** page, accept the License Agreement and click **Next**.
6. Click **Next** to accept the default folder. When you are done, click **Next**.

Note

- Thales recommends that you install CTE in the default installation directory, `C:\Program Files\Vormetric\DataSecurityExpert\agent\`
- You **must** install the CTE Agent on the same drive as Windows. For example, if Windows is installed on the `C:` drive, you must install the CTE Agent on the `C:` drive.

7. On the **Ready to Install** page, click **Install**. When the installation is finished, the **Install Shield Wizard Completed** window opens.
8. On the **InstallShield Wizard Completed** page, make sure the **Register CipherTrust Transparent Encryption now** option is selected and click **Finish**. The installer opens the [Register CipherTrust Transparent Encryption](#) wizard.

Registration

The following procedure describes how to register the CTE Agent after installation is complete.

Use the `register_host` utility to create certificate requests, exchange certificates between the CipherTrust Manager and the host, to enable ransomware detection, and to register CTE on the CipherTrust Manager. After the host is registered, if you selected to enable file system encryption, you can configure CTE, apply GuardPoints,

or perform database backups. If you selected ransomware protection, you can apply the protection to volumes. Run the `register_host` utility in text mode on a terminal window.

Caution

The default host registration timeout is 10 minutes. If the host is unable to reach the CipherTrust Manager within the allotted period because of an extremely slow network connection, set the `REGISTER_HOST_TIMEOUT` environment variable to extend the registration timeout. The variable value is an integer expressed in seconds. You might also have to extend the default TCP timeout.

1. Log on to the host as a Windows user with administrative privileges.
2. Launch the CTE Registration Wizard using one of the following methods:
 - In the system tray, right click the CipherTrust Lock icon and select **Register Host**.
 - Run `...\register_host.exe -vmd -silent`.
3. Reboot the system. CTE automatically displays the registration wizard if CTE is not already registered.
4. In the Register Host dialog box, verify the host's machine name and click **Next**.

Note

For CipherTrust Data Security Platform Services, the host names of the services are:

- **Europe:** `ciphertrust.dpondemand.io`
- **North America:** `us1.ciphertrust.dpondemand.io`

5. On the **Gathering agent information** page, select one or both of the following options and click **Next**.
 - **File System:** Allows you to protect and encrypt CTE files with policies
 - **Ransomware Protection:** Protects volumes from ransomware
6. On the **Gathering Key Manager information** page, enter the FQDN or IP address of the primary CipherTrust Manager.

The default communication port is 443. If you want to specify a different communication port, enter it with the primary key manager host name in the format: `<hostName>:<port#>`. For example: `10.3.200.141:8445`

When you are done, click **Next**. CTE communicates with the selected CipherTrust Manager to validate what features have been licensed and are available to the CTE Agent.

-
7. On the **Gathering host information** page:

File System

- Specify the host name or IP address of the client. You can select the host name from the drop-down list or type it in the field.
- To prevent cloning, select **Enable Hardware Association**. For details, see [Hardware Association Feature](#).
- If you want to have CipherTrust Transparent Encryption - Live Data Transformation available on the client, select **Enable LDT Feature**. For details on LDT, [CTE Agent Live Data Transformation](#).
- If you want the node to be an [Windows AccessOnly](#) node, select **Enable LDT AccessOnly Feature**.

Ransomware

- Specify the host name or IP address of the client. You can select the host name from the drop-down list or type it in the field.
- To prevent cloning, select **Enable Hardware Association**. For details, see [Hardware Association Feature](#).

When you are done, click **Next**.

8. On the **Gathering registration information** page, enter the following:

File System

- **Registration token**: The registration token for the CipherTrust Manager with which you want to register this host.
- **Profile name**: The name of the profile that you want to associate with this host. This name must match exactly the name of the profile in the CipherTrust Manager. If you do not specify a profile name, the CipherTrust Manager associates the default client profile with this client.
- **Host group** (optional): The name of the client group to which the client will be added.
- **Host description** (optional): A user-defined description of the client. This description will be displayed in the CipherTrust Manager.
- **LDT Communication Group**: If you are planning on using LDT over CIFS/NFS on a CipherTrust Manager, enter the name of the LDT Communications Group that this node will join. See [Adding Clients to an LDT Communication Group](#) for more information.

Ransomware

- **Registration token**: The registration token for the CipherTrust Manager with which you want to register this host.
- **Profile name**: The name of the profile that you want to associate with this host. This name must match exactly the name of the profile in the CipherTrust Manager. If you do not specify a profile name, the

CipherTrust Manager associates the default client profile with this client.

- **Host group** (optional): The name of the client group to which the client will be added.
- **Host description** (optional): A user-defined description of the client. This description will be displayed in the CipherTrust Manager.

Warning

The registration information is case-sensitive. If any of it is entered incorrectly, the client registration will not succeed. If the registration fails, click Back in the installer and verify that the case is correct for all entries on this page.

When you are done, click **Register**. CTE contacts the CipherTrust Manager and attempts to register the client with the specified options. The Register Host dialog box displays a message with the results of the registration request.

If the registration completed successfully, click **Finish**.

9. Restart the client to complete the installation process on the client.
10. After the host has rebooted, you can verify the installation by checking CTE processes:
 - a. In the system tray of the protected host, right-click the CipherTrust Lock icon.
 - b. Select **Status**. Review the information in the **Status** window to confirm that the correct CTE version is installed and registered.
 - If you are using CipherTrust Manager version 2.2 or later, you can now use CipherTrust Manager to administer CTE on the client.

If you are using CipherTrust Manager version 2.1 or earlier, change the client password using the manual password creation method. This password allows users to access encrypted data if the client is ever disconnected from the CipherTrust Manager. For details on changing the password, see the CipherTrust Manager documentation.

Setting the Linux Kernel Time Zone

The Linux kernel contains an internal time structure that may or may not contain time zone information. On system configurations that do not contain time zone information, LDT stores and displays timestamps for rekey beginning and ending in UTC (Coordinated Universal Time) rather than the system's local time zone. If this occurs, the administrator can set the kernel's internal time zone to the local time zone if they desire timestamps in their local time zone.

To set the Linux Kernel time zone information, at boot time type:

```
hwclock --systz
```

The command sets the kernel's time zone to the local time zone and resets the System Time based on the current time zone.

Note

On systems that do not set the time zone by default, existing timestamps for completed rekeys remain in UTC, even if you run `hwclock --systz`. Only timestamps for new rekeys display the local time zone.

Enabling LDT on a Protected Host

When you install CTE on a host, you can enable LDT during the registration process as described in [Installing and Registering the CTE Agent Software on Linux](#). If you have already registered the host with CipherTrust Manager, you can enable LDT in the client entry in CipherTrust Manager.

Note

- The LDT license is valid for a certain number of clients. Once you reach this limit, you can either purchase additional LDT licenses, or reclaim a license by removing an LDT client. For details, see [Removing LDT and Security Encryption](#).
- You cannot disable LDT on a client once it has been enabled.

To enable LDT on an existing host:

1. In the CipherTrust Manager Applications Page, open the **CTE** application and click **Clients** in the left-hand menu bar.
2. Click on the name of the client on whom you want to enable LDT.
3. On the Client Details page, select the **Live Data Transformation** check box, then click **Apply** to enable LDT on the protected host.

Note

After LDT has been enabled for the host, the check box is greyed out because you cannot change this option once it has been set.

Using LDT

- [Creating and Viewing Versioned Keys](#)

- Creating LDT Policies or converting a Standard Policy to an LDT Policy
- Quality of Service
- Creating an LDT GuardPoint
- Rotating Encryption Keys (Rekey)
- File System Operations
- Excluding Files or Directories from Rekey
- Using LDT with SAP HANA Fibre Channel Systems (Linux Only)

Creating and Viewing Versioned Keys

For LDT, you create a versioned key that you can add to any number of Live Data Transformation policies. When you add a new key version, CipherTrust Manager pushes the new version to every CTE client that is associated with any of the Live Data Transformation policies that contain that key.

Use the **Keys & Access Management** application in the CipherTrust Manager Applications Page when creating or viewing versioned keys.

Caution

Make sure that all keys you create for LDT are Symmetric. LDT does not support asymmetric keys.

Creating a Versioned Key

1. Log into the CipherTrust Manager Console as an administrator.
2. From the Products page in the CipherTrust Manager Console, click **Keys** in the left hand pane.

Tip

To navigate to the Products page from anywhere in the CipherTrust Manager Console, click the App Switcher icon in the top left corner.

3. Above the Key table, click **Create a New Key**.
4. Enter a Key Name so that you will be able to find this key easily when you want to rotate it. For example, LDT-Key-1.

Note

- When CipherTrust Manager displays the list of available keys, you cannot filter the list by versioned vs. non-versioned. Therefore, it is especially important to name the key in such a way that you can easily search for it by name.
- Using a standard naming convention will also help if you want to create an automatic key rotation schedule for all your LDT keys.

5. In the **Key Metadata > Groups for Key sharing** section, do the following:

- In the **Search** box, type "cte".
- Add CTE Admins and CTE Clients to the key sharing groups by clicking the green **Add** button. The **Key Shared?** check box is automatically selected and the **Add** button changes to a **Remove** button.
- Below the Groups table, click the **CTE Key Properties** check box.

CipherTrust Manager displays the following options for CTE keys:

- **CTE Versioned:** Specifies that this is a versioned key. Make sure this option is selected.
- **Persistent on Client:** Specifies whether the key is stored in persistent memory on the client.

If this option is selected, the key is downloaded and stored (in an encrypted form) in persistent memory on the client.

If this option is *not* selected, the key is downloaded to non-persistent memory on the client. Every time the key is needed, the client retrieves it from the CipherTrust Manager. This is the default setting.

- **Encryption Mode:** Encryption mode of the key. Choose one of the following for LDT keys:
 - CBC
 - CBC-CS1

Encryption using CBC-CS1 keys is known as enhanced encryption. For details, see the *CTE Agent for Linux Advanced Configuration and Integration Guide* or the *CTE Agent for Windows Advanced Configuration and Integration Guide*.

Note

XTS encryption is not supported for protecting directory-based GuardPoints. Do not select XTS as your

encryption mode.

Groups for Key sharing

Search: cte

Group Names	Key Shared?	
CTE Admins	✓	Remove
CTE Clients	✓	Remove

2 Groups 10 per page

☐ Set as "Versioned Key" for backwards compatibility

☒ CTE Key Properties

☒ CTE Versioned ☒ Persistent on Client

Encryption Mode: CBC CS1

- In the Key Behaviors section at the bottom of the page, clear the **Prevent this key from being exported** check box. If the key cannot be exported, the key will not appear in the keys list when you add the key rule to the policy.

If want the option to delete this key later on, clear the **Prevent this key from being deleted** check box. Use caution when deleting keys, as any data encrypted with that key will be inaccessible if you delete the encryption key.

☒ Prevent this key from being deleted ☐ Prevent this key from being exported

Create Cancel

- Click **Create**. The new key appears in the Keys table.

Viewing Versioned Key Information

- Log into the CipherTrust Manager Console as an administrator.
- Open the **Keys & Access Management** application.

3. Click the **Latest Version Only** check box to show only one entry for each versioned key.
4. Find the key in the Keys table.

Tip

You can filter the list by key name using wildcard searches. For example, if you know that the key name contains "LDT", you can search for `*ldt*`. The search is *not* case sensitive.

If the **Version** for a key is 0, then this is the first version of the key and no key rotation has taken place. If the **Version** is greater than 0, the key has been rotated.

5. To find all versions of a key, click the name of the key in the **Key Name** column. CipherTrust Manager displays the ID, version number, state, and date created information for each version of the key.

Modifying Key Rules

CTE v7.4 (Windows) and CTE v7.6 (Linux), and subsequent versions, allows users to modify the Key Rules while an LDT policy is active and enforced on a client. Users can add new rules and modify the existing rules. The following use case is addressed with this change:

1. Users can prioritize and plan the encryption of large files inside a GuardPoint.
2. User can transform the excluded files by adding new Key Rules.

Warning

While making Key Rule changes, you cannot change the order of the rules, or the encryption key rules applied to the file. If the data encryption keys are mismatched, it may result in data corruption.

Note

Dynamic resource sets for CTE Linux are compatible with CipherTrust Manager v2.14 and subsequent versions.

Creating LDT Policies or converting a Standard Policy to an LDT Policy

LDT uses a single Live Data Transformation encryption policy to address both data transformation and ongoing protection. In contrast, if you do not use LDT, you need a separate policy for initial data transformation, or rekey, and another policy to protect the data while it is in production use. For more information about LDT policies, see

LDT Policies.

To create an Live Data Transformation encryption policy:

1. In a web browser, navigate to the URL of the CipherTrust Manager you want to use and log in with CipherTrust Manager Administrator credentials.
2. If the client you want to protect is registered to the default domain (root), proceed to the next step. If you need to change to a different domain, do the following:
 - a. In the top menu bar, click the domain/user name (default: **root/admin**) on the right-hand side.
 - b. Select **Switch Domains**, then select the domain in which the client is registered.
 - c. The logged in user now shows the new domain name/user name.

3. In the CipherTrust Manager Applications Page, open the **CTE** application.
4. In the left-hand menu bar on the Clients page, click **Policies**.
5. Click **Create Policy**. CipherTrust Manager displays the Create Policy Wizard.
6. On the General Info page, set the following options:

Field	Description
Name	A unique name for the policy. Make sure you use a name that is descriptive and easy to remember so that you can find it quickly when you want to associate it with a GuardPoint. For example: LDT-Policy-West

Field	Description
Policy Type	Select Live Data Transformation.
Description	A user-defined description to help you identify the policy later. For example: LDT policy for the West Coast Datacenter.
Learn Mode	Learn Mode provides a temporary method for disabling the blocking behavior of CTE/LDT policies. While useful for quality assurance, troubleshooting, and mitigating deployment risk, Learn Mode is not intended to be enabled permanently for a policy in production. This prevents the policy Deny rules from functioning as designed in the policy rule set. Ensure that the policy is properly configured for use in Learn Mode. Any Security Rule that contains a Deny effect must have Apply Key applied as well. This is to prevent data from being written in mixed states, resulting in the loss of access or data corruption. Apply Key will have no effect when combined with a Deny rule unless the policy is in Learn Mode.

- Click **Next**.
- On the Security Rules page, define the security rules you want to use.

CipherTrust Manager automatically adds a default security access rule with an action of **key_op** and the effects **Permit** and **Apply Key**. This rule permits key operations on all resources, without denying user or application access to resources. This allows it to perform a rekey operation whenever the encryption key rotates to a new version. This rule is required by LDT, so you cannot edit it, move it, or delete it.

To add additional security rules, click Create Security Rule and enter the requested information. If you want to grant user and application access to files at all times, including during initial LDT and subsequent key rotations, add a security rule with the action **all_ops** and the effects **Permit** and **Audit**.

- On the Create Key Rule page, click **Create Key Rule** and enter the following information:

Field	Description
Resource Set	If you want to select a resource set for this key rule, click Select and either choose an existing resource set or create a new one. Resource sets let you specify which directories or files will either be encrypted with the key or will be

Field	Description
	excluded from encryption with this key.
Current Key Name	Click Select to choose an existing key or create a new one. Current key is the key applied to data that you want to protect using LDT. This is either a non-versioned key from a standard policy or a clear_key. You must use clear_key when data is not currently encrypted. When migrating a standard policy to LDT, you must enter the encryption key from the key rule of the standard policy, as the current key of LDT policy.
Transformation Key Name	Click Select to choose an existing versioned key or to create a new one. Transformation key is the versioned key that LDT applies to transform the data. For the initial transformation, the data is transformed from the Current key, to the Transformation key. If the data is currently encrypted, CTE decrypts it using the key specified in the Current Key Name field and re-encrypts it using the key specified in this field. When rotating the Transformation key, LDT transforms the data from a previous version of the transformation key to a new version.

Note

LDT now supports dynamic resource sets. This means that you can alter the resource set, and the policy will pick up the changed resource set and apply it. However, make sure that you **do not** mix encryption keys in your edited resource set. This will cause corruption.

When you are done specifying key rules, click **Next**.

- On the Confirmation page, review the information you entered and click **Save** when you are ready to save the policy.

The following example shows a simple LDT policy that encrypts clear-text files using a versioned key named LDT-Key-1. The **key_op** and **all_ops** actions in the Security Rules panel grant user and application access to files at all times, including during initial LDT and subsequent key rotations.

1 General Info

Name: LDT-Policy-West

Policy Type: Live Data Transformation

Description: LDT policy for the West Coast Datacenter

2 Security Rules

Resource Set	User Set	Process Set	Action	Effect	Browsing
▶			key_op	permit,applykey	No
▶			all_ops	permit,audit,applykey	Yes

3 Key Rules

Resource Set	Current Key Name	Transformation Key Name	Exclusion Rule
	clear_key	LDT-Key-1_xts	No

Security Rule Ordering for Policies

If you want to enforce restrictions when guarding NFS/CIFS shares using an LDT or standard policy with a **CBC-CS1** key, note the following:

CipherTrust Transparent Encryption embeds the LDT and/or IV (initialization vector) attributes in the first 4K of files for NFS/CIFS shares guarded with an LDT or standard policy with a **CBC-CS1** key. Embedding CipherTrust Transparent Encryption attributes increases the actual file size by 4K. CTE hides that extra 4K when reporting the file size to users, or processes, that access the file with the Apply Key effect.

If you need the actual file size, or read/write access on the embedded header, for backup/restore processes for example, then you need a rule that permits access without Apply Key.

LDT Policies

Example 1: Permits Backup and Restore

A policy that allows backup and restore of encrypted data, clear-text access to certain processes, and denies access to all others:

Order	Resource Set	User Set	Process Set	Action	Effect	Browsing	
▶ 1				key_op	permit,applykey	No	
▶ ☐ 2			backup	all_ops	permit,audit	No	⋮
▶ ☐ 3			authorized processes	all_ops	permit,audit,applykey	No	⋮
▶ ☐ 4				all_ops	deny,audit	Yes	⋮

Rule	Purpose
1	Default LDT rule required for LDT policies.
2	Allows for processes in the backup Process Set to access the real file size and backup the CipherTrust

Rule	Purpose
	Transparent Encryption attributes along with the encrypted file data.
3	Allows for processes in the authorized-processes Process Set to access the clear-text data, but it hides the additional 4K from the CipherTrust Transparent Encryption attribute.
4	Denies all other processes access to the data.

Example 2: Permits access to certain Processes

A policy that only allows certain processes clear-text access but allows all others to see the OS file attributes.

Order	Resource Set	User Set	Process Set	Action	Effect	Browsing	
1				key_op	permit:applykey	No	
2			authorized-processes	all_ops	permit:audit:applykey	Yes	
3				f_md_attr_md_read_r...	permit:audit	Yes	
4				all_ops	deny:audit	Yes	

Rule	Purpose
1	Default LDT rule required for LDT policies.
2	Allows for processes in the authorized-processes Process Set to access the clear-text data.
3	Allows for processes not in the authorized-processes Process Set to read the OS file and directory attributes. Note: Processes that match this rule obtain the file size with the 4K header. If a process that is not in the authorized-processes Process Set needs the file size without the header, then the Apply Key must be present in the Effect or you will need an additional rule granting Apply Key to that specific process. That rule must be defined before this rule.
4	Denies processes not in the authorized-processes Process Set from reading any data from the files.

Standard Policies

Example 1: Permits access to certain Processes

A policy that allows backup and restore of encrypted data, clear-text access to certain processes, and denies access to all others:

Order	Resource Set	User Set	ProcessSet	Action	Effect	Browsing	
1			backup	all_ops	permit:audit	Yes	
2			authorized-processes	all_ops	permit:audit,applykey	Yes	
3				all_ops	deny:audit	Yes	

Rule	Purpose
1	Allows for processes in the backup Process Set to access the real file size and backup the CipherTrust Transparent Encryption attributes along with the encrypted file data.
2	Allows for processes in the authorized-processes Process Set to access the clear-text data, but it hides the additional 4K from the CipherTrust Transparent Encryption attribute.
3	Denies all other processes access to the data.

Example 2: Permits access to certain Processes

A policy that only allows certain processes clear-text access but allows all others to see the OS file attributes.

Order	Resource Set	User Set	ProcessSet	Action	Effect	Browsing	
1			authorized-processes	all_ops	permit:audit,applykey	Yes	
2				file_audit_read_secu...	permit:audit	Yes	
3				all_ops	deny:audit	Yes	

Rule	Purpose
1	Allows for processes in the authorized-processes Process Set to access the clear-text data.
2	Allows for processes not in the authorized-processes Process Set to read the OS file and directory attributes. Note: Processes that match this rule obtain the file size with the 4K header. If a process that is not in the authorized-processes Process Set needs the file size without the header, then the Apply Key must be present in the Effect or you will need an additional rule granting Apply Key to that specific process. That rule must be defined before this rule.
3	Denies processes not in the authorized-processes Process Set from reading any data from the files.

For more information, see [Adding Security Rules](#) in the CipherTrust Manager documentation.

Using Auto Mount with LDT Policies

Auto Mount is supported with LDT policies, with CBC/CBS-CS1 keys, on both NFS and local file systems. It is an option provided for guarding a GuardPoint. When selected, it enables automatic guarding of the GuardPoint when accessed, rather than immediately after policy deployment.

Configuring and Guarding an Automount GuardPoint

1. Add this newly created directory as a GuardPoint on CipherTrust Manager using an LDT policy. A GuardPoint configured with a LDT policy using auto mount must use GuardPoint type: **Auto Directory**. The Auto Mount option is not supported with GuardPoint type: manual. When you select GuardPoint type: Auto Directory in a LDT policy, the Auto Mount option displays.

Create GuardPoint

Policy *

VMFS0DT40-AUTOMOUNT-POL

Select

Type *

Auto Directory

Path *

☒ Enter/Browse Path ☐ Upload CSV

/nfs-oxf-fs1/gp

Browse

 To apply the same GuardPoint settings to multiple paths, type paths in the Path field or specify them using the Browse button. A maximum of 200 GuardPaths can be specified.

Auto Mount

☒

Preserve Sparse Region:

☒

Multifactor Authentication:

☐

Cancel

Create

Note

For GuardPoint type: Auto raw, see [File System Mount Points on Linux](#).

2. Once the GuardPoint displays on the agent, mount the device on the GuardPoint. This should trigger guarding.
3. Verify that the GuardPoint has been enabled, that the policy is in effect, and rekey is in progress.

```
voradmin ldt attr get /nfs-oxf-fs1/gp
```

Example

```
LDT stats: version=7, rekey_status=rekeyed
Number of times rekeyed:          1 time
Rekey start time:                 2025/03/27 07:05:19
Last rekey completion time:       2025/03/27 07:05:19
Estimated rekey completion time:  N/A
Policy key version:               21
Pushed Policy key version:        21
Policy ID:
    6a4b49bd-6f34-4646-ae95-8e60e2824ff6
Data stats:
    total=0.0MB, rekeyed=0.0MB
    truncated=0.0MB, sparse=0.0MB
File stats:
    total=0, rekeyed=0, failed=0
    passed=0, skipped=0, created=0, removed=0, excluded=0
```

4. Verify that all files are rekeyed to completion as per policy key rules.

```
voradmin ldt attr get /nfs-oxf-fs1/gp
```

Example

```
LDT stats: version=7, rekey_status=rekeyed
Number of times rekeyed:          2 times
Rekey start time:                 2025/03/27 07:21:52
Last rekey completion time:       2025/03/27 07:22:14
Estimated rekey completion time:  N/A
Policy key version:               22
```

```

Pushed Policy key version:          22
Policy ID:
    6a4b49bd-6f34-4646-ae95-8e60e2824ff6
Data stats:
    total=1.0GB, rekeyed=1024.0MB
    truncated=0.0MB, sparse=0.0MB
File stats:
    total=1, rekeyed=1, failed=0
    passed=0, skipped=0, created=0, removed=0, excluded=0

```

5. Unmount. The unmount should trigger an unguard of the GuardPoint, the way it does for regular auto mount GuardPoints.

Note

Manually unmounting displays a **busy** error. This is the expected behavior, as the unguard operation is in progress. Once unguard completes, the mount point is unmounted automatically.

Example

```
umount /nfs-oxf-fs1/gp
```

Response

```
umount: /nfs-oxf-fs1/gp: target is busy.
```

Behavior of Auto Mount GuardPoints

After you push a policy on a CTE agent, if you check the status, you'll find that the auto mount GuardPoint is not yet guarded because the guard operation is not yet triggered:

```
secfsd -status guard
```

Response

GuardPoint	Policy	Type	ConfigState	Status	Reason
/nfs-oxf-fs1/gp	VMFS0DT40-AUTOMOUNT-POL	auto mount	guarded	not guarded	Not auto-mounted

In the CTE CLI, Auto Mount is controlled by `autofs`. When `autofs` is enabled, accessing the GuardPoint triggers the guard operation.

Example

```
ls /nfs-oxf-fs1/test
secfsd -status guard
```

Response

```
${gp} Policy Type ConfigState Status Reason
-----
/nfs-oxf-fs1/gp VMFS0DT40-AUTOMOUNT-POL auto mount guarded guarded N/A
```

Note

When adding the auto mount GuardPoint, the mount point should be unmounted. If the mount point is mounted with auto mount, then you must manually **unmount** the mount point so that the next time the mount point is accessed, secfsd will guard the GuardPoint.

Running Recovery on Automount GuardPoint with LDT policy

When a system crashes during an active rekey operation, the GuardPoint may enter a state that requires recovery.

```
secfsd -status guard
```

Response

```
GuardPoint      Policy      Type      ConfigState  Status      Reason
-----
/nfs-oxf-fs1/gp VMFS0DT40-AUTOMOUNT-POL automount  unguarded   not guarded  GuardPoint needs LDT recovery
```

The GuardPoint is not guarded, displays the GuardPoint status, and aborts the guard operation, while leaving the mount point mounted. This enables the admin to manually run the `voradmin ldt recover` command.

```
voradmin ldt recover /nfs-oxf-fs1/gp
```

Response

```
Enter YES to disregard failures in LDT recovery as the result of inconsistencies
in underlying file system -> YES
/nfs-oxf-fs1/gp - recovered without failure(s) - status 1
/nfs-oxf-fs1/gp - GuardPoint rkea flags 10032
Unmounted Automount GuardPoint /nfs-oxf-fs1/gp
```

After recovery, the auto mount mount point is unmounted, and the admin is prompted accordingly.

Collecting Agent Information

- Do not use `voradmin ldt list all` with the `-force-mount` option. This could create more issues.
- Change the GuardPoint type from `automount` to `manual` to enable the GuardPoint and collect the Agent information.

Limitations

- CTE does not support nested GuardPoints with auto mount enabled
- Auto mount with LDT policies only supports `auto-fs` mount points.
- The GuardPoint path must be at the same level as the mount point when enabling auto mount on an `autofs` mount point. This ensures that auto mount unguards when the `autofs` mount point times out. If the GuardPoint path is set at any level deeper than the configured `autofs` mount point, the `autofs` mount point will never timeout because the GuardPoint will continue to keep the mount point in a busy state.
- CTE **does not** remove the shadow directory created after unmount.
- CTE **does not** support auto-fs configured using direct mount with an LDT policy.
- CTE **does not** support `systemd automount` with an LDT policy.

Quality of Service

- Purpose of QoS
 - Manage LDT Impact
 - Monitor and Control CPU Usage
 - Monitor and Control Rekey/Scan I/O Rate
- QoS Scheduling During Backup/Restore

LDT runs in real time, while users actively interact with applications. This could impact performance. However, LDT is designed to not adversely affect application or system performance.

Purpose of QoS

Quality of Service (QoS) provides tools for an administrator to minimize the effect of LDT on system and application performance. It provides a set of parameters that administrators can set to control LDT use of system resources, primarily CPU and I/O bandwidth. When the QoS parameters are set appropriately, LDT stays within the defined boundaries to ensure that critical user applications are not adversely affected by LDT operations.

Manage LDT Impact

Administrators can pause or resume LDT operations to manage and control LDT impact to application workload. When data transformation occurs, either during initial or subsequent transformations, it requires substantial host CPU and I/O resources. This can cause contention for resources between the applications simultaneously running on the protected host. The administrator specifies QoS settings on each host, or at a host group level, that is using LDT. When LDT is running, QoS monitors CPU or rekey/scan rate on the host and enforces the QoS settings. QoS can also monitor and enforce an administrator imposed limit on the volume of data undergoing rekey per second. The QoS settings enable you to strike a balance between completing an LDT process and not interfering with host application performance.

Monitor and Control CPU Usage

QoS monitors and controls the use of host system resources during LDT, specifically, CPU usage and rekey/scan rate.

Note

You can control CPU usage or rekey/scan I/O rate, but not both. The CPU usage and rekey/scan I/O rate options are mutually exclusive.

Monitor and Control Rekey/Scan I/O Rate

You can choose Rekey I/O Rate as a threshold to control the LDT processing rate. When this threshold is entered, the Quality of Service continuously monitors LDT transformation and enforces the specified amount of data during:

- **Rekeying:** LDT is transforming the data on active GuardPoints based on the new key version.
- **Scanning:** LDT is analyzing files in GuardPoints. Scanning occurs:
 - Before initial transformation (Linux only)
 - Before a rekey (Linux only)
 - Following an interrupted rekey, such as a reboot on Linux or Windows, and also a directory rename or directory deletion on Windows

You can set the Rekey I/O Rate or CPU Threshold for multiple clients through the QoS Settings section in a CipherTrust Manager client profile. All clients associated with a given client profile will use the QoS thresholds set in that profile unless the thresholds are overridden locally on the individual client. (The default setting for Rekey I/O Rate in the client profile is 0 (zero), which means QoS will run full throttle.)

To set the QoS thresholds locally on a particular client, use the `voradmin ldt ior and <iorate>` command on that client. When you do so, the `voradmin` setting overrides the Rekey I/O Rate or CPU Threshold set in the CipherTrust Manager client profile. If QoS was already set locally on this client and you use `voradmin` to set the Rekey I/O Rate, LDT ignores any CPU threshold previously set.

To resume using the client profile QoS values for a client, use `voradmin ldt ior 0` to set the Rekey I/O Rate to 0 (zero). When you do so, CTE returns to using the Quality of Service settings in the client profile.

A tolerance level is associated with the Rekey I/O Rate. Together, the tolerance and Rekey I/O Rate specify a range for the LDT processing rate. The Quality of Service selects a proper tolerance for a Rekey I/O Rate provided through the `voradmin` command, and maintains the LDT processing rate at the specified Rekey I/O Rate plus or minus the tolerance. The tolerance is selected as follows:

- When the Rekey I/O Rate is less than or equal to 10MB/sec, the tolerance is 3MB/sec.
- When the Rekey I/O Rate is greater than 10MB/sec. and less than 50MB/sec, the tolerance is 4MB/sec.
- When the Rekey I/O Rate is at 50MB/sec or higher, the tolerance is 10% of the specified Rekey I/O Rate.

To set or reset Rekey I/O Rate on a single host, use the `voradmin` command as follows:

- To set the threshold of 50 MB/sec., use the following command:

```
voradmin ldt ior 50
```

- To reset the current threshold:

```
voradmin ldt ior 0
```

For more information about setting the Rekey I/O Rate using `voradmin`, see [Select and Set Rekey I/O Rate](#).

QoS Scheduling During Backup/Restore

QoS scheduling plays an important role when backing up/restoring data without the *Apply Key* rule applied to the backup/restore process. During backup/restore, you **must** pause LDT operations before taking backups. QoS scheduling allows the administrator to enter the schedule for QoS aligned with the backup schedule, and pause the LDT processes for the duration of the backup. The schedule specifies which days of the week, and what times of day, LDT is permitted to run. LDT cannot run at any time that is not permitted by the QoS schedule. QoS suspends LDT operations at all times outside of the schedule.

When setting a QoS schedule, consider your system and application peak demand periods during the day and week. Also consider your schedule for data backups. Schedule LDT to pause when you need all available system resources for other tasks, such as meeting peak user demand or performing data backups.

Note

On Windows, if your backup applications are using VSS, then you do not need to pause LDT on Windows.

How to Set QoS

To set QoS for a host to enforce a threshold on LDT based on CPU percentage:

1. Log into the CipherTrust Manager Console as an administrator.
2. Open the **CTE** application.

3. In the left-hand menu, select click **Profiles**.
4. If you want to add a new profile, click Create Profile and specify a profile name and description.
5. Click the profile name in the **Profiles** table.
6. Click the Quality of Service Configuration section heading to open the QoS options and select one of the following radio buttons:
 - **Rekey by Rate** — Specifies that you want to set a Rekey I/O Rate threshold. Enter a value between 0 and 100 in the associated **LDT QoS Rekey Rate** field. If you specify 0, CTE does not throttle the LDT rekey or scanning processes.
 - **Rekey by CPU**— Specifies that you want to set a CPU Rate threshold. Enter a value between 0 and 99 in the associated **CPU Percentage** field.

If you select this option, LDT applies a tolerance of +/- 2% on CPU threshold settings up to 7%. For threshold over 7%, LDT applies a tolerance of +/- 4%.

If CPU% is set to 0, QoS stops monitoring CPU usage and LDT operations run at maximum rekey rate within the available system resources. Setting CPU percentage to 0 does not affect LDT schedules, so LDT operations are suspended and resumed per QoS schedule.

If you do not enter CPU threshold percentage, LDT applies CPU threshold of 5% capped by default.

If CPU% is set to a very high value, such as 25%, the rekey process competes with other applications to use as many CPU cycles as it can. As a best practice, start with a setting of 10%, and increase or decrease it slowly by 5% until it reaches a reasonable level that does not adversely affect the performance of user applications. The higher the percentage, the more quickly LDT completes its processing. However, this speed causes increased competition for resources, which can significantly degrade the performance of other applications using this host.

Caution

Do not set CPU% to a very high value in an attempt to force faster data transformation. This can potentially exhaust other system resources.

When you select **Rekey by CPU**, the **Cap CPU Allocation** check box becomes available. Check this box to specify that the CPU allowance must never exceed the percentage set in CPU%. If **Cap CPU Allocation** is not checked, and additional CPU resources are available on the host, LDT consumes part of the available resources for rekey above the CPU threshold. Exceeding the threshold may impact your production workload as your production CPU resource consumption fluctuates over time.

For example, if CPU% is set to 10%, but **Cap CPU Allocation** is not set, the rekey process continues consuming available CPU cycles after reaching 10% CPU utilization, at which point the rekey process

starts contending with applications for CPU cycles.

7. In the QoS Schedules section, select the schedule you want to use from the **LDT QoS Schedule** drop-down list. This list includes the following options:

- ANYTIME
- WEEKNIGHTS
- WEEKENDS
- CUSTOM

If you select anything other than CUSTOM, CipherTrust Manager displays the time ranges in which LDT can run in the **Time Ranges** column. If you select CUSTOM, you can then click the **Create New QoS Schedule** button to create a custom schedule. Add one custom schedule entry for each time range in which you want QoS to run.

By limiting LDT to periods of low application usage, you minimize the potential for resource contention between applications and LDT.

The following example shows a profile with the CPU threshold capped at 10%. The QoS schedule is set for 1 am to 4 am on Mondays, Wednesdays, and Fridays.

QoS Best Practices

This section gives tips and examples to help you set QoS parameters for the best results.

Related Topics

- [General Best Practices for QoS](#)
- [Select and Set Rekey I/O Rate](#)

General Best Practices for QoS

- Use Rekey I/O Rate threshold to limit LDT impact, if any, to your production workloads. Rekey I/O Rate approach is a simpler method for a Administrator or system administrator to enforce a limit on the volume of data that LDT should rekey per second. You can choose a threshold, in units of MBs per second, which is a small percentage of peak IOPS from your production workload.

Note

When choosing a threshold on CTE protected hosts with GuardPoints over NFS/CIFS shares, you must consider network bandwidth between your host and NFS/CIFS servers. QoS does not monitor the impact of LDT operations on network connections between your hosts and NFS/CIFS servers. However, the rate selected as LDT Rekey IO rate directly correlates to the network bandwidth to the target NFS/CIFS servers. In the follow-up discussions for selecting optimal rekey IO rate, you must monitor and collect the network traffic instead of disk IO transfers.

- You will see the effects of QoS settings only if the number and/or types of files in the GuardPoints stress the rekey or scan processes. On hosts with a relatively small number of files, the rekey or scan process may complete quickly without hitting a threshold and causing throttling to occur.
- Use QoS CPU parameters as an alternate method for controlling the effect LDT has on application performance.

Set limits on LDT CPU usage whenever runtime monitoring shows that user applications are affected by LDT. Start by setting the CPU parameter to 10%, then increase or decrease in 5% intervals, as needed, to tune the CPU allocation. When an acceptable level is reached, and LDT is not noticeably affecting user applications, leave the QoS CPU parameters at a constant setting.

- Use monitoring tools.

Monitor host CPU utilization with tools like `vmstat`, `top`, and `iostat` on Linux and `perform` on Windows.

You can also monitor and obtain statistics with the `voradmin ldt stats` command.

For more information about `voradmin ldt stats`, see [Obtaining LDT Statistics at the Command Line](#).

- Select CPU resource allocation for LDT from 1% to the available limit minus 5%.

If the monitoring tools indicate system CPU usage, without LDT, it is at N%, available CPU resource is M%, where $M = 100 - N$. Select a percentage within $1 - (M - 5)$ to allocate to LDT CPU usage. However, remember that QoS tolerates 2% - 4% leeway in the actual CPU usage, so adjust your selection by 2 - 4%.

- Do not set CPU resources to 0% or 99% in an attempt to minimize or stop LDT

A CPU% value of 0 or 99 is reserved for disabling the QoS CPU monitoring function. This does not stop LDT or minimize its resource usage; rather the opposite. It enables LDT to run with its maximum rekey rate. Note that when CPU % is not set, LDT clients enforce a 5% CPU threshold by default.

- Cap the CPU allocation.

QoS provides a **CAP CPU Allocation** parameter. Set this parameter to **True**. This ensures that LDT resource usage never exceeds the allocated percentage.

Example: Setting QoS before starting LDT

You can be proactive and set up QoS parameters before enabling GuardPoints that are protected with LDT policies. This ensures QoS starts monitoring and controlling LDT resource usage from the start. The following graph shows an example where 10% of the CPU is assigned to LDT. QoS makes sure that LDT is restricted to use only 10% of the CPU. There is a tolerance level of +/- 4%, so actual LDT usage can range between 5% and 15% of CPU. In the following example, applications use 75% of the CPU resources. As the graph shows, when LDT starts, application CPU utilization drops for a moment, because LDT exceeds the CPU threshold. QoS immediately reduces LDT's CPU usage to 12%, which is within tolerance levels for a 10% setting, and the application CPU share returns to normal.

QoS makes visible improvement immediately when LDT starts

The graph above was obtained on a Linux system running sysbench.

- To find the amount of CPU resources currently in use by applications, type:

```
top -n 1 -b | grep sysbench | awk 'BEGIN {cpu=0} {cpu += $9} END {print cpu}'
```

- To find the amount of CPU currently in use by the LDT-protected host, type:

```
top | grep Cpu
```

- To find the amount of CPU currently in use by LDT, type:

```
voradmin ldt stats | grep CPU
```

Example: Monitoring and controlling resource usage during LDT

Suppose that LDT has started with CPU set to 25%, and users realize their applications are affected. For example, there might be a higher than expected level of LDT I/O operations. To return application performance to normal, reduce the CPU allocation for LDT.

- Set the **CPU parameter** to a lower value, such as 10%.
- Select the **Cap CPU Allocation** option.

QoS restricts LDT CPU usage to 10%. The application user should monitor their application. If the application's performance is still affected, reduce the CPU parameter further, such as to 5%. Repeat this procedure until application performance returns to a satisfactory level.

The following graph shows an example where QoS is not enabled to monitor and control LDT CPU usage from the start. When LDT starts, application CPU usage drops from 65% to 20%. By setting the QoS CPU parameter to 10%, application usage is greatly improved.

CPU usage allocation before and after QoS CPU parameter is set

Example: How QoS CPU settings affect I/O bandwidth

Controlling CPU utilization indirectly controls I/O bandwidth. When LDT is consuming less CPU resources, it is usually performing fewer operations of all kinds, including input and output.

The following graph shows how an application's I/O throughput is affected by LDT, and how QoS can reduce this effect through monitoring and controlling the LDT CPU resource usage.

This graph is from the same system described in [Example: Monitoring and controlling resource usage during LDT](#). No QoS parameters are set at first. When LDT starts, application I/O drops from more than 600 MB per second to below 30 MB per second. By setting the QoS CPU parameter to 10%, the LDT I/O operations drop to below the

application's ability to perform so application I/O operations is greatly improved.

I/O operations before and after QoS CPU limit is set

To obtain the data for this graph:

- Use `iostat` and benchmarking tools on an RHEL system to obtain application I/O throughput.
- Use `voradmin ldt stats` to obtain the LDT I/O throughput and rekey rate.

Select and Set Rekey I/O Rate

You can choose to set the Rekey I/O Rate to control I/O operations from LDT to minimize LDT impact to your production workload. It's assumed that you already know the maximum IOPS on your host system during your production workload. With this information, you can choose a threshold for Rekey I/O Rate and enforce the selected threshold during CipherTrust Transparent Encryption - Live Data Transformation. The work flow is as follows:

1. Set **Rekey I/O Rate** threshold using `voradmin` or in the CipherTrust Manager Console.
2. QoS retrieves the threshold and starts monitoring and controlling LDT according to the specified threshold and the tolerance factor corresponding to the threshold.
3. The selected threshold will be in effect within 2 to 4 minutes after entering the threshold.

When Rekey I/O Rate and CPU or IOWAIT thresholds are set, QoS will monitor and control the LDT processing rate based on the Rekey I/O Rate threshold. The CPU threshold will be ignored.

Set Rekey I/O Rate Threshold

1. Set **Rekey I/O Rate** threshold by using `voradmin`:

```
voradmin ldt ior 10
```

You can also set the Rekey I/O Rate for one or more managed hosts using the Quality of Service section in a client profiles. For more information about using this method, see [How to Set QoS](#).

In the `voradmin` example above, QoS enforces the threshold of 10MB/sec with the tolerance of +/- 3MB/second. Effectively, LDT attempts to rekey the amount of data in the range of 7MBs/second to 13MB/second.

On Linux and Windows, you can use `voradmin ldt ior` to report the current threshold setting without specifying a value for threshold:

```
voradmin ldt ior
QoS Rekey I/O rate threshold: 10 MB/sec
QoS Rekey I/O tolerance: 3 MB/sec
```

2. Be sure the threshold you enter is appropriate for your production workload. To verify this:

a. Observe the Rekey I/O Rate for a few minutes using `voradmin`.

On Linux, you can do this using:

```
voradmin ldt stats
Host level statistics:
File stats: rekeyed=202390, passed=0, created=0, removed=0
Data stats: rekeyed=6.2GB, truncated=0.0MB
QoS: IOR threshold=10MB/sec, tolerance=3MB/sec
current_rekey_rate=2MB/sec, current_iow=0ms
load_factor=50, delay_factor=0, delay_scan=0
```

On Windows, you can do this using:

```
voradmin ldt monitor
Host Stats:
Total number of Guard Points    = 1
Rekey Status                    = Rekey done (Finished rekey on 1 out of 1 G
P's)
Total files to be transformed   = 0
Total files transformed         = 0
Total files in progress        = 0
Total transformation threads    = 0

Current rekey rate              = 0 KB/s
Rekey IO rate threshold        = 1000 MB/s
Rekey IO rate tolerance        = 4 MB/s
```

b. Set an appropriate threshold. Do not set the threshold value too high, as QoS might not be able to achieve it because of other resource bottlenecks.

3. Check the QoS controlling rekey rate.

QoS will monitor and control LDT utilization using the specified threshold. The following figure shows an example of how QoS monitors and controls LDT utilization. In this example, the threshold is 30 MB/sec. Throughput of LDT was nearly 130 MB/sec. QoS brings it down to within the range of 30 MB/second.

4. Disable QoS.

QoS will not monitor and control resources when all the thresholds, CPU, Rekey I/O rate, and IOWAIT are set to 0. When Rekey I/O Rate and IOWAIT are not explicitly set, it is considered to be set to 90 MB/second.

QoS continues to apply its schedules for suspending LDT operations at certain days and times regardless of what values are set for CPU, Rekey I/O Rate, and IOWAIT thresholds.

Summary of QoS Resources

The following table summarizes the available thresholds and the actions of QoS module to enforce the set thresholds:

Scenario	QoS Action
Only Rekey I/O Rate threshold is set	Monitor and control the LDT processing rate based on Rekey I/O Rate
Rekey I/O Rate and CPU threshold are set	Monitor and control the LDT processing rate based on Rekey I/O Rate. CPU threshold is ignored.

Creating an LDT GuardPoint

After you have installed the license and registered the LDT host (see [Installing LDT](#)), you can create an LDT GuardPoint on the host. When you create the LDT GuardPoint, you select a Live Data Transformation policy and apply that policy with its transformation keys to that GuardPoint. CTE automatically gets the Quality of Service settings from the associated Client Profile in CipherTrust Manager.

This section describes two scenarios:

- [Creating an LDT GuardPoint for an Unguarded Directory](#)
- [Converting a Standard GuardPoint to an LDT GuardPoint](#)

Creating an LDT GuardPoint for an Unguarded Directory

To create an LDT GuardPoint on what was previously an unprotected/unguarded directory:

1. Create an Live Data Transformation policy that transforms data from clear text to a versioned key. In the policy, set Current Key to `clear_key` and Transformation Key to the versioned key. For details, see [Creating LDT Policies](#).
2. Set, or modify, the Quality of Service (QoS) parameters in the Client Profile associated with the CTE client to account for LDT on all GuardPoints on this client. For details see [Quality of Service](#).

Note

Stop all applications so that they're not accessing any data in the directory that you intend to guard/protect.

3. In the CipherTrust Manager Applications Page, select the **CTE** application.
4. In the Clients table, click on the name of the client you want to protect.
5. Above the GuardPoints table, click **Create GuardPoint**.
6. In the Create GuardPoint page:
 - a. In the **Policy** field, select the LDT policy you created earlier.
 - b. In the **Type** field, select the type of device. For LDT, you can select **Auto Directory** or **Manual Directory**.
 - c. In the **Path** field, enter the directories you want to protect with this policy or click **Browse** to select them from a Windows-style explorer.

If you want to enter multiple paths, put each path on its own line.
 - d. Keep the **Preserve Sparse Regions** option selected if you want CTE to ignore sparse regions during data transformation.

A *sparse region* is a region within the file size that has not yet been written to. Therefore, it is not allocated with disk blocks. Any attempt to read a sparse region reads stream of zeros as data. A file may have one or more sparse regions, or an entire file may be sparse.

If you select **Preserve Sparse Regions**, LDT detects and skips transforming sparse regions. Therefore, it does not change the number of blocks utilized in the file system. This is the default.

If you disable **Preserve Sparse Regions**, LDT transforms a file without checking or skipping sparse regions, if they exist. Consequently, as LDT operations transform and fill sparse regions with encrypted stream of zeros, sparse regions are allocated with disk blocks. This increases the number of disk blocks utilized in the file system.

- e. Click **Create**.
- f. If you want to use the same policy and GuardPoint type on another path, click **Yes** when prompted. Otherwise, click **No**.

The CipherTrust Manager pushes the GuardPoint configuration to the client and CTE immediately begins transforming the data in the specified folders from clear-text to cipher-text.

7. Once the GuardPoint is in the **Active** state, you can bring applications back online. Data continues to get encrypted in the background while the application is online, according to the QoS settings defined in the policy. Once the rekeying state reaches 100%, or shows rekeyed, that means that all of the current data was successfully encrypted.

Converting a Standard GuardPoint to an LDT GuardPoint

Note

When converting a CIFS GuardPoint, ensure that the client is running the `vmarfs` driver and is a part of an LDT Communication Group. To determine which driver your node has installed, type: `fltmc` from the administrative command line. For more information, see [LDT Communication Groups and LDT GuardPoint Groups](#).

After enabling LDT on a client, you can change a standard GuardPoint to an LDT GuardPoint. LDT GuardPoints provide the advantage of allowing users to access all files in the GuardPoints while encryption is occurring. There is no downtime for the user except for the time needed to apply the GuardPoint.

1. Clone the key:
 - a. In CipherTrust Manager, navigate to the key section in the left navigation bar.
 - b. For the key that needs cloning, click the (...) button at the end of the row and select clone.
 - c. Type a unique name for the cloned key.
 - d. Toggle **CTE Versioned** to on.
 - e. Click **Clone**.
 - f. Select the key and open the CTE properties tab.
 - g. Verify that **CTE Versioned** is selected.

Note

- This is **mandatory** because keys used in Standard policies are not versioned for CTE.

2. Create a new LDT policy that transforms data from the standard/non-versioned key used in the existing GuardPoint, to an LDT versioned key.
 - **Policy name:** Make the new policy name the same as the standard policy name but append it with `_LDTPo1` or something similar to differentiate it.
 - **Security Rules:** Create the **exact same** security rules that are used in the relevant standard policy.
 - **Current key:** Use the encryption key defined in the standard policy.
 - **Transformation key:** Use the corresponding cloned/versioned Key of the current key.
3. Make sure there is no application activity within the GuardPoint.

Caution

This step is critical. Do not skip it. Make sure there is no application activity within the GuardPoint.

4. Remove/Unguard the current GuardPoints.
 - a. Open the **CTE** application and click **Clients** in the left-hand menu bar.
 - b. Click on the name of the client whose GuardPoint you want to change.
 - c. Find the GuardPoint that you want to change in the GuardPoints table, click the (...) button at the end of the row, and select **Unguard**.
5. Guard the directory again using the new LDT policy.
 - Use the steps above in [Creating an LDT GuardPoint for an Unguarded Directory](#) to guard the directory with the new policy.
6. Once the GuardPoint is in the **Active** state, you can bring applications back online. Data continues to get encrypted in the background while the application is online, according to the QoS settings defined in the policy. Once the rekeying state reaches 100%, or shows rekeyed, that means that all of the current data was successfully encrypted.

Rotating Encryption Keys (Rekey)

- [Manual Key Rotation](#)
- [Creating a Key Rotation Schedule](#)
- [Checking the Rekey Status](#)
- [Obtaining Information About Keys Applied to Files](#)
- [Showing GuardPoints During Rekey \(Linux\)](#)
- [Suspending and Resuming Rekey and/or Scan Phase](#)
- [Automatic Suspend and Resume of LDT Operations Due to Insufficient Disk Space](#)
- [Rotating Encryption Keys While a Rekey is in Progress \(Relaunch\)](#)

Manual Key Rotation

If you need to rekey your GuardPoint prior to the expiration of the current key version, you can manually start a rekey process.

On Windows, you cannot rotate a key until all current data transformations that use the same key have completed, whether those transformations are an initial data transformation or a rekey. On Linux, you can rotate the key at any time. For details, see [Rotating Encryption Keys While a Rekey is in Progress \(Relaunch\)](#).

1. In the CipherTrust Manager Applications Page, open the [Keys & Access Management] application.
2. Click **Keys** in the left-hand menu bar.
3. In the Keys table, click on the name of the key that you want to rotate.
4. On the Key Detail page, click the Add button (+) above the table to add a new version.

The new version appears in the Versions table.

Creating a Key Rotation Schedule

In CipherTrust Manager, you can create an automatic key rotation schedule that will automatically rotate all of the keys included in the schedule on a periodic basis. As soon as CipherTrust Manager creates a new version of a key, it pushes the new version to any clients associated with the policies that use the key. If the policy is a Live Data Transformation policy, CTE automatically begins rekeying the data in the LDT GuardPoint with the new version of the key.

1. In the CipherTrust Manager Applications Page, open the **Admin Settings** application.
2. Click **Schedules** in the left-hand menu bar.

CipherTrust Manager displays the existing key rotation and backup schedules that have been defined in the system. Thales strongly recommends that you look at any existing key rotation schedules to make sure that the keys you want to rotate are not already included in one of those existing schedules.

If the existing key rotation schedules do not include the keys you want to rotate, continue with this procedure

to create a new schedule.

3. On the **Schedules** page, click **Add Schedule**.
4. On the **Select Schedule Type** page, click **Key Rotation** and click **Next**.
5. Add a schedule name and description. Make sure you name the schedule as descriptively as possible so that other users can tell at a glance what keys that schedule includes. For example, you could name the schedule "Rotate-LDT-Keys" and use the description "Rotates all keys with "LDT" in their name on a yearly basis."

When you are done, click **Next**.

6. On the **Schedule Config** page, enter the following information:
 - **Duration.** Enter the day and time on which CipherTrust Manager should start using the key rotation schedule in the **Schedule Starts** field. When this day and time is reached, CipherTrust Manager looks at the date in the **Frequency** section and automatically creates a new version on that date.

Enter the day the schedule should end in the **Schedule Ends** field, or select the **Never** check box to tell CipherTrust Manager there is no end date for this key rotation schedule. If you select a date in this field, CipherTrust Manager automatically stops creating new key versions when that day and time are reached.

- **Frequency.** Select the **Basic** radio button to specify the frequency (daily, weekly, monthly, or yearly) and the UTC time at which CipherTrust Manager should automatically rotate the key after the schedule starts.

Select the **Raw (Cron)** radio button to create a cron job to control the key rotation schedule. Specify cron format in the following order:

minute, hour, day of month, month, and day of week

These five values indicate when the job should be executed. These values are mandatory and must be specified in the order given. The allowable values are:

Field	Allowed Values
minute	0-59 or * / , -
hour	0-23 or * / , -
day of month	1-31 or * / , -
month	1-12 or JAN-DEC or * / , - This field is case in-sensitive, so JAN, Jan, or jan are all equally valid.
day of week	0-6 or SUN-SAT or * / , - This field is case in-sensitive, so SAT, Sat, or sat are all equally valid.

Examples:

- December 31 at 2:35 AM UTC could be specified as: `35 2 31 Dec *`.
- On the 25th of every April, August, and December at midnight UTC could be specified as: `0 25 APR, Aug, dec *`.
- Every Monday, Wednesday, and Friday at 8:00 PM UTC could be specified as: `0 20 * * 1,3,5.`

When you enter a **Duration** and a **Frequency**, CipherTrust Manager displays the next several times the key rotation will be run under the **Frequency** field. Make sure the key rotation will be done on the days you expect.

Note

While the specified time is in UTC, the scheduled run times are shown in your local time. Therefore there may not be an exact match between the time set in the **Frequency** field and the displayed run time.

When you are done, click **Next**.

7. On the **Key Rotation Page**, specify the selection criteria you want CipherTrust Manager to use when it selects the keys it will rotate.

Caution

Make sure you are extremely careful when you specify the selection criteria so that you do not accidentally rotate keys that should not be rotated using this schedule. Whenever a new key is added to CipherTrust Manager, CipherTrust Manager compares its name and details to the filters set in all key rotation schedules defined in the Admin Settings application, and it automatically adds the new key to ALL key rotation schedules where it matches the selection criteria.

If your selection criteria is too broad, you could accidentally rotate keys that should not be rotated by this key rotation schedule.

You can enter a key name in the **Name** field, or select any of the available filters from the drop-down lists. The Selected Keys table shows the keys that will be rotated by this schedule.

CipherTrust Manager displays the current list of keys that match this criteria in the **Selected Keys** table. Make sure you go through this list carefully so that you do not rotate keys you do not want to rotate.

For example, you can rotate all keys with "ldt" anywhere in their name by specifying `*ldt*` in the **Name** field:

Add Key Rotation Schedule ✕

1 Select Schedule Type
2 General Info
3 Schedule Config
4 Key Rotation Query

A key rotation query is an object that specifies the keys that need to be rotated. All keys are rotated when it is not provided.

Name ▾ *ldt*

Q

Filters
☒ Basic
☐ Raw

Types ▾
Size ▾
Status ▾
Dates ▾

☒ Latest Version Only

Name: *ldt* ✕
Version: latest ✕

Selected Keys

Key Name	Ver	Modified	Type	Alg	Size
LDT-Key-West-Coast	2	08 Sep 2020, 10:10	Symmetric	AES	256
LDT-Key-East-Coast	3	08 Sep 2020, 10:10	Symmetric	AES	256
My_LDT_Key	0	08 Sep 2020, 10:07	Symmetric	AES	256

Back
Save

If you only want to rotate the keys whose names begin with "ldt", use the query `ldt*` in the **Name** field. In the example above, that removes `My_LDT_Key` from the list of keys that will be rotated.

The search is case insensitive, so "ldt" will also match `LDT`, `ldt`, `ldT`, or any variation thereof.

When you are certain the list of keys to be rotated is accurate, click **Save**.

Checking the Rekey Status

During a rekey, you can check the progress in the CipherTrust Manager Console, however GuardPoint status is not relayed to the CipherTrust Manager in real time. A delay of several minutes before the CipherTrust Manager displays events on the client is likely. When the number of GuardPoints on the managed host is high, for example 100+, the delay in relaying GuardPoint status is due to delays in scheduling and the execution of LDT operations on the managed host for GuardPoints.

To see the progress of a rekey and the estimated completion time:

1. In the CipherTrust Manager Applications Page, open the **CTE** application.
2. Click **Clients** in the left-hand menu bar.
3. Click the **Client Name** of the client whose LDT status you want to check in the Clients table.
4. Find an active LDT GuardPoint and click **Active** in the **Status** column.

CipherTrust Manager displays the GuardPoint Health page, which includes transformation status information such as the basic status (Rekeyed or Rekeying), the last transformation completion time, the last transformation start time, and the estimated rekey completion time.

Obtaining Information About Keys Applied to Files

Key Report Option

In the following command, you can use the `report` option of the `voradmin` command to obtain information about all of the keys in use on the GuardPoint. The report lists all keys used in the GuardPoint. For each key, it gives the key name and key version number. It lists each unique key name and version combination only once, no matter how many files use the key.

The following example shows three keys used in the GuardPoint `/oxf-fs1/gp1`:

```
voradmin ldt key report /oxf-fs1/gp1
LDT_KEY1,1
LDT_KEY2,2
LDT_KEY3,5
```

For an overview of `voradmin ldt`, see [LDT Command-Line Administration: voradmin command](#).

Key Map Option

In the `voradmin ldt key [report|map] <key_name> <guard path>` command, you can use the `map` option to obtain information about which files in a GuardPoint were transformed with a specific key, where:

- `<key_name>` is the name of the key.
- `<guard path>` is the path of the GuardPoint where the key was used.

For example, to view information about the key `LDT_KEY2` in the GuardPoint `/oxf-fs1/gp1`, you would enter:

```
voradmin ldt key map LDT_KEY2 /oxf-fs1/gp1
/oxf-fs1/gp1/file12345.dat10
/oxf-fs1/gp1/file12345.dat10
/oxf-fs1/gp1/file12345.dat10
/oxf-fs1/gp1/file12345.dat10
/oxf-fs1/gp1/file12345.dat10
```

Keys without a version number are used by files in an exclusion key rule or files that have yet to undergo initial key rotation. Use `voradmin ldt key map` in conjunction with `voradmin ldt attr get` to determine if a file using a key without a version number is part of an exclusion key rule or awaiting initial key rotation.

Showing GuardPoints During Rekey (Linux)

Use the following command to display a list of known LDT metadata stores and any associated GuardPoints currently undergoing transformation.

```
voradmin ldt list all
MDS_1:  type=file, nguards=0, name=/disk2/___vorm_mds___
        Guard Table: version 1 nentries 0
MDS_2:  type=file, nguards=0, name=/disk3/___vorm_mds___
        Guard Table: version 1 nentries 0
MDS_3:  type=file, nguards=0, name=/disk4/___vorm_mds___
        Guard Table: version 1 nentries 0
```

For an overview of `voradmin ldt` commands, see [LDT Command-Line Administration: voradmin command](#).

Suspending and Resuming Rekey and/or Scan Phase

The QoS schedule specifies certain time windows when LDT operations must be stopped temporarily. However, you can also suspend or resume LDT at the host/client level at any time.

To suspend LDT through the CipherTrust Manager Console:

1. Open the **CTE** application.
2. Click **Clients** in the left-hand menu bar.
3. Click the **Client Name** of the client on which you want to pause LDT in the Clients table.
4. In the Client Details area, click the **Suspend** button next to the Live Data Transformation field to suspend all LDT operations on the client.

After you pause LDT, the button turns into a Play button so that you can resume LDT operations when ready.

Considerations

- Disabling, or unguarding, an LDT GuardPoint where a rekey is in progress automatically suspends the LDT rekey operation.
- You can also use the `voradmin suspend/resume` command in Windows Powershell to suspend and resume the rekey. However, if you use the `voradmin ldt suspend` command to pause the rekey process, the LDT suspended state is not retained when the system reboots. If you want to retain the state after reboot, suspend the rekey from the CipherTrust Manager.
- On Linux, you can pause LDT during the scan phase of LDT. When paused during scan, LDT suspends operations that traverse through the namespace of GuardPoints in the scan phase of transformation. Suspending LDT during scan stops file lookup operations of LDT. This eliminates performance impact to I/O intensive production workloads, such as file serving type workloads, that access large number of files.

Automatic Suspend and Resume of LDT Operations Due to Insufficient Disk Space

LDT requires adequate storage space headroom to perform LDT operations such as rekeying on GuardPoints. On Linux, if available storage space drops below the threshold required for LDT operations to continue, the LDT operations are automatically suspended. On Windows, LDT will be suspended if there is less than 3 GB free space in the GuardPoint. Once additional storage space is available in the file system, LDT operations automatically resume.

As available space approaches the threshold for automatic suspension, LDT sends an alert to the CipherTrust Manager to notify you that you should free up more storage space before LDT operations are suspended. The alert on the CipherTrust Manager is:

```
Low space on guard point [GuardPoint], increase free space or LDT will be suspended.
```

Behavior of Automatic Suspend and Resume of LDT Operations on ext4 File Systems

By default, ext4 file systems reserve a portion of the storage space for use only by privileged processes to prevent running out of storage space in file systems. In this situation, non-privileged processes are automatically blocked from writing to the file system until the free disk space level reaches the minimum threshold. As LDT operates in privileged mode, LDT operations continue without blockage even if the free disk space threshold is low. Because of this ext4 feature, LDT operations on ext4 file systems may not be suspended due to low available storage space, even when the `df` command reports storage is 100% allocated.

Rotating Encryption Keys While a Rekey is in Progress (Relaunch)

On Linux, if a key is rotated (either manually or automatically when a key version expires) while LDT is in progress on a GuardPoint, the key rotation is processed and queued, and the GuardPoint is marked for relaunch. Relaunch indicates the need to restart LDT after the current transformation completes. If the GuardPoint has been rekeyed and is flagged for relaunch, LDT launches as soon as the GuardPoint is enabled.

When this event occurs, the following message appears in the log file: "LDT: Deferred key rotation on

GuardPoint [GuardPoint] until after completion of current transformation."

When the new key rotation request is queued, files can be in one of three states:

- **Undergoing rekey to a previous key:** Files already undergoing transformation to a previous key when the new rekey request is queued, are rekeyed to the key version already in progress.
- **Scheduled for rekey to a previous key:** Files that start transformation after the new key rotation request is queued are rekeyed to the newest key version.
- **Rekeyed to a previous key:** Files that have already been rekeyed to a previous key remain in that state until all files undergoing rekey, or scheduled for rekey, have been processed. Once the current LDT process for the GuardPoint is complete, LDT automatically relaunches to transform any files that are not rekeyed to the latest key version. This includes any files that were rekeyed before the new key rotation request was queued, or that were undergoing transformation when the new key request was queued.

For example:

```
voradmin ldt attr get /oxf-fs1/gp1
LDT stats: version=2, rekey_status=rekeying,relaunch
  Number of times rekeyed:          1 time
  Rekey start time:                 2024/03/18 16:54:00
  Last rekey completion time:       2024/03/18 16:53:38
  Estimated rekey completion time:  0 days 0 hours 6 minutes
  Policy key version:               344
Data stats:
  total=9.8GB, rekeyed=0.0MB
  truncated=0.0MB, sparse=0.0MB
File stats:
  total=1000, rekeyed=0, failed=0
  passed=0, skipped=0, created=0, removed=0, excluded=0
```

Note

Relaunch is supported on Linux only. It is not supported on Windows.

Relaunch when Directories are renamed

Prior to v7.6.0, when a user renamed a directory, LDT would set a relaunch flag on the GuardPoint during the scan phase of LDT. This relaunch flag would trigger an additional LDT process on the GuardPoint when the current transformation job completed.

As the transformation process can impose significant overhead on production workloads, subsequent relaunch of LDT, as the result of renaming directories, is not efficient.

CTE v7.6.0 records renamed directories during the scan phase, so it can locate the files relocated to other paths during the rekeying phase of LDT. This prevents the GuardPoint from going through another transformation due to the directory being renamed during the scan.

Limitation

You can only rename a maximum of 16 concurrent directories without triggering a relaunch. If more than 16 concurrent directories are renamed during the scan phase, LDT sets the relaunch flag on the GuardPoint.

File System Operations

File system operations may require attention from the Administrator. These operations are divided into the following categories:

- Renaming Files and Directories
 - Renaming Directories on Linux
 - Caveats
 - Example
 - Considerations
- Deleting a File
- File Handling (Windows)
- Enabling GuardPoints in Read-Only mounted file systems (Linux)
- Copying Files Into a GuardPoint
- Behavior of Hard Links Inside and Outside of GuardPoints (Windows)

Renaming Files and Directories

On both Linux and Windows hosts, you can rename files during initial transformation, or rekey operations.

- On Linux, you can now, as of v7.1.1, rename directories in a GuardPoint during a rekey operation.
- On Windows, LDT stops if it is transforming the contents of a folder and a user attempts to rename/move that folder.

You can change the stopping behavior of LDT using the configuration parameter `oxf_stop_on_rename`.

Using the Registry Editor, or the Windows command line, add a registry entry in `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\services\Vmmgmt\Parameters` for `oxf_stop_on_rename`.

Registry Name	Values	Comments
oxf_stop_on_rename	0 - Disabled	LDT does not stop if there is contention.
	1 - Enabled	LDT stops if there is contention.

Registry Name	Values	Comments
		Default: Enabled.

For the target folder in rename operation, LDT is never stopped.

Renaming Directories on Linux

Prior to LDT v7.1.0, you could not rename a directory within an LDT GuardPoint, during the rekeying process. However, starting in LDT v7.1.1, users and applications can now rename directories within an LDT GuardPoint, during the rekeying process.

When a directory is renamed, LDT starts performing single file rekey jobs, on files in that renamed directory. A single file rekey job is a background process that rekeys a specific file, independent of the rekey process occurring on the entire GuardPoint. This process is similar to how files marked with a lazy rekey flag are rekeyed to the latest key version upon access to the marked file. LDT supports a maximum of 16 concurrent renamed directories per GuardPoint in the scan or rekey phases. If an additional directory is renamed while there are already 16 directories being processed, the GuardPoint is marked for relaunch (See [Rotating Encryption Keys While a Rekey is in Progress \(Relaunch\)](#) for more information on the relaunch state). This will make rekey start again upon completion to pick up any additional renamed directories.

Note

If a GuardPoint is already marked for relaunch, directory renames will not trigger single file rekeys. This is because the relaunch of LDT will pick up the files in the renamed directories.

You can view rekey jobs in a GuardPoint using the command `voradmin ldt list all`. Rekey operations for files marked as lazy, as part of CipherTrust Intelligent Remediation, and for directory rename, are listed as separate single file rekey jobs. In the example below, the file `/ldt/renamed/file.0` is undergoing rekey as a single file rekey job, as the result of changing the pathname to the file.

```
voradmin ldt list all

MDS_1:  type=file, nguards=9, name=/ldt/__vorm_mds__

  Guard Table: version 1 nentries 9

  Guard 0: type=GP, state=REKEYING DIRTY, flags=GP LOCKED, gp=/ldt

    File List: count 51

  Guard 1: type=FILE, state=REKEYING DIRTY, flags=FILE LOCKED, gp=/ldt/rename
d_dir/file.0

    File List: count 1
```

LDT can run a maximum of eight concurrent single file rekey jobs for directory renaming. This limit is shared across directory renames for all of the GuardPoints on a system.

Furthermore, while directory rename is in progress on a target GuardPoint, the GuardPoint will not transition into the rekeyed state, even if LDT has completed on the rest of the files in the GuardPoint. As soon as the single file rekey jobs associated with the GuardPoint complete, the GuardPoint transitions into a rekeyed state.

Caveats

The following caveats exist when renaming directories that are in GuardPoints:

1. A directory rename operation changes path names to an unknown number of files. As such, LDT cannot accurately estimate completion time on the target GuardPoint. In such a situation, the rekey progress reflected on the key manager may show that the GuardPoint is in 100% rekeyed status, and the status remains in the 100% rekeying status, until the files in the renamed directories are rekeyed to completion.
2. Directory rename operations also affect the accuracy of LDT statistics. Those files, in a renamed directory that are not rekeyed when the directory is renamed, are no longer accessible as part of rekeying the GuardPoint. However, those files will be rekeyed as part of rekeying the renamed directory. As the GuardPoint level rekey operations fail to find those non-rekeyed files, LDT stats update to reflect those files as 'passed' and their size is added to the 'truncated' stat. When those files are rekeyed, as part of the renaming directory rekey process, the 'rekeyed' status will be correctly updated.
3. The net effect of renaming a directory during a rekey will be reflected in an inaccurate 'passed' count, and the amount of data truncated for each file not rekeyed in the renamed directory.

Example

If there are 1024 files totaling 1 GB in the directory `/ldt/gp/dir`, within the GuardPoint `/ldt/gp` when rekey starts, the stats should appear as follows:

```
ls -l /ldt/gp/dir | wc -l
1024

du -h /ldt/gp/dir
1.0G    /ldt/gp/dir

voradmin ldt stats /ldt/gp

LDT stats on /ldt/gp: version=3, rekey_status=rekeying

Number of times rekeyed:           3 times

Rekey start time:                  2021/06/14 23:53:56

Last rekey completion time:        2021/06/14 21:26:09

Estimated rekey completion time:    N/A

Data stats:

    total=13.8GB, rekeyed=726.0MB, truncated=0.0MB

File stats:

    total=1043, rekeyed=0, failed=0

    passed=0, skipped=0, created=0, removed=0, excluded=0
```

Upon renaming of the directory `/ldt/gp/dir`, any files that have not yet been processed by a GuardPoint level rekey, is added to the **passed** and **truncated** values in the stats:

```
voradmin ldt stats /ldt/gp

LDT stats on /ldt/gp: version=3, rekey_status=rekeying

  Number of times rekeyed:                3 times
  Rekey start time:                      2021/06/14 23:53:56
  Last rekey completion time:2021/06/14 21:26: 09
  Estimated rekey completion time:        N/A

Data stats:

  total=13.8GB, rekeyed=10.6GB, truncated=1.0GB

File stats:

  total=1043, rekeyed=21, failed=0

  passed=1024, skipped=0, created=0, removed=0, excluded=0
```

Considerations

Consider the following issues when renaming directories during a rekey:

- If a directory rename operation occurs during the scan phase of LDT, the GuardPoint will be marked for relaunch and LDT will be launched again at the completion of the current rekey cycle. This is because it is not possible to begin rekey jobs while LDT is in the scan phase.
- When LDT is suspended on a GuardPoint with a renamed directory, additional single file rekey jobs will not be launched until rekey resumes. However, ongoing single file rekey jobs continue until each single file rekey is completely rekeyed. Consequently, suspending LDT while single file rekey operations are in progress only suspends rekey operations at the GuardPoint level, while LDT operations on single rekey files continues without disruption. As a result, stopping CTE service, which requires suspending LDT and disabling GuardPoints, may be delayed until the files currently undergoing rekey, due to directory rename, are completed.
- Ensure that LDT is suspended at the GuardPoint level and there is no single rekey file in progress before starting operations, such as a backup, which requires suspending LDT operations. Failure to do so can result in unexpected problems.
- If files in a renamed directory are moved out of the renamed directory, those files are processed as separate rekey jobs. Those rekey jobs cannot be suspended until the rekey is completed.
- A system crash during a rekey for a directory rename, also affects how LDT performs a recovery. Normally, LDT requires that, after the crash, the recovery completes for all of the affected files in the GuardPoint, before resuming rekey operations. However, with a directory rename, it is possible for the LDT recovery to skip files

that are in the renamed directory because the path name to those files has changed since the scan phase of the key rotation. Instead, recovery for these files is deferred until the next access by LDT, or a user application, when a GuardPoint is enabled.

- LDT recovery log messages are not logged to LDT recovery log files, if the recovery log messages become necessary in the event of a failed recovery attempt. In the event of an error, LDT logs error messages in syslog, blocks access to the file that could not be recovered, and marks the file in rekey error. Files in rekey error must be restored from a backup. Additionally, as files that cannot be found for recovery are now treated as being deferred (only when the directory rename occurs prior to the crash), any orphaned files that might have been moved to the lost& found directory, in the target file system, will not be discovered as orphaned files and consequently skipped by LDT. LDT cannot discern if the orphaned files are missing or were linked to a renamed directory.

Deleting a File

When a file is removed before it is rekeyed, the file is not included in the total number of files transformed in the GuardPoint Health dialog box. Any discrepancy between total number of files to transform and those transformed is due to the removal of files from GuardPoints during LDT.

The **voradmin** command provides more detailed file level statistics related to rekey operations on the host. You can run **voradmin** to get file level statistics:

```
voradmin ldt stats <guard_path>
```

File Handling (Windows Only)

It is critical that you understand how the LDT process handles read-only, binary (executable), NTFS encrypted and NTFS compressed files.

The LDT process is subjected to all of the File System policies and attributes set on the files. In some cases, this prevents LDT from encrypting a file. If users or applications are accessing files while LDT is in progress, LDT cannot change the attributes of the files and encrypt the file. It is critical that you understand how LDT handles various types of files:

- **NTFS Encryption and Compression**

If NTFS encryption and compression is enabled on a file or folder, the LDT process cannot encrypt these files. To maintain the data coherency, LDT skips the encryption of these files. These files display as “passthrough” files in the LDT statistics.

- **Read-Only Files**

When LDT encounters read-only files, it rekeys the file by resetting the read-only attribute and then setting the attributes back again when the rekey completes. If a file is open, LDT skips this file.

- a. If the file is not opened, LDT changes the attributes of the file and stores the original attributes in the file metadata.
- b. LDT starts Rekey on this file.

- c. If a user requests to open a file for writing while rekey is in progress, access is denied. User can only open files for reading.
- d. LDT restores the attributes once rekey is done.

▪ Executable Files

If an executable is running, or files are exclusively locked by the application, the LDT process cannot encrypt those files as it is unable to acquire the required locks on the files. LDT skips these files and changes to the INCOMPLETE state.

Enabling GuardPoints in Read-Only mounted file systems (Linux)

Access to a GuardPoint enabled in a read-only mounted file system is restricted to read operations. You cannot modify data in such file systems, therefore, you cannot perform LDT operations on GuardPoints in read-only file systems. For this reason, LDT automatically suspends operations when GuardPoints are enabled on read-only file systems. LDT ignores all attempts to resume LDT operations until the underlying file system is remounted with read/write access.

Warning

You must disable a GuardPoint before changing the read/write mount options of the underlying file system. After changing the mount options, you can re-enable the GuardPoint. LDT operations adapt to the read/write options of the underlying file system when you enable the GuardPoint. Changing the mount options while a GuardPoint is enabled is unsupported and may result in unexpected errors.

Copying Files Into a GuardPoint

If you copy a file into a GuardPoint without an Apply Key rule, make sure that the file was previously copied from the same GuardPoint, or a GuardPoint protected with the same policy/versioned key. A copy operation, without an Apply Key rule, is the same as a backup or restore of a file from/to an LDT protected GuardPoint.

CTE enforces key rules of an LDT policy while a GuardPoint is enabled. CTE cannot enforce the key rules while a GuardPoint is disabled. Modifying or adding data/files inside a disabled GuardPoint is not only unsupported, but it also results in unrecoverable data corruption.

Warning

Do not add new files or modify existing files inside LDT protected GuardPoints while the GuardPoint is not enabled. This results in unrecoverable data corruption and/or files that cannot be accessed when the GuardPoint is enabled.

Behavior of Hard Links Inside and Outside of GuardPoints (Windows)

When using hard links on Windows, all of the hard links to a file must be within the boundary of a GuardPoint and must use the same key. The following scenarios provide additional details:

- If hard links to the same file are inside a GuardPoint and outside a GuardPoint, the effect on the file depends on what process accesses which hard link first. If the hard link within the GuardPoint is opened first, the file is transformed. If the hard link outside the GuardPoint is opened first, the file won't be transformed.
- If hard links to the same file exist in different GuardPoints with different keys, the file will be corrupted.
- If hard links to the same file exist in the same GuardPoint but with different keys, such as if folder-based rules are used, there will be a conflict in the key.

Note

For v7.2, hardlinks are not supported on CIFS shares.

Excluding Files or Directories from Rekey

When you add a resource set to a key rule in a policy, you can select the **Exclude Rule** option. This informs CipherTrust Manager that the directories and/or files in the resource set use the define key that is excluded from the LDT rekey process. If you specify `clear_key` for the key rule, then the directories and/or files in the resource set will be left unencrypted. Otherwise, you can select any non-versioned key to apply to those directories and/or files.

For more on Exclusion rules, see the following topics:

- [About the Exclusion Attribute for Files Matching an Exclusion Key Rule](#)
- [Requirements for Exclusion Key Rules](#)
- [Usage Notes and Limitations for Configuring Exclusion Key Rules](#)
- [Examples of Exclusion Key Rules](#)
- [Listing All Files Included in an Exclusion Key Rule \(Linux\)](#)
- [Listing All Files Included in an Exclusion Key Rule \(Windows\)](#)
- [Using Dynamic Resource Sets](#)

About the Exclusion Attribute for Files Matching an Exclusion Key Rule

Files matching an exclusion key rule have the status `rekey_excluded` in the LDT attribute. For more information about LDT attributes, see [LDT Metadata in Extended Attributes](#). To check for the exclusion attribute on a file, see [Determining if a File is Included in an Exclusion Key Rule](#).

The Exclusion Attribute is not Persistent

Exclusion from rekey is no longer a persistent property as of v7.6.0.

See [Dynamic Resource Set](#) for more information.

Determining if a File is Included in an Exclusion Key Rule

Use the `voradmin ldt attr get <path to file>` command to check whether a file is associated with an exclusion key rule.

- On Linux, an excluded file will include the status `rekey_excluded` in the `voradmin` output. For example:

```
voradmin ldt attr get /oxf-fs1/gp1/foo.txt
LDT attributes: rekeyed_size=0, rekey_status=rekey_excluded
```

- On Windows, an excluded file will include the attribute `Rekey Status Excluded` in the `voradmin` output. For example:

```
C:\> voradmin ldt attr get c:\gp1\foo.txt
LDT attributes:
Rekey Status Excluded
Initial Rekeyed Size 9 Bytes
Data Transformed 0 Bytes

Key:
Current Key Name/Version (Clear_Key)
New Key Name/Version (Clear_Key)
```

Removing the Exclusion Attribute From a File

To disassociate a file from an exclusion key rule, you must copy the file to a new file that is not associated with the resource set, or exclusion key rule, of that same source file. You can then remove the original file. The new file is created under the default key rule of whatever policy applies to the new file. Moving or renaming a file does not disassociate a file from an exclusion key rule.

For example, assume the following exclusion key rule where `Key_TextFiles` is a non-versioned key:

Exclusion Key Rule: Resource set `=*.txt`, Key = `Key_TextFiles`

If you copy the file `test1.txt` to `test1.foo`, `test1.foo` is created with whatever key is specified in the policy that matches the new file. The key for the new file could be a non-versioned key, versioned key, `clear_key`, or, no key at all if the new file is outside of a GuardPoint. The original file `test1.txt` remains unchanged and encrypted with the `Key_TextFiles` non-versioned key because the file remains in the exclusion key rule.

Rename and Restore (Linux)

The effect of rename, or backup/restore operations, involving files associated or excluded with exclusion key rules, is complex. In some cases, the operations to restore, or rename, causes conflicts between the key associated with the source file, and the key associated with the target file. For example, the result of a rename operation involving a source file, not associated with an exclusion key rule, and target file name associated with a resource set of an exclusion key rule is different from the result of the same operation when the target file name is associated with the resource set of an exclusion key rule with `clear_key`.

Note

Be sure to review the effect of the operations below and avoid administrative operations that cross associations of files across multiple resource sets with conflicting key rules.

Backup/Restore

- See [File Operations shared key Rules](#) for more information.

Rename Operation

- See [File Operations shared key Rules](#) for more information.

Requirements for Exclusion Key Rules

Keep in mind the following requirements when configuring exclusion key rules:

- Before adding an exclusion key rule to an existing policy, you must disable all GuardPoints protected with the policy. Log on to the CipherTrust Manager to disable the GuardPoint.
- You cannot choose a versioned key for the key in an exclusion key rule. Only non-versioned keys or `clear_key` (no encryption) are valid for exclusion key rules.
- All exclusion key rules must be *above* all LDT transformation key rules in the **Key Rules** area in the policy.

Usage Notes and Limitations for Configuring Exclusion Key Rules

Keep in mind the information in the following sections when configuring an exclusion key rule.

Adding an Exclusion Key Rule to an Existing Policy with Versioned Keys (Linux)

When adding an exclusion key rule to an existing policy, the exclusion rule only applies to newly created files. Existing files that match the exclusion key rule remain encrypted with the same versioned key(s) specified in the non-exclusion key rule in the policy and will be rekeyed to the key in the exclusion key rule when the versioned key(s) rotates.

To force an existing file that matches an exclusion key rule to be transformed to the key in the exclusion key rule (non-versioned in this example), use one of the following methods:

- Rotate the versioned key specified in the policy to initiate rekey operations on the GuardPoint.
- Copy the existing file within the GuardPoint. The new file will be associated with the resource set in the exclusion key rule and will be encrypted with the non-versioned key. You can then delete the original file.

To perform a similar conversion on Windows, see [Changing a Folder or Files from Versioned to Non-Versioned Key \(Windows\)](#).

Adding an Exclusion Key Rule for LDT over NFS

For an LDT over NFS GuardPoint with exclusion rules, all files, including excluded files, can only be read in clear when the GuardPoint is enabled. Excluded files on an LDT over NFS GuardPoint will not be readable when the GuardPoint is unguarded/disabled.

Adding an Exclusion Key Rule That is Part of an Active GuardPoint (Linux)

To edit and/or add an exclusion key rule to an LDT policy, all GuardPoints using the policy must first be disabled before the new key rule can be added.

Changing an Exclusion Key Rule That is Part of an Active GuardPoint (Windows)

Changes that you make to an exclusion key rule that is part of an existing policy in an active GuardPoint do not take effect until the GuardPoint that the exclusion key rule is part of is disabled and enabled again.

Overlapping Exclusion Key Rules

Multiple exclusion key rules in the same policy may overlap each other. For example on Linux, if the non-versioned key Key_A is associated with resource `/oxf-fs1/gp1/Folder_Enc_With_KEY_A` and the non-versioned key Key_B is associated with resource `*.txt`, placement of the file `/oxf-fs1/gp1/Folder_Enc_With_KEY_A/foo.txt` overlaps the two key rules. In such a case, the first rule in the policy is enforced on `/oxf-fs1/gp1/Folder_Enc_With_KEY_A/foo.txt` when the file is created and in subsequent file access.

On Windows, if the non-versioned key Key_A is associated with resource `c:\oxf-fs1\gp1\Folder_Enc_With_KEY_A` and the non-versioned key Key_B is associated with resource `*.txt`, then they would overlap on the file `c:\oxf-fs1\gp1\Folder_Enc_With_KEY_A\foo.txt`. In such a case, the first rule in the policy is enforced on `c:\oxf-fs1\gp1\Folder_Enc_With_KEY_A\foo.txt` when the file is created and in subsequent file access.

Application of Exclusion Key Rules on GuardPoint over NFS

When protecting files using an Exclusion Key Rule with `clear_key` in local file systems, files can be accessed in clear even if the GuardPoint is not enabled. Clear access is possible because data is not encrypted in such files and the LDT metadata is managed as part of the secfs extended attribute for such files. Clear access is not possible for such files in a GuardPoint over NFS because LDT metadata is part of the secfs extended attribute

that is stored in the first 4096 bytes of each file. CTE skips the embedded secfs header when reading or writing such files when a GuardPoint is enabled. With a GuardPoint disabled, access to files is not through CTE and reading or writing files in a GuardPoint will not skip the embedded secfs attribute.

Caution About Applications That Create Temporary Files (Windows)

Some applications on Windows create a temporary file version of the original file when you open and modify a file. This behavior can affect how you implement exclusion key rules.

If you have an exclusion key rule that uses a file extension to exclude files that may be opened and modified by such an application, exclude the temporary file name extension also. If you don't exclude the temporary file, the temporary file may be encrypted by another policy that matches the temporary file extension. Then the original file, which is copied from the temporary file, will be unreadable. Also keep in mind that other applications that may create temporary files with the same file extension and consider what policies should affect those temporary files.

This situation can happen with Microsoft Office files such as the `.docx` files used by Microsoft Word. When you open and modify a `.docx` file, Word creates a `.tmp` file version of that file. So for Microsoft Word you should add `*.tmp` to the exclusion key rule resource set if you add `*.docx`.

Rename Operations Crossing Key Rules (Linux)

On Linux, when a rename operation crosses key rules, the rename operation copies the source file to a new file using the new name and removes the original file. If the source file is flagged for exclusion key rule property, the target new file is disassociated with the exclusion key rule if the new name no longer matches the resource set associated with exclusion key rule. For more information, see [About the Exclusion Attribute for Files Matching an Exclusion Key Rule](#).

Using Linked Files with Exclusion Key Rules (Linux)

On Linux, do not create multiple hard links to the same target file, such that the pathname of each hard link is associated with a resource set of an exclusion key, and the key rules have different keys. Accessing the file through the pathname of each hard link results in a different key being applied to the file, resulting in data corruption in the target file due to the application of multiple keys to the same data.

If you must create hard links, be sure the hard link pathnames and the target file are within the same resource set.

Changing a Folder or Files from Versioned to Non-Versioned Key (Windows)

Exclusion key rules provide a way to convert a subset of guarded files or the contents of a folder from being encrypted by a versioned key to being encrypted by a non-versioned key. After this conversion, the excluded files or directory contents will be encrypted at the last version of the versioned key but the encryption keys for those items will not rotate to a new version when the keys for other non-excluded files are rotated. In other words, the excluded files or folder contents will be encrypted by a non-versioned key.

Follow these steps to change selected files or folder contents to a non-versioned key:

1. In the CipherTrust Manager, clone the versioned key that is used in the policy that you plan to edit. Cloning a key creates a non-versioned copy of the existing version of the versioned key.
2. In the CipherTrust Manager, disable the GuardPoint. Disabling the GuardPoint is required before modifying a

policy applied in that GuardPoint.

- Configure one or more resource sets to match the files that you want to exclude. For example, the resource set `star-dot-text` could contain `*.txt` and the resource set `sales-folder` could contain `\sales\*`.
- Add one or more exclusion key rules to convert matching files to a non-versioned key. In the following example, files matching `*.txt` and files in the `sales` folder (as defined in resource sets) will be converted from the current version of the versioned key `AES256_versioned` to `AES256_clone`, assuming `AES256_clone` is a clone of `AES256_versioned`.

Order	Resource	Current Key	Transformation Key	Exclusion Rule
1	star-dot-txt	AES256_clone	AES256_clone	Y
2	sales-folder	AES256_clone	AES256_clone	Y
3		clear_key	AES256_versioned	N

Exclusion key rules must be ordered before other rules.

- On the command line, run the following command to remove the LDT metadata from the files that you want to convert from versioned key to non-versioned key encryption:

```
voradmin ldt attr delete <path_to_files>
```

To recursively delete the LDT metadata from all files matching a pattern in all subfolders, use the following form, including `*` as a wildcard where needed:

```
voradmin ldt attr delete <path_to_files> -filter <filename>.<extension>
```

Note

Be careful when deleting the LDT metadata from files. If you delete the metadata from a file that does not match an exclusion key rule policy, the file will be unreadable after the next rekey.

Given the example exclusion key rule described in step 4, you would need to run this command on all files with the extension `.txt` (first example below) and on the files in `\sales` (second example below).

```
voradmin ldt attr delete c:\gp1 -filter *.txt
voradmin ldt attr delete c:\gp1\sales
```

For more information about using `voradmin` on LDT metadata, run `voradmin ldt attr /?` on the

command line.

6. In the CipherTrust Manager, re-enable the GuardPoint that includes the new exclusion key rule.
7. In the CipherTrust Manager, rotate the key for the policy that includes the new exclusion key rule.

Using the example exclusion key rule in step 4, after completing this procedure, files matching `*.txt` and files in the `sales` folder will have the exclusion attribute set and will be excluded from rekeying (see [About the Exclusion Attribute for Files Matching an Exclusion Key Rule](#)). Files not matching the exclusion key rule will be rekeyed to the next version of the `AES256_versioned` key.

To perform a similar conversion on Linux, see [Adding an Exclusion Key Rule to an Existing Policy with Versioned Keys \(Linux\)](#).

Examples of Exclusion Key Rules

This section describes some examples of how to use an exclusion key rule.

Encrypt Files With Exclusion Property Using a Non-Versioned Key

The following exclusion key rule applies the non-versioned key, `Key_TextFiles`, to any new files that are created with a `*.txt` extension.

Note

Existing `*.txt` files in the GuardPoint during the initial LDT data transformation process are assumed to be already encrypted with the same key that you specify in the exclusion key rule. These existing files are not transformed during the initial encryption or during any subsequent rekeys. The key you specify in the exclusion key rule is applied to new `*.txt` files only.

In the Policy, do the following:

1. Add a Key Rule.
2. In the **Resource Set** field, click **Select**.
3. Select a resource set that specifies *.txt in the File field and click the Exclude Rule** option.

Select Resource Set

Search

2 Results | 2 Resource Sets

+ Create Resource Set

Name	Updated At ↓	Description
☒ RS-all-txt-Files	06 Sep 2020, 19:02	Resource set for *.txt.
☐ LDT-Exclude	06 Sep 2020, 18:49	

2 Resource Sets 10 per page ▾

Exclude Rule: ☒

- Click **Select**. CipherTrust Manager displays the resource set name in the Resource Set field with an icon indicating that this is an Exclusion Rule.
- Select the **Key_TextFiles** key in the **Current Key Name** field.
- Click **Add**.
- Add any other key rules or exclusion key rules to the policy that you want. You must add at least one non-exclusion key rule that specifies the current encryption key and the versioned encryption key that you want to use with this Live Data Transformation policy.

For example, you could add another exclusion key rule that specifies all **.doc** files should be encrypted with the key **Key_DocFiles**, or one that specifies all **.zip** files should be left unencrypted by specifying the key **clear_key**.

Exempt Excluded Files from Encryption (Set to **clear_key**)

The following exclusion key rule sets all files in the resource set **/oxf-fs1/gp1/Clear_Files_Folder** (Linux) or **\oxf-fs1\gp1\Clear_Files_Folder** (Windows) to **clear_key** (in other words, not encrypted). Files in other directories that match other key rules in the same policy may be encrypted. This could allow unrestricted access to the files in **/oxf-fs1/gp1/Clear_Files_Folder** (Linux) or **\oxf-fs1\gp1\Clear_Files_Folder** (Windows) while access may be restricted to files in parallel directories.

- Linux Exclusion Key Rule: The Resource Set **Directory** field should contain **/oxf-fs1/gp1/Clear_Files_Folder**, and the **Key** should be **clear_key**.
- Windows Exclusion Key Rule: The Resource Set **Directory** field should contain **\oxf-fs1\gp1\Clear_Files_Folder**, and the **Key** should be **clear_key**.

Listing All Files Included in an Exclusion Key Rule (Linux)

Determining the files that match an exclusion key rule involves two steps. You list all the keys in a GuardPoint, choose the key that you're interested in, and then run a command to list the files that match that key. This process works for both standard key rules and exclusion key rules.

1. Decide on the GuardPoint that you want to check for excluded files. For example, for the GuardPoint `/oxf-fs1/gp1`, type the following on the command line:

```
voradmin ldt key report /oxf-fs1/gp1
LDT_KEY1,1
LDT_KEY2,2
LDT_KEY3,5
NON_VERSIONED_KEY
```

The number after the comma is the key version number. See [Key Report Option](#) for more information about the `voradmin` key report.

2. From the key report output, choose the key rule for which you want to list matching files. For example, to see the files associated with the `NON_VERSIONED_KEY` in the previous step, you would type:

```
voradmin ldt key map NON_VERSIONED_KEY /oxf-fs1/gp1
/oxf-fs1/gp1/file1.dat10
/oxf-fs1/gp1/file2.dat10
/oxf-fs1/gp1/file3.dat10
/oxf-fs1/gp1/file4.dat10
/oxf-fs1/gp1/file5.dat10
```

See [Key Map Option](#) for more information about the `voradmin` key map report.

Listing All Files Included in an Exclusion Key Rule (Windows)

Determining the files that match an exclusion key rule involves two steps. You list all the keys in a GuardPoint, choose the key that you're interested in, and then run a command to list the files that match that key. This process works for both standard key rules and exclusion key rules.

1. Decide on the GuardPoint that you want to check for excluded files. For example, for the GuardPoint `c:\gp1`, type the following on the command line:

```
C:\> voradmin ldt key report c:\gp1
Keys used for GP, c:\gp1 :
clear_key,0
CS1-LDT-AES256,11
```

The number after the comma is the key version number. The `clear_key` key is not versioned, so the version

number is 0.

- From the key report output, choose the key rule for which you want to list matching files. For example, to show the files associated with the `clear_key` listed above, you would type:

```
C:\> voradmin ldt key map c:\gp1 clear_key,0
Files rekey with key (clear_key,0)-
c:\gp1\file1.txt
c:\gp1\file2.txt
c:\gp1\file3.txt
c:\gp1\file4.txt
c:\gp1\file5.txt
```

Dynamic Resource Sets

The Dynamic Resource Set feature has been modified in CTE v7.8.0, with the inclusion of new key rules, when registered with CipherTrust Manager v2.17, or subsequent versions. The Dynamic Resource Set feature is also now available with Local File Systems, as well as NFS GuardPoints. Support for NFS is available starting with the patch release of CTE v7.7.100.

With Dynamic Resource Sets, you can now add a new key rule to a resource set that includes files that are not encrypted under the dynamic resource style policy. This results in the inclusion of those files for rekey and encryption. LDT launches rekey operations on the affected GuardPoints to encrypt the files associated with the resource set in the newly added key rule. Before inclusion of the key rule, those files associated with the resource set were in clear-text.

Following is an example of a policy applied to GuardPoint `/oxf-fs1/gp1` which includes subdirectories `dir1`, `dir2`, `dir3`, `dir4`. Applying this policy to `/oxf-fs1/gp1` will launch and rekey the files under `/oxf-fs1/gp1/dir1` and `oxf-fs1/gp1/dir2` using the specified key, while the remaining files in `/oxf-fs1/gp1` remain in clear-text. To rekey the files under `/oxf-fs1/gp1/dir3` and `/oxf-fs1/gp1/dir4`, you can update the policy as follows:

The screenshot shows the 'LDT-DYNRES-POL' configuration page. It has tabs for 'Local File Rules' and 'Key Rules'. Below the tabs is a table with 5 columns: 'Index', 'Resource Set', 'Current Key Name', 'Transformation Key Name', and 'Encryption Style'. There are 4 rows of data, each with a checkbox in the first column. At the bottom right, it says '4 Key Rules' and '10 per page'.

Index	Resource Set	Current Key Name	Transformation Key Name	Encryption Style
☐ 1	dir1	clear_key	LDT-KEY1	No
☐ 2	dir2	clear_key	LDT-KEY2	No
☐ 3	dir3	clear_key	LDT-KEY3	No
☐ 4	dir4	clear_key	LDT-KEY4	No

New resource sets were created for `dir3` and `dir4` before adding the new key rules in the policy. Once the updated policy is applied to the GuardPoint, the rekey is launched to encrypt the files associated with `/oxf-fs1/gp1/dir3` and `/oxf-fs1/gp1/dir4` using the encryption keys `LDT-KEY2` and `LDT-KEY3`, respectively. Remaining files in the GuardPoint remain unchanged.

New Key Rule

Files associated with resource sets are encrypted with the key specified in the corresponding key rule. Unlike files associated with the exclusion key rules, files not associated with any key rules are normally not encrypted, and not excluded from rekey, except under the few cases described below.

Following is an example of a policy applied to GuardPoint `/oxf-fs1/gp1` which includes subdirectories `dir1`, `dir2` and `dir3`. In this policy resource set, `dir1` has an exclusion key rule and resource set `dir2` has a key rule to encrypt from `clear` to `LDT-KEY-1`. Other subdirectories under `/oxf-fs1/gp1`, such as `dir3`, are not associated with any key rule.

The screenshot shows a web interface for configuring LDT-DYNRES-POL. It features a table with columns: 'Index', 'Resource Set', 'Current Key Rule', 'Transformation Key Rule', and 'Exclusion Rule'. There are two rows of data. The first row shows a resource set 'dir1' with a current key rule 'AES256' and an exclusion rule 'YES'. The second row shows a resource set 'dir2' with a current key rule 'LDT-KEY-1' and an exclusion rule 'NO'. A '+ Add Key Rule' button is visible in the top right corner of the table area.

Index	Resource Set	Current Key Rule	Transformation Key Rule	Exclusion Rule
1	dir1	AES256	AES256	YES
2	dir2	LDT-KEY-1	LDT-KEY-1	NO

Applying this policy to `/oxf-fs1/gp1` launches and rekeys the files under `/oxf-fs1/gp1/dir1` and `/oxf-fs1/gp1/dir2` using the specified key, while the files in `/oxf-fs1/gp1/dir3` remain in clear-text due to them not being associated with any key rule. This is reflected in the following examples for rekey statuses:

Example 1

```
voradmin ldt attr get /oxf-fs1/gp1/dir1/foo.txt
```

Example Response

```
LDT attributes: rekeyed_size=0, rekey_status=rekey_excluded
Key:      name=AES256, version=none
```

Example 2

```
voradmin ldt attr get /oxf-fs1/gp1/dir2/foo.txt
```

Example Response

```
LDT attributes: rekeyed_size=10485760, rekey_status=none
Key:      name=LDT-KEY-1, version=0
```

Example 3

```
voradmin ldt attr get /oxf-fs1/gp1/dir3/foo.txt
```

Example Response

```
LDT attributes: rekeyed_size=0, rekey_status=rekey_no_keyrule
Key:           name=clear_key, version=none
```

Rekeying

To rekey the files under `/oxf-fs1/gp1/dir3` you can update the policy as follows:

Once the updated policy is applied to the GuardPoint, the rekey launches to encrypt the files associated with `/oxf-fs1/gp1/dir3` using the encryption key LDT-KEY2. The remaining files in the GuardPoint remain unchanged.

Example

```
voradmin ldt attr get /oxf-fs1/gp1/dir3/foo.txt
```

Example Response

```
LDT attributes: rekeyed_size=10485760, rekey_status=none
Key:           name=LDT-KEY-2, version=0
```

As depicted above, the files previously marked as `rekey_no_keyrule` due to their association with a no rekey rule, were encrypted/rekeyed after adding the new key rule with the resource set that includes those files. Note that moving any of those files to other directories associated with key rule(s) for encryption will associate those files with the key rule corresponding to the target location, and consequently, encrypting those files in the new location under different key rules. Refer to the section below for the effect of operations, such as renaming files or directories or restoring files, to the association of the file with the resulting key rule.

Effect of Adding a New Key Rule Resulting in Rekey

Addition of a new key rule for encrypting the files associated with a resource set will increment the policy key version resulting in rekey launch on the affected GuardPoints.

Following is an example of a policy applied to GuardPoint `/oxf-fs1/gp1` which excludes subdirectory `dir1` and includes subdirectory `dir2` before adding a new key rule. The Policy Key Version is 19, before adding a new key rule.

Example

```
voradmin ldt attr get /oxf-fs1/gp1
```

Example Response

```
LDT stats: version=7, rekey_status=rekeyed
Number of times rekeyed:      1 time
Rekey start time:             2024/10/01 14:52:25
Last rekey completion time:   2024/10/01 14:52:25
Estimated rekey completion time: N/A
Policy key version:           19
Pushed Policy key version:    19
Policy ID:
    5e128f2c-3789-4985-85eb-b392c3108e25
Data stats:
    total=30.0MB, rekeyed=10.0MB
    truncated=0.0MB, sparse=0.0MB
File stats:
    total=3, rekeyed=1, failed=0
    passed=0, skipped=0, created=0, removed=0, excluded=2
```

After adding a new key rule resulting in launching rekey on the GuardPoint, the Policy Key Version of the GuardPoint changes to 20.

The screenshot shows the 'LDT-DYNRES-POL' configuration page. It has tabs for 'Security Rules' and 'Key Rules'. Below the tabs is a table titled 'Ordered Translated Key Rules'. The table has columns: 'ID', 'Resource ID', 'Custom Key Rule', 'Translation Key Rule', and 'Key Rule'. There are three rows of data. The first row has a green status icon. A '+ Add Key Rule' button is in the top right corner.

ID	Resource ID	Custom Key Rule	Translation Key Rule	Key Rule
1	1001	Custom Key Rule	AdmKey	Key
2	1002	Custom Key Rule	LDT Key 1	Key
3	1003	Custom Key Rule	LDT Key 2	Key

Example

```
voradmin ldt attr get /oxf-fs1/gp1
```

Example Response

```
LDT stats: version=7, rekey_status=rekeyed
Number of times rekeyed:      2 times
Rekey start time:             2024/10/01 14:54:57
Last rekey completion time:   2024/10/01 14:54:57
Estimated rekey completion time: N/A
Policy key version:           20
Pushed Policy key version:    20
Policy ID:
    5e128f2c-3789-4985-85eb-b392c3108e25
```

```
Data stats:
    total=30.0MB, rekeyed=10.0MB
    truncated=0.0MB, sparse=0.0MB
File stats:
    total=3, rekeyed=1, failed=0
    passed=1, skipped=0, created=0, removed=0, excluded=1
```

Feature changes for Dynamic Resource Sets after upgrading CipherTrust Transparent Encryption or CipherTrust Manager

CTE v7.6 does not differentiate between files that are not associated with any key rules, and with those associated with an exclusion key rule. As the result, files not associated with key rules are flagged as `rekey_excluded`, instead of `rekey_no_keyrule`. This behavior extends into CTE v7.7 if the CTE client is registered with CipherTrust Manager v2.16. Registering CTE v7.7, or a subsequent version, to CipherTrust Manager v2.17 or a subsequent version, enables CTE to differentiate between files associated with an exclusion key rule and those not associated with any key rule.

The following sections describe the effect of upgrading CipherTrust Transparent Encryption v7.6 and registration of a CTE client with CipherTrust Manager v2.16 and v2.17, and the new behavior when using Dynamic Resource Sets with CipherTrust Transparent Encryption v7.8.0 and CipherTrust Manager v2.17.

Scenario #1: CTE v7.6 client registers with CipherTrust Manager v2.16

When a CTE v7.6 client registers with CipherTrust Manager v2.16, or a previous version, and then CTE is upgraded to CTE v7.7, the behavior remains the same as in CTE v7.6. Note that the behavior in this scenario is that files not associated with key rules are marked as `rekey_excluded` instead `rekey_no_keyrule`.

Scenario #2: CTE v7.6 client registers with CipherTrust Manager v2.17 and then upgrades to CTE v7.7

Prior to upgrading CTE to v7.7, the files not associated with any key rule have already been marked with a `rekey_excluded` flag. As the `rekey_excluded` flag indicates exclusion from rekey, those files set to `rekey_excluded` must be reset to `rekey_no_keyrule` status after the upgrade.

If the user adds a new key rule immediately after upgrading CTE, before resetting the `rekey_excluded` flag, the files associated with the new key rule skip rekey. To avoid this, after CTE is upgraded to v7.7, run the `voradmin admin` command with the option `update-nokeyrule` to replace the `rekey_excluded` with `rekey_no_keyrule`.

Resetting `rekey_excluded` to `rekey_no_keyrule`

To reset the `rekey_excluded` to `rekey_no_keyrule` on the GuardPoint, type:

```
voradmin ldt attr update-nokeyrule ${gp}
```

Following is an example of a policy applied to GuardPoint `/oxf-fs1/gp1`, on a host with CTE v7.6, which excludes subdirectory `dir1` and includes subdirectory `dir2`.

Order	Resource Set	Current Key Name	Transformations Key Name	Exclusion Rule
1	HELLO	HELLO	HELLO	YES
2	HELLO	HELLO	LDT-HELLO	NO

In the following example, the file in `/oxf-fs1/gp1/dir3` remains in clear-text and `rekey_excluded`:

```
voradmin ldt attr get /oxf-fs1/gp1/dir3/foo.txt
```

Example Response

```
LDT attributes: rekeyed_size=0, rekey_status=rekey_excluded
Key:      name=clear_key, version=none
```

The file continues to remain in clear-text but is now marked as `rekey_no_keyrule`:

```
voradmin ldt attr get /oxf-fs1/gp1/dir3/foo.txt
```

Example Response

```
LDT attributes: rekeyed_size=0, rekey_status=rekey_no_keyrule
Key:      name=clear_key, version=none
```

Scenario #3: CTE v7.7 client registers with CipherTrust Manager v2.16, and then CipherTrust Manager is upgraded to v2.17, or a subsequent version

After upgrading CipherTrust Manager to v2.17, you **must** perform a capability synchronization between the CipherTrust Manager and all registered CTE agents.

To initiate a capability synchronization:

1. Go to CipherTrust Manager.
2. Click **Transparent Encryption > Settings > Client Information and Capabilities > Get Capability**

Client Information and Capabilities

Empty CTE Agent Information Log Volume ?

Remove Agent Information

Request Capabilities from All Clients ?

Get Capability

After the CipherTrust Manager upgrade is complete, the behavior remains the same as described above for CTE v7.7 with CipherTrust Manager v2.17 and subsequent versions.

File Operations Causing Key Rule Changes

Some file operations may result in changing the association of target files to a different key rule. For example, renaming a file associated with a key rule can result in changing the association. Renaming a directory can have the same result in a wider scope where all, or a subset of files, under the renamed subdirectory may share the resource set and be associated with the key rule of the resulting resource set. Another example is backing up and restoring files. Restoring a file into a different location in a GuardPoint will also change the association of the restored file to the key rule of the target location. Such operations will not only change the key rule association, but they may also change the rekey status and result in encrypting or decrypting data in the target file.

Files under an LDT policy are accessed based on their LDT attribute. As LDT attributes specify the rekey status and the encryption key applied to the data in target file, this information may not agree with the key rule associated with the file in the LDT policy.

Note

Be sure to understand the consequence of changing the association of target files to different key rules.

Restoring files Causing Key Rule Changes

As noted, restoring a file into a different location in a GuardPoint will change the association of the restored file to the key rule of the target location, as well as change the rekey status and data in the target file. The following table indicates how restoring files affects the key status and the key applied to the restored files.

- **Source Key Rule:** Key rule of the file at the time of backup
- **Target Key Rule:** Key rule of the file restored into the GuardPoint

Source Key Rule	Target Key Rule	Effect	Comment
rekey_excluded (Key A)	Encrypted Key B	rekey_excluded (Key A)	
rekey_excluded (Key A)	rekey_no_keyrule	rekey_no_keyrule (Key A)	Note 1
rekey_excluded (Key A)	rekey_excluded (Key A)	rekey_excluded (Key A)	
rekey_excluded (Key A)	rekey_excluded (clear_key)	rekey_excluded (Key A)	Note 2
rekey_excluded (clear_key)	Encrypted (Key B)	rekey_excluded (clear_key)	Note 3
rekey_excluded (clear_key)	rekey_no_keyrule	rekey_no_keyrule (clear_key)	Note 4
rekey_excluded (clear_key)	rekey_excluded (Key A)	rekey_excluded (clear_key)	Note 3
rekey_excluded (clear_key)	rekey_excluded (clear_key)	rekey_excluded (clear_key)	
rekey_no_keyrule	Encrypted (Key A)	rekey_no_keyrule, Encrypted Key A	Note 5
rekey_no_keyrule	rekey_no_keyrule	rekey_no_keyrule	
rekey_no_keyrule	rekey_excluded (clear_key)	rekey_excluded (clear_key)	
rekey_no_keyrule	rekey_excluded (Key A)	rekey_excluded (clear_key)	Note 3
Encrypted (Key A)	rekey_no_keyrule	rekey_no_keyrule (Key A)	Note 6
Encrypted (Key A)	Encrypted (Key A)	Encrypted (Key A)	
Encrypted (Key A)	rekey_excluded (Key B)	rekey_excluded (Key A)	Note 7
Encrypted (Key A)	rekey_excluded (clear_key)	Local - rekey_excluded (clear_key) NFS – rekey_excluded (Key A)	Note 8

Note

1. **rekey_excluded:** Status not preserved and changes to **rekey_no_keyrule**.
2. **rekey_excluded:** Status preserved, data remains encrypted.
3. **rekey_excluded:** Status preserved; however, data remains clear despite the key rule associated with the target location.

4. **rekey_excluded**: Status is not preserved.
5. **rekey_no_keyrule**: Status preserved on the restored file; however, the file will be encrypted during the next rekey process.
6. **rekey_no_keyrule**: Status preserved on the restored file; however, data in the file remains encrypted.
7. **rekey_excluded**: Status preserved; however, data remains encrypted to the same key despite the key rule associated with the target location.
8. Different results between GuardPoints on local and NFS.

Renaming files and shared key rules

The following table displays the results of renaming files affecting the key status and the key applied to the file under the new name. Note that renaming files may change the association of the file to another resource set.

Source Key Rule	Target Key Rule	Effect	Comment
Encrypted (Key A)	rekey_excluded (clear_key)	rekey_excluded (clear_key)	
Encrypted (Key A)	rekey_no_keyrule	rekey_no_keyrule (clear_key)	
Encrypted (Key A)	rekey_excluded (Key A)	rekey_excluded (Key A)	
Rekey_excluded (clear_key)	Encrypted (Key A)	Rekey_excluded (clear_key)	
Rekey_excluded (clear_key)	rekey_no_keyrule	Rekey_excluded (clear_key)	
Rekey_excluded (clear_key)	rekey_excluded (Key A)	Rekey_excluded (clear_key)	
Rekey_excluded (Key A)	Encrypted (Key A)	Rekey_excluded (Key A)	
Rekey_excluded (Key A)	rekey_no_keyrule	Rekey_excluded (Key A)	
Rekey_excluded (Key A)	Rekey_excluded (clear_key)	Rekey_excluded (Key A)	
Rekey_no_keyrule	Encrypted (Key A)	Rekey_no_keyrule Encrypted (Key A)	Note 1
Rekey_no_keyrule	Rekey_excluded (Key A)	Rekey_no_keyrule	Note 2
Rekey_no_keyrule	Rekey_excluded (clear_key)	Rekey_no_keyrule	

Note

1. **rekey_no_keyrule**: Preserved after file rename; however, the file will be encrypted during the next rekey process.
2. **rekey_no_keyrule**: Preserved after file rename; however, data remains clear despite the key rule associated with the target location.

Renaming directories and shared key rules

The following table indicates the result of renaming directories affecting the key status and the key applied to each file under the new directory pathname. Note that renaming files may change the association of the file to another resource set.

Source Key Rule	Target Key Rule	Effect	Comment
Encrypted (Key A)	rekey_excluded (clear_key)	Encrypted (Key A)	Note 1
Encrypted (Key A)	rekey_no_keyrule	Encrypted (Key A)	Note 1
Encrypted (Key A)	rekey_excluded (Key A)	Encrypted (Key A)	Note 1
Rekey_no_keyrule	Encrypted (Key A)	Rekey_no_keyrule Encrypted (Key A)	Note 2
Rekey_no_keyrule	rekey_excluded (clear_key)	Rekey_no_keyrule	
Rekey_no_keyrule	rekey_excluded (Key A)	Rekey_no_keyrule	Note 3

Note

1. **rekey_status** and **encryption key**: Do not immediately change after rename. During the next rekey process, LDT will decrypt the data in the renamed directory and set the **rekey_status=rekey_excluded** or **rekey_status=rekey_no_keyrule** to match the rekey status of the target key rule.
2. **rekey_status** and **encryption key**: Do not immediately change after rename. During the next rekey process, LDT will encrypt the data in the rename directory.
3. **rekey_no_keyrule**: Preserved after directory rename; however, data remains clear despite the key rule associated with the target location.

Using LDT with SAP HANA Fibre Channel Systems (Linux Only)

You must add additional CTE commands to the HANA administrator entry. To do so, edit the `/etc/sudoers` with a text editor and add entries for `/usr/bin/voradmin` and `/usr/bin/vmsec`:

Example:

```
hanadm ALL=NOPASSWD:
/usr/bin/secfsd,/usr/bin/voradmin,/usr/bin/vmsec,/sbin/multipath,/sbin/multipath
d,/etc/init.d/multipathd,/usr/bin/sg_persist,/bin/mount,/bin/umount,/bin/kill,/us
r/bin/lsof,/sbin/vgchange,/sbin/vgscan
```

If you are using an ext3 file system, you must mount it with extended attributes. To do so, edit the storage section of the `global.ini` file using a text editor and add the following lines:

```
partition_*_data__mountOptions = -o user_xattr
partition_*_log__mountOptions = -o user_xattr
```

LDT Administration

This section contains the following topics:

- LDT Metadata in Extended Attributes
- DFS(R) and Replication (Windows)
- Backing Up and Restoring LDT GuardPoints
- LDT Command-Line Administration: voradmin command
- Migrating a GuardPoint to a Different LDT Policy
- Removing LDT and Security Encryption
- Uninstalling the Agent while LDT is Rekeying GuardPoints
- Detecting Loss of NAS connection to an LDT GuardPoint Group

LDT Metadata in Extended Attributes

An *extended attribute* is a name/value pair permanently associated with a file or directory stored in a file system. CipherTrust Transparent Encryption (CTE) creates and maintains its own user extended attributes on LDT GuardPoint directories and files. The extended attributes are used to store metadata related to each file or directory that is protected using an LDT policy.

On Linux, LDT sets extended attributes on GuardPoint directories. The LDT attribute of an LDT GuardPoint stores the following metadata:

- Current key version.

-
- Rekey status.
 - Rekey start and end times.
 - Estimated completion time.
 - Total amount of data transformed.
 - Total number of files transformed.
 - Current key signature and applied key signature.

On both Linux and Windows, LDT sets extended attributes on files. The LDT attribute of a file stores the following metadata:

- Name of the current key.
- Name of the versioned key.
- Version number of the versioned key.
- LDT rekey status of the file.

In most cases, the current and new key names are the same. The exception is during initial transformation from a legacy policy to an LDT policy, when the file has been encrypted with the current key and is being transformed to the current version of the transformation key.

Note

Before you set up a GuardPoint for LDT, ensure that there is sufficient disk space available in your file system for LDT metadata. The amount of disk space you need depends on the number of files in your GuardPoint. For more information about the disk space requirement, see [Planning for LDT Attribute Storage](#).

The state of a file changes during LDT operations. The extended attributes are continually updated to reflect the current file status, which falls into one of the following categories:

- Rekeyed to the current version of the key.
- Rekeyed to the previous version of the key, or the initial key state (before the first LDT rekey has been performed).
- Partially rekeyed, where some regions of the file are rekeyed to the new key version and other regions are still keyed to the previous key version or the initial key.

Listing Extended Attributes

You can list extended attributes of files by using native operating system commands, or system calls. As part of GuardPoint administration, CTE can modify or delete extended attributes.

Note

This functionality is only available for local file systems. It is not supported for files in NFS Share GuardPoints.

In Linux, LDT attributes are set on GuardPoint directories and regular files in GuardPoint directories protected with LDT policies. The CTE extended attribute name is `::secfs:xattr:`.

The following examples use the native Linux operating system command `attr` to display the LDT attribute for the GuardPoint `/oxf-fs1/gp1` and the file `/oxf-fs1/gp1/File_1.txt`.

Example Getting File Attributes

```
attr -l /oxf-fs1/gp1/File_1.txt
Attribute "::secfs:xattr:" has a 1044 byte value for /oxf-fs1/gp1/File_1.txt
Attribute "selinux" has a 37 byte value for /oxf-fs1/gp1/File_1.txt
```

Example Getting GuardPoint Attributes

```
attr -l /oxf-fs1/gp1
Attribute "::secfs:xattr:" has a 1044 byte value for /oxf-fs1/gp1
Attribute "selinux" has a 37 byte value for /oxf-fs1/gp1
```

Example of `voradmin ldt attr get` for Linux File Attributes

In the following example, the file `/oxf-fs1/gp1/File_1.txt` has the same name for current and new keys at the same key version. In the following example, if the versioned key `LDT_KEY` is at version 755, the file is rekeyed to the latest key version under the LDT policy.

```
voradmin ldt attr get /oxf-fs1/gp1/File_1.txt
LDT attributes: rekeyed_size=4096, rekey_status=none
Key:    name=LDT_KEY, version=755
```

Example of `voradmin ldt attr get` for Linux GuardPoint Attributes

The following is example of an LDT attribute on a GuardPoint directory on Linux:

```
voradmin ldt attr get /oxf-fs1/gp1
LDT stats: version=1, rekey_status=rekeying
  Number of times rekeyed:      3 times
  Rekey start time:             2018/08/04 16:24:45

```

Example of `voradmin ldt attr get` for Windows GuardPoint Attributes

The attribute for the GuardPoint `c:\GP 1` contains the status (rekeyed) and statistics specific to the GuardPoint and LDT. Following is sample output of `voradmin` command on Windows for statistics on a file:

```
C:\> voradmin ldt attr get c:\GP\Test.txt
LDT attributes:
  Rekey Status      Rekeyed
  Initial Rekeyed Size 10 Bytes
Key:
  Key Name/Version    (LDT_KEY, 28)
```

The attribute for GuardPoint `C:\GP` contains the status (rekeyed) and statistics specific to the GuardPoint and LDT:

```
C:\> voradmin ldt attr get c:\gp\

```

MDS File (Linux)

In addition to LDT attributes, the LDT process on Linux requires persistent storage for additional metadata related to encrypting, or rekeying, files in GuardPoints. LDT allocates the storage space as soon as the LDT process starts on a GuardPoint. It maintains this storage space during the entire transformation process, until the GuardPoint is completely transformed.

Storage for this metadata is allocated and managed in a special file, called the MDS (metadata store) file. The

MDS file resides inside a GuardPoint directory so each GuardPoint has its own MDS file.

The MDS file is a CTE protected file with the name `__vorm_mds__`. For example:

```
ls -l /oxf-fs1/gp1/__vorm_mds__
-rwxr-xr-x. 1 root  root 31754474496 Dec  8 09:09 /oxf-fs1/__vorm_mds__
du -B 1024 /oxf-fs1/gp1/__vorm_mds__
25056    /oxf-fs1/__vorm_mds__
```

As shown above, the MDS file is sparse. In the example, the file size is approximately 30GB, however the file is allocated with approximately 25MB of disk storage. LDT automatically creates the MDS file the first time the LDT process starts on any GuardPoint in the file system namespace. It populates the MDS file with all of the metadata for the GuardPoint at the beginning of the LDT process. Disk space allocated to the MDS file is freed and the MDS file in the GuardPoint directory is removed when the LDT process completes on the GuardPoint.

Warning

The MDS file is protected. You cannot remove it unless the administrator runs the `voradmin` command to manually remove the MDS file once it is no longer needed. See [Deleting LDT Metadata \(Linux\)](#) for more information.

LDT automatically allocates and de-allocates disk space for the MDS file as part of the LDT process. De-allocation of disk space for a GuardPoint does not change the MDS file size, although it frees the disk blocks. MDS files are sparse and very large in size. The MDS file is automatically removed from GuardPoints when the files have been successfully rekeyed.

Note

The metadata storage (MDS) file name has changed from `__vorm_mds__` to `__vorm_mds__`. GuardPoints will automatically rename the MDS file when guarding with a CTE 7.6.0 agent. LDT NFS GuardPoints will rename once all of the hosts, with the same share guarded, have been upgraded.

Planning for LDT Attribute Storage

Before a GuardPoint is enabled for LDT, make sure that there is sufficient free disk space in the file system to which the GuardPoint belongs. Free space is required for LDT attributes and (in Linux) metadata in the MDS file. LDT attributes are created during the initial encryption and are never freed until the GuardPoint is permanently unguarded and removed from the protection of an LDT policy. In contrast, disk space for metadata in the MDS file is temporary, kept only during the live transformation process.

When planning how much free disk space to reserve for LDT on a GuardPoint, consider the following:

- Number of files in the GuardPoint
- (Linux) Average length of absolute pathnames of files in the GuardPoint

The LDT process pre-allocates disk space for the Linux MDS file based on a minimum of 200K files with an average pathname of 1024 bytes per GuardPoint. The minimum space amounts to 325MB of disk space for the

MDS file for each GuardPoint, even if file count is very low. (In Windows, LDT reserves the space when the file is rekeyed.)

Using voradmin To Estimate Disk Space Required for LDT

In **Linux**, you can use the `voradmin ldt space` command to estimate the amount of disk space required for LDT attributes and the MDS file. The result is rounded to the nearest MB. The syntax of the command is:

```
voradmin ldt space <guard path>
```

Note

In **Windows**, LDT requires 10% of the underlying file system space, or a minimum of 2GB disk space, for LDT to start.

The following example shows how to estimate the required disk space to perform CipherTrust Transparent Encryption - Live Data Transformation on 1501 files in the GuardPoint `/oxf-fs1/gp1`. Estimate the disk space before protecting `/oxf-fs1/gp1` using an LDT policy. For example:

```
voradmin ldt space /oxf-fs1/gp1
/oxf-fs1/gp1: found 1501 files without LDT extended attributes
LDT disk space requirements: total 169MB (LDT attributes=6MB, MDS=163MB)
```

The `voradmin` command reports that 1501 files in `/oxf-fs1/gp1` without LDT attributes. These files are new to LDT. 6MB of space is required for the LDT extended attributes and 163MB for metadata in the MDS file.

The following example shows the output of the same command after encryption completes. This estimates the additional disk space needed for the next LDT rekey operation. For example:

```
voradmin ldt space /oxf-fs1/gp1
/oxf-fs1/gp1: found 0 files without LDT extended attributes
LDT disk space requirements: total 163MB (LDT attributes=0MB, MDS=163MB)
```

The `voradmin` command still reports on the same 1501 files, but because encryption has occurred using LDT, the files all have their LDT attributes. No additional space is required for LDT extended attributes on the next run. However, since the MDS file is transient and deletes after it finishes encrypting the GuardPoint, it requires additional space for the next key rotation.

Note

Windows estimates space using the following equations:

```
Permanent Space = Number of Files * 4K
Temporary Space = 128K * (Number of CPU * 2)
```

Displaying Metadata

Use the following command to see LDT file attributes or GuardPoint attributes:

```
voradmin ldt attr get [<file name path> | <guard path>]
```

For an overview of `voradmin ldt`, see [LDT Command-Line Administration: voradmin command](#).

Verifying Metadata (Windows only)

Use the following command to verify if the metadata is corrupt:

```
voradmin ldt attr verify [<file name path> | <guard path>]
```

For an overview of `voradmin ldt`, see [LDT Command-Line Administration: voradmin command](#).

DFS(R) and Replication (Windows)

The Distributed File System Replication (DFS(R)) service is a multi-master replication engine used to maintain synchronized folders on multiple servers. Replicating data to multiple servers increases data availability and provides users in remote sites with fast, reliable access to files.

If you are creating GuardPoints in a DFS(R) environment, you must first add the DFS(R) private folder guard path to the exclusion list in the Windows Registry. LDT should not attempt data transformation on this read-only directory.

1. Using the Registry Editor, or the Windows command line, add a registry entry in: `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\services\Vmmgmt\Parameters` named "LDTEXCLUSIONGPLIST" of type REG_MULTI_SZ.
2. Add the `DfsrPrivate` and `System Volume Information` directory path to the `LDTEXCLUSIONGPLIST`.

For example, if the DFS(R) private directory path is `D:\data\DfsrPrivate`, add this string in `LDTEXCLUSIONGPLIST`.

3. Reboot the system to make the change take effect.

Note

LDT does not perform a rekey on the DFS(R) private directory. Its rekey status is always "N/A".

If an application, or user, is performing a rename or a delete folder operation inside a GuardPoint with an LDT policy, this may restart the rekey process. Files which are already rekeyed will not be rekeyed again.

- If a rename or a delete operation is already performed on rekeyed files/folder, then the rekey process does not

restart.

- If a rename or delete operation is performed in a folder where a rekey is in progress, LDT needs to stop the rekey process and restart the rekey again.

Backing Up and Restoring LDT GuardPoints

This section describes procedures and considerations related to backing up and restoring data in LDT GuardPoints.

In addition to the files in a GuardPoint, LDT stores metadata in extended file attributes. These LDT attributes contain information that is required for decrypting the files and for the proper operation of LDT. Therefore, it is critical that your backup application also backs up the extended attributes of the files along with file data.

Note

For backing up and restoring a CTE LDT over NFS GuardPoint, see [Backup and Restore LDT on NFS GuardPoints](#).

Clear Text Backup and Restore

A policy that applies a Security Rule with the Apply Key effect on backup/restore operations does not require any special rules for data access by backup applications. Under such a policy, backup applications always read clear data and store clear data in backup media. The backup application is not required to back up the LDT extended attributes, and a QoS schedule is not required to suspend LDT during backups.

Encrypted Backup and Restore

Note

Only the host designated as the primary host for an LDT GuardPoint Group can perform encrypted backup or restore operations on GuardPoints over NFS.

When a policy does not enforce a Security Rule with the Apply Key effect on backup/restore operations, the policy does not decrypt data on I/O operations from that backup application. Under such a policy, the backup application stores encrypted data and the LDT extended attributes of the file on the backup media.

In Linux, LDT operations must be suspended during backup. Suspending LDT completes the ongoing rekey operations on regions of files before starting the backup. During live transformation, LDT first preserves those regions of a file to be rekeyed in the MDS file. Then it updates some of the metadata in order to update the status of the data preserved in the MDS file in preparation for the rekey. Then it starts rekeying and updating those regions in the underlying file.

Suspending LDT waits for ongoing rekey operations to complete, and saves the metadata in the LDT extended attribute section of the MDS file. Suspending LDT ensures that the rekey status stored in the LDT extended attribute accurately reflects the rekey status of the data in the entire file during backup.

Note

This requirement does not apply to LDT for Windows.

The following table summarizes the state of the data in files in backup media:

LDT State of File	Security Policy	Backup Metadata or Alternate Data Streams Along with File data	Effect
Not rekeyed	Permit	Yes	Data in backup may be in clear format or encrypted with older key version.
Rekey in progress	Permit	Yes	File in backup storage is partially rekeyed. Some parts are in clear format or encrypted with older key version, and other parts are encrypted with current key version.
Rekey complete	Permit	Yes	File in backup storage is in the encrypted format with new key version.

LDT Policy for Encrypted Backup and Restore

Suppose you have an LDT policy allowing a backup user, or a backup process, to perform an encrypted backup. The backup user, or the backup process, reads encrypted data from files and stores the same encrypted data in backup media.

For example, suppose you wanted to back up GuardPoint `/oxf-fs1/gp1` protected by `My_LDT_Policy_1`. The key version before the key rotation is 8. The following steps occur:

1. Key version 8 expires and is rotated to version 9.
2. Rotating the encryption key triggers LDT to start running on the data under the GuardPoint.
3. The QoS schedule suspends LDT because a backup process is running.
4. The backup process begins, runs and later ends.
5. The QoS schedule resumes LDT.
6. LDT on the GuardPoint completes.

Note

Although the backup/restore scenarios and examples described in the rest of this section are specific to LDT on Linux platform, the concepts also apply to LDT on the Windows platform.

Consider the state of the three files in the GuardPoint during the LDT process, right after LDT is suspended in preparation for the backup. You can obtain the state of each file through the `voradmin ldt attr get` command, which examines the LDT state of each file captured in the LDT extended attributes of those files. (For an overview of `voradmin LDT`, see [LDT Command-Line Administration: voradmin command](#)).

- *File_1.dat* is rekeyed/encrypted to completion. The applied and new key versions are at version 9 of the key.

```
voradmin ldt attr get /oxf-fs1/gp1/data_files /file_1.dat
LDT attributes: rekeyed_size=1440743424, rekey_status=none
Key:      name=LDT_AES256_KEY, version=9
```

- *File_2.dat* is partially rekeyed/encrypted. The applied key version is at version 8 and the transformation key is at version 9.

```
voradmin ldt attr get /oxf-fs1/gp1/data_files/file_2.dat
LDT attributes: rekeyed_size=1440743424, rekey_status=rekeying, state_saved
Current Key:    name=LDT_AES256_KEY, version=8
New Key:        name=LDT_AES256_KEY, version=9
```

- *File_3.dat* has not been rekeyed/encrypted. The applied key and transformation key are both at version 8,

which is the version before the current key rotation.

```
voradmin ldt attr get /oxf-fs1/gp1/data_files/file_3.dat
LDT attributes: rekeyed_size=1440743424, rekey_status=none
Key:      name=LDT_AES256_KEY, version=8
```

While LDT is suspended on the GuardPoint, the backup process starts and archives these three files, including extended attributes, in the backup media.

```
my_backup --preserve=xattr /oxf-fs1/gp1/data_files/file_1.dat \
  /backup-media/oxf-fs1/gp1/data_files/file_1.dat
my_backup --preserve=xattr /oxf-fs1/gp1/data_files/file_2.dat \
  /backup-media/oxf-fs1/gp1/data_files/file_2.dat
my_backup --preserve=xattr /oxf-fs1/gp1/data_files/file_3.dat \
  /backup-media/oxf-fs1/gp1/data_files/file_3.dat
```

Note

- On Linux platforms, you must perform backups on a GuardPoint during periods when LDT is not actively transforming data in the GuardPoint. You must schedule backups in conjunction with LDT schedules or during periods when LDT is paused. Make sure to coordinate with the backup administrator and schedule accordingly.
- If the preferred method of backup is to create device level snapshots of the file system on the managed host or in the storage array subsystem, you must ensure that the schedule for creating snapshots pauses LDT before a snapshot is created.

Backup/Restore of Metadata Store File in GuardPoints Undergoing Rekey

- Restoring a GuardPoint from a Backup
- Potential Warnings During Restore Operation

Backing up an entire GuardPoint using commands such as `cp`, `tar`, or `rsync`, or even commercial backup products that sweep the file system namespace for backing up files is supported. This method of backup performed while LDT is in progress over GuardPoints poses some challenges when files in GuardPoints are backed up in an encrypted format. The challenge with this method of backup is the existence of the LDT Metadata Store file (MDS) in the GuardPoint during the backup or restore process, and strict protection enforced on MDS files preventing deletion or modification to MDS files.

Secondly, your backup utility must backup and restore extended attributes of files and the GuardPoint directory. Because LDT extended attributes are also protected similarly to MDS files, your backup must be enabled to restore extended attributes for files. To overcome both restrictions, your policy on the GuardPoint must include a security rule without Apply Key Effect to enable your backup utility to replace MDS files, and LDT extended attributes for files, as part of backup/restore operations. Additionally, your backup utility must be signed with a signature set from CipherTrust Manager for added security, and be executed with the option to preserve extended attribute options available with the standard Linux utilities.

The following table lists the supported backup utilities, required options to preserve extended attributes, and supported versions of the utilities.

Command	Required options	Supported version
cp	--preserve=all	OS default
tar	--xattrs	OS default
rsync	-vapIXWP --inplace	OS default
netbackup	overwrite existing files	v7.6.1 and v7.7.3

You can also backup and restore GuardPoint data, including the MDS file, if the requirements listed above on the backup utility are satisfied.

Note

You must suspend LDT on the GuardPoint before performing a backup or restore.

You can check your GuardPoint to determine if you can use this method of backup. If the directory of your GuardPoint is a mount point, MDS files reside inside your GuardPoint and you can use this method of backup for backing up or restoring your GuardPoint. However, GuardPoint directories below file system mount points must be checked and verified to use this method of backup. To verify, you can run the `voradmin` command to determine the MDS file associated your GuardPoint.

Example:

```
voradmin ldt list all
MDS_1: type=file, nguards=1, name=/oxf-fs1/gp1/__vorm_mds__

Guard Table: version 1 nentries 1
Guard 0: type=GP, state=REKEYING SUSPENDED (vadm), flags=GP LOCKED, gp=/oxf-fs1/gp1
File List: count 4308
```

You cannot restore to a GuardPoint during LDT, even after suspending LDT. Restoring to a GuardPoint in rekeying state will result in loss of data and potentially, data corruption. Follow the steps below to perform a full level restore of the GuardPoint.

Restoring a GuardPoint from a Backup

To properly restore GuardPoints along with the MDS file:

1. With the same tool that was used for backup, restore to the GuardPoint.
2. Once restore is complete, the GuardPoint needs to be disabled and enabled again. For manual GuardPoint, run the `secfsd` command as shown below. For auto-guards, disable and enable GuardPoints on CipherTrust Manager.

```
# secfsd -unguard <${gp}>
# secfsd -guard <${gp}>
```

- Disabling GuardPoint will remove the MDS file restored to the GuardPoint and flag the GuardPoint for RELAUNCH to restart LDT. Although the restored MDS file includes critical metadata for execution of LDT, the restored file does not hold data for any files in partial rekeyed status at the time the MDS file is restored. As such, the restored MDS file is automatically removed when GuardPoint is disabled. Once the GuardPoint is enabled, LDT is automatically relaunched on the GuardPoint as the result of RELAUNCH flag. Relaunching LDT will encrypt every file to the latest key version under LDT policy.

Potential Warnings During Restore Operation

When using `cp` for backup/restore, the `cp` command may report a failed attempt to preserve permissions on the Metadata Store File (MDS) during a restore. If you encounter the below message, continue to proceed with the restore steps since this will not affect the MDS file or dataset that is being restored.

```
cp: preserving permissions for '/oxf-fs1/gp1/__vorm_mds__ ': Permission denied
```

When using `rsync` for backup/restore, the `rsync` command may report a failed attempt to set extended attribute when restoring the MDS file on system with selinux configured in enforced mode. If user encounters the below message, continue to proceed with the restore steps since this will not affect the MDS file or dataset that is being restored.

```
rsync: copy_xattrs: lsetxattr("/oxf-fs1/gp1/__vorm_mds__ ", "security.selinux") failed: Permission denied (13)
rsync: rsync_xal_set: lsetxattr("/oxf-fs1/gp1/__vorm_mds__ ", "security.selinux") failed: Permission denied (13)
```

Restore an Encrypted Backup

[Restore a File Fully Rekeyed to the Latest Key Version](#)

[Restore a Partially Rekeyed/encrypted File](#)

[Restore a File Not Rekeyed/encrypted with an Older Key Version](#)

This section illustrates restoration of the three files from the backup media to the same GuardPoint, `/oxf-fs1/gp1`. The files are restored to a different directory under the GuardPoint.

Restore a File Fully Rekeyed to the Latest Key Version

Recall that *file_1.dat* was archived in the backup media when it was fully rekeyed to version 9 of the key. As the current version of the key is also 9, *file_1.dat* is restored from backup without any changes. After restoring the file, the state of the restored file and its applied and current key versions remain unchanged, as compared to the original file that was backed up.

```
my_backup --preserve=xattr /backup-media/oxf-fs1/gp1/data_files \
```

```

/file_1.dat /oxf-fs1/gp1/restored_files/file_1.dat

voradmin ldt attr get /oxf-fs1/gp1/restored_files/file_1.dat
LDT attributes: rekeyed_size=1440743424, rekey_status=none
Key:      name=LDT_AES256_KEY, version=9

voradmin ldt attr get /oxf-fs1/gp1/data_files/file_1.dat
LDT attributes: rekeyed_size=1440743424, rekey_status=none
Key:      name=LDT_AES256_KEY, version=9

```

Restore a Partially Rekeyed/encrypted File

Recall that *file_2.dat*, archived in the backup media, was partially rekeyed between versions 8 and 9. As the current version of the key was 9 at the time of backup, *file_2.dat* is restored to the GuardPoint with the same version of the key from the time of backup. The file is flagged for *lazy rekey*, meaning that a background rekey operation is scheduled to transform the file to the latest key version the next time an application tries to access the file.

At the completion of restoration, the file is fully transformed to the key version (v9). The key version is also the latest one in the policy. Although the file is flagged for lazy rekey (LAZY_RK), the file does not need to be transformed to the latest key version because it's already there. Had the file been partially rekeyed from version 7 to version 8 of the key at the time of backup, the restored file would have completed rekeying to version 8 at the end of the restoration. Therefore, the LAZY_RK flag would initiate a background transformation to update the key version to the latest key version when the file is accessed.

If this file is not accessed by any application, the file remains unchanged in the GuardPoint. It is not transformed to the latest key version. To trigger a rekey, access the file with an application, such as a file explorer.

- Access the file with an application, such as a file explorer.

```

my_backup --preserve=xattr /backup-media/oxf-fs1/gp1/data_files/ \ file_1.dat /oxf-fs1/gp1/restored_files/
file_2.dat

```

```

voradmin ldt attr get /oxf-fs1/gp1/restored_files/file_2.dat LDT attributes: rekeyed_size=1440743424,
rekey_status=lazy_rekey Key: name=LDT_AES256_KEY, version=9

```

```

voradmin ldt attr get /oxf-fs1/gp1/restored_files/file_2.dat LDT attributes: rekeyed_size=1440743424,
rekey_status=none Key: name=LDT_AES256_KEY, version=9

```

Restore a File Not Rekeyed/encrypted with an Older Key Version

Recall *file_3.dat* was archived in the backup media when it was keyed to version 8 of the key, one version below the latest version at the time of backup. At completion of the restoration, *file_3.dat* is restored from backup to the same version, version 8, that it was keyed to when it was backed up.

However, the file is flagged for lazy rekey. After restoring the file, it is keyed to version 8 and flagged for lazy rekey (LAZY_RK). The file is rekeyed to the latest key version, version 9, as soon as an application accesses the file. If this file is not accessed by any application, the file remains unchanged in the GuardPoint.

```

my_backup --preserve=xattr /backup-media/oxf-fs1/gp1/data_files \
/file_3.dat /oxf-fs1/gp1/restored_files/file_3.dat

```

```

voradmin ldt attr get /oxf-fs1/gp1/restored_files/file_3.dat
LDT attributes: rekeyed_size=1440743424, rekey_status=lazy_rekey
Key:      name=LDT_AES256_KEY, version=8

sum /oxf-fs1/gp1/restored_files/file_3.dat
39994 1406976

voradmin ldt attr get /oxf-fs1/gp1/restored_files/file_3.dat
LDT attributes: rekeyed_size=1440743424, rekey_status=none
Key:      name=LDT_AES256_KEY, version=9

```

Restoring Non-LDT Backup Data to an LDT GuardPoint

This section describes how to restore data encrypted with a non-versioned key to an LDT GuardPoint.

If the backup was performed with the Apply Key effect, the backup files are in clear text. Simply restore the clear text files to the LDT GuardPoint with the Apply Key effect. All files will be encrypted with the versioned key.

If the backup of the non-LDT GuardPoint was performed without the Apply Key effect, the backup is encrypted, and you must do the following:

Note

The following example is for a manual guarding. The steps may differ slightly if your GuardPoint is configured for auto guard.

1. Create a temporary directory for restoring the files, type:

```
mkdir -p /oxf-fs1/tmp_restore
```

2. Restore the encrypted backup files into the temporary directory, type:

```
cp -pr /backup-media/oxf-fs1/gp1/data_files/* /oxf-fs1/tmp_restore
```

3. Create a Standard Policy with the Apply Key effect for all operations, using the same key as the policy applied on the GuardPoint at the time of backup.
4. Create and enable a new GuardPoint for the temporary directory using the Standard Policy just created.

```
secfsd -guard /oxf-fs1/tmp_restore
```

5. Ensure that the temporary GuardPoint and LDT GuardPoint are both enabled.

```
secfsd -status guard
```

GuardPoint	Policy	Type	ConfigState	Status	Reason
-----	-----	----	-----	-----	-----
/oxf-fs1/gp1	LDT_AES256	manual	guarded	guarded	N/A
/oxf-fs1/tmp_restore	AES256	manual	guarded	guarded	N/A

- Move the restored files from the temporary folder to the GuardPoint enabled with the LDT policy. The CTE agent encrypts the files in the LDT GuardPoint using the current key version in effect for the LDT policy.

```
mv /oxf-fs1/tmp_restore/* /oxf-fs1/gp1
```

- Unguard the temporary GuardPoint and remove the temporary restore directory.

```
secfsd -unguard /oxf-fs1/tmp_restore
rm -fr /oxf-fs1/tmp_restore
```

- Delete the temporary GuardPoint on the CipherTrust Manager.

Using fsfreeze (Linux only)

If you use the `fsfreeze` command to quiesce access to the file system before creating a snapshot, refer to the `fsfreeze` section in CTE Admin Guide in the Linux Utilities chapter on how to run the `fsfreeze` command to quiesce access to both the file system and the GuardPoint(s).

Warning

Do not use LDT schedules and do not pause LDT to align backup schedules with LDT. Instead, use the `fsfreeze` command.

- Running `fsfreeze -f` on the GuardPoint directory pauses LDT operations in-progress and freezes access to both the GuardPoint and the underlying file system.
- Running `freeze -u` reverses `freeze -f`, allowing access to underlying file system and resuming LDT operations.

LDT Backups Using a File System or Storage-Level Snapshot Tool

You can make a file system snapshot using a Logical Volume Manager service or mirroring/splitting storage level LUNs of a file system inside the storage subsystem. LDT does not have requirements for where and how you create a file system snapshot. However, it is required that you **suspend LDT processes before you take the file system snapshot**. Suspending LDT ensures data and metadata consistency between files and LDT extended attributes.

You may choose to suspend LDT manually on the managed host using `voradmin ldt suspend` command or `fsfreeze -f`, or suspend LDT on the CipherTrust Manager.

Note

Be aware that suspending LDT on the CipherTrust Manager suspends LDT on the entire host.

After creating a file system snapshot, you can resume LDT processes on the GuardPoint using `voradmin ldt resume`, or `fsfreeze -u`, or resuming LDT on the CipherTrust Manager. Do not mix the use of `fsfreeze` and `voradmin ldt suspend` to pause and resume LDT. CTE suspends or resumes LDT processes during live transformation when freezing or unfreezing GuardPoint access using `fsfreeze -f` or `-u` option.

Note

You can make sure LDT is suspended at backup time by setting the QoS schedule

You can mount a file system snapshot for data recovery. Configuration for GuardPoints must be duplicated over the mount point of the snapshot file system. Make sure to use the same LDT policy. Enabling GuardPoints over or under the snapshot mount point provides access to the protected files for recovery. You can choose to manually resume key rotation on the GuardPoints of the snapshot file system, although this is not necessary.

Following is an example of the `fsfreeze` command used to freeze access to the file system `/oxf-fs1` in order to create a snapshot of the file system device. This examples illustrates three GuardPoints enabled inside the file system namespace, `/oxf-fs1/gp-1`, `/oxf-fs1/gp-2`, and `/oxf-fs1/gp-3`. Executing the command `fsfreeze -f` targets any of the GuardPoints in the `/oxf-fs1` mount point and suspends LDT processes on all of the GuardPoints. Then it freezes access to the file system.

```
fsfreeze -f /oxf-fs1/gp-1
voradmin ldt list all
MDS_1:  type=file, nguards=1, name=/oxf-fs1/gp-3/__vorm_mds__
        Guard Table: version 1 nentries 1
        Guard 0: type=GP, state=REKEYING SUSPENDED (vadm), flags=GP LOCKED, gp=/o
xf-fs1/gp-3
        File List: count 4308

MDS_2:  type=file, nguards=1, name=/oxf-fs1/gp-2/__vorm_mds__
        Guard Table: version 1 nentries 1
        Guard 0: type=GP, state=REKEYING DIRTY, flags=GP LOCKED, gp=/oxf-fs1/gp-2
        File List: count 4308

MDS_3:  type=file, nguards=1, name=/oxf-fs1/gp-1/__vorm_mds__
        Guard Table: version 1 nentries 1
        Guard 0: type=GP, state=REKEYING SUSPENDED (vadm), flags=GP LOCKED, gp=/o
xf-fs1/gp-1
        File List: count 4308
```

After the file system snapshot is created, executing the `fsfreeze -u` command on any of the GuardPoints in the file system namespace unfreezes access to the file system and resumes LDT processes on all of the GuardPoints.

```
fsfreeze -u /oxf-fs1/gp-1
```

```

voradmin ldt list all
MDS_1:  type=file, nguards=1, name=/oxf-fs1/gp-3/___vorm_mds___
        Guard Table: version 1 nentries 1
        Guard 0: type=GP, state=REKEYING DIRTY, flags=GP LOCKED, gp=/oxf-fs1/gp-3
        File List: count 4308

MDS_2:  type=file, nguards=1, name=/oxf-fs1/gp-2/___vorm_mds___
        Guard Table: version 1 nentries 1
        Guard 0: type=GP, state=REKEYING DIRTY, flags=GP LOCKED, gp=/oxf-fs1/gp-2
        File List: count 4308

MDS_3:  type=file, nguards=1, name=/oxf-fs1/gp-1/___vorm_mds___
        Guard Table: version 1 nentries 1
        Guard 0: type=GP, state=REKEYING DIRTY, flags=GP LOCKED, gp=/oxf-fs1/gp-1
        File List: count 4308

```

Support for Volume Level Snapshots on NAS Shares with LDT on Linux

CTE supports volume level snapshot capabilities of NAS shares. You may choose to enable the snapshot service on an LDT-protected GuardPoint as long as the GuardPoint is enabled before the snapshot service is activated. Note that the snapshot service is deactivated before the GuardPoint is disabled. Keeping the snapshot service active when the GuardPoint is not enabled may result in data corruption or inconsistent LDT metadata at file or GuardPoint levels.

Windows Backup and Snapshots

On Windows, most backup applications use Volume Snapshot Service (VSS) for the backup. Using VSS is required for backing up files in LDT GuardPoints. VSS service provides a consistent view of the data to backup and restore applications by taking a snapshot of the volume. Windows Backup uses the snapshot volume, while other applications can continue using the original volume for normal I/O operations. VSS snapshot volume uses a “Copy on write” mechanism to provide a consistent view of the data. Some of the high-level steps of the Windows backup process are:

1. Backup application takes a snapshot of the volume using the VSS service.
2. Backup application mounts this VSS volume to read the data to be backed up.
3. The CTE Agent uses the same policy as that of the original volume to protect these snapshots.
4. The CTE Agent applies the policy and rules to all the I/O requests coming from the backup and restore applications.

Note

Make sure that you have enough disk space allocated for this procedure. When LDT rekeys files, it triggers the VSS copy-on-write technology, which makes a copy of that sector for the volume, for that previous snapshot, before it writes the new encrypted data to the original volume. This action can consume a lot of the space allocated for snapshots by VSS.

LDT Backup and Restore Troubleshooting

Restored files to a GuardPoint protected with conflicting key rules

When restoring an encrypted file from backup media to an LDT protected GuardPoint without the Apply Key effect, and the file in the backup media does not have an LDT extended attribute, the file restored to the GuardPoint is set with an LDT extended attribute that specifies the current key version of the key in the policy associated with the data in the restored file. As the key and key version in the policy do not match the key that was applied to the data at the time of backup, the file restored to the LDT protected GuardPoint is unreadable.

When restoring an encrypted file from backup media to an LDT protected GuardPoint without Apply Key effect, and the key specified in the LDT extended attribute of the file in backup media conflicts with the key rules of the policy on the GuardPoint, the restore operation fails and flags the restored file in error. You can only remove the file, or truncate it, to clear the error status on the file. Access to such files, except remove or truncate, fail with an EINVAL error.

LDT Command-Line Administration: voradmin command

Use the **voradmin** utility to gather statistics and administer LDT on a host/client . It has slightly different syntax and command capabilities depending on whether the host/client is running Linux or Windows.

To use **voradmin**:

1. Log in to the host running the CTE Agent with LDT enabled.
2. At the command line, type **voradmin**.
3. Follow the usage outputs onscreen to find the available commands and their syntax. The general syntax is:

```
voradmin ldt <command> [args]
```

Command	OS	Description
<code>voradmin ldt attr get delete <guard path> <object path></code>	W/L	Get or delete attributes for a GuardPoint or Object path.
<code>voradmin ldt exlist <add remove get> <guard path></code>	W	GuardPoint path to add in exclusion list.
<code>voradmin ldt group <check info remove repa ir comm_info> [hostname] <guard path></code>	W/L	Various info about the group.
<code>voradmin ldt ior <threshold></code>	W/L	QoS Rekey rate threshold value in MB/sec.

Command	OS	Description
<code>voradmin ldt key <report map <key> <guard path></code>	W/L	Creates a report, or map, containing statistics after each key rotation on a GuardPoint.
<code>voradmin ldt list all</code>	W/L	List all MDS files and GuardPoints undergoing LDT processing.
<code>voradmin ldt monitor [interval]</code>	W	Monitor LDT progress. If an interval is specified (in units of seconds), it continually updates the monitoring output at the specified interval.
<code>voradmin ldt rekey report <guard path> [<output file>]</code>	L	Generate a rekey report manually for a Guardpath.
<code>voradmin ldt report <guard path> <log file></code>	W	Full GuardPoint or log file path.
<code>voradmin ldt rescan <guard path></code>	W	Rescan a GuardPoint for CIP remediation.
<code>voradmin ldt resume <guard path> all</code>	W/L	Resume guarding the GuardPoint directory.
<code>voradmin ldt rmltd <guard path> voradmin ldt rmstore <guard path></code>	L	Both the <code>rmstore</code> and <code>rmltd</code> options remove the LDT metadata information remaining in a GuardPoint directory after permanent unguarding of the specified GuardPoint. The <code>rmstore</code> option removes the MDS file, if it exists. The <code>rmltd</code> removes the MDS file and the files in LDT Private Directory for GuardPoints over NFS shares. Note: GuardPoints over NFS shares are only supported if you are using the CM as your key manager.
<code>voradmin ldt skip <show> <guard path> <filename></code>	W	Display the files skipped during data transformation.
<code>voradmin ldt space</code>	W/L	Estimates disk space needed for

Command	OS	Description
<code><guard path></code>		metadata and MDS store information.
<code>voradmin ldt summary <guard path></code>	W/L	Reports the exact number of files encrypted in the GuardPoint in real time.
<code>voradmin ldt suspend <all><guard path></code>	W/L	Suspend the rekey on a specified GuardPoint, or all the GuardPoints, on this host.
<code>voradmin ldt stats [<guard path>] [<interval>]</code>	W/L	Obtains transformation LDT statistics such as: • Current rekey status • Start time • Estimated completion time • Percentage completed • Total data • Amount of data transformed • Total files • Number of files transformed • Number of files skipped • Number of files remaining for rekey

Migrating a GuardPoint to a Different LDT Policy

To change the LDT policy that an LDT GuardPoint uses, complete the following steps to ensure that the GuardPoint is migrated properly from one LDT policy to another LDT policy.

Note

This procedure is for the migration of local file system GuardPoints only. For information about migrating NFS GuardPoints to `clear_key`, see [Migrating GuardPoints over NFS from or to an LDT Policy](#).

Scenario

The GuardPoint is currently attached to LDT-Policy-1, which rekeys from `clear_key` to `LDT-Key-1`. The objective is to migrate the data in the GuardPoint to another versioned key, `LDT-Key-2`. Migration to `LDT-Key-2` requires detaching the GuardPoint from `LDT-Policy-1`, and then attaching it to `LDT-Policy-2`, assuming `LDT-Key-2` is the versioned key specified in `LDT-Policy-2`. To do so:

1. Clone the latest version of the key `LDT-Key-1` to a non-versioned key such as `LDT-Key-1-Clone`.

- a. From the Products page in the CipherTrust Manager Console, click **Keys** in the left hand pane.

Tip

To navigate to the Products page from anywhere in the CipherTrust Manager Console, click the App Switcher icon in the top left corner.

- b. Click the name of the versioned key that you want to clone.
 - c. In the Key Details area, find the version that you want to clone.
 - d. Click the (...) button at the end of the row and select **Clone** to clone the selected version of the key.
2. Identify or create a new versioned key that you want LDT to use to re-encrypt the data. For example, **LDT-Key-2**.
 3. Create a new Live Data Transformation policy that specifies **LDT-Key-1-Clone** as the Initial Key and **LDT-Key-2** as the Transformation Key.
 4. Make sure that all data transformation has completed on the GuardPoint. To verify this, use the `voradmin ldt attr get <GuardPoint>` command.
 5. In your key manager, unguard the GuardPoint.
 6. On the host, remove the existing LDT attributes on the GuardPoint using the `voradmin ldt attr delete <GuardPoint>` command.

```
voradmin ldt attr delete /oxf-fs1/gp1
LDT metadata has been removed from all files in GuardPoint [/oxf-fs1/gp1]
LDT attributes deleted from 10 files in /oxf-fs1/gp1
LDT: Metadata has been removed from all files in guard point [/oxf-fs1/gp1]
```

7. Guard the directory using the new LDT policy.
 - If you have selected Auto Guard, data transformation begins as soon as the host gets the new policy information from the key manager.
 - If you have selected Manual Guard, use the `secfsd -guard <GuardPoint>` command on the host to begin data transformation.

Removing LDT and Security Encryption

If you want to stop using LDT on a GuardPoint or on a whole host/client , follow the instructions in the following sections.

- Migrating a GuardPoint Out of LDT
- Deleting LDT Metadata (Linux)
- Deleting LDT Metadata (Windows)
- Removing LDT from a Host

Migrating a GuardPoint Out of LDT

Migrating a GuardPoint from LDT removes the security encryption. It also provides an Administrator with the flexibility to relax the compliance requirement, when strict compliance for frequent key rotation on specific data is no longer mandatory. The following sections describe how to migrate a GuardPoint from LDT to a non-LDT policy, or to remove encryption protection from it.

Converting a GuardPoint from an LDT Policy to a Standard Policy

If you want to do more than just change the policy on a GuardPoint from an LDT policy to a non-LDT policy, see [Deleting LDT Metadata \(Linux\)](#) or [Deleting LDT Metadata \(Windows\)](#).

Note

- Converting LDT CIFS/NFS GuardPoints from Live Data Transformation policies to Standard CTE policies is not supported.
- LDT CIFS/NFS-protected GuardPoints cannot be migrated to clear_key.
- Reverse migration **is not** supported for network shares.

1. Clone the versioned key associated with the LDT GuardPoint to a non-versioned key.

The clone function creates a new key with the same cryptographic encryption material as the current version of the cloned versioned key.

This allows LDT to use the cloned key in a non-LDT policy to convert the GuardPoint from an LDT to a non-LDT managed policy.

- a. In CipherTrust Manager, click **Keys** in the navigation bar.
- b. Click the name of the versioned key that you want to clone.
- c. In the Key Details area, click the (...) button at the end of the row showing the current version of the key and select **Clone** to clone the current version.
- d. Enter a new name for the key in the **Key Name** field. Do not select the **CTE Versioned** option for the clone.

- e. Click **Clone**.
2. Open the **CTE** application and click **Clients** in the left-hand menu bar.
3. Click on the name of the client whose GuardPoint you want to migrate.
4. Find the GuardPoint you want to migrate in the GuardPoints table, then click the (...) button at the end of the row and select **Disable**.
5. After LDT disables the GuardPoint, click the (...) button at the end of the row and select **Unguard**.
6. (Linux only) Ensure that the GuardPoint is removed on the managed host:

```
secfsd -status guard  
No ${gp}s configured
```

7. LDT creates extended attributes for every file under the GuardPoint as well as the GuardPoint directory. Now that the LDT policy does not manage the GuardPoint, you must remove the extended attributes for every file in the GuardPoint, type:

```
voradmin ldt attr delete /<${gp}>
```

8. The command may take some time depending on the number of files in the GuardPoint.

Note

For all of the file system mount points that contain an LDT protected GuardPoint, you must clean up the metadata first. See [Deleting LDT Metadata \(Linux\)](#).

9. Create a non-LDT policy using the cloned key you created earlier in this procedure.
 - a. In the **CTE** application, click **Policies** in the left-hand menu bar and then click **Create Policy**.
 - b. Enter a name for the policy in the **Name** field.
 - c. In **Policy Type**, choose **Standard**.
 - d. Click **Next**.
 - e. On the Security Rules page, click **Next** to skip adding a security rule.
 - f. On the Key Selection Rules, click **Create Key Rule**.
 - g. In the **Key Name** field, select the cloned key you created earlier.

- h. Click **Add**.
 - i. Click **Next**
 - j. Confirm that the key rule is correct and click **Save**.
10. Apply the non-LDT policy to the GuardPoint.

Caution

Make sure that you have removed all of the LDT metadata from the GuardPoint before applying the non-LDT policy.

- a. Open the **CTE** application and click **Clients** in the left-hand menu bar.
- b. Click on the name of the client whose GuardPoint you want to migrate.
- c. Click **Create GuardPoint**.
- d. In the *Create GuardPoint* dialog box, select the Policy that you just created in the **Policy** field.
- e. Select the **Type: Auto Directory** or **Manual Directory**.
- f. In the **Path** field, and enter or browse to the directory to protect.
- g. When you are done, click **Create**.

Remove Protection from a GuardPoint

When compliance may no longer require protecting data in a GuardPoint, you may choose to unprotect/decrypt it. Before removing protection from your GuardPoint, you must decrypt the data in your GuardPoint by setting it to clear. You have two options to decrypt your data:

- While a GuardPoint is protected and enabled under an LDT policy, you can use copy or backup/restore commands to save files in your GuardPoint to a location outside of your GuardPoint.
- Use the `dataxform` command to transform your GuardPoint to clear in an offline transformation process.

For GuardPoints over NFS, you must backup the entire GuardPoint before you unguard the GuardPoint. Then you can restore the files from backup over the GuardPoint directory after you remove the protection on the GuardPoint.

Copying Files to Decrypt Them

If you choose to copy your files, you must create a directory outside of the GuardPoint and then copy the files into the GuardPoint directory. After finishing copying, complete the following steps:

1. Open the **CTE** application and click **Clients** in the left-hand menu bar.

2. Click on the name of the client whose GuardPoint you want to remove.
3. Find the GuardPoint you want to remove in the GuardPoints table, then click the (...) button at the end of the row and select **Disable**.
4. After LDT disables the GuardPoint, click the (...) button at the end of the row and select **Remove**.
5. (Linux only) Ensure that the GuardPoint is removed on the managed host:

```
secfsd -status guard
No ${gp}s configured
```

This completes removal of the GuardPoint under an LDT policy. You can now remove the original files and data within the GuardPoint namespace.

Using Dataxform Command to Transform the Files

If you choose to use the `dataxform` command to transform data in your GuardPoint to clear, use the `voradmin` command to verify that earlier versions of the versioned key are not in use on your GuardPoint. Complete the following steps to clear all metadata in your GuardPoint. Then, transform your GuardPoint to clear.

1. Clone the versioned key associated with the LDT GuardPoint to a non-versioned key.
 - a. In the CipherTrust Manager Applications Page, open the **Keys & Access Management** application.
 - b. Click the name of the versioned key that you want to clone.
 - c. In the Key Details area, click the (...) button at the end of the row showing the current version of the key and select **Clone** to clone the current version.
 - d. Enter a new name for the key in the **Key Name** field. Do not select the **CTE Versioned** option for the clone.
 - e. Click **Clone**.
2. Create a Standard policy using the cloned key you just created.
 - a. In the **CTE** application, click **Policies** in the left-hand menu bar and then click **Create Policy**.
 - b. Enter a name for the policy in the **Name** field.
 - c. In **Policy Type**, choose **Standard**.
 - d. Enable the **Data Transformation** option.
 - e. Click **Next**.
 - f. On the Security Rules page, click **Next** to skip adding a security rule.
 - g. On the Key Selection Rules, click **Create Key Rule**.

- h. In the **Key Name** field, select the cloned key you created earlier.
 - i. Click **Add**, then click **Next**.
 - j. On the Data Transformation page, click **Create Data Transformation Rule**.
 - k. In the **Transformation Key Name** field, select `clear_key`.
 - l. Click **Add**, then click **Next**.
 - m. Confirm that the key rule and data transformation rule are correct and click **Save**.
3. Click **Clients** in the left-hand menu bar.
 4. In the Clients table, click on the name of the client whose GuardPoint you want to remove.
 5. Find the GuardPoint you want to remove in the GuardPoints table, then click the (...) button at the end of the row and select **Disable**.
 6. After LDT disables the GuardPoint, click the (...) button at the end of the row and select **Remove**.

Before you apply the offline data transformation policy to your GuardPoint, you must clean up the LDT metadata from your GuardPoint. LDT creates extended attributes for every file under the GuardPoint, as well as the GuardPoint directory. Now that the LDT policy does not manage the GuardPoint, you can remove the extended attributes for every file in the GuardPoint.

7. Remove the extended attributes of files in a GuardPoint, type:

```
voradmin ldt attr delete <${gp}>
```

The command may take some time depending on the number of files in the GuardPoint. After metadata deletion is complete, you can apply the offline transformation policy on the GuardPoint.

8. CipherTrust Manager, guard and enable the GuardPoint with the Standard policy you created earlier.
9. After enabling your GuardPoint, run the `dataxform` command on the managed host to transform the GuardPoint to a `clear_key`, type:

```
dataxform --rekey --gp /<${gp}>/ --preserve_modified_time --preserve_access_time --cleanup_on_success
```

10. After completion of `dataxform`, unguard the GuardPoint.
11. Remove the GuardPoint from the `dataxform` policy in CipherTrust Manager.

Deleting LDT Metadata (Linux)

To remove the metadata associated with the GuardPoint, you must run the `voradmin` command on the managed

host to remove the LDT metadata associated with the GuardPoint.

Warning

Before you attempt to remove an MDS file, make sure that no LDT-protected GuardPoints remain configured under the file system mount point.

In the following example:

- `/oxf-fs1` is the mount point
- `/oxf-fs1/gp1` is the LDT-protected GuardPoint

To delete the metadata associated with the GuardPoint:

1. Ensure that the GuardPoint is not enabled on the host. Run the command below and verify that the GuardPoint pathname does not appear in the output of the `secfsd` command, type:

```
secfsd -status guard
```

2. Run the `voradmin` command to remove LDT attributes on the GuardPoint, type:

```
voradmin ldt attr delete <GuardPoint path>
```

For example:

```
voradmin ldt attr delete /oxf-fs1/gp1
LDT metadata has been removed from all files in GuardPoint /oxf-fs1/gp1
```

Deleting the LDT Private Space Directory for NFS Shares

As described in [LDT Metadata Management Over NFS/CIFS Shares](#), LDT creates and manages LDT NFS metadata in the LDT Private Space Directory inside the GuardPoint. To remove the LDT Private Space Directory and the files it contains, use the `voradmin ldt rmltd <GuardPoint>` command. For example:

```
voradmin ldt rmltd /nfs-oxf-fs1/gp1
Enter YES if GuardPoint /nfs-oxf-fs1/gp1 is no longer associated with an LDT poli
cy -> YES
LDT metadata on /nfs-oxf-fs1/gp1 has been removed.
```

Deleting LDT Metadata (Windows)

Use the following command to delete the CTE extended attribute for a file or a GuardPoint. This is useful when removing a GuardPoint from under an LDT policy (see [Migrating a GuardPoint Out of LDT](#)).

```
voradmin ldt attr delete [<file name path> | <guard path>]
```

For an overview of `voradmin ldt`, see [LDT Command-Line Administration: voradmin command](#).

Removing LDT from a Host

Once you have registered a host and enabled LDT, you cannot disable the LDT feature by unchecking the LDT box. You must unregister the host from the CipherTrust Manager, then register it again without LDT. When you remove the LDT feature from a host entirely, the host's LDT license becomes available for use on another host.

1. Stop all applications from accessing data in LDT GuardPoints on the host.
2. Migrate data in every LDT GuardPoint using the steps described in the section [Remove Protection from a GuardPoint](#).

Warning

Potential data loss. Ensure that you have decrypted the data and, optionally, copied it out of the GuardPoint. Once the CTE Agent software is removed, access to data is no longer controlled by CTE. If the data was encrypted, it remains encrypted, and there is no way to read it.

3. Remove the GuardPoints on the host from the CipherTrust Manager.
 - a. Remove the LDT metadata from those GuardPoints.
 - b. Remove the MDS files associated with those GuardPoints, if necessary. See [Deleting LDT Metadata \(Linux\)](#) for more information.
4. Remove the host from the CipherTrust Manager. For details, see the *CTE Agent for Linux Advanced Configuration and Integration Guide* or the *CTE Agent for Windows Advanced Configuration and Integration Guide*.
5. Re-install the agent on the host.
6. Register the host with the CipherTrust Manager. This time, do not select the CipherTrust Transparent Encryption - Live Data Transformation option. See [Enabling LDT on a Protected Host](#).

Uninstalling the Agent while LDT is Rekeying GuardPoints

You cannot uninstall the CTE Agent if LDT is rekeying any GuardPoints on that host/client .

If you want to uninstall the CTE Agent from a host/client that contains LDT GuardPoints, you must first unencrypt the files on each LDT GuardPoint using the steps noted in the previous sections.

Detecting Loss of NAS connection to an LDT GuardPoint Group

This section describes the LDT over NFS mechanism for detection of loss of a NAS (Network attached storage) connection to an LDT over NFS GuardPoint on all members of the LDT GuardPoint Group. LDT over NFS monitors LDT operations on NAS servers for detection of loss of NFS connection and implements steps to recover from loss of NAS access. This section describes the procedures and considerations for recovering an LDT over NFS GuardPoint from loss of NAS connection on a member of LDT GuardPoint Group.

Brief Overview of LDT Rekey Operations

Rekey operations within LDT GuardPoint Groups are executed on the primary host in coordination with other members of the LDT GuardPoint Group. Coordination includes interlocking access to files by applications and rekey operations. It also includes the primary host updating persistent LDT metadata on behalf of the application file or IO operations on any member of the LDT GuardPoint Group. Such active coordination is critical to the correct operations of LDT over NFS. Loss of NAS connection on any of the members in LDT GuardPoint Group disrupts the coordination between primary and other members. LDT manages loss of the NAS access on all members of the LDT GuardPoint Group to ensure data and metadata correctness with minimal impact to production workloads.

This section describes the LDT over NFS mechanism for detection of loss of NAS connection to an LDT over NFS GuardPoint on a member (primary/secondary) host of the group and also describes the procedures and considerations for recovering an LDT over NFS GuardPoint from the loss of NAS connection on a member host of the group.

Effects of loss of NAS connection on a GuardPoint

Loss of NAS connection on any member of an LDT GuardPoint Group, including primary hosts, will have negative effects on active LDT operations on the target NAS, and across the entire LDT GuardPoint Group and applications accessing files inside the affected GuardPoints. Regardless of the LDT status (active or suspended), connection loss of one member ripples through all of the LDT GuardPoint Group members. The following scenarios can occur during loss of NAS access while LDT operations are in active or suspended state:

- Application file operations (read/write, truncate, rename, etc.) on files undergoing rekey can be blocked and consequently affect subsequent LDT operations on the same files. Rekey operations will be delayed, or even not started, as the result of pending file IO operations by applications.
- Pending LDT rekey IO operations will not complete and consequently, block or prevent, subsequent rekey operations from starting as well as block applications attempting to access such files.
- Rotation of a key will block launching rekey on the affected GuardPoints.

LDT over NFS I/O monitoring system to detect loss of NAS connection

To avoid the ripple effect of loss of NAS connection across entire LDT GuardPoint Groups, LDT monitors LDT level operations that access LDT metadata, such as MDS and LDT rekey attributes, and reads/modifies cipher-text data inside files undergoing rekey. LDT monitors progress on LDT operations in-progress. If an operation fails to complete within 30 seconds, LDT declares the pending operation incomplete and takes action to recover from the operation.

LDT over NFS Monitoring Control Thread

LDT starts a special control thread on every CTE host to monitor LDT operations for potential timeouts due to NAS connection loss. The monitoring begins when the first LDT over NFS protected GuardPoint is enabled. This thread monitors LDT operations on all LDT protected GuardPoints on the CTE host.

The LDT over NFS IO monitoring system monitors only LDT level operations. The control thread does not monitor application file operations on the files in the same GuardPoints that LDT over NFS monitoring thread is monitoring. If an application file operation hangs due to loss of NAS connection, the LDT over NFS monitoring control thread will detect it when the LDT operation starts and then timeouts on the same file.

Managing loss of NAS connection to a GuardPoint on the PRIMARY host

LDT takes action to recover from the loss of the NAS connection for LDT GuardPoint Group with multiple CTE clients as members of those groups. The action depends on whether the loss of the connection is detected on the primary host, or other members of the LDT GuardPoint Group. LDT takes no action to recover the LDT GuardPoint Group consisting of one member, a single node. The member of such a group is the LDT primary host for the GuardPoint, and LDT operations are blocked in the event of loss of a NAS connection with those operations resuming after the NAS connection is restored. The recovery action for Groups multiple clients depends on the type of loss.

Managing Primary host losing NAS connection to a GuardPoint - Primary Demotion

As soon as the monitoring thread detects the loss of the NAS connection to a GuardPoint on the primary host, the control thread initiates Primary Self-Demotion to demote the primary host from the primary role and responsibility for the GuardPoint. In this scenario, LDT on the primary host will start the demotion process for the affected GuardPoint in order to elect another member of LDT GuardPoint Group for the primary role. Election of another member triggers the failover process of LDT operations from the demoted primary host to the newly elected primary host. The election and the failover process is transparent and enables LDT to continue rekey operations using the newly elected primary host for all healthy members of the LDT GuardPoint Group.

The detection and recovery action resumes LDT operations and is fully transparent. It does not involve administrator intervention except when finishing rekey operations that were in progress on the demoted primary host when the loss of the NAS connection was detected. From the perspective of the newly promoted primary host, those files are in LDT **INCOMPLETE** status and resuming rekey on LDT **INCOMPLETE** files requires administrator intervention.

When the failover from primary role occurs, the newly elected primary host identifies the files undergoing rekey and marks those files as LDT **INCOMPLETE** status. At this stage, the self-demoted primary host remains in the LDT GuardPoint Group as an active member but without access to the NAS server. Due to the loss of the NAS access, LDT on the self-demoted primary host blocks all new user attempts to access files in the GuardPoint. It then continues to participate in the transformation of the remaining files in the GuardPoint with the newly elected primary host.

Rekey Completion on GuardPoint with INCOMPLETE Files

Although the newly-elected primary host resumes rekey and transforms the remaining files in the GuardPoint, it does not resume transformation on INCOMPLETE files until the self-demoted primary host has been recovered through the manual administrator intervention. Files in **INCOMPLETE** rekey status are the last files in the GuardPoint after administrator intervention.

Recovering self-demoted primary host

The self-demoted primary host can be recovered manually by shutting down the host with the host membership

removed from the LDT GuardPoint Group. A successful shutdown process that halts the host automatically removes the host membership from the LDT GuardPoint Group. Therefore, it is critical for the self-demoted primary host to reach the halt state at the completion of the shutdown. However, the shutdown process may not reach the halt state due to pending IO operations as the result of the loss of NAS connection.

Shutdown failure on self-demoted primary host

If you are using LDT over NFS with GuardPoints across multiple NAS shares, and a primary node loses the connection with a NAS server but does not reach the halt state, then the other GuardPoints from the other NAS shares, that are also guarded on that self-demoted primary node, must be manually removed from the LDT GuardPoint Group for recovery.

When you must manually force the host to halt, this is referred to as an ungraceful failure. Remedy this issue from the newly promoted primary server:

1. Remove the self-demoted primary host from the GuardPoint. Type:

```
voradmin ldt group remove <hostname_of_self-demoted primary> <guardpoint_path>
```

Note

- When you run the `voradmin ldt group remove` command for other GuardPoints, from other NAS servers present on that node, and if the node is the primary for any of those GuardPoints, then primary failover is triggered.

2. Repeat the command on any other GuardPoints on other NAS servers that are guarded by the self-demoted primary host.
3. Run the recover command for the GuardPoints that were on the node that lost connection to the NAS server. Type:

```
# voradmin ldt demotion recover <guardpoint_pathname>
```

For more information, see the following two sections:

- [Failover for LDT GuardPoint Group](#)
- [Secondary Host Failure](#)

Self-demoted primary host reaches HALT state

If the shutdown process on the self-demoted primary does reach the halt state, then the self-demoted primary host has already been removed from LDT GuardPoint Group. Your next step in the recovery process depends on the status of NAS connection of the host.

If a loss of NAS connection persists, disable the GuardPoints on NAS servers that cannot be accessed on the self-demoted primary host:

- Change the guard status of the GuardPoints configured for Auto Guard to remain disabled on the self-demoted primary host
- Do not enable GuardPoints configured for Manual Guard if the self-demoted primary host has rebooted

You can then proceed with the following voradmin command to resume rekey operations on the files in INCOMPLETE status. This command must be executed on the newly elected primary host.

```
# voradmin ldt demotion recover <guardpoint_pathname>
```

If the loss of NAS connection has been resolved by the time the self-demoted primary host reboots, you can allow CTE start-up services to enable the GuardPoints configured for Auto-Guard on the host, or you can manually enable a GuardPoint configured for Manual Guard. After enabling the GuardPoints, you can perform the following command on the newly-elected primary host to resume rekey on files currently in INCOMPLETE status: use # voradmin ldt demotion recover

Upon completion of the recovery steps, the remaining files in INCOMPLETE status will be rekeyed and the GuardPoint itself will transition to rekeyed state.

Note

Self-demoted primary hosts must be rebooted after the promotion of a member to primary host.

Handling loss of the NAS connection to a GuardPoint on a non-PRIMARY host

In the event of a non-primary host losing NAS connection, the LDT over NFS IO monitoring thread on the non-primary host will detect the loss of the NAS connection and trigger self-isolation from LDT GuardPoint Group.

The outcome of self-isolation is that LDT on the non-primary host blocks all users' access to the affected GuardPoint and begins acknowledging all LDT requests from the primary host. Effectively, it does not perform subsequent operations requested by the primary host, but it sends positive responses to the primary host so that the primary host can continue rekey operations.

Recovery steps for recovery from a self-isolated secondary host are the same as those for the recovery of a self-demoted primary host.

LDT over NFS demotion-related Alarms to CipherTrust Manager

LDT sends the following alarms to CipherTrust Manager during primary host self-demotion, election of a new primary host after demotion, recovery of the self-demoted primary host, and recovery and transformation of the INCOMPLETE files on the new primary host:

[CGS3347i] LDT over NFS-ALERT: Primary host of GuardPoint [GuardPoint] demoting

LDT on the primary host sends this alarm to notify of the loss of the NAS connection on the primary host, for the specified GuardPoint, and the initiation of the self-demotion process.

[CGS3348i] LDT over NFS-ALERT: Primary host of GuardPoint [GuardPoint] demoted

LDT on the self-demoted primary host sends this alarm for the specified GuardPoint when the self-demotion process completes.

[CGS3349e] LDT over NFS-ALERT: Demotion of Primary host of GuardPoint [GuardPoint] failed, error [ErrorNumber]

LDT on the primary host sends this alarm if the self-demotion attempt fails for the specified GuardPoint. The error code included in the alarm indicates the reason for failure. Notify Thales Support in the event of this alarm.

[CGS3355i] LDT over NFS-ALERT: INCOMPLETE file. After DEMOTION, Admin intervention is required for full recovery, GuardPoint [GuardPoint] objID [InodeNumber] error [ErrorNumber]

LDT on the newly-elected primary host sends this alarm for each file detected in INCOMPLETE status.

[CGS3357i] LDT over NFS-ALERT: Manual recovery invoked to recover the DEMOTED GuardPoint[GuardPoint]

LDT sends this alarm from the newly-elected primary host when the administrator executes the `voradmin` command to begin the recovery process.

[CGS3358e] LDT over NFS-ALERT: DEMOTED GuardPoint recovered on the newly-elected primary host while the old primary host is still alive, objID [InodeNumber]

LDT sends this alarm from the self-demoted primary host before the recovery steps, if the self-demoted host receives a request for an LDT operation on a file in INCOMPLETE status from the newly-promoted host. This alarm indicates that the newly promoted host has begun recovery of files in INCOMPLETE status without first recovering the self-demoted primary host.

[CGS3354e] LDT over NFS-ALERT: Manual recovery failed on DEMOTED GuardPoint [GuardPoint] objID [InodeNumber] error [ErrorNumber]

LDT sends this alarm from the newly elected primary host, during recovery of an INCOMPLETE file, when it encounters any errors during LDT rekey related to the recovery of the file or during the resumption of rekey on the file.

[CGS3359i] LDT-NFS-ALERT: Secondary host DEMOTED due to loss of NAS connection, GuardPoint [GuardPoint]

LDT on a self-demoted secondary host sends this alarm for the specified GuardPoint when the self-demotion process completes on the self-demoted secondary.

Introduction to LDT over CIFS

Live Data Transformation is now extended to network share deployments through a distributed architecture system, which allows users to encrypt data on CIFS/NFS shares without any application downtime. CTE agents can support encryption of data workloads for both direct-attached storage and network shares with zero encryption downtime and automated key rotation capabilities. This allows you to meet compliance requirements, without disrupting business applications.

The administration of LDT protected GuardPoints over NFS/CIFS shares is similar to the administration of GuardPoints in local file systems. The requirements related to policies, versioned keys, security and key rules, QoS, and file level rekey operations, for GuardPoints over local file systems, also apply to GuardPoints over NFS/CIFS shares.

The distributed aspect of LDT over NFS/CIFS shares extends the LDT administration across multiple hosts sharing access to the same GuardPoints. This section describes the extended administration of LDT across multiple hosts and how you can use LDT for data transformation across those multiple hosts.

LDT over CIFS/NFS High-Level Overview

As mentioned, the LDT operation for transformation of data over CIFS/NFS is almost the same as for GuardPoints in local file systems. LDT uses the same workflow for transforming data in files and GuardPoint management. The difference between local file systems and NFS/CIFS shares is the number of hosts involved in the transformation of GuardPoints. As multiple hosts can access the same GuardPoint over NFS/CIFS, LDT operations for transforming files in shared a GuardPoint must be coordinated across the CTE hosts enabling the GuardPoint. Coordination entails multiple file-level and LDT operations to ensure the data transformed from the previous key to the new key is not accessed by any other application on any hosts on which the GuardPoint is enabled.

Note

LDT support for NFS shares is restricted to Linux, and LDT support for CIFS shares is restricted to Windows. This means that LDT on Linux does not support LDT protected GuardPoints on CIFS shares,

and similarly, LDT On Windows does not support LDT protected GuardPoints on NFS shares.

LDT architecture for supporting NFS/CIFS shares is based on a distributed architecture. In this architecture, a single CTE host is delegated the responsibility for transforming the entire dataset in a GuardPoint. Other CTE hosts, sharing access to the same GuardPoint, participate in the data transformation process by the transforming host. The transforming host is referred to as the **LDT GuardPoint Group primary host**, and the participating hosts in the data transformation process are **LDT GuardPoint Group secondary hosts**. In this architecture, an LDT GuardPoint Group is composed of at least four or more CTE hosts (all Linux or Windows) sharing access to the same LDT protected GuardPoint (over NFS or CIFS shares, respectively).

Within an LDT GuardPoint Group, the LDT primary host executes the same operations for data transformation as those executed on GuardPoints in a local file system. The extended architecture of LDT over NFS/CIFS involves the secondary hosts in the group for execution of LDT operations initiated by primary host. For example, when a file is selected and initialized for rekey, the selection and initialization process is not local to the primary host. The primary host performs an extended selection and initialization operation across the members of the group. Once the operation is successfully performed and acknowledged by each member, the primary host proceeds with the next step in the transformation process on the selected file. Below are other extended LDT operations performed by the primary host in conjunction with members of the LDT GuardPoint Group:

1. Locking/unlocking data for rekey.
2. Suspending/resuming LDT.
3. Applying a new key to the GuardPoint.
4. Launching LDT, or concluding LDT, on the GuardPoint associated with the LDT GuardPoint Group.
5. Certain file operations, initiated on a secondary host, that change LDT metadata. For such operations, the secondary host performing the file operation notifies the primary host to update and commit all metadata changes for the operation.

LDT Communication Groups and LDT GuardPoint Groups

The LDT Communication Group provides the services for management and monitoring for the members of the LDT GuardPoint Group, and supports the LDT Messaging Services. An LDT Communication Group contains a collection of LDT-enabled CTE clients that are all on the same network, managed by one CipherTrust Manager and can communicate with each other over that network. An LDT GuardPoint Group consists of CTE clients guarding a common NFS/CIFS share. An LDT Communication Group enables the primary host of an LDT GuardPoint Group to communicate with the secondary hosts that are members of that LDT GuardPoint Group.

LDT Communication Group

- An LDT Communication Group is mandatory when using LDT over NFS/CIFS across all CTE clients managed through CipherTrust Manager. CipherTrust Manager pushes the LDT Communication Group details to all of the CTE clients in a group.
- The first CTE client added to the group is initially designated as the master node. The remaining CTE clients are replicas. All active communications go through the master node.

- All CTE clients intending to guard NFS/CIFS shares with an LDT policy must be able to communicate with each other. In order for the CTE clients to communicate, they must be on the same network, in the same data center and in a single LDT Communication Group. The agents can specify the LDT Communication Group to join at the time of registration.

Note

Even if the CTE clients do not guard the same share, they must be in the same LDT Communication Group on CipherTrust Manager.

LDT Communication Group Limitations

1. You must create an LDT Communication Group on your CipherTrust Manager and manually add all of the CTE clients to it.
2. Minimum of **three CTE clients required** for membership to the LDT Communication Group for proper and continuous operations of LDT services across all LDT GuardPoint Groups. The three clients are called the **triad**.
3. The majority of the CTE clients must be fully operational for proper LDT operations across all LDT GuardPoint Groups.

The LDT Communication Group requires that the majority of CTE clients are active, in order for the LDT Communication Group to work properly. If 50% of the LDT Communication Group servers, or 2 out of 3 **triad** nodes fail, then the LDT Communication Group cannot recover from that situation. To fix this issue, you must either:

- Reboot all of the CTE clients in the entire LDT Communication Group.
 - In Windows, restart **secfsd** through the **Control Panel > Services** page on all of the CTE clients in the entire LDT Communication Group.
4. The name of the LDT Communication Group cannot contain special characters.
 5. If you are repurposing a CTE client that is currently being used for LDT over NFS/CIFS, but still runs CTE and is still registered to the same CM, then you must:
 - a. Remove all CIFS/NFS LDT GuardPoint Groups from the host prior to removing the host from the LDT Communication Group.
 - b. Reboot the host.
 6. Remove a host from the LDT Communication Group if the host is being decommissioned, meaning that you plan to power it down for the foreseeable future, or while CTE is being uninstalled.

LDT Communication Group Considerations

- The LDT Communication Group must be specified at the time of client registration.

Note

For upgrades, add the agents to the LDT Communication Group using the **Add Client** function on CM. See [Adding Clients to an LDT Communication Group](#) for more information.

- Do not shut down the entire LDT Communication Group at once. This is so that maintenance cycles can activate and run. Perform maintenance in a round robin fashion.
- Remove a host from the LDT Communication Group if the host is being decommissioned, meaning that you plan to power it down for the foreseeable future, or while CTE is being uninstalled.
- The CTE host that is the LDT Communication Group master is critical for proper operations of LDT across all LDT GuardPoint Groups. Thales recommends that you dedicate a separate host as your LDT Communication Group master, although it is not mandatory. This isolates the host from unexpected system failures, hence preventing failover of the LDT Communication service to another CTE client critical for your production workload.
- Thales recommends using a minimum of three nodes for optimal performance. All three nodes must be located in the same data center.
- Before rebooting a node, Thales recommends stopping the secfsd service:

For **Windows**:

- a. Go to **Control Panel > Services (local)**.
- b. Select **secfsd**.
- c. Select **Stop the Service**.

For **Linux**, type:

```
/etc/vormetric/secfs stop
```

To create and manage LDT Communication Group in the UI, see: [Managing LDT Communication Groups](#).

Multiple LDT Communication Groups Considerations

CipherTrust Transparent Encryption now supports multiple LDT Communication Groups. Be careful to not misconfigure the multiple LDT Communication Groups:

- You cannot use identical NFS/CIFS share paths in multiple LDT Communication Groups registered to a **single**

CipherTrust Manager. Each share path must be unique.

- You cannot use identical NFS/CIFS share paths in an LDT Communication Group with the same name on **multiple** CipherTrust Managers. LDT Communication Group names must be unique.

Moving Client Nodes from one LDT Communication Group to another LDT Communication Group

If you are repurposing a CTE client node that is currently used for LDT over NFS/CIFS in an LDT Communication Group, but still runs CipherTrust Transparent Encryption and is still registered to the same CipherTrust Manager, then you must **remove** all CIFS/NFS LDT GuardPoints from the host prior to removing the host from the LDT Communication Group. Then you can reboot the host and add that CTE client node to another LDT Communication Group.

LDT GuardPoint Group

As described, an LDT GuardPoint Group is a group of three or more CTE hosts sharing access to the same GuardPoint over NFS/CIFS. A CTE host with n number of GuardPoints has membership to n number of distinct LDT GuardPoint Group and is specific to the GuardPoint directory. A CTE host guarding multiple GuardPoints over NFS/CIFS is a member of multiple LDT GuardPoint Groups.

LDT GuardPoint Group Primary

One CTE host in each LDT GuardPoint Group assumes the **Primary** role for that group. The CTE host that enables a GuardPoint directory first is assigned the primary role for the group associated with the GuardPoint directory. Subsequent hosts enabling the same GuardPoint are assigned **Member** or **Secondary** status. A CTE host can be a primary for a group, or multiple groups, and a secondary for other groups.

LDT manages primary host departure from the group during transformation. Departure of a primary host can occur as the result of disabling a GuardPoint directory on the primary host, or an unexpected failure of a primary host. In the event of the primary host departure from the group, LDT elects and delegates the primary role to one of the members of the group.

For additional information, see:

- [Failover](#)
- [LDT GuardPoint Group Commands](#)
- [Responsibilities of the Primary host](#)
- [Designation of Primary role and Primary Set in an LDT GuardPoint Group](#)

LDT GuardPoint Group Capability Level

In CTE 7.6.0, LDT NFS introduces a feature called: Capability Level, which is for an LDT GuardPoint Group. The feature is based on the compatibility level for each member in the group. The Capability Level of a member determines what features that host can access and use, and allows the group to decide on a common capability level at which to run. This allows support for multiple versions of CTE in the same LDT GuardPoint Group as the group runs at the capability level of the least capable member. The capability level of the group is calculated when a member leaves the group, or a primary failover occurs. As lesser capable members depart the group, the overall capability level of the group increases. The capability level of a group cannot be decreased. As such, members at a lesser capability level cannot join once the capability level of the group has increased. New

members joining an existing group will attempt to join with the highest capability level supported by the host and, if rejected, retry with progressively lower capability levels until the group accepts the join request. If the group is running at a capability level that exceeds the joining member's highest capability, that host is not allowed to join the group.

When a new feature is introduced that is unavailable to, or incompatible with, older versions of CTE agents, the maximum capability level of the newer agents is increased to a value greater than the maximum capability level of the older agents. If there is a group with a mix of the new and old agents, the group runs at the capability level of the older agent. This means that no member of the group will be allowed to use the new feature, regardless of the actual version of CTE running on the member. Only after all of the members running the older agent have left the group will the group be upgraded to the new capability level and use of the new feature is enabled. Older agents will no longer be allowed to join the group as there are now features in use that are not available to, or compatible with, older agents. If the LDT GuardPoint Group needs to contain the older agent, then a member running that older agent must be present at all times to ensure that the compatibility level of the group is not upgraded to the level of the newer agents.

LDT GuardPoint Groups with Different CTE Versions (Linux Only)

LDT does not allow key rotation to begin in an LDT GuardPoint Group over NFS when hosts in that group are not homogenous, meaning they are running different versions of CTE. When an LDT GuardPoint Group containing a mix of CTE versions needs to rotate a key, the rekey is blocked and the GuardPoint is marked with the relaunch flag. This persists until the group only contains homogenous hosts; after which rekey automatically starts. If rekey is already in progress on a GuardPoint, disparate hosts are blocked from joining the group until rekey completes. This block on joining also includes when the GuardPoint is rekeyed but flagged for relaunch.

Note

Patch releases within the same major/minor version do not block rekey from starting; ex. 7.8.0.x and 7.8.0.y.

Scenario

For example, given an LDT GuardPoint Group over NFS with:

- One CTE 7.6.x host as the primary
- One CTE 7.6.x host as a member
- Two CTE 7.7.y hosts as members

When the key rotates, the GuardPoint transitions into the rekeyed/relaunch state and remains there until only CTE 7.6.x or CTE 7.7.y hosts remain.

While the GuardPoint is in the rekeyed/relaunch state, no disparate CTE hosts are allowed to guard. This remains true even if the CTE 7.6.x primary unguards, and one of the CTE 7.7.y members is promoted into the primary role. Only after all CTE 7.6.x hosts have unguarded will CTE 7.7.y hosts be allowed to guard, at which point rekey can begin. However, after all of the CTE 7.6.y hosts have unguarded, no CTE 7.6.y hosts will be able to guard moving forward, as the group is now running at the CTE 7.7.x level.

Note

- Thales recommends that you upgrade CTE on all hosts in an LDT GuardPoint Group group during the same maintenance window. If that is not possible, Thales recommends that subsequent maintenance windows for upgrades occur before the key is scheduled to rotate.
- It is possible that a host that was previously part of the group, could fail to rejoin after a reboot due to key rotation occurring and blocking hosts with mismatched versions from joining. Upgrade all hosts to the same version of CTE to ensure that key rotation does not block any host from joining.
- CTE 7.6.0 agents prior to 7.6.0.134 acting as primary will start rekey even if there are CTE 7.7.0 hosts in the group; CTE 7.7.0 hosts will log an alert in this case. Thales recommends all CTE 7.6.0 hosts using LDT NFS GuardPoints be upgraded to CTE 7.6.0.134 or a subsequent version.

CTE Version Capability Levels

- CTE 7.5.0 members are automatically assigned to a maximum capability level of **2**
- CTE 7.6.0 members can run at a maximum capability level of **3**

The difference in capability between CTE 7.5.0 and CTE 7.6.0 is due to the inclusion of sharing LDT NFS GuardPoints with Windows. See [Windows/Linux Compatibility](#) for more information on this feature.

- CTE 7.7.0 members can run at a maximum capability level of **4**

To find the capability level of an LDT GuardPoint Group, type:

```
voradmin ldt group capability <GuardPoint Path>
```

This command outputs the capability level that the current host is running at for the specified GuardPoint. If the host is the primary host, then the value also represents the capability level for the entire group.

Reference Information

- [Use Case for Setting up LDT Communication Group and LDT GuardPoint Group](#)

Designation of Primary role and Primary Set in an LDT GuardPoint Group

The first host that enables a GuardPoint over NFS/CIFS share is designated as the primary host for the LDT GuardPoint Group. The primary role designation persists until the GuardPoint is disabled on the primary host or the primary host crashes. Designation of another CTE host for the primary role is the result of the old primary crashing, or disabling the GuardPoint. Another member of the LDT GuardPoint Group will be elected to assume the primary role for the LDT GuardPoint Group.

A secondary host **is not** a proper candidate for promotion to primary role if any of the following conditions exist for the GuardPoint on the secondary host:

-
- The NAS share is mounted as read-only on the CTE host
 - The CTE host has not received the latest policy information from CipherTrust Manager
 - The latest key version available to the CTE host is not the most recent key version available to other members of the LDT GuardPoint Group

The read-only access to the GuardPoint directory restricts the designated host from performing LDT operations. LDT operations require read and write access to the NAS share.

The second and third conditions are most likely a transient communication failure between CipherTrust Manager and the designated CTE host. Once the communication issue between CipherTrust Manager and the CTE host is resolved, the CTE host will be updated with the most recent policy information, and it will accept subsequent designations for promotion to primary role.

In addition to the previous conditions, is usually the result of IO or networking issues between CTE host and the NAS share. If this occurs, disable the CTE host and remove it from the LDT GuardPoint Group. Removal of the CTE host triggers election of another CTE host for the primary role. If you are unable to disable the GuardPoint on the CTE host, you must reboot the host, and then remove the host from the LDT GuardPoint Group using the `voradmin ldt group remove` command.

The Designated Primary Set (DPS) contains a list of CTE hosts from which a primary role can be chosen by the LDT/LGS service. CipherTrust Manager administrators can create a DPS by choosing the hosts from the CTE client groups membership that can be promoted to the primary role. Thales recommends that CTE administrators inform the CipherTrust Manager administrator of their choice for DSP membership. The CipherTrust Manager administrator can update DPS as needed. The selected clients should be systems with sufficient resources that can sustain production workloads and the load from rekeying GuardPoints on the primary host. Note that the first CTE client enabling a GuardPoint assumes the primary role for that GuardPoint, regardless of the membership of the client to DPS. Election of another CTE host for promotion to primary role will be a member of the DPS, unless none of the members of the DPS has the GuardPoint enabled. In such a case, one of the members of the LDT GuardPoint Group on which the GuardPoint is enabled will be promoted to the primary role.

A Designated Primary Set (DPS) is created and assigned to a single LDT GuardPoint Group within a LDT GuardPoint Group. With the DPS assigned to a GuardPoint, the election of a new client for the primary role will be from the DPS.

In a Linux environment with a mix of clients from the client group and individual clients guarding the same NAS share, if you guard the NAS share on an individual client first, and later guard it through the client group, the individual client that guarded first is the primary client for the GuardPoint group.

Recommendations for selecting members for DPS

- A designated primary set (DPS) should contain at least two fully operational and highly available nodes with minimal risk of crashes, network issues, or reboots. Ideally, these nodes should be in the same subnet, or in closely connected subnets to ensure uninterrupted LDT operations.
- Only select server class systems capable of carrying out the rekey load without interruptions as the result of frequent reboots. Do not select transient hosts, such as a laptop.
- Avoid disabling GuardPoints on a primary host as much as possible. Disabling GuardPoints on the primary client triggers election of another member from DPS.
- Minimize selecting the same preferred primary for multiple GuardPoints for better load distribution unless the primary host can carry out the LDT load.

- When removing a host from the DPS, ensure that at least two eligible nodes remain. If only one remains, add another node to maintain high-availability. If all DPS nodes are removed, a non-DPS node is promoted to primary node during failover.
- To remove a node from an LDT Communication Group that is part of a DPS, first remove it from the DPS, then the client group, and finally LDT Communication Group.
- Do not include transient nodes in the DPS. They can cause GuardPoint failures.

Limitations

- A Designated Primary Set is fully enforced when all members the client group are DPS-capable.
- If a client group with DPS enabled has non-DPS capable members, the GuardPoints will not be pushed to the non-DPS capable clients.
- Insufficient systems could cause slower rekey rates.

Configuration

When configuring a Designated Primary Set:

- You can **only** choose clients from the client group membership as the designated primary client.
- You must guard the NAS share on the client group **first**.

This Designated Primary Set feature is supported with CipherTrust Manager and CTE agents installed with:

Software	Minimum Version
CipherTrust Transparent Encryption	7.7.0
CipherTrust Manager	2.17

Prerequisites

Be sure to have completed the following configuration steps for guarding a share on your clients before creating a Designated Primary Set:

1. Configure a [CIFS/SMB connection](#) if your CTE clients are Windows clients.
2. Create an LDT Communication Group. See [Managing LDT Communication Groups](#) to create LDT Communication Groups.
3. Create an LDT Client Group. See [Managing Client Groups](#) to create Client Groups.

Note

- Modifications made to a Designated Primary Set list are updated/pushed to the members of the client group associated with the DPS.
- A Designated Primary Set (DPS) is fully enforced when all members of the client group are DPS-capable CTE agents. This means that the clients must be agents installed with CTE 7.7.0 or subsequent versions. If any member of the client group enabled with DPS is a non-DPS capable client, the GuardPoint will not be pushed to non-DPS capable clients.

Creating a Designated Primary Set

1. In CipherTrust Manager, click **Transparent Encryption > Clients > Client Groups**.
2. Click the desired client group name.
3. Select the **Designated Primary Set** tab.

It displays the list of Designated Primary Sets. Expand the desired Designated Primary Set to see its details.

4. Click **Create Designated Primary Set**.
5. In the **General Info** screen, provide a name for the Designated Primary Set and select an LDT Communication Group. Click **Next**.
6. In the **Add Clients** screen, select, or search for, the clients for the primary set.

Note

- A Designated Primary Set **must** contain at least one client.
- Add two or more clients to the Designated Primary Set to have available clients in DPS for election to the primary role, in the case of LDT primary promotion.
- During the promotion process, if the corresponding GuardPoint is not enabled on any members of the DPS, another client in the LDT GuardPoint Group that is not a member of the DPS will be promoted to the primary role. As such, it is a best practice to select multiple clients for the Designated Primary Set for each GuardPoint.
- Select/un-select designated primaries **only** when guarding NFS/CIFS shares in a client group.

7. In the **Confirmation** screen, review the details of Designated Primary Set.

-
8. Click **Create**. The screen displays a message indicating whether the Designated Primary Set was created successfully.
 9. Click **Close** to close the screen. The Designated Primary Set displays in the **Designated Primary Set** tab.
 10. After you have created a Designated Primary Set for a client group, you can create a corresponding LDT GuardPoint for it.

Adding New Clients to a Designated Primary Set

To add new clients to an existing Designated Primary Set:

1. Under **Clients > Client Groups**, click the desired client group name.
2. Select the **Designated Primary Set** tab.
3. Expand the desired Designated Primary Set.
4. Click **Add Clients**.
5. Select the checkboxes for the desired client names.
6. Click **Add**.

Changing the Designated Primary Set Associated with a GuardPoint

You can modify the Designated Primary Set associated with a GuardPoint, after the GuardPoint is created.

To change the Designated Primary Set associated with a GuardPoint:

1. Open the **Transparent Encryption** application from the CipherTrust Manager console.
2. Click the client group name in the **Client Group Name** column.
3. On the **GuardPoints** tab, click the ellipsis corresponding to the desired GuardPoint.
4. Click **View/Edit**. The Edit GuardPoint dialog box is displayed.
5. In the **Designated Primary Set** drop-down list, select a different client.
6. Click **Save**.

The GuardPoint is updated successfully with the new Designated Primary Set.

Validating the Designated Primary Set

In CipherTrust Transparent Encryption, you can get the list of designated primary clients for the guard path if you have configured a Designated Primary Set.

- To get the list, type:

```
voradmin ldt group get_dp <guard path>
```

Example

```
voradmin ldt group get_dp /test/nov25
```

Response

```
LDT GuardPoint Primary: 192.68.34.54  
LDT GuardPoint Designated Primary List: 192.68.34.53,192.68.34.54
```

Note

If the DPS is not configured and you type the command to get the list, the command output shows N/A for the designated primary list:

```
LDT GuardPoint Primary: 192.168.34.54  
LDT GuardPoint Designated Primaries: N/A
```

Responsibilities of the Primary host

As described earlier, the primary host in the LDT GuardPoint Group is responsible for performing data transformation operations. In addition:

1. On Linux, the primary host drives execution of committing a new key version to all members of the LDT GuardPoint Group. During this process, the primary host sends a message to all members, inquiring if each member has received the new key version from CipherTrust Manager. If all members have received the new key, then the primary host, and the members, commit the new key version to their GuardPoints. If at least one member does not have the new key version, the primary host delays committing the new key version and retries the commit process in 30 seconds.

The delay in committing the new key version avoids applications accessing files encrypted with the new key version. Without the delay, the primary host would proceed to rekey the GuardPoint, and consequently, applications running on those member(s), without the latest key version, would be blocked when accessing files encrypted with the latest key version.

Note

The delay only affects rekey operations re-encrypting existing files to the new key version. It does not affect newly created files which inherit the latest key version, that may not have been committed across the entire LDT GuardPoint Group by the primary host. If newly created files are accessed on CTE hosts which do not have the latest key version, the process of accessing such files will be blocked until the latest key version becomes available on those CTE hosts.

2. On Linux, the primary host is also responsible for updating and committing LDT metadata for file operations in progress on the secondary hosts. For example, truncating a file while the primary host is rekeying the file requires changing the LDT metadata for that file. As the primary host is updating the LDT metadata during the rekey process, the member host truncating the file does not update the metadata that the primary host is changing. Instead, the secondary host sends a message to the primary host, requesting LDT metadata changes for the truncate operation, and the primary host provides the metadata updates for the truncate operation triggering the secondary to proceed. The host then commits or discards the metadata changes for the truncate operation after the secondary hosts completes it and notifies the primary host of their status. This process forces the primary host to engage with the hosts that perform truncate operations, strictly on those files that the primary host is rekeying.
3. Operations such as file or directory rename initiated on a member of the group also involves engagement of the primary host, if the primary host is actively rekeying the affected files or GuardPoints. Renaming a subdirectory on a secondary host engages the primary host to scan a list of files under the renamed subdirectory. The primary host performs the scan outside of the scope of the GuardPoint level rekey process and starts separate file level rekey operations for each file not undergoing rekey in the renamed subdirectory. The primary host conducts up to 8 concurrent file level operations, and the GuardPoint level rekey operation does not complete until every file in the renamed subdirectory is rekeyed. File level rekey operations are slow as compared to GuardPoint rekey operations, therefore, subdirectories with a large number of renamed files delay rekey completion time.

Responsibilities of non-primary hosts

When secondary hosts in the LDT GuardPoint Group perform file operations on files that the primary host is actively rekeying, it must notify the primary host of those operations. Truncating a file on secondary hosts, as described earlier, is an example of a secondary host notifying the primary host for updating LDT metadata.

Secondary hosts can also be selected for promotion to the primary role within an LDT GuardPoint Group. A host elected for promotion checks whether it's capable of assuming the primary role for the LDT GuardPoint Group, and if capable, it accepts and promotes itself to assume the primary role for the LDT GuardPoint Group.

Note

Ensure that at least one secondary host is always qualified to accept promotion to primary status.

Connectivity to CipherTrust Manager and mounting NFS shares with read and write access are critical for qualifying secondary hosts for promotion to the primary role.

GuardPoint Directories (Linux Only)

The pathname of a GuardPoint directory does not have to be fixed across all members of the group. For example, if host_1 mounts the share at `/nfs-host-1/gp-dir` and host_2 mounts the same share at `/nfs-host-2/gp-dir`, the LDT GuardPoint Group for the GuardPoint represents both pathnames.

GuardPoint Directories (Windows Only)

GuardPoints for Windows directories use the UNC format. See [Creating a GuardPoint on a CIFS Share Drive on CipherTrust Manager](#) for more information.

Overhead in LDT over NFS/CIFS

The primary host performs LDT operations across all members of an LDT GuardPoint Group. It sends a message, for each operation, to all members of the LDT GuardPoint Group and waits for acknowledgment from all members before executing the operation. A message holds information specific to an operation that the primary host wants to perform, such as file initialization for rekey, lock/unlock operations, LDT launch on GuardPoint, etc. Each member of the LDT GuardPoint Group validates each operation requested by the primary host before responding to the request. This coordination incurs significant overhead in execution of LDT operations on GuardPoints over NFS/CIFS shares in contrast to the same operations performed over GuardPoints in local file systems. It also increases network traffic across all members of LDT GuardPoint Group and potentially increasing overhead in your network infrastructure.

This overhead can pose challenges for LDT to achieve the desired rekey IO rate specified under QoS. Delays incurred in delivery of requests and responses can slow down LDT operations such that the expected rekey IO rate becomes difficult to achieve. Consider the bandwidth of your network infrastructures, number of GuardPoints on the primary host and number of members sharing access to those GuardPoints before setting the rekey IO rate. With multiple GuardPoints on the same primary host such that some of those GuardPoints are over NFS/CIFS and others on locally attached storage devices, rekey IO rate on GuardPoints over NFS/CIFS shares will likely be significantly lower.

Failover for the LDT Communication Group Master and the LDT GuardPoint Group

Failover for the LDT Communication Group Master

CTE clients in an LDT Communication Group have a master/replica relationship. The first client that joins the group is initially designated as the master node. The other clients are replica nodes. The master node must be functional in order for communications to persist. All communications happen through the master node.

A host can leave the LDT Communication Group in one of two ways:

Graceful Failover for the LDT Communication Group Master

There are two cases for graceful failover:

▪ Reboot

If the master node becomes unavailable because it's rebooted by the administrator or as part of a maintenance cycle, but there are other live CTE clients in the LDT Communication Group, then the LDT Communication Group automatically elects a replica CTE client to become the new master node and fails over to it.

▪ Power Off

When a master node powers off, a new master is automatically elected, but if the initial master node is being decommissioned, then you should remove it from the LDT Communication Group.

Note

Any CTE client that is being decommissioned, regardless of its role in the LDT Communication Group, needs to be removed from the LDT Communication Group See [Remove].

Ungraceful Shutdown/Failure for the LDT Communication Group Master

An ungraceful failure is when a CTE client fails abruptly due to a hardware or software failure. It means that the administrator did not trigger the client to either shutdown, reboot or become unreachable, but the client still transitioned into that state. This is applicable to the master node failing as well.

If an LDT Communication Group master node fails ungracefully, it is handled automatically. A new master is elected by the remaining nodes. Meanwhile, LDT operations may continue to fail for all LDT GuardPoints. Operations will resume once a new LDT Communication Group master node is functional.

In the event that all, or a majority of, the CTE clients in an LDT Communication Group fail (**ungraceful** shutdown):

Ensure that **all** of the CTE clients in the LDT Communication Group are active (rebooted, powered on and accessible through the network), to reestablish the cluster.

1. All LDT NFS/CIFS GuardPoints must be unguarded before you remove a CTE client from the LDT Communication Group.
2. Once a CTE client is removed from the LDT Communication Group, it must either be rebooted or shut down.
3. Whenever a graceful exit, or failover event, is in progress for the LDT Communication Group, LDT operations will be affected across the entire LDT Communication Group, which means that GuardPoints could be affected.

Failover for the LDT GuardPoint Group Primary

Gracefully

Graceful Failover occurs when the primary node exits cleanly or gracefully. Then the LDT GuardPoint Group automatically fails over to one of the available secondary hosts, and the secondary host is promoted to the new primary host for the LDT Communication Group.

- Triggered when the GuardPoint is disabled on the primary
- Triggered when the `secfs` service is manually stopped on the primary
- Triggered during a reboot if `secfs` stops cleanly before shutdown
- Triggered when the primary node is removed from the LDT Communication Group

All CTE clients guarding the share, or trying to guard the share, depend on the primary being available.

Graceful Failover

Graceful Failover occur when a node in the LDT GuardPoint Group:

- Performs a reboot
- Performs a Shutdown
- Disables a GuardPoint from CipherTrust Manager
- Unguards a GuardPoint

Note

Remember that if the primary client exits gracefully, then a new primary is elected through failover.

Ungraceful Failover

Ungraceful Failover occurs when the primary node fails, unexpectedly, or **ungracefully**. Then an administrator will need to manually remove the primary from the group so that a secondary member can become the primary host. This also enables the failed primary host to guard again and become a member of the group in the future.

- Triggered if the primary crashes, or reboots, without a clean `secfs shutdown`. A secondary node is promoted to primary after executing a `voradmin` command.

To identify the primary node, type:

```
voradmin ldt group list <absolute guardpoint> (Windows)
voradmin ldt group list <guardpoint> (Linux)
```

!!! note

You can only run this command on a host where the `#{gp}` is currently guarded.

To restore, or repair, the original node after an ungraceful failover, type the following on the LDT GuardPoint Group secondary node:

```
voradmin ldt group repair <failed host> <guard path>
```

Example: If nodes A, B, and C are part of the LDT GuardPoint Group protecting the network share `/test/path1`, and the primary node crashes and comes back online, run the following command on either node B or C:

```
# voradmin ldt group repair /<primary IP> <absolute GuardPoint> (Windows)

# voradmin ldt group repair /<primary ip> <${gp}> (Linux)
```

You can also use the repair command to remove a secondary node that is no longer guarding a GuardPoint but still shows in the Group Info list. This command repairs the host and keeps it in the group.

Example: If nodes A, B, and C are part of the LDT GuardPoint Group protecting the network share `/test/path1`, and the primary node crashes and does not come back online, run the following command on either node B or C to remove a primary host from the group and automatically select a secondary host as the primary, type:

```
voradmin ldt group remove A /test/path1
```

If a secondary host fails ungracefully, you can use the same command to remove that host.

Note

If you plan to reboot a primary node for maintenance or a software update, a graceful primary failover is typically triggered as part of the secfs service shutdown. However, if stopping the secfs service takes too long, and the system proceeds to reboot before the shutdown completes, it can result in an ungraceful failover. To ensure a graceful primary failover, Thales recommends manually stopping the secfs service before initiating the reboot. This allows the GuardPoint to be cleanly disabled and failover to proceed as expected.

Note

Do not use this command in the case of a temporary failure when the failed primary host crashes and then reboots.

Ungraceful Exits

Ungraceful exits occur when a node in the LDT GuardPoint Group:

- Is forced to power off | shutdown | reboot
- Suffers a hardware failure
- Power cycles
- Has a kernel crash

Note

Remember that if the primary host fails ungracefully, then an administrator must manually remove the primary.

Troubleshooting Ungraceful Exits

After the reboot, if you see the following logs in `secfsd.log`, and if `secfsd -status guard` displays the GuardPoint as unguarded, then the reboot did not happen gracefully and the present scenario is classified as an ungraceful exit.

```
lgs_joining: host(xyz_1.com) is already PRIMARY for GPID(060cd923-6026-4341-81e3-f8cc367df90d) in comm server. It seems like a crash+reboot scenario. Informing others about primary failure
```

If this occurs, follow the node repair steps in the previous section, [Failover for LDT GuardPoint Group](#) to recover the structure.

- **Linux** `secfsd.log`: `/var/log/vormetric/secfsd.log`
- **Windows** `secfsd.log`: `C:\ProgramData\Vormetric\DataSecurityExpert\agent\log\secfsd.log`

Secondary Host Failure

In the event that a secondary host crashes, you must first remove that failed secondary host from the entire LDT GuardPoint Group that the host was a member of before allowing that CTE host to rejoin that same LDT GuardPoint Group after the host is restored. The following steps must be performed in exact order for each GuardPoint that was enabled on the host prior to the crash. (You can get the list of GuardPoints from CipherTrust Manager.) For each GuardPoint:

1. On any CTE client that is a member of the LDT GuardPoint Group for that GuardPoint, run the `voradmin ldt group list` command to identify the failed host. The role of the failed host is UNRESPONSIVE within the group, type:

```
# voradmin ldt group list <GuardPoint Path>
```

Role	State	Hostname	GuardPoint Path
UNRESPONSIVE	N/A	Host-3	N/A
PRIMARY	JOINED	Host-1	/nfs/gp

2. On the primary CTE client for the GuardPoint, run the `voradmin ldt group remove` command to remove the failed host from the LDT GuardPoint Group, type:

```
# voradmin ldt group remove <hostname> <GuardPoint Path>
```

Failure Scenario Examples

Following are some basic failure scenarios and suggested recovery steps:

Secondary node crash (Non-Triad node)

Scenario

- Nodes A, B, C, D, E, and F are part of the LDT Communication Group.
- Nodes A, B, and C are the Triad nodes.
- An NFS/CIFS share is guarded on nodes D, E, and F, forming an LDT GuardPoint Group, where node D is the LDT primary.

After the LDT GuardPoint Group has been active for a while, node E, a secondary node, crashes.

Troubleshooting Scenario

If node E remains down:

- From the LDT primary (node D), verify the status of the LDT GuardPoint Group, type:

```
voradmin ldt group check <guard path>
```

- If node E displays as UNKNOWN, even after rebooting, check if the network share is mounted on E. If it's not mounted, fix the network connectivity. Once resolved, node E should rejoin the LDT GuardPoint Group as a secondary.
- If node E does not resume, remove the node from the LDT GuardPoint Group. On the LDT primary node D, type:

```
voradmin ldt group remove E <guard path>
```

Primary Node Crash(Non-Triad Node)

Scenario

Same setup as above, with node D acting as the LDT primary. After some time, node D crashes.

Troubleshooting Scenario

1. If node D does not resume, remove the node from the LDT GuardPoint Group. On any secondary nodes, type:

```
voradmin ldt group remove D <guard path>
```

2. If node D resumes, but fails to guard the share, repair the LDT GuardPoint Group from any of the secondary nodes (E or F), type:

```
voradmin ldt group repair D <guard path>
```

Communication Group in Inconsistent State

Scenario

- Nodes A, B, C, D, and E are part of the LDT Communication Group.
- A, B, and C are Triad nodes.
- An NFS/CIFS share is guarded on nodes C, D, and E, with D as the primary and C and E as secondaries.

Nodes A and B (both Triad nodes) fail at the same time (gracefully or ungracefully), the LDT Communication Group enters an inconsistent state.

Troubleshooting Scenario

Restart the secfsd service on all nodes to restore the LDT Communication Group.

For **Windows**:

1. Go to **Control Panel > Services (local)**.
2. Select **secfsd**.
3. Select **Stop the Service**.
4. Wait a few moments and select, **Start the service**.

For **Linux**:

1. Type:

```
/etc/vormetric/secfs stop
```

2. Type:

```
/etc/vormetric/secfs start
```

Primary Node Ungraceful Reboot (Triad Node)

Scenario

- Nodes A, B, C, and D are in the LDT Communication Group.

- Nodes A, B, and C are the Triad nodes.
- A NFS/CIFS share is guarded on all nodes
- Node A is the primary for the GuardPoint.

Node A undergoes maintenance or a software update, and is rebooted with the expectation of a graceful failover to one of the secondary nodes. However, failover does not occur, and once node A comes back up, it fails to guard the network share and in the output of `secfsd -status guard`, it displays: `Group Join Failed, needs LDT repair`

Explanation

During the shutdown, the `secfs` service is stopped, which disables all GuardPoints. A successful disable operation triggers failover to another secondary node. However, if the system proceeds with shutdown before the service is cleanly stopped, it results in an ungraceful shutdown, and the failover does not occur.

Troubleshooting Scenario

- Run the repair command from any active secondary node, type:

```
voradmin ldt group repair <failed hostname> <guard path>
```

LDT GuardPoint Group Commands

Prerequisites for CIFS Share drives

Prior to running the `voradmin ldt group` commands, you must:

1. Ensure that you have access and permission to read/write to/from the CIFS share.
2. Mount the CIFS share using the `net use` command, or login to the CIFS shares using Windows Explorer.

Group check

The `group check` command is used to send out an internal ping to all hosts that are registered with the master as part of the LDT Communication Group. Each functioning host responds. Then the host displays a message of the hosts in the LDT Communication Group that did not respond. This allows an administrator to easily find the problem.

Syntax

```
voradmin ldt group check <gp_path>
```

Example (Windows)

```
voradmin ldt group check \\192.168.1.160\share
```

Hostname	Role	State	GuardPoint Path

192.168.1.161	PRIMARY	JOINED	\\192.168.1.160\share
192.168.1.162	SECONDARY	JOINED	\\192.168.1.160\share

Example (Linux)

```
voradmin ldt group check /nfs1/gp
```

Role	State	Hostname	GuardPoint Path
PRIMARY	JOINED	host1.domain	/nfs1/gp1
SECONDARY	JOINED	host2.domain	/nfs1/gp1

Info

Use the `info` command to display information about the cluster.

Syntax

```
voradmin ldt group comm_info <gp_path>
```

Example (Windows)

```
voradmin ldt group comm_info \\192.168.1.160
```

```
LDT Communication Group Master IP:      10.171.34.111
LDT Communication Group Master Port:    7024
LDT Communication Group Name:           tanmay_windows
LDT Communication Group Servers:        10.171.34.111,10.171.34.120,10.171.34.11
9
```

Example (Linux)

```
voradmin ldt group comm_info /nfs1/gp1
```

```
LDT Communication Group Name:           tanmay-linux
LDT Communication Group Master IP:      10.171.47.121
LDT Communication Group Master Port:    7024
LDT Communication Group Servers:        10.171.47.241,10.171.47.121,10.171.47.75
```

Remove

This command allows a client to be manually removed from the group safely. Use the `Remove Host` command if a client dies without properly leaving the group.

Note

Only run this command on clients which will be powered off. Do not run it on a client which may simply have temporary network issues.

Syntax

```
voradmin ldt group remove <hostname> <GuardPoint pathname>
```

Example (Windows)

```
voradmin ldt group remove host42 \\server\share
```

WARNING: This command will forcibly remove host42 from the LDT group for gp_path. You should only perform this step if the host is guaranteed to be powered off, otherwise a loss of data may result. Do you wish to continue? (Y/N)

Example (Linux)

```
voradmin ldt group remove host2 /nfs-ldt
```

host2 has been removed from the group for GuardPoint /nfs-ldt

Repair

Run the following command to manually clean up the group and allow the primary to rejoin as a member. The Client will complete the guard operation once the group has been repaired.

```
voradmin ldt group repair /<primary IP> <absolute GuardPoint> (Windows)
```

```
voradmin ldt group repair /<primary IP> <${gp}> (Linux)
```

Sharing LDT NFS/CIFS GuardPoints between Linux and Windows

An LDT GuardPoint Group is used to organize clients guarding the same NFS or CIFS share. In CTE 7.5.0 or previous versions, each group could only contain Linux or Windows members, and not a mix of the two. Starting with CTE 7.6.0, it is now possible to have Windows clients as AccessOnly clients to guard a share that is part of a Linux LDT GuardPoint Group. Refer to [Configuring CTE Windows LDT AccessOnly nodes](#) for more information on AccessOnly clients.

Windows LDT is capable of mixing AccessOnly, and non-AccessOnly clients, in an LDT GuardPoint Group accessing a share through CIFS protocol. This capability is possible because of the CIFS protocol supporting exclusive access to a file from a remote node. Linux LDT does not support AccessOnly clients because the NFS protocol does not support exclusive file access capability. Therefore, an AccessOnly client is not privy to LDT messages between clients. The Windows client can only access a Linux based LDT GuardPoint Group while a GuardPoint is rekeyed. As such, Windows clients can only guard after the Linux primary client has completed rekey on the GuardPoint. Subsequently, the GuardPoint must be unguarded on Windows clients before any subsequent key rotation begins. Failure to do so will cause data corruption as any write operation from the Windows client may write without any coordination with the Linux primary client performing transformation.

The capability to allow Windows and Linux clients to guard the same GuardPoint is supported on GuardPoint directories which have been guarded for the first time, and completed the initial transformation, by a CTE 7.6.0 Linux client. This restriction is in place because there are metadata format changes in newly created GuardPoints to support sharing access between Linux and Windows clients.

Note

Access to shared GuardPoints is available through NFS on Linux and CIFS on Windows.

Windows clients are blocked from accessing files marked with a lazy_rekey flag. This is because the files marked with a lazy_rekey flag will launch the data transformation process the next time a Linux member of the LDT GuardPoint Group accesses the file without any awareness of Windows clients sharing access to the GuardPoint.

Although there is no communication between Windows and Linux clients for sharing access to GuardPoints, there is awareness of shared access across the clients because of the LDT metadata changes applied to the newly created GuardPoints for sharing on both platforms. Both platforms apply compatible LDT metadata when creating new files.

Finally, suspending rekey does not qualify Windows clients to guard and share access. Rekey must be completed before Windows clients can attempt to guard.

LDT Communication Group

All members of an LDT Communication Group must be Linux CTE clients. Windows clients do not belong to LDT Communication Groups because of AccessOnly mode configuration.

Limitations

- Only new GuardPoints are supported in v7.6.0.
- All existing CTE clients must be upgraded to CTE Agent v7.6.0, or a subsequent version.
- Guarding a GuardPoint for the first time on Windows disqualifies the GuardPoint for sharing between Windows and Linux, and subsequent attempts on a Linux client to guard.
- Windows AccessOnly client fails to guard the GuardPoint while rekey is suspended.
- All Windows clients must unguard before the key rotates on CipherTrust Manager.

Limitations

The following limitations exist for LDT over CIFS/NFS:

Windows

- Only supported for customers using unstructured data.
- LDT over CIFS is not supported on single processor systems.
- All nodes sharing a CIFS drive **must** have homogenous system drivers installed. You **cannot** have some nodes installed with the `vm\lfs.sys` driver and some installed with the `vm\filtr.sys` driver. That scenario is not supported.

Note

To determine which driver your node has installed, type: `fltmc` from the administrative command line.

Linux

- Although CTE supports GuardPoints over NFS shares using NFS v3 and v4 protocols, Thales strongly recommends using NFS v4 protocols, or a subsequent version, when using LDT policies.
- CTE **does not support** mixing NFS v3 and v4 protocols on different CTE hosts for accessing the same GuardPoint. All members of an LDT GuardPoint Group must access the same GuardPoint using the same NFS protocol version.
- When installing CTE patches, make sure that the new patch is compatible with CTE latest release. Follow instructions in the release note for a patch release, if any, for upgrading CTE hosts sharing access to the same GuardPoints across multiple hosts.
- Other current limitations will be removed over the next several patches. Refer to the release notes to determine which limitations, noted below, have been removed:
 - a. Applications will experience performance degradations on secondary hosts when targeting files undergoing rekey, even while LDT is suspended. LDT disables read-ahead on files undergoing rekey on secondary hosts resulting in lower IO throughput.
 - b. Loss of network connectivity to the NAS server from the primary host during active rekey can block access to files undergoing rekey across all members of LDT GuardPoint Groups for all GuardPoints on the NAS server.
 - c. If the secfsd daemon fails on a secondary host, it will require rebooting the host and removing the secondary host from each LDT GuardPoint Group on that secondary host prior to reboot. If the secfsd daemon fails on the primary host, it also requires rebooting the primary host and the delegation of the primary role to one of the secondary members of the LDT GuardPoint Group.

Key Guidelines for Configuration of an LDT Communication Group

1. You must create an LDT Communication Group on your CipherTrust Manager and manually add all of the CTE clients to it sequentially.
2. Minimum of three CTE clients required for membership to the LDT Communication Group for proper and continuous operations of LDT services across all LDT GuardPoint Groups. (Four is better, but three is required).
3. The first three nodes of the LDT Communication Group are critical and **cannot** be removed or shutdown/

reboot simultaneously.

4. All nodes, Windows and Linux, **must be running** CTE 7.5.0, or a subsequent version, in order for the nodes to communicate properly.
5. The majority of the CTE clients must be fully operational for proper LDT operations across all LDT GuardPoint Groups.

The LDT Communication Group requires that the majority of CTE clients are active, in order for the LDT Communication Group to work properly. If 50% of the LDT Communication Group servers, or 2 out of 3 **triad** nodes fail, then the LDT Communication Group cannot recover from that situation. To fix this issue, you must either:

- Reboot all of the CTE clients in the entire LDT Communication Group.
 - In Windows, restart **secfsd** through the **Control Panel > Services** page on all of the CTE clients in the entire LDT Communication Group.
6. The name of the LDT Communication Group cannot contain special characters.
 7. If you are repurposing a CTE client that is currently being used for LDT over NFS/CIFS, but still runs CTE and is still registered to the same CM, then you must:
 - a. Remove all CIFS/NFS LDT GuardPoint Groups from the host prior to removing the host from the LDT Communication Group.
 - b. Reboot the host.
 8. Remove a host from the LDT Communication Group if the host is being decommissioned, meaning that you plan to power it down for the foreseeable future, or while CTE is being uninstalled.
 9. Triad nodes must be on the same subnet with low-latency network connections to ensure stable failover.
 10. If a triad node is permanently down, remove it from CipherTrust Manager to allow a new node to join the triad. If 2 out of 3 triad nodes fail, the LDT Communication Group cannot recover automatically. Once the crashed nodes are back, restart **secfs** on all nodes in the group to restore communication.

Key Guidelines for Configuration of an LDT GuardPoint Group

- Failover, after an ungraceful failure, is manual. If a primary node becomes unavailable and LDT cannot automatically reassign the primary to another CTE client, the administrator must manually assign another CTE client as the primary node. See [Failover](#) for more information.

LDT Communication Group and LDT GuardPoint Group

- For continuous and seamless synchronization and control between all clients (excluding Windows AccessOnly clients) in an LDT Communication Group, in the LDT over CIFS/NFS environment, the **secfsd** service on each client must be continuous and uninterrupted. LDT support for NFS and CIFS depends on continuous
-

availability of the `secfsd` process for management and availability of LDT GuardPoint Groups and continuous flow of LDT messages from primary hosts to members of the LDT GuardPoint Groups during rekey.

In the event that the `secfsd` process abruptly fails and/or restarts for any reason, the LDT GuardPoint Groups will be erased on the CTE hosts and the LDT message flow to/from the CTE client to other members of the LDT GuardPoint Groups stops. The only method for recovering from this event is to reboot the CTE host. **Do not** terminate the `secfsd` process on the primary host, as this results in the election and promotion of another member of the LDT GuardPoint group to the primary role.

LDT Reverse Migration

- Converting LDT CIFS/NFS GuardPoints from Live Data Transformation policies to Standard CTE policies is not supported.
- LDT CIFS/NFS-protected GuardPoints cannot be migrated to `clear_key`.
- Reverse migration is **not** supported for network shares.
- LDT over CIFS/NFS **DOES NOT** support rolling back migrations.

Prerequisites

For LDT over CIFS/NFS to work properly, see Installation Prerequisites of the CipherTrust Quick Start Guide.

Space Required

The space requirements for share drives is the same as the requirements for local file systems. However, you must plan for additional space for metadata. Refer to [Planning for LDT Attribute Storage](#) for calculating space.

Network and Port requirements

- Ports 7024 and 7025 must be open on all triad nodes.
- Port 7024 is used for master-replica communication.
- Port 7025 is used for communication group monitor process.
- For optimized performance, put the triad nodes on the same subnet. Locate them close to each other with a low-latency network connections. High round-trip time (RTT), or unstable networks, can cause unnecessary master failovers and impact LDT GuardPoint Group health.

Supported Versions

Linux

Upgrade your CTE Agents to CTE v7.2.0 or later, and your CipherTrust Manager to version 2.7 or later, in order to

support LDT GuardPoints on NFS shares. It is not supported for earlier versions. You can use the standard upgrade procedure for both the CTE Agents and CipherTrust Manager. See the [CTE Agent for Linux Quick Start Guide](#) for more information.

Windows

On Windows, you must install the full version of CTE 7.2. Guarding CIFS/SMB shares with LDT GuardPoints is not supported in the upgrade version of CTE. Refer to the [CTE Agent for Windows Quick Start Guide](#) for more information. Requirements for GuardPoints

On Windows, the requirements for GuardPoints created on CIFS shares using LDT are different from those created on local directories or for those created on CIFS shares using standard CTE policies. You cannot mix the two on a single host. Instead, each host must contain either LDT CIFS share GuardPoints or local directory/standard policy GuardPoints.

If you want to use LDT on a CIFS share which contains GuardPoints on a host on which the CTE Agent is already installed, you must:

1. Remove any existing local directory GuardPoints.
2. Uninstall the current version of CTE Agent from the host.
3. Install CTE Agent version 7.5.0 or higher and respond **Yes** when prompted about guarding network shares.

If you do not see this prompt during installation, make sure that you have fully uninstalled the previous version of the CTE Agent.

Administering LDT over CIFS/NFS with CipherTrust Manager

The following sections contain information about the administration tasks required for using LDT over CIFS/NFS.

- [Adding a CIFS Connector for CipherTrust Manager](#)
- [Configuring CTE Windows LDT AccessOnly nodes](#)
- [Policy and GuardPoint Management](#)
- [Key Rotation Commitment](#)
- [LDT Metadata Management Over NFS/CIFS Shares](#)
- [Backup and Restore LDT on NFS GuardPoints](#)

Adding a CIFS Connector for CipherTrust Manager

In order to create GuardPoints on a CIFS share, you must obtain credentials for the CIFS share and add it as a connector in CipherTrust Manager.

CIFS Credentials

Prior to guarding data on the CIFS share, LDT needs permissions to access the share drive and its data and for

saving metadata to the CIFS share. CipherTrust Manager stores the CIFS Share credentials centrally. Credentials are protected similarly to the way CTE protect keys and policies. These credentials are associated with a GuardPoint. The CM pushes the credentials to the host and LDT uses them. Thales recommends customers create a new LDT account that contains a user name, password and domain, to access the CIFS share with read/write permissions. Users must not share their user accounts.

Adding the CIFS Share to CipherTrust Manager

In order for LDT to access that CIFS share and encrypt the data, you must provide the credential data when you add a CIFS share as a connector in CipherTrust Manager:

1. Log in to CipherTrust Manager as an administrator.
2. On the main screen, in the sidebar on the left, click **Access Management > Connections**.
3. Click **Add Connection**.
4. Click **File-Share**.
5. In the Select File-Share type field, select **CIFS/SMB** and click **Next**.
6. Enter a name and description for the connection and click **Next**.
7. Enter appropriate information for the fields:
 - **Host:** IP or FQDN of the CIFS share server
 - **Port:** Port where the CIFS service is running on the host
 - **Username:** Username to access the CIFS share
 - **Password:** Password to access the CIFS share
 - **Domain:** Domain under which the username is configured (Optional)
 - **Path:** Path to the CIFS file-share for which the credentials need to be tested (Optional)

Note

If you want to change a user name, domain or password of a CIFS credential in a CM connection, then you need to create a new connection on CM and change the GuardPoint to use the new connection.

LDT AccessOnly nodes

- Configuring CTE Windows Deployment for LDT AccessOnly nodes
- Configuring LDT for CIFS shares (with LDT AccessOnly nodes) Mapped to Multiple IP addresses

CTE Windows Deployment for LDT AccessOnly nodes

Currently, Windows clients that attempt to access CIFS paths must be part of an LDT Communication Group. The LDT Communication Group assigns the role of primary node to one of the clients, which performs LDT data rekeying. All of the other clients are assigned as secondary nodes, and they do not participate in rekeying data.

This is important to note because there are specific use cases which require that some of the nodes accessing a GuardPoint do not join the LDT Communication Group, such as when:

- All of the nodes accessing the GuardPoint are not able to communicate to other servers in the LDT Communication Group due to differences in security policies. Nodes with weaker security policies are left out of the LDT Communication Group to ensure the LDT Communication Group maintains a highest level of security.
- Certain nodes, which go through frequent network disconnects, should not participate in the LDT

Communication Group to again, ensure the highest level of security. For example, windows endpoint protection clients or laptop users.

To overcome these limitations, CipherTrust Transparent Encryption has a new feature called **Windows AccessOnly**. AccessOnly clients:

- **Do not** participate in data transformation.
- **Cannot** become part of an LDT Communication Group
- **Have** the same CIFS GuardPoint applied on them as other LDT GuardPoint Group nodes

Best Practices with AccessOnly nodes

- Do not assign a primary or secondary role to them.
- Apply GuardPoints on CIFS paths from LDT GuardPoint Group nodes, BEFORE applying the same GuardPoints to Access Only nodes.

The following illustration shows a typical setup for a network with LDT clients and Windows AccessOnly clients:

Note

- An AccessOnly node can set a GuardPoint, however, a node in the LDT Communication Group will be the system to rekey the GuardPoint.
- When an LDT rekey is in-progress, AccessOnly nodes cannot access the files being rekeyed.

Warning

All CTE AccessOnly agents, in an LDT Communication Group, **must** have CTE v7.4.0 or subsequent versions, installed. Agents that contain a previous version **must be** upgraded.

Setup and Configure Windows AccessOnly Nodes for LDT CIFS

The new role, **LDT AccessOnly**, can be assigned to any CipherTrust Transparent Encryption Windows client in multiple ways.

1. Agent registration:

- During Agent registration, a new option **AccessOnly (No LDT Transformation)** displays. Select it to setup the client as a Windows AccessOnly client.

Note

If you enable it, then the option to specify an LDT Communication Group name is disabled.

2. On CipherTrust Manager:

- In the client details page, there is a checkbox to enable/disable LDT AccessOnly.

Note

You cannot assign a node to be Windows AccessOnly before removing it from an LDT Communication Group.

Creating the Setup

1. On CipherTrust Manager, create a Windows LDT AccessOnly Client Group.

2. Add the Windows LDT AccessOnly clients to the Windows Client Group.
3. Create the GuardPoint.
 - a. Select the same LDT policy that you used for the clients participating in initial transformation.
 - b. Mount **the same** path on **each** client to participate in the transformation of the GuardPoint, or in the client group containing those clients. Example path: `\\192.168.1.100\Share1\Data1`.
4. Once the has fully completed initial data transformation, and the status is REKEYED, then create the GuardPoint in the Windows Access-Only Client Group. All Windows LDT AccessOnly clients will now be able to guard and access the files.
 - a. Select the same LDT policy that you used for the clients participating in initial transformation.
 - b. Mount **the same** path on **each** client to participate in the transformation of the GuardPoint, or in the client group containing those clients. Example path: `\\192.168.1.100\Share1\Data1`.

Converting a Windows AccessOnly node to an LDT node

1. Unguard/Disable the GuardPoint from the Windows AccessOnly node.
2. Un-check the **LDT Access Only** option in the CipherTrust Manager Client Window.
3. Add the client to a relevant LDT Communication Group.
4. Enable/Apply the GuardPoint on the CIFS path from this converted LDT node.

Converting an LDT node into a Windows AccessOnly node

- You **must remove them** from the LDT Communication Group **before** enabling the **LDT Access Only** option.

Backup/Restore from Access-Only nodes when LDT is in progress

- While LDT is in progress, backup/restore from Windows AccessOnly nodes is not recommended. Backup/Restore must be performed from **Primary** or **Secondary** nodes in the LDT Communication Group. This is because while LDT is in progress, files under rekey may not be accessible from Windows AccessOnly nodes. This may cause the Backup/Restore process to fail as file access is denied.

Configuring LDT for CIFS shares Mapped to Multiple IP addresses

This feature allows you to apply the same GuardPoint to two IP addresses that point to the same CIFS share. This can be useful because different applications may use different IP addresses for accessing data.

Note

This feature is available only when using LDT AccessOnly nodes.

Network Setup for CIFS shares Mapped to Multiple IP addresses

The following illustration shows how to setup your network. The table below explains the setup in more detail:

In the above sample diagram:

#	Description
1	LDT nodes are connected to Network 1
2	LDT AccessOnly nodes are connected to Network 2
3	CIFS server is connected to both Network 1 and 2, and have one IP address corresponding to each network
4	CIFS server may also be connected to more networks, based on use case and requirement
5	CipherTrust Manager can be connected to Network 1, 2 or some other network
6	Network 1 and 2 nodes can reach CipherTrust Manager and vice versa

Creating the Setup

1. Register LDT nodes from Network 1 on CipherTrust Manager and add them to the LDT Communication Group.
2. Create a CIFS\SMB share connection on CipherTrust Manager, using one of the two IP addresses of the CIFS machine, preferably IP 1.

3. Register the Windows AccessOnly nodes from Network 2 to CipherTrust Manager.
4. Create two **Client Groups**: one for the LDT nodes and one for the Windows AccessOnly nodes
5. Apply **GuardPoints** in both client groups using the respective network IP addresses.
6. Access the protected CIFS path using the respective IP addresses.

Policy and GuardPoint Management

You can use the same LDT policies that you use for protecting GuardPoint directories in local file systems and NFS/CIFS shares. The only exception is that for LDT protected GuardPoints, it only supports backup/ restore of files that do not use Apply Key.

Security Rule Ordering for Policies

If you want to enforce restrictions when guarding NFS/CIFS shares using an LDT or standard policy with a **CBC-CS1** key, note the following:

CipherTrust Transparent Encryption embeds the LDT and/or IV (initialization vector) attributes in the first 4K of files for NFS/CIFS shares guarded with an LDT or standard policy with a **CBC-CS1** key. Embedding CipherTrust Transparent Encryption attributes increases the actual file size by 4K. CTE hides that extra 4K when reporting the file size to users, or processes, that access the file with the Apply Key effect.

If you need the actual file size, or read/write access on the embedded header, for backup/restore processes for example, then you need a rule that permits access without Apply Key.

LDT Policies

Example 1: Permits Backup and Restore

A policy that allows backup and restore of encrypted data, clear-text access to certain processes, and denies access to all others:

Order	Resource Set	User Set	Process Set	Action	Effect	Browsing	
1				Reg. Op	permit, applykey	No	
2			backup	all_ops	permit, audit	Yes	
3			authorized-processes	all_ops	permit, audit, applykey	Yes	
4				all_ops	deny, audit	Yes	

Rule	Purpose
1	Default LDT rule required for LDT policies.
2	Allows for processes in the backup Process Set to access the real file size and backup the CipherTrust Transparent Encryption attributes along with the encrypted file data.
3	Allows for processes in the authorized-processes

Rule	Purpose
	Process Set to access the clear-text data, but it hides the additional 4K from the CipherTrust Transparent Encryption attribute.
4	Denies all other processes access to the data.

Example 2: Permits access to certain Processes

A policy that only allows certain processes clear-text access but allows all others to see the OS file attributes.

Order	Resource Set	User Set	ProcessSet	Action	Effect	Browsing	
1				key_op	permit:applykey	No	
2			authorized-processes	all_ops	permit:audit,applykey	Yes	
3				f_read,f_read_dir	permit:audit	Yes	
4				all_ops	deny:audit	Yes	

Rule	Purpose
1	Default LDT rule required for LDT policies.
2	Allows for processes in the authorized-processes Process Set to access the clear-text data.
3	Allows for processes not in the authorized-processes Process Set to read the OS file and directory attributes. Note: Processes that match this rule obtain the file size with the 4K header. If a process that is not in the authorized-processes Process Set needs the file size without the header, then the Apply Key must be present in the Effect or you will need an additional rule granting Apply Key to that specific process. That rule must be defined before this rule.
4	Denies processes not in the authorized-processes Process Set from reading any data from the files.

Standard Policies

Example 1: Permits access to certain Processes

A policy that allows backup and restore of encrypted data, clear-text access to certain processes, and denies access to all others:

Order	Resource Set	User Set	ProcessSet	Action	Effect	Browsing	
1			backup	all_ops	permit:audit	Yes	
2			authorized-processes	all_ops	permit:audit,applykey	Yes	
3				all_ops	deny:audit	Yes	

Rule	Purpose
1	Allows for processes in the backup Process Set to access the real file size and backup the CipherTrust Transparent Encryption attributes along with the encrypted file data.
2	Allows for processes in the authorized-processes Process Set to access the clear-text data, but it hides the additional 4K from the CipherTrust Transparent Encryption attribute.
3	Denies all other processes access to the data.

Example 2: Permits access to certain Processes

A policy that only allows certain processes clear-text access but allows all others to see the OS file attributes.

Order	Resource Set	User Set	ProcessSet	Action	Effect	Browsing	
1			authorized-processes	all_ops	permit:audit,applykey	Yes	
2				file_audit_read_secu...	permit:audit	Yes	
3				all_ops	deny:audit	Yes	

Rule	Purpose
1	Allows for processes in the authorized-processes Process Set to access the clear-text data.
2	Allows for processes not in the authorized-processes Process Set to read the OS file and directory attributes. Note: Processes that match this rule obtain the file size with the 4K header. If a process that is not in the authorized-processes Process Set needs the file size without the header, then the Apply Key must be present in the Effect or you will need an additional rule granting Apply Key to that specific process. That rule must be defined before this rule.
3	Denies processes not in the authorized-processes Process Set from reading any data from the files.

For more information, see [Adding Security Rules](#) in the CipherTrust Manager documentation.

Creating a GuardPoint on a CIFS Share Drive on CipherTrust Manager

Creating GuardPoints on a CIFS share drive requires you to add the CIFS share drive to CM as a connector first, and then select it as a network drive.

To add the CIFS share in the CipherTrust Manager Connection Manager, see [Adding a CIFS Connector for CipherTrust Manager](#).

Note

For the host name, use the IP address if the host name does not work.

GuardPoint Naming

When creating GuardPoints in a CIFS share, you must use the UNC name. A Universal Naming Convention (UNC) format name defines the location of files and other resources that exist on a network. UNC provides a format so that each shared resource can be identified with a unique address.

UNC names must conform to the `\\SERVERNAME\SHARENAME` syntax, where **SERVERNAME** is the name of the Provisioning Server and **SHARENAME** is the name of the shared resource.

- UNC names can also include the directory path:

`\\SERVERNAME\SHARENAME\DIRECTORY\FILENAME`

- To define a folder that contains a configuration database file in:

`C:\Program Files\Oracle\customer_data`

- On the shared server, enter:

`\\server1\customer_data`

Selecting the CIFS Share Drive for Guarding

When you create a GuardPoint for CIFS shares, you will have more options when browsing for the file system to guard. You can select to guard a local path, or a network path.

To create the GuardPoint on the CIFS share:

1. In CTE, select **Clients**.
 2. Click on the Client to access it.
 3. Click **Create GuardPoint**.
 4. Select a **policy** and **type**.
 5. For Path, click **Browse**.
-

6. In the Browse Path dialog, select **Network Path**.

Use the GuardPoint Settings on another GuardPoint

1. If you want to guard another GuardPoint on a different path, click **yes** to the question: **Would you like to use these GuardPoint settings on another guard point with a different path?**
2. Select the path for the GuardPoint and click **Create**.

Verifying the GuardPoint

- Before starting the application or accessing the data, you must ensure that the GuardPoints are guarded successfully. Check the status on CM or by running the `voradmin ldt stats` command.
- For Linux, LDT Communication Group member hosts cannot guard or unguard GuardPoints that have single file rekey jobs in progress. Attempts to guard or unguard result in a warning message and the operation is automatically retried until all single file rekey jobs are finished and the state of the GuardPoint can be changed.

Accessing the GuardPoint

If a GuardPoint is applied on a CIFS share on a CTE client, you can only access the data from a CTE client that has CTE installed on it. You cannot access the CTE client from an agent that does not have CTE installed.

Pausing and Resuming LDT per host and per GuardPoint

Rekey operations on a GuardPoint can only be paused or resumed by the primary host for that GuardPoint. You must run the `voradmin` command on the primary host for the GuardPoint. If multiple GuardPoints reside on the same CTE host, and the host is the primary for some of the GuardPoints and the secondary for other

GuardPoints, the `voradmin` command is applied only on the GuardPoints for which the CTE host holds the primary role.

The same applies if you pause or resume GuardPoints on a host using CipherTrust Manager. Pausing or resuming LDT on a host from CipherTrust Manager only applies to the GuardPoints for which the host holds the primary role.

Migrating GuardPoints over NFS from or to an LDT Policy

GuardPoints over NFS can be guarded using policies with key rules specifying a mix of CBC or CBC-CS1 keys.

You can migrate to an LDT policy from clear text (no existing policy) or from a standard CTE policy. If the standard policy uses:

- **CBC keys**

The CBC keys are transformed during the initial data transformation when LDT embeds the LDT metadata in the beginning of each file. LDT shifts the existing data in the files by 4096 bytes to make room for the LDT metadata.

- **CBC-CS1 keys**

The IV attribute is already embedded in the protected files. LDT transforms the files in those GuardPoints without shifting the existing data because the required IV attribute already exists.

Migration out of an LDT policy is only *partially* supported because of the shift to the existing data that was done to accommodate the LDT metadata. You can only migrate from a Live Data Transformation policy that uses CBC or CBC_CS1 keys to a different Live Data Transformation policy that uses CBC or CBC_CS1 keys. You cannot remove the Live Data Transformation policy from a guarded directory, and you cannot migrate from a Live Data Transformation policy to a standard CTE policy. The migration support matrix is shown in the following table.

Source Policy Type	Target Policy Type	Supported?
Live Data Transformation using CBC or CBC_CS1 keys	Live Data Transformation using CBC or CBC_CS1 keys	Yes
Live Data Transformation	No policy (unguarded directory)	No
Live Data Transformation	Standard CTE policy	No
Standard Policy using CBC or CBC_CS1 keys	Live Data Transformation using CBC or CBC_CS1 keys	Yes

The only method for migrating an NFS GuardPoint from LDT to clear-text or to a CTE standard policy that uses CBC or CBC_CS1 keys is the following:

1. Perform a full backup of files in the NFS GuardPoint in clear text. Make sure that you disable the security rule for the backup process in the LDT policy, if the security rule skips Apply Key as part of backup operation.
2. Upon completion of full backup, unguard the directory on the key manager and then remove the LDT Private Space directory (`ldtprivspace`) in the NFS GuardPoint using the `voradmin ldt rmltdt <GuardPoint>` command.
3. Remove the remaining files inside the NFS GuardPoint directory and restore the full backup of the files in clear-text over the NFS GuardPoint directory. If you are migrating to a standard CTE policy, you can now proceed with re-guarding the NFS GuardPoint directory using the standard policy.

Multiple GuardPoint Pathnames

If you have multiple LDT hosts guarding and sharing the same LDT GuardPoint directory with different local pathnames, the pathname that will be associated with LDT operations is the pathname used on the LDT host designated with primary status.

When you are entering `voradmin ldt` commands, you must use the primary host's local pathname for the GuardPoint when you specify the GuardPoint parameter. If another host is promoted to the primary status for the GuardPoint, and the GuardPoint directory pathname is different from the pathname on the previous primary host, then LDT changes the the pathname of the GuardPoint to the pathname of the new primary host.

For example, let's say you have two hosts (`LDT_Host_1` and `LDT_Host_2`) with the same directory in an NFS share mounted on different mount points on each host, and subsequently, you must enter the new primary host's local pathname for the GuardPoint:

- GuardPoint on `LDT_Host_1`: `/nfs-oxf-fs1-host1/gp`
- GuardPoint on `LDT_Host_2`: `/nfs-oxf-fs1-host2/gp`

When the GuardPoint is first added to `LDT_Host_1`, that starts the initial data transformation:

```
secfsd -guard /nfs-oxf-fs1-host1/gp
secfsd: Guardpoint initialization in progress
```

MDS has the GuardPoint configured for rekey at `/nfs-oxf-fs1-host1/gp`.

```
voradmin ldt list all

MDS_1:  type=file, nguards=0, name=/nfs-oxf-fs1-host1/gp/__vorm_mds__
        Guard Table: version 1 nentries 1
        Guard 0: type=GP, state=REKEYING DIRTY, flags=GP LOCKED, gp=/nfs-oxf-fs
1-host1/gp
        File List: count 4
```

When the GuardPoint is enabled on `LDT_Host_2`, the host joins the LDT GuardPoint Group for the GuardPoint.

```
secfsd -guard /nfs-oxf-fs1-host2/gp
secfsd: Path is guarded
```

Unguard the GuardPoint on `LDT_Host_1` while rekey in progress:

Note

This operation triggers the promotion of `LDT_Host_2` to primary status:

```
secfsd -unguard /nfs-oxf-fs1-host1/gp secfsd: Path is not guarded
```

On `LDT_Host_2`, guard the same directory mounted at the different path:

```
voradmin ldt list all

secfsd -guard /nfs-oxf-fs1-host2/gp
secfsd: Path is guarded
```

MDS now has the GuardPoint configured for rekey at /nfs-oxf-fs1-host2/gp on LDT_Host_2.

```
voradmin ldt list all
MDS_1:  type=file, nguards=0, name=/nfs-oxf-fs1-host2/gp/___vorm_mds___
        Guard Table: version 1 nentries 1
        Guard 0: type=GP, state=REKEYING SUSPENDED (qos), flags=GP LOCKED, gp=/nfs-oxf-fs1-host2/gp
        File List: count 4
```

Key Rotation Commitment

The primary host drives the execution of the process for checking and committing a new key version across all members of LDT GuardPoint Groups associated with the affected GuardPoints. The primary host commits and launches LDT if all members have also received the same key version from CM. If a member has not received the new key version, the primary delays launching LDT and continues checking for the availability of the key versions with all of the members of the LDT GuardPoint Group.

The primary host triggers an ALARM on CM if a member of the LDT GuardPoint Group has not received the new key version. The message for this displays as:

LDT-NFS-ALERT: Some members of the LDT GuardPoint Group for [GuardPoint Pathname] have not received the latest key version.

After receiving this message, check the status of the connections between CTE hosts and CM to make sure each member is in an active state and in communication with CM, type:

```
voradmin ldt attr get /nfs-oxf-fs1/gp1

LDT stats: version=5, rekey_status=rekeyed
  Number of times rekeyed:      1 time
  Rekey start time:             2022/01/08 09:12:14

    passed=0, skipped=0, created=0, removed=0, excluded=0
```

LDT Metadata Management Over NFS/CIFS Shares

CTE manages LDT metadata as extended attributes in local file systems for each file and GuardPoint directory. Because the NFS/CIFS protocol does not support extended attributes, CTE embeds LDT metadata into each file

to be encrypted inside the GuardPoint, over NFS/CIFS shares, during the initial data transformation. The size of the LDT metadata is 4096 bytes, so the size of each file in the NFS/CIFS share is increased by 4096 bytes. The presence of LDT metadata and larger file sizes is not visible to users and applications as long as the GuardPoint remains enabled. The same file stored in an LDT protected GuardPoint, over NFS/CIFS and a non-protected directory, is identical to other users and applications despite the presence of the embedded LDT attribute and the additional 4096 bytes.

As the Linux example below illustrates, the presence of the attributes embedded during the initial transformation of the file is invisible to users and applications. Note that the size of the file after transformation appears unchanged until the GuardPoint is disabled.

```
ls /nfs-oxf-fs1/gp1

cp /etc/hosts /nfs-oxf-fs1/gp2

ls -l /nfs-oxf-fs1/gp2/hosts
-rw-r--r--. 1 root root 241 Jan  3 16:14 hosts

secfsd -guard /nfs-oxf-fs1/gp2
secfsd: Guard point initialization in progress

voradmin ldt attr get /nfs-oxf-fs1/gp2/hosts
LDT attributes: rekeyed_size=0, rekey_status=none
Key:      clear_key

ls -l /nfs-oxf-fs1/gp2/hosts
-rw-r--r--. 1 root root 241 Jan  3 16:15 /nfs-oxf-fs1/gp2/hosts

secfsd -unguard /nfs-oxf-fs1/gp2
secfsd: Path is not guarded

ls -l /nfs-oxf-fs1/gp2/hosts
-rw-r--r--. 1 root root 4337 Jan  3 16:15 /nfs-oxf-fs1/gp2/hosts

voradmin ldt attr get /nfs-oxf-fs1/gp2/hosts
LDT attributes: rekeyed_size=4096, rekey_status=none
Key:      name=LDTNFS_KEY_1, version=1482
```

As noted, CTE also manages the LDT attribute for each GuardPoint directory as an extended attribute. For GuardPoints over NFS/CIFS shares, LDT stores the LDT metadata for each GuardPoint in the LDT Attribute File associated with the directory. In general, there are multiple metadata files that LDT manages for GuardPoints over NFS. Those metadata files are stored in the LDT Private Space Directory inside each GuardPoint directory. The directory name of LDT Private Space is `vorm_ldtprivspace`. The directory is created inside the GuardPoint directory at the time of initial transformation. The LDT metadata file for a GuardPoint is also created in the `vorm_ldtprivspace` directory of the GuardPoint at the time of initial transformation. The name of the file is `::vorm:ldtxattr::`, similar to the MDS file which is also protected against user modification or deletion. The size of the LDT metadata file is 4096 bytes. For example:

```
ls -l /nfs-oxf-fs1/gp1/vorm_ldtprivspace/
total 4
-rwxr-xr-x. 1 root root 4096 Jan  4 12:13 __vorm:ldtxattr__
```

Note

The LDT Attribute file is protected, and it can only be manually removed using `voradmin ldt rmldt <GuardPoint Path>`. For details, see [Deleting LDT Metadata \(Linux\)](#).

Backup and Restore LDT on NFS GuardPoints

Native backup capabilities in an NAS server is the recommended method for backing up and restoring GuardPoints on a NAS share. You may also backup or restore GuardPoints on NAS shares on the host designated as the primary host for an LDT GuardPoint Group, as described earlier.

Backup LDT on NFS GuardPoint

Backups of the NAS servers are remote from an LDT perspective.

It is extremely important that while you are backing up the NAS server:

- LDT is **not** performing data transformation in the GuardPoint
- No client is modifying data in the GuardPoint

This rule applies for:

- Initial data transformation
- Automatic or manual key rotation
- Backups of an entire GuardPoint, or any subset of files within a GuardPoint namespace.

Restore LDT on NFS GuardPoints

All clients must have their GuardPoints disabled prior to **restoring** the backup on the NAS server. GuardPoints is required because LDT over NFS clients are unaware of changes being performed to the files, and LDT metadata for the files, on the NAS server.

Upgrading CTE agent in an LDT Communication Group

Upgrading from 7.2.0. to 7.3.0

- [Upgrading CTE Agents from 7.2.0 to 7.3.0](#)

Upgrading to 7.4.0

You can [Upgrade CTE](#) from previous versions to 7.4.0 with no special considerations.

Warning

For CTE Agents using LDT over CFS/NFS, you **MUST** upgrade to v7.4.0 **BEFORE** you can upgrade to 7.5.0. You cannot upgrade to 7.5.0 from versions previous to 7.4.0.

Upgrading to 7.5.0 and Post 7.5.0

Note

CipherTrust Transparent Encryption 7.5.0, and subsequent versions, have architectural design changes which require all nodes, Windows and Linux, to run CTE 7.5.0 in order for the LDT Communication Group nodes to communicate properly. The architecture design changes introduces [New Terminologies](#). It is critical to understand these new terms.

- Upgrading CTE Agents in an LDT Communication Group from 7.4.0 to 7.5.0 and post 7.5.0

Best Practices for Upgrading

Only perform an upgrade when LDT is **NOT** in progress or is in a SUSPENDED state.

Triad Nodes

- Upgrade the LDT Communication Group replica nodes one at a time, before upgrading the LDT Communication Group primary node. When the LDT Communication Group primary is upgraded, the primary fails over to one of the secondary nodes, which becomes the new primary node.

LDT GuardPoint Group

- Upgrade the secondary nodes first, followed by the primary node.

To check the current node role and status of the LDT Communication Group, type:

```
voradmin ldt group list <guard path>
```

Upgrading the LDT Agents in an LDT Communication Group from 7.2.0 to 7.3.0

Note

This is applicable for Linux **and** Windows.

When upgrading from CTE 7.2.0, all nodes in an LDT Communication Group **must be** upgraded together to 7.3.0. Rolling upgrades **do not work** because CTE 7.3.0 introduces security improvements and authentication features that involve the LDT Communication Group. All nodes must contain CTE 7.3.0 in order to be able to communicate.

For example, if an LDT Communication Group contains 10 nodes, then, with 7.2.0, you could upgrade them individually and still expect secfsd communication services to operate as expected. Note that the 10 nodes in the LDT Communication Group may or may not guard the same CIFS/NFS share, but they use the same LDT Communication Group master for communicating. With 7.2.0, if node1 were to be upgraded from 7.2.0.xxx to 7.2.0.yyy, then this does not affect the progress of LDT. Also, node1 is able to use all services correctly because it is admitted to the group by the upgraded communication master. So in this case, a rolling upgrade is possible.

With 7.3.0, Thales is introducing authentication for the LDT communication group nodes. Therefore, only nodes that have the capability to authenticate themselves can be part of the LDT Communication Group. As a result, for an upgrade operation, the entire set of 10 nodes in the LDT Communication Group have to be scheduled for maintenance at the same time. In the maintenance window, you must upgrade all nodes to 7.3.0. After a successful upgrade, the administrator should verify that all GuardPoints are green and working as expected. Any node with 7.2.0 will not be able to authenticate to the LDT Communication Group and, therefore, will not be admitted into the LDT Communication Group.

Procedure

1. Start a maintenance window by removing all nodes, in the LDT Communication Group, from production.
2. Upgrade all nodes to 7.3.0.
3. Verify that all GuardPoints are guarded on all nodes as expected, type:

```
voradmin ldt group check <gp path>
```

4. Verify that the LCG communications master is up and running, in **Windows**, by typing: `voradmin ldt group comm_info`

Note

Linux is adding support for this command in a subsequent version.

5. When finished upgrading, add the nodes back into production.

New Terminology

The architecture design changes introduces new terminologies. It is critical to understand these new terms.

New LDT Communication Group Terms

- **Triad nodes**

The triad nodes are the first three servers in the LDT Communication Group.

- **Subordinate nodes**

The subordinate nodes are the remaining nodes in the LDT Communication Group.

GuardPoint Terms

- **Primary node**

The node that performs LDT rekeying of data.

- **Secondary node**

All of the other clients in the LDT GuardPoint Group are assigned as secondary nodes.

Note

They do not participate in rekeying data. Secondary nodes can be promoted to primary nodes if a primary node fails.

- **LDT GuardPoint Group**

An LDT GuardPoint Group contains a collection of LDT-enabled CTE clients that are all on the same network, managed by one CipherTrust Manager, guarding a common NFS/CIFS share and can communicate with each other over that network. An LDT GuardPoint Group enables the primary host of an LDT GuardPoint Group to communicate with the secondary hosts that are members of that LDT GuardPoint Group.

CTE Terminology

Following is a complete list of CTE terms which includes the new LDT terms.

The guide uses the following terminology:

Term	Description	OS Applies to
CTE	CipherTrust Transparent Encryption is a suite of products that allow you to encrypt and guard your data. The main software component of CTE is the CTE Agent, which must be installed on every host whose devices you want to protect. Notes • This suite was originally called Vormetric Transparent Encryption (VTE), and some of the names in the suite still use "Vormetric". • For example, the default installation directory is /opt/vormetric/DataSecurityExpert/agent/ for Linux and AIX, and C:\Program Files\Vormetric\DataSecurityExpert\agent\ for Windows.	Windows/Linux/AIX
CTE Agent	The software that you install on a physical or virtual machine in order to encrypt and protect the data on that machine. After you have installed the CTE Agent on the machine, you can use CTE to protect any number of devices or directories on that machine.	Windows/Linux/AIX

Term	Description	OS Applies to
CTE Capabilities	CipherTrust Transparent Encryption agent version-specific features like Multi-Factor Authentication.	Linux
CTE-K8s	CipherTrust Transparent Encryption for Kubernetes. Policy-based encryption of data stored on persistent volumes	Linux
CTE-RWP or RWP	CipherTrust Transparent Encryption with Ransomware Protection. Ransomware protection for volume-level (Windows)/GuardPoint (Linux) data storage through process behavior monitoring and analytics.	Windows/Linux
CTE UserSpace (CTE-U)	CipherTrust Transparent Encryption (formerly known as ProtectFile FUSE). File system level encryption and access control solution for Linux servers.	Linux
Data Transformation	Encrypting or decrypting data.	Windows/Linux/AIX
Domain Sharing	This allows Clients in one domain to get cross-domain resources, specifically GPs.	Windows/Linux/AIX
GuardPath	A directory to which a CTE Kubernetes data protection and encryption policy has been applied. CTEK8s will control access to, and monitor changes in, this device and directory, encrypting new or changed information as needed.	Linux
GuardPoint	A device, or directory, to which a CTE data protection and encryption policy has been applied. CTE will control access to, and monitor changes in, this device and directory, encrypting new or changed information as needed.	Windows/Linux/AIX
Host /Client	In this documentation, host and client are used interchangeably to refer to the physical or virtual machine on which the CTE Agent is installed.	Windows/Linux/AIX
In-place Data transformation	Encryption mechanism for block devices.	Linux
Key Manager	An appliance that stores and manages data encryption keys, data access policies, administrative domains, and administrator profiles. Thales offers CipherTrust Manager, a key manager for use with CTE.	Windows/Linux/AIX

Term	Description	OS Applies to
LDT (Live Data Transformation)	After initial GuardPoint enablement, LDT performs initial encryption, or rekeying, in the background, unnoticed by users. The data stays live and available. This accelerates CTE deployments and eliminates the need to block applications and user access to data during encryption or rekey operations, which can inconvenience users and affect operational efficiency.	Windows/Linux
LDT Communication (Comm) Group	A group of LDT clients who communicate with each other, and are responsible for, initial data transformation and future key rotation of CIFS/NFS GuardPoints.	Windows/Linux
LDT GuardPoint Group	An LDT GuardPoint Group contains a collection of LDT-enabled CTE clients that are all on the same network, managed by one CipherTrust Manager, guarding a common NFS/CIFS share and can communicate with each other over that network. An LDT GuardPoint Group enables the primary host of an LDT GuardPoint Group to communicate with the secondary hosts that are members of that LDT GuardPoint Group.	Windows/Linux
LDT Primary node	The LDT GuardPoint Group node that performs LDT rekeying of data.	Windows/Linux
LDT Secondary node	All of the other clients in the LDT GuardPoint Group are assigned as secondary nodes. Note: Secondary nodes do not participate in rekeying data, however, they can be promoted to primary nodes if a primary node fails.	Windows/Linux
LDT Subordinate nodes	The subordinate nodes are the remaining nodes in the LDT Communication Group.	Windows/Linux
LDT Triad nodes	The triad nodes are the first three servers in the LDT Communication Group.	
Learn Mode	Logging mode for audit logs to help generate security policies. Learn Mode allows access to guarded paths while logging access details. Users can analyze the content users and processes are accessing, the data used, and	Windows/Linux

Term	Description	OS Applies to
	define GuardPoint policies accordingly.	
MFA	Multifactor authorization ensures that the access credentials presented belong to the actual person. After logging in to the system, when a user tries to access a CipherTrust Transparent Encryption GuardPoint, it triggers a second factor authorization to verify the user with a second form of authentication, like sending a passcode to the users's registered cell phone, that they then have to input into the application.	Windows/Linux
Profile	Shared configuration resource for Client logging, Quality of Service, Multi-Factor Authentication, Ransomware Protection and key manager communication settings.	Windows/Linux/AIX
Signature	The hash of an entity. Where Entity can be the process or the docker image.	Windows/Linux/AIX
Versioned key and Key versions	Keys whose name remains the same but keybytes are different for each different version.	Windows/Linux/AIX

Upgrading CTE agents in an LDT Communication Group from 7.4.0 to 7.5.0 and post 7.5.0

When upgrading the CTE agent version on all nodes of an LDT Communication Group, you must stop CTE on all of the nodes to be upgraded before upgrading them.

1. Unguard the GuardPoints on the nodes to be upgraded:
 - a. Go to the CipherTrust Manager UI.
 - b. In the GuardPoint window, click the ellipsis on the right side of a GuardPoint and select disable to disable the GuardPoint.
 - c. Repeat the steps for all of the GuardPoints on the nodes to be upgraded.
2. Stop the CTE service on all of the nodes to ensure that all of the GuardPoints are unguarded.

For **Windows**:

- a. Go to **Control Panel > Services (local)**.
- b. Select **secfsd**.

- c. Select **Stop the Service**.

For **Linux**, type:

```
/etc/vormetric/secfs stop
```

3. Upgrade **CTE** on all of the nodes.
4. If your setup contains **manual directory** type GuardPoints, then you must run `secfsd -guard <gp>` to guard the GuardPoints again after the upgrade.
5. Verify that the GuardPoints are guarded on all of the nodes. Type:

```
# secfsd -status guard
```

Quality of Service for LDT CIFS/NFS GuardPoints

You can perform QoS administrative functions on the current primary CTE host. If the same CTE host is acting as a primary and secondary for multiple GuardPoint, the LDT schedule and/or Pause/Resume administrative options target those GuardPoint for which the host has assumed the primary role. This restriction is enforced through QoS functions available on CipherTrust Manager and the voradmin command.

Note

- The current pause/resume state of LDT at the host/client level, is contained in the `/var/vormetric/vorm-prs` file. This file is not protected. If it is accidentally removed or changed, it will be re-created and updated to reflect the correct pause/resume status within 30 seconds or less.
- Be sure to pause or resume LDT on the primary host only.

Suspending LDT from the CTE Agent CLI and CipherTrust Manager GUI

Promotion of a secondary host, to the primary role, can alter the current pause/resume state of the GuardPoint on the newly promoted host. The new state of the GuardPoint depends on the pause/resume state and how the pause/resume was initiated on the primary host prior to promotion. The following bullet points outline two ways to initiate pause/resume and the limitation of pause/resume on an LDT NFS GuardPoint:

Pause/Resume using CTE Agent CLI

- The voradmin command to suspend the GuardPoint is a persistent state that will be retained even after a system reboot.
- The suspended state enforced by the new primary after a promotion process.

- Suspend/resume on an LDT NFs GuardPoint through a voradmin command can only be executed on the primary host.

Pause/resume using CipherTrust Manager GUI

- Pressing the pause button on a specific client, on the CipherTrust Manager client tab, only suspends the GuardPoint(s) on that host.

In the event of a promotion, the GuardPoint resumes rekey on the new primary host, if the host tab on the CipherTrust Manager, for the newly promoted primary, is not set to suspend state.

- When using a client group, pressing the pause button sets the pause setting on all of the client that are members of that client group.

In the event of a promotion, the GuardPoint remains in the suspended state on the newly promoted primary host, until the pause button is pressed to resume rekey.

Alerts

This section lists the alerts for LDT over NFS and describes what to do in each case. LDT generates alerts when issues arise that require attention from the Administrator. Without prompt attention, alerts can delay the rekey process or cause the process to remain incomplete.

Linux Alerts

Guard/Unguard alerts

Label	Alert	Description
I_LDT_NFS_PTS_ACCESS_FAILURE	Failed to preserve time stamps: GuardPoint [GuardPoint] objID [objID] error [error]	Primary host sends this alert to notify of the failed attempt to preserve time stamps on the specified inode number in the GuardPoint. The reason for the failure is reported using the error code.
E_LDT_NFS_REKEY_OP_FAILED	Failed to start or stop rekey on GuardPoint [%s] over NAS share, error [error]	Primary host sends this alert if it fails to start or stop rekey on a specified GuardPoint. The error code in the alert provides the error code associated with the failed attempt.

LDT Communications Group alerts

Label	Alert	Description
W_LDT_COMMGRP_MASTER_DOWN	LDT Communication Master is down	Each member of an LDT GuardPoint Group sends this warning reporting that the LDT Communication Group Master

Label	Alert	Description
		associated with the group is down.
I_LDT_COMMGRP_MASTER_UP	LDT Communication Master is up	Each member of LDT GuardPoint Group sends this notice reporting that the LDT Communication Group Master associated with the group is no longer down.
W_LDTGRP_PRIMARY_LEFT	LDT Group Primary host left the group for GuardPoint [%s]	This warning reports that the specified GuardPoint has been disabled on the host designated as the primary host for the GuardPoint. LDT immediately designates another member in the LDT GuardPoint Group as the primary host for the group.
I_LDTGRP_PRIMARY_ELECTED	LDT Group Primary host has been elected for GuardPoint [GuardPoint]	Every member of an LDT GuardPoint Group for a specific GuardPoint sends this notice to report the election of a member of the group as the primary host for the GuardPoint.
I_LDTGRP_PRIMARY_PROMOTED	Host has been promoted to LDT Group Primary role for GuardPoint [GuardPoint]	The host promoted to the primary role for the GuardPoint sends this notice.
W_LDTGRP_PRIMARY_REFUSED	Host cannot be promoted to LDT Group Primary role for GuardPoint [GuardPoint]	This warning reports that the host sending the alert was elected for promotion to the primary role for the GuardPoint, and the host rejected the request. Read-only access to a GuardPoint or the host not having the latest policy key version are common reasons for a host to reject the promotion.
E_LDTGRP_PRIMARY_EFAILED	Election of this host for LDT Group Primary role has failed for GuardPoint [GuardPoint]	The host elected and accepted the primary role for the GuardPoint sends this error message if the host fails to perform the operations required for promotion to the primary role for the GuardPoint.
E_LDTNFS_FOVER_FOP	File operation recovery failed on new primary host after primary election, GuardPoint [%s] objID [%llu] error [%d] source [%d]	This error message reports that the host promoted to primary status was unable to complete the file operation that was initiated prior to the unexpected failure and departure of the previous primary host from the group. The file inode number is the objID in the message. The error code indicates the reason for the failure. The source identifies the operation that the new primary host failed to complete.

Label	Alert	Description
E_LDTNFS_RECOVERY_FAILED	LDT recovery failed on new primary host after primary election, GuardPoint [%s] objID [%llu] error [%d]	This error message reports that the host promoted to primary status was unable to recover incomplete rekey operation on the specified file inode number in the specified GuardPoint after unexpected failure and departure of the previous primary host from the group. The error code indicates the reason for the failure. The error code indicates the reason for the failure.
W_LDTNFS_PROMOTION_TOOLONG	Promotion too long	Promotion process taking too long, causing a delay in file operations, GuardPoint [%s] objID [%llu]. This warning occurs when a request to the primary host is delayed for a long time because a new primary has not been promoted.
E_LDTNFS_FOP_FAILED	File operation failed on secondary host, GuardPoint [%s] objID [%llu] error [%d] source [%d]	This alert from the primary host reports primary host failure to update LDT related metadata on behalf of a member performing a file operation that requires making changes to LDT metadata. File operations performed on secondary hosts to files undergoing rekey, such as truncate or rename, involves the primary host to intervene for updating LDT metadata.
W_LDTNFS_KEY_ROTATE_ENOKEY	Some members of LDT GuardPoint Group for [%s] have not received latest key version	This warning is initiated by the primary host when at least one member of the group for the specified GuardPoint Group has not received the latest policy key version that the primary host is committing. Make sure that all member of the LDT GuardPoint Group are connected to the CM.
W_LDTNFS_LAZY_RK_FAILURE	Lazy rekey operation failed to rekey <file name>, error <error code>	This alert reports failure to rekey the specified file name. The error code provides the reason for the error.

Windows Alerts

Guard/Unguard alerts

Label	Alert	Description
E_LDT_GUARD_FAILED	Failed to enable/apply GuardPoint	Guard operation failed

Label	Alert	Description
E_LDT_UNGUARD_FAILED	Failed to disable/delete GuardPoint	Unguard operation failed

Credentials alert

Label	Alert	Description
E_LDT_CIFS_INVALID_CRED	Failed to enumerate GuardPoint <.. \GP0>, Verify the provided CIFS credentials.	CIFS credentials may be expired or may not have permission to access.
E_LDT_CIFS_LOGIN_FAILED	Failed to authenticate a user	Failed to authenticate user using given credential.
[CGA] [ERROR] [4] [CGA3142E]	Not guarding path; Reason: Resource not available	If the agent logs display this message during CIFS GuardPoint creation, you can safely disregard. The GuardPoint will be created after the credentials are authorized. It may take a few minutes.

LDT Communication Group alerts

Label	Alert	Description
E_LDT_LGS_JOINING_FAILED	Failed to join GuardPoint group	CTE client was unable to join the LDTGuardPoint group
E_LDT_LGS_LEAVING_FAILED	Failed to leave GuardPoint group	CTE client was unable to leave the LDT GuardPoint group

Troubleshooting LDT CIFS

The majority of the CTE clients must be fully operational for proper LDT operations across all LDT GuardPoint Groups.

If 50% or more CTE clients fail, LDT Communication Group cannot recover from that situation. To fix this issue, you must reboot all of the CTE clients in the entire LDT Communication Group.

The LDT Communication Group requires that the majority of CTE clients are active in order to work properly. If 50% or more CTE clients fail, LDT Communication Group cannot recover from that situation. To fix this issue, you must either:

- Reboot all of the CTE clients in the entire LDT Communication Group.
- In Windows, restart **secfsd** through the **Control Panel > Services** page all of the CTE clients in the entire LDT Communication Group.

Troubleshooting LDT

- [Protecting LDT GuardPoints against Failure in Underlying File Systems \(Linux\)](#)

- Alerts Playbook
- Error Messages
- Warning and Info Messages
- Recommendations and Considerations
- Troubleshooting LDT CIFS
- Troubleshooting LDT Encryption Failures

Monitoring and Statistics

This section describes how to find the runtime status of LDT and how to get statistics about its operation.

Note

When you check GuardPoint status on the CipherTrust Manager, be aware that the status is not relayed in real time. There can be a delay of several minutes before the CipherTrust Manager becomes aware of events on the host. When you configure the host and CipherTrust Manager for one-way communication, the delay is longer, up to an hour, because LDT sends statistics to the CipherTrust Manager only once per hour.

To find out when the CipherTrust Manager last received a status update from the host, check the Last Status Update timestamp in the GuardPoint Health dialog (for information about how to display this dialog, see [Obtaining Statistics with GuardPoint Status](#)). For the most up-to-date statistics, inspect the host/client. Run the `voradmin` command on the managed hosts to retrieve status and statistics pertaining to GuardPoints.

Obtaining Statistics with GuardPoint Status

During and after data transformation, you can view statistics about any GuardPoint on any client in your system. Either use the CipherTrust Manager, as described in this section, or use the `voradmin` command, as described in [Obtaining LDT Statistics at the Command Line](#).

To display the GuardPoint status in CipherTrust Manager:

1. Open the **CTE** application and click **Clients** in the left-hand menu bar.
2. Click on the name of the client whose GuardPoint you want to view.
3. Click the Status of the GuardPoint you want to view in the GuardPoints table.
4. CipherTrust Manager displays the GuardPoint Health dialog box with various statistics about the GuardPoint.

Obtaining LDT Statistics at the Command Line

You can obtain LDT statistics from the command line using the following command:

```
voradmin ldt stats <guard path> [interval]
```

This command displays transformation statistics for a GuardPoint, or for all GuardPoints, if none are specified. If you specify an interval (in units of seconds), the command continually updates the statistics on the given interval. If no GuardPoint is specified, the command returns the aggregate statistics at the host level, including specific statistics related to QoS. If a GuardPoint is specified, statistics include:

- Current rekey status
- Rekey Start time
- Last rekey completion time
- Estimated Rekey completion time
- Data Statistics including the amount of data transformed
- File statistics including:
 - Number of files transformed
 - Number of files skipped
 - Number of files remaining for rekey

Obtaining a Rekey Report

LDT generates a report automatically after completion of a key rotation. The report lists the files in the GuardPoint and the key and version of the key applied to each file. This kind of report may be a common compliance requirement.

The administrator can also request a rekey report during rekey, if the need to see the partial transformation results so far.

About the rekey report

On Linux hosts, LDT writes rekey reports to a local file on the agent host in `/var/log/vormetric/`. The file name begins with `ldtaudit-log-`. It is followed by the file system directory name, GuardPoint directory name, and a timestamp. For example, for a GuardPoint at `/oxf-fs2/gp2` with rekey completed on November 19, 2016, just after 2:00 p.m. (hour 14), the rekey report file name would be `ldtaudit-log-_oxf-fs2_gp2-2016111914917`.

The report includes:

- Total number of files in the GuardPoint
- Number of files transformed
- Rekey start and end times
- List of all files transformed

- Applied key and key version for each file (for example, files in different resource sets might have used different keys)

Manually generating a rekey report

To generate a rekey report manually, use the following command:

```
voradmin ldt rekey report <GuardPoint> [<logfile>]
```

In **<GuardPoint>**, type the GuardPoint path. In **<logfile>**, you can optionally direct the output to a file. If no logfile is specified, the report displays on **stdout**.

Monitoring Ongoing LDT Operations at the Command Line (Windows only)

Use the following syntax to monitor LDT progress. If an interval is specified (in units of seconds), it continually updates the monitoring output at the specified interval.

```
C:\> voradmin ldt monitor [interval]
```

For an overview of **voradmin ldt**, see [LDT Command-Line Administration: voradmin command](#).

Protecting LDT GuardPoints against Failure in Underlying File Systems (Linux)

LDT Recovery Challenges

The main challenge with LDT recovery is a failure to access files or specific blocks in files inside a GuardPoint. Before LDT runs the recovery process on a GuardPoint, the underlying file system was recovered before file system was mounted. File system recovery may create orphan files in the **lost+found** directory inside the mount point. If an orphan file belongs to the GuardPoint, LDT cannot recover the file as the file is no longer in the same directory as it was prior to the crash while it was undergoing rekey.

LDT Recovery Enhancement

LDT has been improved for handling inconsistencies in the underlying file system during execution of LDT recovery. When enabling a GuardPoint after a system crash, LDT performs consistency checks on the files undergoing rekey at the time of crash before enabling GuardPoint. If the LDT recovery process is unable to recover any of the affected files, the GuardPoint will not be enabled and LDT will send the following alert to the CipherTrust Manager:

```
[CGS3266E] LDT-ALERT: Cannot enable guard point [GuardPoint] due to inconsistencies in underlying file system encountered during LDT recovery.
```

You can check the status of a GuardPoint and the reason for failing to enable a GuardPoint using the **secfsd -status guard** command. For example, the GuardPoint/**mnt/gp** failed to guard because **Guard point needs LDT recovery** as reported in the **Reason** column for the following example GuardPoint.

GuardPoint	Policy	Type	ConfigState	Status	Reason
-----	-----	-----	-----	-----	-----
/mnt/gp	LDT220	manual	guarded	not guarded	Guard point needs LDT recovery

Details on the specific issues encountered, including any files that could not be recovered, are reported to a log file in the `/var/log/vormetric` directory. The log file name is in the format:

```
ldt_recovery_log:<guardpoint_name>:<timestamp>.txt
```

The log file name starts with `ldt_recovery_log`, followed by the GuardPoint pathname and the date and time of the recovery attempt. The GuardPoint pathname and date and time are separated with “.”. For example:

```
/var/log/vormetric/ldt_recovery_log:_mnt_gp:2018-12-08-14:6:12.txt
```

Refer to the issues listed in the log file, and resolve those issues before enabling the GuardPoint again. A GuardPoint cannot be enabled in subsequent guard attempts until those issues are resolved. Each attempt generates a new log file. Check the LDT log file for missing files whose inode numbers match inode numbers of orphan files in `lost+found`. If there is a match, restore the file from `lost+found` to the pathname specified in the LDT recovery log file. Be sure to run the `mv` command to restore the file to the original location, do not run the `cp` command. After resolving all or some of the reported issues, you must run the command `voradmin ldt recover <GuardPoint>` to repeat the recovery process.

```
voradmin ldt recover <GuardPoint>
```

Running this command resolves the problems that can be corrected and clears the failed recovery status on the GuardPoint, allowing the GuardPoint to enable automatically within 30 seconds. If the GuardPoint does not enable, you can enable it using `secfsd -guard` command, if manual guard, or enable it on the CipherTrust Manager, if auto-guard. Note that if you are unable to resolve all of the reported issues, you accept the loss of some data or files, as reported in the latest recovery log file for the GuardPoint, when you run the command `voradmin ldt recover <GuardPoint>`.

Recovery Alerts

LDT sends two alerts to CipherTrust Manager if LDT fails to resolve the issues encountered during recovery.

The alert below is an error report sent to the CipherTrust Manager whenever LDT encounters failure during recovery prior to enabling GuardPoint. This alert also reports the GuardPoint specified in the message is not enabled:

```
[CGS3266E] LDT-ALERT: Cannot enable guard point [GuardPoint] due to inconsistencies in underlying file system encountered during LDT recovery.
```

The alert below is a warning report sent to the CipherTrust Manager only if `voradmin ldt recover` encounters errors and continues anyway. This alert reports the GuardPoint specified in the message has been enabled with some files in error status.

```
[CGS3267W] LDT-ALERT: LDT manual recovery on guard point [GuardPoint] completed with [#] errors.
```

The full message body does not currently appear in the logs on the CipherTrust Manager. At this time, the

CipherTrust Manager shows the message ID without the message body.

Alerts Playbook

This section lists the LDT alerts and describes what to do in each case. LDT generates alerts when issues arise that require attention from the Administrator. Without prompt attention, alerts can delay the rekey process or cause the process to remain incomplete.

The alerts are grouped into the following categories:

- Failure to Enable GuardPoints
- Failure to Suspend or Resume LDT Operation
- Insufficient Resources
- Failed to Update LDT Attribute
- Rekey Stopped
- Incomplete Key Rotation
- Skipped Key Rotation
- Failed to Update LDT Metadata During Scan Phase
- File system inconsistencies after system crash

Failure to Enable GuardPoints

The following alerts trigger when LDT fails to enable a GuardPoint:

- **LDT-ALERT: Cannot enable GuardPoint due to wrong policy applied to [GuardPoint]**

This message indicates that there was an attempt to apply an LDT policy to a GuardPoint that was previously guarded with a different LDT policy:

The GuardPoint status changes to **Incorrect policy** .

Solution

Unguard the GuardPoint and re-guard with the correct policy or, if you want to change the policy associated with the GuardPoint, clean up the LDT metadata and the re-guard. For details on cleaning up the GuardPoint, see [Deleting LDT Metadata \(Linux\)](#).

- **LDT-ALERT: Failed to update LDT attribute (Linux only)**

LDT failed to create or update an LDT extended attribute of a file in a GuardPoint.

Solution

An I/O error is the most common cause of failure when updating an LDT extended attribute. For I/O errors, fix the problem at the host OS or storage level.

If you cannot find and fix the host OS or storage issue, contact Customer Support for troubleshooting and recovery.

- **LDT-ALERT: Failure to Enable GuardPoint Due to Mismatched Policy or Key** (Linux only)

The following status indicates that a node has attempted to apply an LDT policy to a GuardPoint that uses a policy or key version that is different than the primary host.

- The GuardPoint status changes to **Stale Policy**.

Solution

Wait for the CipherTrust Manager to send the new policy to all members of the LDT group. If left in this state, the GuardPoint will automatically be guarded once the policy version matches the primary version. If the GuardPoint does not guard, make sure network connection between CipherTrust Manager and CipherTrust Transparent Encryption host is active and running, and the policy applied to the GuardPoint on the CTE host matches the policy applied across all members of LDT GuardPoint Group.

- **LDT-ALERT: Failure to Enable GuardPoint due to Unavailability of LDT Communication Group** (Linux only)

The following status indicates that the LDT Communication Group is not yet running on the host.

- The GuardPoint status changes to **LDT Group Services is not initialized**.

Solution

Wait for the LDT Communication Group to start up. This can occur if the attempt to guard the GuardPoint occurs immediately after LDT start up. The GuardPoint will automatically complete the guard operation once the LDT Communication Group completes initialization.

Note

The LDT Communication Group may require up to a minute to start up after rebooting the CTE host.

- **LDT-ALERT: Failure to Enable or Disable GuardPoint due to Single File Rekey** (Linux only)

The following status indicates that a GuardPoint is busy with single file rekey jobs and cannot be interrupted to allow a member to join or leave the group.

- When guarding, the status changes to **Single file rekey in progress, retrying**.
- When unguarding the status changes to **Busy, will continue to retry**.

Solution

Wait for the single file rekey to finished so that the group allows members to join or leave. The status of a single file rekey can be found by running `voradmin ldt list all` on the primary host. This command lists all of the single file rekey jobs as `type=FILE`. The GuardPoint will automatically complete the guard or unguard operation once all single file rekey jobs are completed.

▪ LDT-ALERT: Failure to Enable GuardPoint on Primary Host after Crash

The following status indicates that the primary host failed to leave the group correctly, and is now attempting to re-join the group.

- The GuardPoint status changes to, **Group join failed, GuardPoint needs LDT repair**

Solution

Run the following commands to manually clean up the group and allow the primary to rejoin as a member. Client will complete the guard operation once the group has been repaired.

```
voradmin ldt group repair /<primary IP> <absolute GuardPoint> (Windows)
voradmin ldt group repair /<primary IP> <${gp}> (Linux)
```

▪ LDT-ALERT: Failure to Enable GuardPoint due to mismatched NFS Version (Linux only)

The following status indicates that a member is attempting to guard an NFS share mounted with a different version than what the primary uses.

- The GuardPoint status changes to, **NFS version mismatch with primary**

Solution

Unguard on the member, unmount the NFS share, and remount it with the same NFS version as the primary.

▪ LDT-ALERT: Failure to Enable GuardPoint due to mismatched LDT Message Versions (Linux only)

The following status indicates that the member is using a message version that is incompatible with the primary.

- The GuardPoint status changes to, **LDT message version mismatch with primary.**

Solution

Unguard and verify that the member is running the same version of CipherTrust Transparent Encryption as the primary. If this problem persists, contact Thales Support for further troubleshooting. Note that the LDT message service in CipherTrust Transparent Encryption v7.2 and CipherTrust Transparent Encryption v7.3 are incompatible. When members of an LDT GuardPoint Group consist of CTE 7.2 and 7.3 hosts, this failure is expected and the solution is to upgrade those members running CipherTrust Transparent Encryption 7.2 to

CipherTrust Transparent Encryption 7.3 or a subsequent version. All members of the LDT GuardPoint Group must be running the same version of CipherTrust Transparent Encryption.

Failure to Suspend or Resume LDT Operation

- **LDT-ALERT: Failed to suspend rekey on GuardPoint [GuardPoint]**

Solution: An I/O error is the most common cause of failure when updating the persistent state of a GuardPoint. For I/O errors, you must fix the problem at the host OS or storage level.

The appropriate corrective action depends on when this problem occurs and the reason for the suspension. If the suspend request was at the host level as part of a QoS schedule, or it was initiated by a user on the CipherTrust Manager, the failure occurred at the host level rather than the specified GuardPoint.

Otherwise, the source is probably the initiation of a suspension on a specific GuardPoint before backup. If the backup operation is in progress when this alert message occurs, you must fix the cause of the suspension failure and then restart the backup. If the backup has already completed when the alert message occurs, the backup image on the GuardPoint may have inconsistent data and LDT metadata. Discard this backup image and do a fresh backup.

If you cannot find and fix the host OS or storage issue, contact Thales Support for troubleshooting and recovery.

- **LDT-ALERT: Failed to resume rekey on GuardPoint [GuardPoint]**

- **LDT-ALERT: Failed to resume rekey on all GuardPoints**

Solution: An I/O error is the most common cause of failure when updating persistent state of a GuardPoint. For I/O errors, you must fix the problem at the host OS or storage level.

The appropriate corrective action depends on when this problem occurs and the source of the problem. If the resume request was at the host level as part of a QoS schedule, or the resume request was initiated by a user on the CipherTrust Manager, the failure occurred at the host level rather than the specified GuardPoint.

Otherwise, the source is probably initiation of a resume operation on a specific GuardPoint after a backup is completed.

If you cannot find and fix the host OS or storage issue, contact Thales Support for troubleshooting and recovery.

Insufficient Resources

The following alerts trigger when there are not enough resources for LDT operations.

- **LDT-ALERT: Aborting rekey of file [FileName] due to insufficient disk space**

The key rotation process was stopped on a GuardPoint because there was not enough available disk space.

Solution: Resize or free up space in the file system where the PathName resides. Key rotation automatically starts again when sufficient free space becomes available.

- **LDT-ALERT: Failed to launch transformation on [GuardPoint]**

LDT failed to launch the data transformation process on the specified GuardPoint.

Solution: The most common causes of this failure are:

- Low amount of system resources, such as free disk space.
- Check the system logs for insufficient free space in underlying file systems. You can free up space by removing older files or resizing your underlying file system. You may resize the file system on-line or off-line.

For other issues, contact Customer Support.

- **LDT-ALERT: QoS failed to start**

The Quality of Service subsystem failed to launch QoS services due to lack of system resources.

Solution: A low amount of available memory is the most common cause of this failure.

Contact Customer Support.

- **LDT-ALERT: Skipped key rotation on GuardPoint [GuardPoint] due to insufficient disk space**

- **LDT-ALERT: MDS file [PathName] exceeded diskspace quota on gp [GuardPoint]**

There was not enough storage space in one or more file systems containing GuardPoints undergoing rekey.

Solution: Check the file systems where your GuardPoints reside to see how much space it is using. Add more storage space as needed. After the condition is corrected and disk space is available, LDT operations resume automatically.

- **LDT-ALERT: Low space on guard point [GuardPoint], increase free space or LDT will be suspended.**

Available storage space in the file system containing the GuardPoint is nearing the threshold below which LDT rekeying cannot continue. If available space does drop below that threshold, rekeying will be automatically suspended.

Solution: Check the file system where your GuardPoint resides to see how much space is available. Make more free space available if necessary. After the condition is corrected and storage space is available, rekeying resumes automatically.

Failed to Update LDT Attribute

The following alerts trigger when LDT extended attributes are not properly updated.

- **LDT-ALERT: Failed to update LDT attribute on GuardPoint [GuardPoint]. Error: [ErrorNumber]**

Solution

I/O error is the most common cause of failure when updating LDT extended attributes. For I/O errors, fix the problems at the host OS or storage level. In Linux, if you experience an I/O error, identify the file that had the error, and restore it from backup. See [Backing Up and Restoring LDT GuardPoints](#).

In Windows, you can recover a file that has corrupt metadata as follows:

- If the file is fully encrypted, remove the metadata. Type:

```
voradmin ldt attr delete <file name path>
```

Then apply the same policy that was used to encrypt the data.

- If the file was only partially rekeyed, restore the file from a backup.

If you cannot find and fix the underlying host OS or storage issue that is causing corrupt metadata, contact Customer Support for troubleshooting and recovery.

Rekey Stopped

The following alert is specific to Windows and is triggered when rekey is stopped before it completes normally.

LDT-ALERT: Suspending rekey of binary file [PathName] during its execution

LDT operations encountered an executable file that is running.

LDT cannot rekey a running executable file until the execution of the binary file stops.

Solution (Windows)

1. Obtain the name of the executable file from the alert message.
2. Stop execution of the binary file.

Incomplete Key Rotation

- **LDT-ALERT: Failed to rotate key on GuardPoint [GuardPoint]. Another rekey operation is already in progress (Windows only)**
- **LDT-ALERT: Key rotation failed on GuardPoint [GuardPoint]**

LDT failed to complete the key rotation process on the specified GuardPoint. On Windows, this may occur if a key rotation process is already in progress on the GuardPoint. This pre-existing rekey operation could be active, or it could be in a suspended state, either because of the QoS schedule or a manual pause initiated by the administrator. See [Suspending and Resuming Rekey and/or Scan Phase](#).

Solution

1. On Linux, you can run the following command to see whether key rotation is in progress on the GuardPoint.

```
voradmin ldt list all
```

2. On Linux or Windows, check the rekey status of GuardPoints in the CipherTrust Manager Console.
3. If key rotation is already in progress on a Windows GuardPoint, wait for the key rotation to complete.

Contact Customer Support if this error occurs on Linux or if the cause of key rotation failure on Windows is not a key rotation in progress.

Skipped Key Rotation

The following alerts trigger when LDT skips key rotation.

- **LDT-ALERT: Skipped key rotation on GuardPoint [GuardPoint]. It is on a read-only file system**

Key rotation is skipped on a specified GuardPoint because the mount point where the GuardPoint resides does not permit write operations.

Solution:

Remount the file system where the GuardPoint resides, and change the mount option to read/write.

- **LDT-ALERT: Failed to rotate key on GuardPoint [GuardPoint] during pre-commit**
- **LDT-ALERT: Failed to rotate key on GuardPoint [GuardPoint] during commit**
- **LDT-ALERT: Skipped key rotation on GuardPoint [GuardPoint]. Error: [ErrorNumber]**
- **LDT-ALERT: Failed to update LDT attribute on GuardPoint [GuardPoint]. Error: [ErrorNumber]**

LDT failed to start a key rotation process on a GuardPoint during a guard operation or when processing a key rotation notification from the CipherTrust Manager. For [ErrorNumber], a Linux error number is substituted, such as `errorcode 17`.

Solution: The host returns error code 17 during LDT key rotation if it cannot perform the key rotation because there is already a rekey in progress. This pre-existing rekey operation could be active, or it could be in a suspended state, either because of the QoS schedule or a manual pause initiated by the administrator. See [Suspending and Resuming Rekey and/or Scan Phase](#).

An I/O error is the most common cause of failure when updating the persistent state of a GuardPoint. For I/O errors, fix the problem at the host OS or storage level.

If you cannot find and fix the host OS or storage issue, contact Customer Support for troubleshooting and recovery.

Failed to Update LDT Metadata During Scan Phase

LDT triggers the following alerts when LDT cannot properly update metadata during the scan phase. (See [LDT Runtime Flow](#) for information about the scan phase.)

- **LDT-ALERT: Scan error on [GuardPoint] removing MDS guard for relaunching dataxform**

LDT failed to update metadata when restarting a scan on the specified GuardPoint.

Solution: An I/O error is the most common cause of failure when updating LDT metadata. For I/O errors, fix the problem at the host OS or storage level and then restart operations.

If you cannot find and fix the underlying host OS or storage issue that is causing the error, contact Thales Support for troubleshooting and recovery.

- **LDT-ALERT: Online Dataxform failed during post scan stage on [GuardPoint]**

LDT failed to update metadata when transitioning from scan to rekey phase on the specified GuardPoint.

Solution: An I/O error is the most common cause of failure when updating LDT metadata. For I/O errors, the problem must be fixed at the host OS or storage level and the operation restarted.

If you cannot find and fix the underlying host OS or storage issue that is causing the error, contact Customer Support for troubleshooting and recovery.

File system inconsistencies after system crash

LDT sends two alerts to the CipherTrust Manager if LDT fails to resolve the issues encountered during recovery.

The alert below is an error report sent to the CipherTrust Manager whenever LDT encounters failure during recovery prior to enabling GuardPoint. This alert also reports the GuardPoint specified in the message is not enabled:

- **LDT-ALERT: Cannot enable guard point [GuardPoint] due to inconsistencies in underlying file system encountered during LDT recovery**

The alert below is a warning report sent to the CipherTrust Manager only if `voradmin ldt recover` encounters errors and continues anyway. This alert reports the GuardPoint specified in the message has been enabled with some files in error status.

- **LDT-ALERT: LDT manual recovery on guard point [GuardPoint] completed with [#] errors.**

Solution: See [Protecting LDT GuardPoints against Failure in Underlying File Systems \(Linux\)](#).

Error Messages

This section describes runtime error messages. For information about other types of runtime messages, see [Alerts Playbook](#) and [Warning and Info Messages](#).

Failed to Transform File During Rekey

LDT could not complete transformation on a file.

Related Messages:

-
- **LDT: Rekey failed for file [PathName] on GuardPoint [GuardPoint]**
 - **LDT: Extended attribute of inode [InodeNumber] is corrupted under GuardPoint [GuardPoint]**

Solution

An I/O error is the most common cause of failure when updating LDT metadata. For I/O errors, fix the problem at the host OS or storage level, and then restore the file from a backup.

If you cannot find and fix the underlying host OS or storage issue that is causing the error, contact Customer Support for troubleshooting and recovery.

Failure to Suspend LDT

A request to stop LDT processing did not succeed. The suspend request was at the host level as part of a QoS schedule, or the suspend request was initiated by a user on the CipherTrust Manager.

Related Messages:

- **LDT: Failed to suspend rekey on all GuardPoints**
- **LDT operations could not be suspended on the host**

Solution: An I/O error is the most common cause of failure when updating the persistent state of a GuardPoint. For I/O errors, fix the problem at the host OS or storage level.

If a backup operation is in progress when this message occurs, you must fix the cause of the suspend failure and then restart the backup. If the backup has already completed when the alert message occurs, the backup image on the GuardPoint may have inconsistent data and LDT metadata. Discard this backup image and do a fresh backup.

If you cannot find and fix the host OS or storage issue, contact Customer Support for troubleshooting and recovery.

Failure to Start or Stop Transformation

The following general messages are recorded when there are errors attempting to start or stop LDT:

- **LDT: Failed to abort key rotation on GuardPoint [GuardPoint]**
- **LDT: Failed to start**
- **LDT: Failed to stop**
- **LDT: Failed to exit**

Solution

Examine system logs for additional information as to the cause. If you cannot find and fix the underlying host OS or storage issue that is causing the error, contact Customer Support for troubleshooting and recovery.

Failure to Restart Transformation

The following message is recorded when an attempt to restart transformation after a system reboot fails because the file system is mounted as read-only. Transformation on the specified GuardPoint cannot continue until the file system is mounted with write permission.

- **LDT: Skipped LDT recovery on read-only file system [GuardPoint]**

Solution

Re-mount the file system with write permissions.

Failure to Schedule Relaunch

The following message indicates that a rekey request was sent to a Linux GuardPoint that was already undergoing data transformation, and an error was encountered when LDT attempted to defer the rekey request until after the current data transformation completes:

- **LDT: Failed to flag GuardPoint [GuardPoint] for deferred key rotation, error [Error]**

Solution

Contact [Thales Tech Support](#) for help.

Temporary Failure to Start Transformation on a File

The following messages are recorded when there are communication issues or lack of resources on the host. Once the condition is corrected, transformation of the file continues automatically:

- **LDT: Insufficient memory condition encountered during LDT on GuardPoint [GuardPoint]**
- **LDT: Encryption key for file [PathName] unavailable for LDT, possibly due to loss of communication to CipherTrust Manager**
- **LDT: Aborting rekey of file [PathName] due to lack of free memory. Try closing other application to resolve the issue**

Solution

Resolve the communication issues or increase the available resources, then verify that LDT has resumed processing.

Transient Condition while enabling GuardPoint

The following messages are recorded when a request is made to guard an LDT GuardPoint when GuardPoint initialization is already in progress. During the GuardPoint initialization, the system initializes MDS file associated with the GuardPoint in preparation for LDT. Initialization of the MDS file can take a few minutes. During this time, if the system retries the guard operation, one of the following messages displays.

Related Messages:

-
- **Not re-guarding path `[path]` (Reason: GuardPoint initialization already in progress)**
 - **Not re-guarding path `[path]` from container `[container]` (Reason: GuardPoint initialization already in progress)**

Solution

Wait for the current GuardPoint initialization to complete and then resubmit the new GuardPoint initialization request if desired.

Transient Failure to Read LDT Attributes from NFS

NFS may incorrectly return 0's when reading LDT metadata from files in NFS shares. As LDT doesn't expect 0's returned for LDT attributes, it retries the read operation, and the second operation succeeds and returns valid LDT attribute.

The first read attempt returning 0's results in the first warning message logged in the system log file as LDT attribute validation fails. However, the second read attempt succeeds and reads valid LDT attribute data, resulting in the second message logged in response to the first message. You can ignore the first warning message if both messages appear together in system log.

Failed to transform passthrough files for AD database files (Windows Only)

LDT skipped the transformation of passthrough files for all AD database files. The problem occurs when the AD database remains in the default folder location.

Related Messages:

- **Skipping transformation of passthrough file `[filename]`. The file resides in the boot directory. CTE cannot encrypt boot directory files.**
- **Skipping transformation of passthrough file `[filename]`. CTE cannot encrypt these files. They are already encrypted using NTFS encryption or compressed.**
- **Skipping transformation of passthrough file `[filename]`. File is not in a GuardPoint directory.**

Solution

To fix this issue, move the AD database to any folder other than `c:\windows` or `c:\program files`.

Warning and Info Messages

This section describes runtime warning messages. For information about other types of runtime messages, see [Alerts Playbook](#) and [Error Messages](#).

Stopping Transformation of a File on Volume Dismount (Windows only)

The following warning message is recorded when transformation of a file is stopped because the containing volume is dismounted.

-
- **LDT: Volume dismounted. Aborting transformation at file [PathName]**

Issues with Policy or System Configuration

The following warning messages are recorded when CTE cannot perform LDT on the GuardPoint, because there are errors in the policy associated with the GuardPoint, or the file system containing the GuardPoint is not supported by LDT. Files in the GuardPoint can still be accessed, but no LDT encryption occurs.

- **LDT: The GuardPoint [GuardPoint] does not have a valid transformation policy, there is no new key rule**
- **LDT: The GuardPoint [GuardPoint] does not have a valid transformation policy, there is no key_op rule**
- **LDT: The GuardPoint [GuardPoint] does not support online rekey, only file operations from the offline data transform process will be allowed**

Failure to Enable GuardPoint During Cleanup

LDT records the following informational message when a user attempts to enable a newly added GuardPoint. This message displays if the GuardPoint directory was previously guarded with an LDT policy and the LDT metadata cleanup is in progress when user is guarding under the new policy.

- **LDT: Cannot enable GuardPoint [GuardPoint] during LDT clean-up process**

Solution

Retry the operation once the cleanup completes.

General LDT Operations

The following informational messages are recorded during various LDT operations. No action is required.

- **LDT: Successfully suspended rekey on GuardPoint [GuardPoint]**
- **LDT: Successfully suspended rekey on all GuardPoints**
- **LDT: Successfully resumed rekey on GuardPoint [GuardPoint]**
- **LDT: Successfully resumed rekey on all GuardPoints**
- **LDT: Rekey operation completed on GuardPoint [GuardPoint]**

Missing LDT extended attribute

The following warning message reports that the file with the specified inode number in the specified GuardPoint directory does not have an LDT extended attribute, therefore, access to the file is denied.

- **LDT: Extended attribute of inode [InodeNumber] is missing under GuardPoint [GuardPoint]**

Solution

LDT cannot determine the encryption key associated with the data in the file, therefore, you can only remove the file.

Locking Contention

The following messages are recorded during the rekey process on a file. When user access to the file is very high, it causes a high degree of locking contention between the rekey process and user access. The second message reports when the contention is no longer in effect and the rekey process has resumed accessing file to rekey.

- LDT: Exclusive access for rekey delayed on inode [*InodeNumber*]
- LDT: Exclusive access for rekey granted after delay on inode [*InodeNumber*]

Initiation and completion of LDT metadata cleanup

The following messages are recorded at the beginning and completion of LDT metadata cleanup through voradmin command.

- LDT: Metadata will start getting removed from all files in GuardPoint [*GuardPoint*]
- LDT: Metadata has been removed from all files in GuardPoint [*GuardPoint*]

The secfs component doesn't support data transform on the GuardPoint

The following warning messages displays when offline dataxform command was accidentally executed on an active LDT GuardPoint.

```
Checking if <guardpoint> is a guard point with a rekey policy applied
The secfs component doesn't support data transform on <guardpoint>
Verify this is a guardpoint with valid data transformation policy, and check the
system log files for any other problems. It may be
due to one or more of following reasons; 1.policy has no valid key rule(s), and/o
r 2. policy has no key_op rule, and/or 3. policy
has valid permit rule(s), and/or 4. policy rule that contains key_op in the actio
n field also specifies other actions.
```

This action results in an input/output error when creating new files in the GuardPoint.

Solution

For auto GuardPoint:

1. Disable the GuardPoint on CipherTrust Manager.
2. Delete the `dataxform_auto_lock` file in the GuardPoint.
3. Enable the GuardPoint on CipherTrust Manager.

For a manual GuardPoint:

1. Unguard using `secfsd -unguard <guardpoint>`.

2. Delete the `dataxform_auto_lock` file in the GuardPoint.
3. Enable the GuardPoint using `secfsd -guard <guardpoint>`.

Dataxform command fails with file `<GuardPoint>` Invalid xf mode

The following warning message displays when offline dataxform command was executed on an unguarded LDT GuardPoint.

```
dataxform command fails with file "<gp>" invalid xf mode
```

This action creates the `dataxform_auto_lock` file in the GuardPoint which causes the write error when creating new files in the GuardPoint, if the GuardPoint was enabled prior to deleting the file.

Solution

Before enabling the GuardPoint, delete the `dataxform_auto_lock` file in the GuardPoint.

Recommendations and Considerations

The following information provides guidance for a better user experience.

- [All Platform Recommendations and Considerations](#)
- [Windows Recommendations and Considerations](#)

All Platform Recommendations and Considerations

- [Binary Re-signing](#)
- [Check for available disk space for LDT metadata](#)
- [LDT Requirements for Backup](#)
- [Learn Mode](#)
- [Quality of Service \(QoS\)](#)
- [Upgrade to CTE 7.2.0.128](#)

Binary Re-signing

Any executable that is part of either a Signature set or a Host setting, and that resides in a GuardPoint that uses an LDT policy, will use different signatures for an LDT key rotation. The result is that the Host Settings binaries will no longer be authenticated, or that the Signature Set policy rules will no longer trigger for those binaries.

To prevent these issues, the Security Administrator must manually re-sign each affected binary after each key rotation.

Alternatively, CTE can generate unencrypted signatures of binaries inside GuardPoints to avoid these problems. For details, see the CipherTrust Manager documentation.

Check for available disk space for LDT metadata

Before launching LDT on a GuardPoint:

1. Check the available free disk space in the file system where your GuardPoint resides.
2. Type the following command to check the disk space requirement of LDT on a target GuardPoint:

```
voradmin ldt space /oxf-fs1/gp1
/oxf-fs1/gp1: found 1501 files without LDT extended attributes
LDT disk space requirements: total 169MB (LDT attributes=6MB, MDS=163MB)
```

In this example, the output shows that LDT requires 169MB of available disk space to launch and execute LDT on `/oxf-fs1/gp1`.

Note

Make sure that the free space in your file system exceeds the disk space requirement for LDT.

LDT Requirements for Backup

CTE offers the option to backup encrypted data from files through a security rule, which skips the Apply Key function when reading encrypted files by backup applications or processes. Such files can also be restored from backup streams, to the same or a different GuardPoint, without Apply Key. If you choose to restore to another GuardPoint, the target GuardPoint must be protected with the same key and security rules as the source GuardPoint.

If you backup encrypted data from files inside GuardPoints with LDT policies, LDT imposes a hard requirement on the backup application, or process, to backup or restore LDT metadata. The LDT metadata is stored as an extended attribute on Linux and as alternate data streams on files on Windows platforms. If the backup process cannot backup the metadata, then LDT protected GuardPoints must be backed up in clear key.

Customers are required to verify their backup application, or process, to ensure extended attributes (on Linux) or alternate data streams (on Windows) are backed up and restored through their backup/restore processes.

Note

Make sure that you suspend LDT operations before you start the backup process, and resume them after the backup process completes.

Learn Mode

Learn Mode provides a temporary method for disabling the blocking behavior of regular CTE or LDT policies. While useful for quality assurance, troubleshooting, and mitigating deployment risk, Learn Mode is not intended to be enabled permanently for a policy in production. This prevents the policy Deny rules from functioning as designed in the policy rule set.

Ensure that the policy is properly configured for use in Learn Mode. Any Security Rule that contains a Deny effect must have Apply Key applied as well. This is to prevent data from being written in mixed states, resulting in the loss of access or data corruption.

Note

Apply Key will have no effect when combined with a Deny rule unless the policy is in Learn Mode.

Quality of Service (QoS)

By default, the QoS component of LDT does not monitor live transformation operations unless you enable QoS on your host by entering QoS parameters in the CipherTrust Manager profile associated with the client. To avoid overhead of LDT on your production system, you must select QoS parameters suitable to your production environment. For information on tuning QoS, see [Quality of Service](#). It is critical that you understand the impact of LDT on your system and how to manage this impact using QoS.

Upgrade to CTE 7.2.0.128

Since the first release of the LDT feature, Thales has made several improvements in the areas of error handling, interoperability with applications, and Quality of Service (QoS). Thales strongly recommends that new deployments use version 7.2.0.128 (or later) of CTE. Thales further recommends that customers who have already deployed the LDT feature upgrade to version 7.2.0.128.

Windows Recommendations and Considerations

- File Handling
- File Modification
- Logical Sector Size

File Handling

The CTE-LDT process is subjected to all of the File System policies and attributes set on the files. In some cases, this prevents CTE-LDT from encrypting a file. If users or applications are accessing files while CTE-LDT is in progress, CTE-LDT cannot change the attributes of the files and encrypt the file. It is critical that you understand how CTE-LDT handles various types of files:

- NTFS Encryption and Compression

If NTFS encryption or compression is enabled on a file or folder, the CTE-LDT process cannot encrypt these

files. To maintain the data coherency, CTE-LDT skips the encryption of these files. These files display as “passthrough” files in the CTE-LDT statistics.

- **Read-Only Files**

As the CTE-LDT process performs a read-encrypt-write operation on a file, it cannot encrypt read-only files. The CTE-LDT process skips these files and changes to the INCOMPLETE state.

- **Exclusively Locked Files**

If an executable file is running, or if files are exclusively locked by the application, the LDT process **cannot** encrypt those files, as it is unable to acquire the required locks on the files. LDT skips these files and changes to the INCOMPLETE state.

File Modification

The CTE-LDT process performs a read-encrypt-write operation on the files that need to be encrypted, (also known as rekeying). Previously, file modification and access dates were changed when CTE-LDT was processing. In order to maintain compatibility for applications, we addressed this issue by saving a copy of the original access and modification times, and restoring them after the encryption completed. Preserved timestamps are updated during the rekey process, if an application/user accesses the files during rekey.

Logical Sector Size

CTE-LDT Windows transformation is supported if the **logical sector size** is more than 512 Bytes. (A logical sector size of 4K is supported.) To find the logical sector size of the file system, type:

```
> fsutil fsinfo ntfsInfo <volume pathname>
```

For example:

```
> fsutil fsinfo ntfsInfo C:
NTFS Volume Serial Number :      0x5092568a92567506
NTFS Version      :              3.1
LFS Version       :              2.0
Number Sectors    :              0x000000001c004eeb
Total Clusters    :              0x00000000038009dd
Free Clusters     :              0x00000000008bb274
Total Reserved    :              0x0000000000001864
Bytes Per Sector   :              512
.
.
.
```

Troubleshooting LDT Encryption Failures

If you use Windows quotas, which allow you to limit the amount of storage space a user account can use on a drive, you may not be allowing enough space for LDT. LDT uses an extra 4K per file for an LDT policy. If the extra space is not considered, and the space permitted by quotas is exceeded in a directory, then LDT may not be able to transform files or rekey those files later.

LDT also requires space for temporary recovery metadata that exists during transform or rekey of a file. If the file metadata exists, but the recovery metadata cannot be created and written to, then rekey of that file fails.

So make sure to allocate enough space for LDT transformation, rekeying, and recovery of metadata when setting quotas.

CipherTrust Transparent Encryption

CTE Agent Windows Advanced Configuration Guide

This document covers the following information:

- Overview of CTE
- Getting Started with CTE for Windows
- Special Cases for CTE Policies
- Enhanced Encryption Mode
- Utilities for CTE Management
- Upgrading CTE on Windows
- Uninstalling CTE from Windows
- Troubleshooting and Best Practices

Overview of CTE

For very large data sets, initial encryption deployments can affect data availability, require unacceptable maintenance windows or require cloning and synchronizing data. Encrypting millions of files can span hours or even days, which can delay encryption, or require extra disk space and data synchronization, which can be labor-intensive. Rekeying large data sets can demand significant processing time and lengthy maintenance windows. Security and IT teams face tough tradeoffs, having to choose between security and availability.

CipherTrust Transparent Encryption operates with minimal disruption, effort, and cost. Its transparent approach enables security organizations to implement encryption without changing application, networking, or storage architectures. CipherTrust Live Data Transformation builds on these advantages, offering patented capabilities that deliver breakthroughs in availability, resiliency and efficiency.

CTE includes several unique utilities to help you encrypt and manage your data. It also integrates with several third-party platforms such as Oracle, Microsoft SQL, and Quantum StorNext.

This document describes the installation and advanced configuration options for CTE, as well as detailed information about how to integrate CTE with the supported third-party products.

CTE Terminology

The guide uses the following terminology:

The guide uses the following terminology:

Term	Description	OS Applies to
CTE	CipherTrust Transparent Encryption is a suite of products that allow you to encrypt and guard your data. The main software component of CTE is	Windows/Linux/AIX

Term	Description	OS Applies to
	the CTE Agent, which must be installed on every host whose devices you want to protect. Notes • This suite was originally called Vormetric Transparent Encryption (VTE), and some of the names in the suite still use "Vormetric". • For example, the default installation directory is <code>/opt/vormetric/DataSecurityExpert/agent/</code> for Linux and AIX, and <code>C:\Program Files\Vormetric\DataSecurityExpert\agent\</code> for Windows.	
CTE Agent	The software that you install on a physical or virtual machine in order to encrypt and protect the data on that machine. After you have installed the CTE Agent on the machine, you can use CTE to protect any number of devices or directories on that machine.	Windows/Linux/AIX
CTE Capabilities	CipherTrust Transparent Encryption agent version-specific features like Multi-Factor Authentication.	Linux
CTE-K8s	CipherTrust Transparent Encryption for Kubernetes. Policy-based encryption of data stored on persistent volumes	Linux
CTE-RWP or RWP	CipherTrust Transparent Encryption with Ransomware Protection. Ransomware protection for volume-level (Windows)/GuardPoint (Linux) data storage through process behavior monitoring and analytics.	Windows/Linux
CTE UserSpace (CTE-U)	CipherTrust Transparent Encryption (formerly known as ProtectFile FUSE). File system level encryption and access control solution for Linux servers.	Linux
Data Transformation	Encrypting or decrypting data.	Windows/Linux/AIX
Domain Sharing	This allows Clients in one domain to get cross-domain resources, specifically GPs.	Windows/Linux/AIX
GuardPath	A directory to which a CTE Kubernetes data protection and encryption policy has been applied. CTEK8s will control access to, and monitor changes in, this device and directory, encrypting new or	Linux

Term	Description	OS Applies to
	changed information as needed.	
GuardPoint	A device, or directory, to which a CTE data protection and encryption policy has been applied. CTE will control access to, and monitor changes in, this device and directory, encrypting new or changed information as needed.	Windows/Linux/AIX
Host /Client	In this documentation, host and client are used interchangeably to refer to the physical or virtual machine on which the CTE Agent is installed.	Windows/Linux/AIX
In-place Data transformation	Encryption mechanism for block devices.	Linux
Key Manager	An appliance that stores and manages data encryption keys, data access policies, administrative domains, and administrator profiles. Thales offers CipherTrust Manager, a key manager for use with CTE.	Windows/Linux/AIX
LDT (Live Data Transformation)	After initial GuardPoint enablement, LDT performs initial encryption, or rekeying, in the background, unnoticed by users. The data stays live and available. This accelerates CTE deployments and eliminates the need to block applications and user access to data during encryption or rekey operations, which can inconvenience users and affect operational efficiency.	Windows/Linux
LDT Communication (Comm) Group	A group of LDT clients who communicate with each other, and are responsible for, initial data transformation and future key rotation of CIFS/NFS GuardPoints.	Windows/Linux
LDT GuardPoint Group	An LDT GuardPoint Group contains a collection of LDT-enabled CTE clients that are all on the same network, managed by one CipherTrust Manager, guarding a common NFS/CIFS share and can communicate with each other over that network. An LDT GuardPoint Group enables the primary host of an LDT GuardPoint Group to communicate with the secondary hosts that are members of that LDT GuardPoint Group.	Windows/Linux
LDT Primary node	The LDT GuardPoint Group node	Windows/Linux

Term	Description	OS Applies to
	that performs LDT rekeying of data.	
LDT Secondary node	All of the other clients in the LDT GuardPoint Group are assigned as secondary nodes. Note: Secondary nodes do not participate in rekeying data, however, they can be promoted to primary nodes if a primary node fails.	Windows/Linux
LDT Subordinate nodes	The subordinate nodes are the remaining nodes in the LDT Communication Group.	Windows/Linux
LDT Triad nodes	The triad nodes are the first three servers in the LDT Communication Group.	
Learn Mode	Logging mode for audit logs to help generate security policies. Learn Mode allows access to guarded paths while logging access details. Users can analyze the content users and processes are accessing, the data used, and define GuardPoint policies accordingly.	Windows/Linux
MFA	Multifactor authorization ensures that the access credentials presented belong to the actual person. After logging in to the system, when a user tries to access a CipherTrust Transparent Encryption GuardPoint, it triggers a second factor authorization to verify the user with a second form of authentication, like sending a passcode to the users's registered cell phone, that they then have to input into the application.	Windows/Linux
Profile	Shared configuration resource for Client logging, Quality of Service, Multi-Factor Authentication, Ransomware Protection and key manager communication settings.	Windows/Linux/AIX
Signature	The hash of an entity. Where Entity can be the process or the docker image.	Windows/Linux/AIX
Versioned key and Key versions	Keys whose name remains the same but keybytes are different for each different version.	Windows/Linux/AIX

CTE Components

The CTE solution consists of two parts:

- The *CTE Agent software* that resides on each protected virtual or physical machine (host). The CTE Agent performs the required data encryption and enforces the access policies sent to it by the *key manager*. The communication between the CTE Agent and the key manager is encrypted and secure.

After the CTE Agent has encrypted a device on a host, that device is called a GuardPoint. You can use CTE to create GuardPoints on servers on-site, in the cloud, or a hybrid of both.

- A *key manager* that stores and manages data encryption keys, data access policies, administrative domains, and administrator profiles. After you install the CTE Agent on a host and register it with a key manager, you can use the key manager to specify which devices on the host that you want to protect, what encryption keys are used to protect those devices, and what access policies are enforced on those devices.

Note

For a list of CTE versions and supported operating systems, see the [CTE Compatibility Portal](#).

How to Protect Data with CTE

CTE uses policies created in the associated key manager to protect data. You can create policies to specify file encryption, data access, and auditing on specific directories and drives on your protected hosts. Each GuardPoint must have one and only one associated policy, but each policy can be associated with any number of GuardPoints.

Policies specify:

- Whether or not the resting files are encrypted.
- Who can access decrypted files.
- What level of file access auditing is applied when generating fine-grained audit trails.

A Security Administrator accesses key manager through a web browser. You must have administrator privileges to create policies using key Manager. The CTE Agent then implements the policies once they are pushed to the protected host.

CTE can only enforce security and key selection rules on files inside a guarded directory. If a GuardPoint is disabled, access to data in the directory goes undetected and ungoverned. Disabling a GuardPoint and then allowing unrestricted access to that GuardPoint can result in data corruption.

Getting Started with CTE for Windows

This section describes how to install CTE for Windows, register it with your selected key manager, and then create a simple GuardPoint on the protected host. It contains the following topics:

-
- [Installation Workflow](#)
 - [Installing CTE with No Key Manager Registration](#)
 - [Configuring CTE for Windows with CipherTrust Manager](#)
 - [Multifactor Authentication for CTE GuardPoints](#)
 - [Choosing a Login Name Type](#)
 - [Ransomware Protection](#)
 - [Guarding Data on CIFS Servers and Clients](#)

Installation Workflow

In order to install and configure CTE, you need to perform the following high-level tasks: 1. Select which key manager you want to use. The Vormetric Data Security Manager and the CipherTrust Manager have different requirements and support different features, so you must make this decision first. For details, see [CTE Components](#).

1. If you want to install the CTE Agent without registering with a key manager, see [Installing CTE with No Key Manager Registration](#). However, you cannot protect any data on the host until it has been registered.

Otherwise, set up your systems according to the requirements of the selected key manager. For details, see [Configuring CTE for Windows with CipherTrust Manager](#).

2. Create your policies, encryption keys, and GuardPoints using the selected key manager. For details, see [Guarding a Device with CipherTrust Manager](#).

Installing CTE with No Key Manager Registration

The following procedure installs the CTE Agent on the host but does not register it with a key manager. You cannot protect any data on the host until the CTE Agent is registered with one of the supported key managers. For a comparison of the available key managers, see [CTE Components](#).

If you want to register the CTE Agent immediately after installing it, see [Configuring CTE for Windows with CipherTrust Manager](#).

1. Log on to the host as a Windows user with System Administrator privileges.
2. Copy the CTE installation file onto the Windows system.
3. Double-click the installation file. The InstallShield Wizard for CipherTrust Transparent Encryption opens.
4. Verify the version of CTE you are installing and click **Next**.
5. On the *License Agreement* page, accept the License Agreement and click **Next**.
6. Click **Next** to accept the default folder. When you are done, click **Next**.

Note

- Thales recommends that you install CTE in the default installation directory, `C:\Program Files\Vormetric\DataSecurityExpert\agent\`
- You must install the CTE Agent on the same drive as Windows. For example, if Windows is installed on the `C:` drive, you must install the CTE Agent on the `C:` drive.

7. On the *Ready to Install* page, click **Install**. When the installation is finished, the **Install Shield Wizard Completed** window opens.
8. To tell the installer that you want to register later, clear the check box for **Register CipherTrust File System now**, then click **Finish**.
9. Reboot the host system to complete the installation.

Configuring CTE for Windows with CipherTrust Manager

This section describes how to install and configure CTE on Windows systems that you plan to register with a CipherTrust Manager.

The installation and configuration process consists of three basic steps:

1. [Installation Prerequisites](#)

Gather the information needed for the installation and set up your network.

2. [Interactive Installation on Windows](#)

Install CTE interactively on a protected host and register the protected host with CipherTrust Manager.

[Silent Installation on Windows](#)

Install CTE silently (non-interactive) on a protected host and register the protected host with CipherTrust Manager.

3. [Registration](#)

Register the protected host with CipherTrust Manager and make sure that CipherTrust Manager and CipherTrust Transparent Encryption can communicate with each other. This can be done as part of the initial installation or at any point after the CTE Agent has been installed.

4. [External Certificates](#)

Use for communication between CTE and CM. Install the external certificate before registering CipherTrust Transparent Encryption with CipherTrust Manager.

5. Validating CipherTrust Manager and CipherTrust Transparent Encryption with a Local CA Certificate

Ensure that registration by the CTE agent is serviced only by the expected key manager by providing a copy of the CA certificate that will be used to authenticate the TLS communications with the key manager.

6. Setting the CM log for Ransomware Protection

Configure the logging level for CipherTrust Manager for Ransomware Protection.

Interactive Installation on Windows

The Windows interactive install uses a standard InstallShield wizard that asks you a series of questions during the installation. You can also install CTE using a silent installer which pre-packages the install information. This allows you to install CTE on a large number of hosts. (For more information, see [Silent Installation on Windows](#)).

After you install CTE, you are prompted to register it immediately with a key manager. CTE must be registered with a key manager before you can protect any of the devices on the host. However, you may postpone the registration if you plan to register CTE later.

The following procedure describes how to install the CTE Agent on the host and then register the CTE Agent with a CipherTrust Manager..

1. Log on to the host as a Windows user with System Administrator privileges.
2. Copy the CTE installation file onto the Windows system.
3. Double-click the installation file. The InstallShield Wizard for CipherTrust Transparent Encryption opens.
4. Verify the version of CTE you are installing and click **Next**.
5. On the **License Agreement** page, accept the License Agreement and click **Next**.
6. Click **Next** to accept the default folder. When you are done, click **Next**.

Note

- Thales recommends that you install CTE in the default installation directory, `C:\Program Files\Vormetric\DataSecurityExpert\agent\`
- You **must** install the CTE Agent on the same drive as Windows. For example, if Windows is installed on the `C:` drive, you must install the CTE Agent on the `C:` drive.

7. On the **Ready to Install** page, click **Install**. When the installation is finished, the **Install Shield Wizard Completed** window opens.
 8. On the **InstallShield Wizard Completed** page, make sure the **Register CipherTrust Transparent Encryption now** option is selected and click **Finish**. The installer opens the [Register CipherTrust Transparent Encryption](#) wizard.
-

Silent Installation on Windows

Silent install refers to using the command line to install CTE in a non-interactive session. Use silent install to roll out CTE installations or upgrades to large numbers of hosts or to reduce your time and interaction as an administrator. Thales provides two types of installation binaries for silent installation:

- Self-extracting `.exe`
- Windows Inst

Note

Thales supports installing or upgrading CTE with Microsoft System Center Configuration Manager (SCCM) using MSI installation binaries. For details, see your SCCM documentation.

For details, see one of the following procedures:

- [Silent Installation Using the exe File](#)
- [Silent Installation Using the MSI File](#)

Silent Installation Using the exe File

The following sections discuss how to install CTE for Windows silently and then register the CTE Agent with a CipherTrust Manager using the exe file. To install silently using the MSI file or using the Microsoft System Center Configuration Manager (SCCM), see [Silent Installation Using the MSI File](#).

Prerequisites

The following prerequisites must be met for CTE to install and register to CipherTrust Manager properly:

- CipherTrust Manager installed and configured.
- CipherTrust Manager must contain a Client Profile. See [Changing the Profile](#) for more information.
- CipherTrust Manager must contain a registration token. See [Creating a Registration Token](#).
- Optionally, the name of the host group that you want this client to be a member.
- CipherTrust Manager must contain an LDT Communication Group if you will use CTE to guard data over CIFS/ NFS shares using LDT policies. See [Managing LDT Communication Groups](#) for more information.

Procedure

1. Log on to the host as a Windows user with System Administrator privileges.
2. Copy the CTE installation `exe` file onto the Windows system.

3. Run the installation file using the following syntax:

```
"<Installation_executable>" /s /v" /qn INSTALLDIR=\"install-dir\" REGISTERHOST
OPTS=\"Options\""
```

Example

```
"C:\installer\vee-fs-7.8.0-45-win64.exe" /s /v" /qn INSTALLDIR=\"C:\Program
Files\Vormetric\DataSecurityExpert\" REGISTERHOSTOPTS=\"192.168.13.249 -enable
ldt -useip -usehwsig -
token=123456789. ...123456789 -domain=domain1 -description=\"\"EXE silent inst
all example\"\"\""
```

Note

If you want to enter an option with spaces in any value, it must be surrounded by two double-quotes with an escape character () before each double-quote. If the syntax is incorrect, the installation fails.

where:

- **Installation_executable** is the name of the executable, example: vee-fs-7.8.0.75-win64.exe
- **/s** (required) specifies that this is a silent install.
- **/v** (required) specifies that you want to pass command line options and values of public properties through to the installer.
- **ENABLE_LDT_CIFS=Yes** is an optional parameter that indicates you plan to use CTE-LDT with CIFS share GuardPoints on this host with a CipherTrust Manager. If you specify this option, you will *not* be able to guard any local directories on this host, even if those directories use a Standard CTE policy. Only CTE-LDT GuardPoints on CIFS shares will be supported for this host.
- **/qn** (required) specifies that the install should be non-interactive and that no GUI should be displayed.
- **INSTALLDIR=\"install-dir\"** is an optional parameter specifying the installation directory you want to use. If you omit this parameter, CTE installs in the directory C:\Program Files\Vormetric\DataSecurityExpert\agent\

Note

Thales recommends that you install CTE in the default directory if at all possible.

- **REGISTERHOSTOPTS=**"Options\" (required if you want to register CTE) is a list of options that you want the installer to use. The common options are:

Parameter	Description
CipherTrust Manager host name	Required if you want to register CTE with a CipherTrust Manager.
-accessonly	Enables access-only mode for LDT. (Default is full access mode.) In access-only mode, nodes are not be allowed to become part of an LDT Communication Group or participate in data transformation, but they will continue to access a protected LDT CIFS GuardPoint.
-agent=your.agent.name.com	FQDN of the host on which the CTE Agent is being installed. If this value is not specified, the installer uses the host's IP address.
-description	Specifies a description for the host. This description is displayed in the CipherTrust Manager. If an entry for this host already exists, and the host already has a description, CipherTrust Manager does not overwrite the existing description, even if this option is specified.
-enableldt	Specify this option to automatically enable and register CTE-LDT (Live Data Transformation) for this host on your key manager during the silent install.
-enable_host_check/-disable_host_check	When using CipherTrust Data Security Platform Services (CDSPaaS), set this value to 1 to enable SSL certificate host name checks. Set to 0 to disable. Default: 0. This also forces CTE to enable the verify peer feature during registration. Use only when the CDSPaaS web server certificates contain the target DNS name or IP address.
-hostgroup	Specifies the optional host/client group with which this host/client will be associated.

Parameter	Description
-log <log_file_path_&_name>	Record installation steps in a log file.
-port <port#>	Specifies the port number this CTE Agent should use.
-profile	Specifies the client profile in the CipherTrust Manager that will be associated with this client. If this value is omitted, the CipherTrust Manager uses the default client profile.
-rwp	Enables Ransomware Protection.
-silent	Make this a silent installation.
-token	The registration token for the CipherTrust Manager with which you plan to register this client. Required for registration.
-usehwsig	Specify this option when you want to associate this installation with the machine hardware for cloning prevention.
-useip	Use the IP address of the protected host instead of host name. Used when -agent is not supplied.
-vmd	Defines what kind of agent is being installed.

Example: Custom Install Directory and Host Description with Spaces

The following example specifies that:

- The CTE Agent will be installed in the custom directory `C:\cte\custom dir`.
- The CipherTrust Manager host name is `my-key-mgr.example.com`.
- The CipherTrust Manager registration token is `12345` (-token parameter).
- The host will be registered using the host name `my-host.example.com` (-agent parameter).
- The host will be registered with the description `This host was silently installed` (-description parameter). Again, the spaces in the description require the same syntax as in the installation directory name. For example: `-description=\"\"This host was silently installed\"\"`

Note

The examples below are shown on several lines for readability. When you enter the command, all parameters should be on the same line.

```
vee-fs-7.8.0.75-win64.exe /s /v" /qn
INSTALLDIR=\"\"C:\cte\custom dir\" registerhostopts=\"my-key-mgr.example.com
agent=my-host.example.com -token=12345
description=\"\"This host was silently installed\"\""
```

Example: LDT, LDT AccessOnly and Hardware Acceleration

The following example specifies that:

- The CTE Agent will be installed in the default installation directory (the `INSTALLDIR` parameter is omitted).
- The CipherTrust Manager host name is `my-key-mgr.example.com`.
- The host will be registered using its IP address and not its host name (`-useip` parameter).
- The CTE-LDT (`-enableldt` parameter), LDT AccessOnly (`-accessonly`), and hardware association (`-usehwsig` parameter) features are enabled.

```
vee-fs-7.8.0.75-win64.exe /s /v" /qn
registerhostopts=\"my-key-mgr.example.com -token=12345 -useip -enableldt -acces
sonly -usehwsig\""
```

Example: LDT over CIFS/NFS

The following example specifies that:

- The CTE Agent will be installed in the default installation directory (the `INSTALLDIR` parameter is omitted).
- The CipherTrust Manager host name is `my-key-mgr.example.com`.
- The host will be registered using its IP address and not its host name (`-useip` parameter).
- The CTE-LDT (`-enableldt` parameter) and LDT Group (`-ldtgroup` parameter) features are enabled.

```
vee-fs-7.8.0.75-win64.exe /s /v" /qn
registerhostopts=\"my-key-mgr.example.com -token=12345 -useip -enablel
dt -ldtgroup=\"\"LDT-CG1\"\""
```

Silent Installation Using the MSI File

The following sections discuss how to install CTE for Windows silently and then register the CTE Agent with a CipherTrust Manager using the MSI file. To install silently using the exe file, see [Silent Installation Using the exe File](#).

Prerequisites

The following prerequisites must be met for CTE to install and register to CipherTrust Manager properly:

- CipherTrust Manager installed and configured.
- CipherTrust Manager must contain a Client Profile. See [Changing the Profile](#) for more information.
- CipherTrust Manager must contain a registration token. See [Creating a Registration Token](#).
- Optionally, the name of the host group you want this client to be a part of.
- CipherTrust Manager must contain an LDT Communication Group if you will use CTE to guard data over CIFS/ NFS shares using LDT policies. See [Managing LDT Communication Groups](#) for more information.

Procedure

1. Log on to the host as a Windows user with System Administrator privileges.
2. Copy the CTE installation `msi` file onto the Windows system.
3. Run the installation file using the following syntax:

```
msiexec.exe /i "<Installation_executable>" /qn INSTALLDIR="install-dir" REGISTERHOSTOPTS="REGISTERHOSTOPTS_Options"
```

Example: IP method

```
msiexec.exe /i "C:\installer\vee-fs-7.8.0-87-win64.msi" /qn INSTALLDIR="C:\cte\custom dir" REGISTERHOSTOPTS="10.171.63.222 -enableldt -useip -usehwsig -token=123456789...123456789 -domain=domain1 -description=""testsilentinstallation""
msiexec /i "<Installation_executable>" /qn INSTALLDIR="install-dir\" REGISTERHOSTOPTS="REGISTERHOSTOPTS_Options" -token
```

Example: IP method

```
msiexec.exe --% /i "C:\Users\Administrator\Desktop\vee-fs-7.8.0.75-win64.msi" /qn REGISTERHOSTOPTS="10.171.63.222 -enableldt -useip -token=wrkzr8836034m2PC"
```

```
PBqW1fQk -description=testslientinstallation" -log="C:\install.log" /norestart
```

Example: FQDN method

```
msiexec.exe --% /i "C:\Users\Administrator\Desktop\vee-fs-7.8.0.75-win64.msi"
/qn REGISTERHOSTPTS="10.171.63.222 -enableldt -agent=w2k22x64-61119.sj-clab.c
om -token=wrkzr8836034m2PCPBqW1fQk -description=testslientinstallation" -lo
g="C:\install.log" /norestart
```

where:

- **Installation_executable** is the name of the executable, example: **vee-fs-7.8.0-87.66-win64.msi**
- **/i** (required) enables CTE installation.
- **ENABLE_LDT_CIFS=Yes** is an optional parameter that indicates you plan to use CTE-LDT with CIFS share GuardPoints on this host with a CipherTrust Manager. If you specify this option, you will not be able to guard any local directories on this host, even if those directories use a Standard CTE policy. Only CTE-LDT GuardPoints on CIFS shares will be supported for this host.
- **/qn** (required) specifies that the install should be non-interactive and that no GUI should be displayed.
- **/norestart** Prevents the agent from rebooting after installation.
- **INSTALLDIR="install-dir\"** is an optional parameter specifying the installation directory you want to use. If you omit this parameter, CTE installs in the directory **C:\Program Files\Vormetric\DataSecurityExpert\agent**

Note

Thales recommends that you install CTE in the default directory if at all possible.

- **REGISTERHOSTPTS="\Options\"** (required if you want to register CTE to a CipherTrust Manager). It is a list of options that you want the installer to use. The common options are:

Parameter	Description
CipherTrust Manager host name	Required if you want to register CTE with a CipherTrust Manager.
-accessonly	Enables access-only mode for LDT. (Default is full access mode.) In access-only mode, nodes are not

Parameter	Description
	be allowed to become part of an LDT Communication Group or participate in data transformation, but they will continue to access a protected LDT CIFS GuardPoint.
-agent=your.agent.name.com	FQDN of the host on which the CTE Agent is being installed. If this value is not specified, the installer uses the host's IP address.
-description	Specifies a description for the host. This description is displayed in the CipherTrust Manager. If an entry for this host already exists, and the host already has a description, CipherTrust Manager does not overwrite the existing description, even if this option is specified.
-enableldt	Specify this option to automatically enable and register CTE-LDT (Live Data Transformation) for this host on your key manager during the silent install.
-enable_host_check/-disable_host_check	When using CipherTrust Data Security Platform Services (CDSPaaS), set this value to 1 to enable SSL certificate host name checks. Set to 0 to disable. Default: 0. This also forces CTE to enable the verify peer feature during registration. Use only when the CDSPaaS web server certificates contain the target DNS name or IP address.
-hostgroup	Specifies the optional host/client group with which this host/client will be associated.
-log <log_file_path_&_name>	Record installation steps in a log file.
-port <port#>	Specifies the port number this CTE Agent should use.
-profile	Specifies the client profile in the CipherTrust Manager that will be associated with this client. If this value is omitted, the CipherTrust Manager uses the default client profile.
-rwp	Enables Ransomware Protection.
-silent	Make this a silent installation.
-token	The registration token for the CipherTrust Manager with which you plan to register this client. Required

Parameter	Description
	for registration.
-usehwsig	Specify this option when you want to associate this installation with the machine hardware for cloning prevention.
-useip	Use the IP address of the protected host instead of host name. Used when -agent is not supplied.
-vmd	Defines what kind of agent is being installed.

Example: Custom Install Directory and Host Description with Spaces

The following example specifies that:

- The CTE Agent will be installed in the custom directory `C:\cte\custom dir`. The spaces in the installation directory name require it to be in double-quotes. For example: `INSTALLDIR="C:\cte\custom dir"`.
- The CipherTrust Manager host name is `my-key-mgr.example.com`.
- The CipherTrust Manager registration token is `12345` (`-token` parameter).
- The host will be registered using the host name `my-host.example.com` (`-agent` parameter).
- The host will be registered with the description `This host was silently installed` (`-description` parameter). Because description is inside a double-quoted string, you must escape the double-quotes `-description=\"This host was silently installed\"`

Note

The examples below are shown on several lines for readability. When you enter the command, all parameters should be on the same line.

```
msiexec /i vee-fs-7.8.0-87-87-win64.msi /qn
INSTALLDIR="C:\cte\custom dir" registerhostopts="my-key-mgr.example.com
-agent=my-host.example.com -token=12345 -description=Description_without_spaces_and_no_double_quotes"
```

To pass arguments successfully, you must use a hyphen and the equal sign.

Warning

Once the above command is executed, the server reboots automatically. To avoid automatic reboot (i.e. restarting manually), use the `msiexec /norestart` parameter. An example below:

```
msiexec /i vee-fs-7.8.0-87-win64.msi /qn /norestart INSTALLDIR="C:\cte\custom dir" registerhostopts="my-key-mgr.example.com -agent=my-host.example.com -token=12345 -description=Description_without_spaces_no_double_quotes"
```

Example: CTE-LDT, LDT AccessOnly and Hardware Acceleration

The following example specifies that:

- The CTE Agent will be installed in the default installation directory (the `INSTALLDIR` parameter is omitted).
- The CipherTrust Manager host name is `my-key-mgr.example.com`.
- The host will be registered using its IP address and not its host name (`-useip` parameter).
- The CTE-LDT (`-enableldt` parameter), LDT AccessOnly (`-accessonly`), and hardware association (`-usehwsig` parameter) features are enabled.

```
msiexec /i vee-fs-7.8.0-87-win64.msi /qn registerhostopts="my-key-mgr.example.com -token=12345 -useip -enableldt -accessonly -usehwsig"
```

Validating CM and CTE with a Local CA Certificate**Note**

This feature is not compatible when using CipherTrust Transparent Encryption with CipherTrust Data Security Platform Services (CDSPaaS).

To ensure that registration by the CTE agent is serviced only by the expected key manager, you can provide a copy of the root CA certificate that will be used to authenticate the TLS communications with the key manager, during the registration process.

Note

You can only download the CA certificate when you are a root user in the root domain. You cannot

download the certificate from a subdomain. It will not work.

Prerequisite

Make sure that you have previously [created the client](#) in CipherTrust Manager.

Using a Local CA Certificate

1. Extract the root CA certificate from the CipherTrust Manager.
 - a. Log on to CipherTrust Manager as an administrator.
 - b. In the left navigation pane, click **CA > Local**. The list of available CAs displays.
 - c. Click the ellipsis icon corresponding to the CA.
 - d. Click **Download** to download the CA.
 - e. Copy the certificate to a directory on the agent system.
2. To install the root CA certificate into the CTE client, add it to the registration command line:

Note

You must have administrator privilege to complete this step.

```
C:\Windows\system32> C:\Program Files\Vormetric\DataSecurityExpert\agent\shared\bin\
register_host.exe -silent -log= -vmd -agent= -token= -cafile=
```

Example

```
C:\Program Files\Vormetric\DataSecurityExpert\agent\shared\bin\register_host.e
xe -silent -log=c:\vte_reg_log.txt -vmd 10.171.36.175 -agent=ani-vm-217-3519
0.sjcicd.com -token=mMEz3Y60b9D4L7QuvK5S0mhulRm8DYI8odV5j30dvuHqk6LhZqE0FeIZHI
LYTmDiE9 -cafile=C:\tmp\Austin175.pem
```

3. Confirm in CipherTrust Manager that the client is registered and healthy.

Using external certificates for communication between CTE Agent and CipherTrust Manager

Note

This feature is not compatible when using CipherTrust Transparent Encryption with CipherTrust Data Security Platform Services (CDSPaaS).

Note

This feature is not compatible when using CipherTrust Transparent Encryption with CipherTrust Data Security Platform Services (CDSPaaS).

Overview

Use for communication between CTE and CipherTrust Manager. Install the external certificate before registering CipherTrust Transparent Encryption with CipherTrust Manager.

Prerequisites

The external certificate must be:

- On the file system
- In PEM format

A key pair must already exist for the client:

- Must have Encryption type of either:
 - sha256WithRSAEncryption
 - ecdsa-with-SHA384
- Must be Encrypted with a pass phrase

Initial setup

1. Obtain your external CA certificate.
2. Create a certificate using the external CA certificate and key.

CipherTrust Manager Setup

To setup CipherTrust Manager to communicate through an external certificate:

1. Import the CA certificate into the CipherTrust Manager, click **CA > External > Add External CA**.

Note

In the Add External CA dialog, copy and paste the `<ca_certificate_name>.pem` file content from the UI page and provide a user-friendly name.

For more information, see [Using an Externally Generated Server Certificate for an Interface](#)

2. Add the CA certificate to the list of trusted sources for the web interface, click **Admin Settings > Interfaces > web > Edit > External Trusted CAs**.
3. Restart the web server, click **Admin Settings > Services > web > Restart**.
4. [Create a Registration Token](#) for the CTE agent.

CTE Agent setup

1. Create a directory on the system to hold the required files, for example:
 - `/root/cert_files` (**Linux/AIX**)
 - `c:\temp\cert_files` (**Windows**)
2. Copy or create the following files in this directory:
 - `client_cert.pem`
 - `client_key.pem`
 - `passphrase` - this is currently expected as plain text
3. For **Linux/AIX** systems, to add the directory path to the environment, type:

```
$ export EXTERNAL_CERT_DIR=/root/cert_files
```

4. For **Windows** system, invoke `registerhost.exe` from the command line and add this argument:

```
c:\> register_host.exe -extcertdir=c:\temp\cert_files
```

5. Register the CTE client with the CM server as normal. If this is being done as part of an installation, then the above steps should be done before the installation, or, on windows, added to the registration parameters passed to the installer.

Post Registration

During registration, the certificate file is uploaded to the CipherTrust Manager, and the certificate and key files are imported into the CTE pem store. The key is decoded using the provided passphrase, then re-encoded using a random key using the normal CTE key security mechanisms for TLS keys. There is no need to keep the input files after registration is successful, so for security reasons they should be removed / shredded.

Certificate Renewal

The location of the external certificate files (i.e. the `EXTERNAL_CERT_DIR` or `-extcertdir` parameters) will be recorded in the CTE agent configuration file, `agent.conf`. When the current certificate is approaching expiration date (i.e. approx. 60 days prior to expiration) the CTE agent will look in this directory for an updated set of files.

If a new certificate file is present, then the file will be read and pushed to the CM, and if accepted, then the certificate and key will be imported into the CTE pem store, and the VMD process restarted to use the new certificate.

If no new certificate is present, a WARNING level message will be written to the logs and/or uploaded to the CM as per the logging settings, and the CTE agent will check again after 24 hours.

If the user wishes to change the directory path to store the new certificates, then the entry in the `agent.conf` file should be updated and the vmd service restarted. Alternatively, the user can update the external certificate set using the following command (this will not update the saved path):

```
# vmutil -a vmd -d <ext_cert_Dir> updatecerts
```

If the user fails to update the certificate set prior to expiration then communication with the CM may be blocked, and re-registration will be required.

Note

Any renewed certificates must have exactly the same common name field as the original certificate, or the CipherTrust Manager will reject the update.

Registering CTE After Installation is Complete

The following procedure describes how to register the CTE Agent after installation is complete.

Use the `register_host` utility to create certificate requests, exchange certificates between the CipherTrust Manager and the host, to enable ransomware detection, and to register CTE on the CipherTrust Manager. After the host is registered, if you selected to enable file system encryption, you can configure CTE, apply GuardPoints, or perform database backups. If you selected ransomware protection, you can apply the protection to volumes. Run the `register_host` utility in text mode on a terminal window.

Caution

The default host registration timeout is 10 minutes. If the host is unable to reach the CipherTrust Manager within the allotted period because of an extremely slow network connection, set the **REGISTER_HOST_TIMEOUT** environment variable to extend the registration timeout. The variable value is an integer expressed in seconds. You might also have to extend the default TCP timeout.

1. Log on to the host as a Windows user with administrative privileges.
2. Launch the CTE Registration Wizard using one of the following methods:
 - In the system tray, right click the CipherTrust Lock icon and select **Register Host**.
 - Run `...\register_host.exe -vmd -silent`.
3. Reboot the system. CTE automatically displays the registration wizard if CTE is not already registered.
4. In the Register Host dialog box, verify the host's machine name and click **Next**.

Note

For CipherTrust Data Security Platform Services, the host names of the services are:

- **Europe:** `ciphertrust.dpondemand.io`
- **North America:** `us1.ciphertrust.dpondemand.io`

5. On the **Gathering agent information** page, select one or both of the following options and click **Next**.
 - **File System:** Allows you to protect and encrypt CTE files with policies
 - **Ransomware Protection:** Protects volumes from ransomware
6. On the **Gathering Key Manager information** page, enter the FQDN or IP address of the primary CipherTrust Manager.

The default communication port is 443. If you want to specify a different communication port, enter it with the primary key manager host name in the format: **<hostName>:<port#>**. For example: `10.3.200.141:8445`

When you are done, click **Next**. CTE communicates with the selected CipherTrust Manager to validate what features have been licensed and are available to the CTE Agent.

7. On the **Gathering host information** page:

File System

- Specify the host name or IP address of the client. You can select the host name from the drop-down list or type it in the field.
- To prevent cloning, select **Enable Hardware Association**. For details, see [Hardware Association Feature](#).
- If you want to have CipherTrust Transparent Encryption - Live Data Transformation available on the client, select **Enable LDT Feature**. For details on LDT, [CTE Agent Live Data Transformation](#).
- If you want the node to be an [Windows AccessOnly](#) node, select **Enable LDT AccessOnly Feature**.

Ransomware

- Specify the host name or IP address of the client. You can select the host name from the drop-down list or type it in the field.
- To prevent cloning, select **Enable Hardware Association**. For details, see [Hardware Association Feature](#).

When you are done, click **Next**.

8. On the **Gathering registration information** page, enter the following:

File System

- **Registration token:** The registration token for the CipherTrust Manager with which you want to register this host.
- **Profile name:** The name of the profile that you want to associate with this host. This name must match exactly the name of the profile in the CipherTrust Manager. If you do not specify a profile name, the CipherTrust Manager associates the default client profile with this client.
- **Host group** (optional): The name of the client group to which the client will be added.
- **Host description** (optional): A user-defined description of the client. This description will be displayed in the CipherTrust Manager.
- **LDT Communication Group:** If you are planning on using LDT over CIFS/NFS on a CipherTrust Manager, enter the name of the LDT Communications Group that this node will join. See [Adding Clients to an LDT Communication Group](#) for more information.

Ransomware

- **Registration token:** The registration token for the CipherTrust Manager with which you want to register this host.
- **Profile name:** The name of the profile that you want to associate with this host. This name must match exactly the name of the profile in the CipherTrust Manager. If you do not specify a profile name, the CipherTrust Manager associates the default client profile with this client.

- **Host group** (optional): The name of the client group to which the client will be added.
- **Host description** (optional): A user-defined description of the client. This description will be displayed in the CipherTrust Manager.

Warning

The registration information is case-sensitive. If any of it is entered incorrectly, the client registration will not succeed. If the registration fails, click Back in the installer and verify that the case is correct for all entries on this page.

When you are done, click **Register**. CTE contacts the CipherTrust Manager and attempts to register the client with the specified options. The Register Host dialog box displays a message with the results of the registration request.

If the registration completed successfully, click **Finish**.

- Restart the client to complete the installation process on the client.
- After the host has rebooted, you can verify the installation by checking CTE processes:
 - In the system tray of the protected host, right-click the CipherTrust Lock icon.
 - Select **Status**. Review the information in the **Status** window to confirm that the correct CTE version is installed and registered.
 - If you are using CipherTrust Manager version 2.2 or later, you can now use CipherTrust Manager to administer CTE on the client.

If you are using CipherTrust Manager version 2.1 or earlier, change the client password using the manual password creation method. This password allows users to access encrypted data if the client is ever disconnected from the CipherTrust Manager. For details on changing the password, see the CipherTrust Manager documentation.

Setting the CM log for Ransomware Protection

Setting the CipherTrust Manager log for Ransomware Protection

You need to configure the logging level on CipherTrust Manager to INFO instead of the default, which is ERROR.

To define client log configurations for a profile:

- Open the **Transparent Encryption** application.
- In the left pane, click **Settings > Profiles**.

3. Click on the name of the relevant profile.
4. Click **CLIENT LOGGING CONFIGURATION** to expand it.
5. Set the **Log Level** to **INFO**.
6. Click **Update**. The changes are effective immediately and apply to the clients linked with the profile.

The CTE client logs can be seen on the **Records > Client Records** page of the CipherTrust Manager GUI. Filter the records by **Client Type** and look for the **CTE** records.

Guarding a Device with CipherTrust Manager

After you register a client with a CipherTrust Manager, you can create as many standard GuardPoints on the client as you need. These GuardPoints can protect an entire device or individual directories.

Note

For guarding using LDT on a local drive, or on a CIFS/Share drive, refer to [CTE-Live Data Transformation with CipherTrust Manager guide](#).

In order to guard a device or directory, you need to use the CipherTrust Manager Console to:

1. [Access the CipherTrust Manager domain](#) in which the client is registered.
2. Identify or [create an encryption key](#) that CTE will use to encrypt the data on the device or directory.
3. Identify or [create a policy](#) for the device or directory that specifies the access controls and the encryption keys to use for the device or directory.
4. [Assign a GuardPoint](#) to the device or directory.

The following example creates a simple policy and uses it to guard a directory on a registered client. For all of the following procedures, you must be logged into the CipherTrust Manager Console as a CipherTrust Manager Administrator, and you must be in the domain with which the client is registered.

For details about any of these procedures or the options for domains, encryption keys, policies, and GuardPoints, see the CipherTrust Manager documentation.

Access the CipherTrust Manager Domain

1. In a web browser, navigate to the URL of the CipherTrust Manager Console you want to use and log in with CipherTrust Manager Administrator credentials.
2. If the client you want to protect is registered to the default domain (root), proceed to [Create an Encryption Key](#). If you need to change to a different domain, do the following:
 - a. In the top menu bar, click the user name **root/admin** on the right-hand side.

- b. Select **Switch Domains**, then select the domain in which the client is registered.
- c. The logged in user now shows the new domain name/user name.

Create an Encryption Key

Note

The following procedure is based on CipherTrust Manager version 2.2. If you are using a different version, see the CipherTrust Manager documentation for the version that you are using.

1. From the Products page in the CipherTrust Manager Console, click **Keys** in the left hand pane.

Tip

To navigate to the Products page from anywhere in the CipherTrust Manager Console, click the App Switcher icon in the top left corner.

2. Above the Key table, click **Create a New Key**.
3. In the **Key Name** field, add a name for the key. This name must be unique. For example, Simple-Key.
4. In the **Key Usage** section, make sure **Encrypt** and **Decrypt** are selected.
5. Click **Create**. CipherTrust Manager displays the properties for the new key.

6. In the general options area, enable the **Exportable** option.

You can also enable the **Deletable** option in this section if you want a CipherTrust Manager Administrator to be able to delete the key.

ID	2e58c582...61136313	Owner	Global	Object Type	Symmetric Key
UUID	e3ad9c3e...7f047711	Created	05 Mar 2021, 05:13	Algorithm	AES
MUID	e3ad9c3e...7b333c9f	Last Modified	05 Mar 2021, 05:13	Size	256
KeyID	N/A	Exportable	☒	Deletable	☐

7. In the **Key Access** section, do the following:

- a. In the Search Groups box, type "cte".

If no groups are displayed, make sure the **Added Only** option is *disabled*.

- b. Click the **All** check box for both the CTE Admins and CTE Clients groups.

KEY ACCESS								
Key Owner								
Q cte								
2 Results 2 groups								
Group	Read	Use	Decrypt	Encrypt	Sign	Sign/Verify	Export	All
CTE Admins	☒	☒	☒	☒	☒	☒	☒	☒
CTE Clients	☒	☒	☒	☒	☒	☒	☒	☒

- c. When you are done, click **Update**.

8. Click the **CTE** tab and set the following properties:

- **CTE Versioned:** Specify whether the key is versioned. By default, the key is set as versioned.

For a standard policy, you should clear this check box. If you do not, the key will *not* appear in the keys list when you add the key rule to the standard policy.

- **Persistent on Client:** Specify whether the key is stored in persistent memory on the client.

When the check box is selected, the key is downloaded and stored (in an encrypted form) in persistent memory on the client.

When the check box is left clear, the key is downloaded to non-persistent memory on the client. Every time the key is needed, the client retrieves it from the CipherTrust Manager. This is the default setting.

- **Encryption Mode:** Encryption mode of the key. The options are:

- CBC
- CBC-CS1
- XTS

Encryption using the XTS and CBC-CS1 keys is known as enhanced encryption.

When you are done, click **Update**.

Create a Standard Policy

1. In the Applications page of the CipherTrust Manager Console, select the **Transparent Encryption** application.
2. In the sidebar on the Clients page, click **Policies**.
3. Click **Create Policy**. CipherTrust Manager displays the Create Policy Wizard.
4. On the General Info page, set the following options:

Field	Description
Name	A unique name for the policy. Make sure you use a name that is descriptive and easy to remember so that you can find it quickly when you want to associate it with a GuardPoint. This example uses "Simple-Policy".
Policy Type	The type of policy you want to create. In this example, we will create a Standard policy.
Description	A user-defined description to help you identify the policy later. For example: Standard policy for new GuardPoints.
Learn Mode	Learn Mode provides a temporary method for disabling the blocking behavior of CTE/LDT policies. While useful for quality assurance, troubleshooting, and mitigating deployment risk, Learn Mode is not intended to be enabled permanently for a policy in production. This prevents the policy Deny rules from functioning as designed in the policy rule set. Ensure that the policy is properly configured for use in Learn Mode. Any Security Rule that contains a Deny effect must have Apply Key applied as well. This is to prevent data from being written in mixed states, resulting in the loss of access or data

Field	Description
	corruption. Apply Key will have no effect when combined with a Deny rule unless the policy is in Learn Mode.
Data Transformation	If you select Standard as the policy type, also select the the Data Transformation option to tell CTE that you want to change the current encryption key used on the data in the GuardPoint, or that you want to encrypt clear-text data for the first time. This option is only displayed for Standard policies.

When you are done, click **Next**.

- On the Security Rules page, define the security rules that you want to use.

CipherTrust Manager automatically adds a default security access rule with an action of **key_op** and the effects **Permit** and **Apply Key**. This rule permits key operations on all resources, without denying user or application access to resources. This allows it to perform a rekey operation whenever the encryption key rotates to a new version.

To add additional security rules, click **Create Security Rule** and enter the requested information. For details about adding security rules, see the CipherTrust Manager documentation.

When you are done, click **Next**.

- On the Create Key Rule page, click **Create Key Rule** and enter the following information:

Field	Description
Resource Set	If you want to select a resource set for this key rule, click Select and either choose an existing resource set or create a new one. Resource sets let you specify which directories or files will either be encrypted with the key or will be excluded from encryption with this key.
Current Key Name	Click Select to choose an existing key or create a new one. If the data has not yet been encrypted, select clear_key . Otherwise select the name of the non-versioned key that is currently being used to encrypt the data. In this example, select clear_key .
Transformation Key Name	Click Select to choose an existing versioned key or to create a new one.

Field	Description
	CTE uses the versioned key specified in this field to encrypt the data in the GuardPoint. If the data is currently encrypted, CTE decrypts it using the key specified in the Current Key Name field and re-encrypts it using the key specified in this field.

When you are done, click **Next**.

- On the Data Transformation page, click **Create Data Transformation Rule** and enter the following information:

Field	Description
Resource Set	If you want to select a resource set for this key rule, click Select and either choose an existing resource set or create a new one. Resource sets let you specify which directories or files will either be encrypted with the key or will be excluded from encryption with this key.
Transformation Key Name	Click Select to choose an existing key or to create a new one. CTE uses the key specified in this field to encrypt the data in the GuardPoint. If the data is currently encrypted, CTE decrypts it using the key specified in the Current Key Name field and re-encrypts it using the key specified in this field. For this example, select the key Simple-Key you created in Create an Encryption Key.

When you are done, click **Next**.

- Click **Next**.
- On the confirmation page, review the information for the policy and click **Save**.

Create Policy

- 1 General Info 2 Security Rules 3 Key Rules 4 Data Transformation 5 Confirmation

Review the provided policy details.

Create a GuardPoint

Caveats

- You cannot have a symlink reside inside of a GuardPoint that is pointing to another location in that same GuardPoint
- You cannot have a symlink reside inside of a GuardPoint that points to the root of that same GuardPoint

Prerequisites

- Stop all applications that are accessing the device you want to protect. In this example, we are going to protect the following directories with the same policy and encryption key.
 - C:\HR Files\
 - C:\Accounting Files\
 - C:\Shared Resources\HR\
 - C:\Shared Resources\Accounting\

Tip

If you want to encrypt data without taking the device offline, you must use CipherTrust Transparent Encryption - Live Data Transformation.

Procedure

1. In the Applications page of the CipherTrust Manager Console, select the **CTE** application.
2. In the Clients table, click on the name of the client you want to protect.
3. Above the GuardPoints table, click **Create GuardPoint**.
4. In the Create GuardPoint page:
 - a. In the **Policy** field, select the policy you created earlier.
 - b. In the Type field, select the type of device. You can guard a directory or a raw/block device. For this example, select **Auto Directory**.
 - c. In the **Path** field, enter the directories you want to protect with this policy or click **Browse** to select them from a explorer window.

If you want to enter multiple paths, put each path on its own line. For example:

Create GuardPoint [X]

Policy: *
Simple-Policy [Select]

Type: *
Auto Directory [v]

Path: *
C:\HR Files\
C:\Accounting Files\
C:\Shared Resources\HR\
C:\Shared Resources\Accounting\ [Browse]

- d. Click **Create**.
- e. If you want to use the same policy and GuardPoint type on another path, click **Yes** when prompted.

Otherwise, click **No**. For this example, click No.

The CTE clients pull the GuardPoint configuration information from the CipherTrust Manager.

5. Type the following to transform the data:

```
dataxform --rekey --print_stat --preserve_modified_time --gp <pathToGP>
```

When the data transformation has finished, applications can resume accessing the now-protected data. (See the [CTE Data Transformation Guide](#) for more information.)

Installation Prerequisites

This section lists the installation requirements and options you should consider before installing CTE.

Installation Method Options

Requirements

There are two methods for installing CTE:

- **Interactive installation:** This is the most common and recommended type of installation. Use this for installing CTE on one host at a time using a standard InstallShield installation and registration wizard. See [Interactive Installation on Windows](#).
- **Silent installation:** Create pre-packaged installations by providing information and answers to the installation questions. Use silent installations when installing on a large number of hosts. See [Silent Installation on Windows](#).

Network Setup Requirements

- The IP addresses, routing configurations, and DNS addresses must allow connectivity of the Windows system on which you plan to install CTE to the CipherTrust Manager. After the Windows system is registered as a client with the CipherTrust Manager, the client must be able to poll the CipherTrust Manager in case there are any changes to the encryption keys, policies, or GuardPoints.
- It must also allow for connectivity of the CipherTrust Manager to all clients where you install CTE as well as communication between different CTE clients that plan to enable LDT over NFS/CIFS.
- If the system is a virtual machine, the VM must be deployed and running.

Port Configuration Requirements

The following port information applies to both Windows and Linux systems.

Communication through a Firewall

If a protected client must communicate with CipherTrust Manager through a firewall, see the CipherTrust Manager documentation to determine which of the ports must be opened through the firewall.

Communication with CipherTrust Manager

The default port for http communication between CipherTrust Manager and the CTE Agent is **443**. If this port is already in use, you can set the port to a different number during the CTE Agent installation.

Communication for LDT over CIFS/NFS

All nodes that intend to use **LDT over CIFS/NFS** GuardPoint must have the following ports open:

- 7024
- 7025

Note

When you are registering a CipherTrust Transparent Encryption client with CipherTrust Manager, you can manually include a destination port number, (Default: 443). If you enter a port value, using the syntax `<hostname or IP address>:<port number>` then CipherTrust Transparent Encryption **does not** perform a port scan. CipherTrust Transparent Encryption uses the port number provided to verify the target server type using a TLS operation.

If you do not enter a port number, CipherTrust Transparent Encryption performs a port scan to check which ports are listening, including port 443.

Hardware Association Feature

CTE's hardware association feature associates the installation of CTE with the machine's hardware. When enabled, hardware association prohibits cloned or copied versions of CTE from contacting the key manager and acquiring cryptographic keys. Hardware association works on both virtual machines and hardware clients.

You can enable hardware association during CTE registration process. You can disable hardware association by re-running the registration program.

To verify if hardware association (cloning prevention) is enabled on the protected client, access the Windows command line and run the `vmsec.exe hwok` command. The default location of `vmsec.exe` is `C:\Program Files\Vormetric\DataSecurityExpert\agent\vmd\bin`.

To change the status from enable to disable or vice versa:

1. Open the system tray and right-click on the CipherTrust Lock icon.
2. Select **Register Host**.
3. Follow the prompts to re-register CTE with the CipherTrust Manager.

-
4. Select **Enable hardware association** in the wizard.

Multifactor Authentication for CTE GuardPoints

CipherTrust Transparent Encryption is supporting Multifactor Authentication through integration with various MFA providers. CipherTrust Transparent Encryption will continue to integrate with additional providers.

- [Introduction to Multifactor Authentication](#)
- [Current Compatible Multifactor Authentication Providers](#)

- [Remote Authentication for Multifactor Authentication](#)
- [Administration for Multifactor Authentication](#)
- [Troubleshooting Multifactor Authentication](#)

Introduction to Multifactor Authentication

Why do companies need Multifactor Authentication

Every day, the threat of ransomware attacks increase in frequency, sophistication, and effectiveness. Victims of ransomware attacks can be blocked from data, applications, and systems – making an organization unable to function.

Credential compromise is the leading cause of ransomware attacks, because credentials give hackers the access they need to hold your systems hostage. Unfortunately, credentials can be stolen, shared, bought or hacked. Once the hackers gain entry, the threat actors will often look to compromise privileged access credentials to further infiltrate your network and steal sensitive data.

What is Multifactor Authentication

Multifactor authorization ensures that the access credentials presented belong to the actual person. After logging in to the system, when a user tries to access a CipherTrust Transparent Encryption GuardPoint, it triggers a second factor authorization to verify the user with a second form of authentication, like sending a passcode to the user's registered cell phone, that they then have to input into the application.

How does Multifactor Authentication work

The following diagram explains how Multifactor Authentication operates in a CipherTrust Transparent Encryption environment.

Step	Description
1	Multifactor Authentication is performed when a user tries to access a file in a GuardPoint. NOTE: Multifactor Authentication is only enforced when a file, in a GuardPoint, is first accessed by the user. Multifactor Authentication is not enforced during IO activity, (read/write requests). Therefore, if the file has already been opened by a user/application, Multifactor Authentication will not be enforced on that file.
2	CipherTrust Transparent Encryption sends a message to the Multifactor Authentication provider to verify the user.
3	Multifactor Authentication provider sends a verification request to the user's registered device. NOTE: If Multifactor Authentication is using Password Authentication, this step is not required.
4	Multifactor Authentication provider confirms/denies user access.
5	If authenticated, user has access to the MFA-enabled GuardPoint based on the CipherTrust Transparent

Step	Description
	Encryption access policy. If denied, user does not gain access to the GuardPoint.

For more information on Multifactor Authentication, see [Multifactor Authentication](#).

Compatible MFA Providers

Thales will be continually adding new MFA providers to CipherTrust Transparent Encryption. When the MFA providers pass compatibility testing, they will be added to this page. Select the MFA provider that you are using and follow the instructions below to set up CipherTrust Transparent Encryption for the MFA.

- [Safenet Trusted Authentication](#)
- [OKTA](#)
- [KeyCloak](#)
- [Cisco DUO](#)
- [Microsoft Azure Entra ID Support](#)

Using STA for Multifactor Authentication for CTE GuardPoints

Prerequisites

- Have a CipherTrust Manager set up with:
 - [Client Profile enabled for Multifactor Authentication](#)
 - [Registration token](#)
- Integrate with SafeNet Trusted Access by creating and managing your access controls in [SafeNet Trusted Access](#).

Selecting the Proper Template

Note

Make sure that, in SafeNet Trusted Access, you choose the custom template: **CTE_OIDC**.

If the **CTE_OIDC** template is not available in your account:

1. Create an app using the **Generic Template**.
2. For the Integration Protocol, select **OIDC**.

3. Configure **VALID REDIRECT URL** as: `http://127.0.0.1:5560/auth/callback`.

Note

Port 5560 is the default CTE OIDC login port. If the CTE admin changes it through the `voradmin mfa` command, you must change that value in the redirect URL.

Create an OIDC Connection with CipherTrust Manager

1. Log on to the CipherTrust Manager GUI as an administrator.
2. In the left pane, click **Access Management > Connections**.
3. In the Connections, click **Add Connection**.
4. Click **OIDC** and then click **Next**.
5. Provide a name for the connection and click **Next**.
6. Enter values for the configuration information.

Note

Refer to your Multifactor Authentication provider profile for the values:

- URL of OIDC provider:

Linux

- For KeyCloak, select the URL of the OIDC provider

Windows

- For Thales SafeNet Trusted Access, select **Well Known Configuration URL**
- For all other providers, select the URL of the OIDC provider
- Client-ID as configured for the OIDC client
- Client-Secret as shown for the OIDC client

7. Click **Next** and in the Add Products window, select **CTE** for product.
8. Click **Add Connection**.

For more on the SafeNet Trusted Access OIDC template, see [OIDC applications](#).

Using Okta for Multifactor Authentication for CTE GuardPoints

Integration with Okta requires creating an OIDC connection in CipherTrust Manager, after you create an OIDC template in Okta.

Prerequisites

- Have a CipherTrust Manager set up with:
 - Client Profile enabled for Multifactor Authentication
 - Registration token

On the Okta platform

1. Create an admin user.
2. Create one or more Okta users. **Note** that Okta requires the username to be in email format.
 - Create **domain users** in the format: `<username>@<domain>.com`
 - Create **host specific users** in the format: `<username>@<hostname>.com`
 - Create **non-domain users** in the format: `<username>@localhost.com`.

Non-domain users map to system users with implicit host domain access on each host.

3. Create an OIDC application (“App Integration”) with the following settings:
 - **Application type:** Web Application
 - **Client Authentication:** Client Secret
 - **Grant type:** Authorization Code
 - **Login/Sign-in Redirect URIs:** `http://127.0.0.1:<CTE-OIDC-Login-Port>/auth/callback`
 - **Default value of CTE-OIDC-Login-Port:** 5560, if CTE admin changes this port, they must provide the updated value.
4. Note the OIDC parameters:
 - Client-ID as configured for the OIDC client
 - Client-Secret as shown for the OIDC client

On CipherTrust Manager

The Provider Url for the Okta account is in the following format:

<https://<okta-account>.okta.com/.well-known/openid-configuration>

Create an OIDC connection on CipherTrust Manager

1. Log on to the CipherTrust Manager GUI as an administrator.
2. In the left pane, click **Access Management > Connections**.
3. In the Connections, click **Add Connection**.
4. Click **OIDC** and then click **Next**.
5. Provide a name for the connection and click **Next**.
6. Enter values for the configuration information.

Note

Refer to your Multifactor Authentication provider profile for the values:

- URL of OIDC provider:

Linux

- For KeyCloak, select the URL of the OIDC provider

Windows

- For Thales SafeNet Trusted Access, select **Well Known Configuration URL**
- For all other providers, select the URL of the OIDC provider
- Client-ID as configured for the OIDC client
- Client-Secret as shown for the OIDC client

7. Click **Next** and in the Add Products window, select **CTE** for product.
8. Click **Add Connection**.

Using Keycloak for Multifactor Authentication for CTE GuardPoints

Integration with Keycloak requires creating an OIDC connection in CipherTrust Manager, after you create an OIDC template in Keycloak.

Prerequisites

- Have a CipherTrust Manager set up with:
 - [Client Profile enabled for Multifactor Authentication](#)

- Registration token
- CipherTrust Transparent Encryption host and Keycloak server must have their time's synchronized. If they are not time-synced, then Multifactor Authentication login fails with the following error:

Failed to verify ID Token: oidc: token is expired (Token Expiry: 2022-11-08 22:42:20 -0800 PST)

On the Keycloak platform

1. Create an admin user.
2. Login to the realm and create one or more users.
3. Create a password for the user.
4. Create an OIDC client in realm with the following settings enabled:
 - **Valid Redirect URIs:** Configure in the format:
`http://127.0.0.1:<CTE-OIDC-Login-Port>/auth/callback`
 - **Default value of CTE-OIDC-Login-Port:** 5560, if CTE admin changes this port, they must provide the updated value.
 - **General Settings:**
 - **Client Type:** OpenID Connect
 - **Client ID:** Client name
 - **Capability Config:**
 - **Client Authentication:** On
 - **Authorization:** On
 - **Authentication Flow:** Standard Flow
5. Note three OIDC parameters:
 - Provider URL format:
 - For **non-TLS**: `http://<keycloak-ip>:<keycloak-port>/realms/<realm-name>/.well-known/openid-configuration`
 - For **TLS**: `https://<keycloak-ip>:<keycloak-port>/realms/<realm-name>/.well-known/openid-configuration`

Note

If KeyCloak is configured for TLS, the KeyCloak certificate (if self-signed), or certificate chain, including the root CA, and any intermediate CAs, must be imported into the CipherTrust Transparent Encryption client machine. Import the self-signed certificate as a root CA. CipherTrust Transparent Encryption will fail to connect to the provider if certificates are not imported. To import a certificate: see [Importing Certificates Using MMC](#)

- Client-ID as configured for the OIDC client
- Client-Secret as shown for the OIDC client

Create an OIDC connection on CipherTrust Manager

1. Log on to the CipherTrust Manager GUI as an administrator.
2. In the left pane, click **Access Management > Connections**.
3. In the Connections, click **Add Connection**.
4. Click **OIDC** and then click **Next**.
5. Provide a name for the connection and click **Next**.
6. Enter values for the configuration information.

Note

Refer to your Multifactor Authentication provider profile for the values:

- URL of OIDC provider:

Linux

- For KeyCloak, select the URL of the OIDC provider

Windows

- For Thales SafeNet Trusted Access, select **Well Known Configuration URL**
- For all other providers, select the URL of the OIDC provider
- Client-ID as configured for the OIDC client
- Client-Secret as shown for the OIDC client

7. Click **Next** and in the Add Products window, select **CTE** for product.
8. Click **Add Connection**.

Using Cisco DUO for Multifactor Authentication for CTE GuardPoints

Integration with Cisco DUO requires creating an OIDC connection in CipherTrust Manager, after creating a DUO account.

On the DUO platform:

1. [Create an account on Cisco Duo](#).
2. Login to your Cisco DUO account as an admin and click **Users** in the left navbar to create/add one or more users.
3. While creating a user, set the **Status** as **Active**
4. Click **Applications** in the left navbar.
5. Click **Protect an Application**.
6. In the search field, type **Web SDK**.
7. In the Web SDK field, click **Protect**.
8. In the application created, note the values for:
 - **Client ID**
 - **Client Secret**
 - **API hostname**

Note

https:// is the value for the URL of the OIDC Provider.

Create an OIDC Connection with CipherTrust Manager

1. Log on to the CipherTrust Manager GUI as an administrator.
2. In the left pane, click **Access Management > Connections**.
3. In the Connections, click **Add Connection**.

4. Click **OIDC** and then click **Next**.
5. Provide a name for the connection and click **Next**.
6. Enter values for the configuration information.

Note

Refer to your Multifactor Authentication provider profile for the values:

- URL of OIDC provider:

Linux

- For KeyCloak, select the URL of the OIDC provider

Windows

- For Thales SafeNet Trusted Access, select **Well Known Configuration URL**
- For all other providers, select the URL of the OIDC provider
- Client-ID as configured for the OIDC client
- Client-Secret as shown for the OIDC client

7. Click **Next** and in the Add Products window, select **CTE** for product.
8. Click **Add Connection**.

Using Microsoft Azure Entra ID Multifactor Authentication for CTE GuardPoints

Create an OIDC Application in Entra ID

1. Select **Microsoft Entra ID** from your Azure Homepage.
2. Click **App Registration**.
3. Create a **New Registration**.
4. Record the client ID. You will need it when you create an OIDC connection on CipherTrust Manager.
5. Click **Certificates and Secrets** in the left Nav bar.
6. Create a new **Client Secret**. This is the Client Secret value that you will enter in CipherTrust Manager.
7. For the Redirect URI, select **Web**.
8. Enter redirect URL with your local host name: `http://<localhost>:5560/auth/callback` and save

it.

- Click on the name of your registration and click **Endpoints**.
- Copy the value for the Endpoint for **OpenID Connect metadata document**. This is the OIDC Provider value that you will enter in CipherTrust Manager.

Create an OIDC Connection in CipherTrust Manager

- Log on to the CipherTrust Manager as an administrator.
- In the left pane, click **Access Management > Connections**.
- In the Connections, click **Add Connection**.
- Click **OIDC** and then click **Next**.
- Provide a name for the connection and click **Next**.
- Enter values collected in the previous section for the configuration information.
 - OIDC Provider: <value for the Endpoint for OpenID Connect metadata document>
 - Client ID
 - Client Secret
- Click **Next** and in the Add Products window, select **CTE** for product.
- Click **Add Connection**.

Set Client Profile in CipherTrust Manager

- In CipherTrust Manager, open the Transparent Encryption application.
- In the left pane, click **Settings > Profiles**.
- Select the desired client profile.
- Expand **MULTIFACTOR AUTHENTICATION**.
- Select the OIDC Connection that you created for Entra ID.
- Select **MFA Exempted User Set** from the drop-down list. This user set will be exempted from MFA so MFA will not be enforced on the users of this set. See [Exempting some users from authentication with a Whitelist](#) for more information.

Domain Mapping

Domain mapping is required for Entra ID. If you try to log in prior to mapping the domain, CTE generates an error.

You must map the domain **from** the Entra ID domain **to** the domain of the existing CTE host. Ask your System Administrator for the domain information.

1. To set the domain, type:

```
voradmin mfa domains-map set <domain1>:<domain2>
```

Example

```
voradmin mfa domains-map set thalesgroup.com:qa.com
```

Response

```
Restart secfsd service to affect changes.
```

Note

You can map multiple domains using a comma in between domain names. For example:

```
voradmin mfa domains-map set <domain-1-onMFA-provider>:<domain-1-onHost>,<domain-2-onMFA-provider>:<domain-2-onHost>
```

2. To stop secfsd, type:

```
net stop secfsd
```

3. To restart secfsd, type:

```
net start secfsd
```

Use Cases for MFA on CTE

When using Multifactor Authentication with CipherTrust Transparent Encryption, after successfully completing the [MFA provider](#), you can enable it on a:

- Client
- GuardPoint

- GuardPoint, while exempting certain users/applications/processes from authentication

Enable Multifactor Authentication on a client

You can enable Multifactor Authentication for all of the GuardPoints on a client. When Multifactor Authentication is enabled at the client level, CTE enforces the configuration for all GuardPoints configured on the client. It overrides any MFA configuration set for individual GuardPoints.

1. Open **CipherTrust Manager > Transparent Encryption** application.
2. Select the relevant client.
3. In the upper pane, select **Multifactor Authentication**.

4. Select **Apply**. All of the Multifactor Authentication switches are toggled to the **on** position.

5. If the MFA column doesn't display with all switches set to on, click **Refresh GuardPoints** to display the Multifactor Authentication column.

Note

To disable Multifactor Authentication on a GuardPoint, deselect Multifactor Authentication in the upper pane and click **Apply**.

Enable Multifactor Authentication on a GuardPoint

You can enable Multifactor Authentication for individual GuardPoints on clients.

1. Open **CipherTrust Manager > Transparent Encryption** application.
2. Select the relevant client.
3. Select the **GuardPoints** tab.

4. Click the settings icon.
5. Select **Multifactor Authentication** to enable Multifactor Authentication for the GuardPoints.

6. Click **OK**. The Multifactor Authentication column displays.

7. Toggle the Multifactor Authentication switch to enable Multifactor Authentication for the selected GuardPoints.

Note

To disable Multifactor Authentication on a GuardPoint, deselect the Multifactor Authentication toggle switches.

Enable Multifactor Authentication for Client Groups

Multifactor authentication cannot be enabled at the client group level. However, you can enable Multifactor Authentication for individual GuardPoints on client groups.

While propagating the Multifactor Authentication-enabled GuardPoints to the member clients, CipherTrust Transparent Encryption checks the Multifactor Authentication capability of the member clients. If a client is Multifactor Authentication-capable, the GuardPoints are added to the client. If a client is not Multifactor Authentication-capable, the GuardPoints are skipped.

Exempting some users or processes from authentication with a Whitelist

When you activate CTE Multifactor Authentication, all users attempting to log in to the CTE client must successfully pass through CTE Multifactor Authentication to gain entry to the MFA-enabled GuardPoints. However, there are specific exemptions to this rule. Users whose system services, or applications, initiate automatically during system boot-up cannot undergo authentication through CTE Multifactor Authentication, as Multifactor Authentication necessitates user interaction. To accommodate such cases, exempt these users from Multifactor Authentication enforcement within the Client Profile by including them in the user set exemption list.

Typically, only system users responsible for running system services are included in this list. However, since many system applications operate under the root user, or even under normal application user accounts, you must also add these system administrator/application users to the list. These users form part of the user set, commonly referred to as a whitelist.

Caution

Be careful when adding a user to the whitelist. The exemption applies for the entire client. Users on this list can bypass Multifactor Authentication and access all MFA-enabled GuardPoints. If a system service, or application, accesses only one GuardPoint among multiple GuardPoints, Thales advises you to leave that specific GuardPoint without Multifactor Authentication enforcement.

Note

You **cannot** share the whitelist between Windows and Linux operating systems. Each client profile must contain a unique Multifactor Authentication whitelist. Therefore, the User Set contains different users in Windows and Linux platforms. A CTE Windows client and a CTE Linux client **cannot** share the same client profile when Multifactor Authentication is enabled.

Creating a User Set

See [Creating User Sets](#) for information on creating a User Set in a Policy Element.

Adding the User Set to the Client Profile

To add an Multifactor Authentication whitelist to the client profile:

1. Create your [Client Profile](#) if it is not already created.
2. Click on your client profile to open it.
3. Click **Multifactor Authentication**.
4. In the **Select OIDC connection** field, select the OIDC connection that you created.
5. In the **Select the MFA exempted User Set** field, select the User Set that contains the people/applications that are exempted from authorization.
6. Click **Update**.

Remote Authentication for Multifactor Authentication

By default, CipherTrust Transparent Encryption works with a local Multifactor Authentication login. In CipherTrust Transparent Encryption v7.6 and subsequent versions, you can configure remote authentication for Multifactor Authentication. This allows a user to log into Multifactor Authentication through a machine other than a CTE client. This allows you to enable authentication from remote endpoints accessing CIFS shares, exported by a CTE

agent.

Note

- Your Windows remote access system logon account name, and your Multifactor Authentication account name, **MUST** be the same.
- The MFA username, including the domain-name, in the format domain\username or username@hostname, must exist on the MFA provider.

Remote Authentication configuration requires a non-encrypted private key and certificate. The CipherTrust Transparent Encryption OIDC service uses the key and certificate for TLS communication. CTE stores encrypted keys and certificates internally.

Prerequisites

- Create a firewall rule on a CTE agent to allow all incoming TCP traffic on the Multifactor Authentication login port.
- Generate a private key and certificate. You must know the name and location of these files.
- In the Keycloak setup, set the **redirect-url** parameter for OIDC configuration using the following format: `https://<cte-hostname>:<mfa login port>/auth/callback`.

Note

- The Administrator can choose to use a wildcard ('*'), if the same configuration is reused across many CTE agents.

- You must have administrator access so that you can restart secfsd service:
 - a. To stop secfsd service, type:

```
net stop secfsd
```
 - b. To start secfsd service, type:

```
net start secfsd
```

Starting Remote Authentication for Multifactor Authentication

To configure remote authentication:

1. In a command line, type:

```
voradmin mfa remote-config set [<privateKeyFile> <certificateFile>]
```

Example

```
voradmin mfa remote-config set private-key.pem cert.pem
```

Response

```
voradmin mfa remote-config set  
Restart secfsd service to affect changes.
```

2. Restart the secfsd service.

Disabling Remote Authentication for Multifactor Authentication

To disable remote authentication:

1. In a command line, type:

```
voradmin mfa remote-config unset
```

Response

```
Restart secfsd service to affect changes.
```

2. Restart the secfsd service.

Validating Certificate and Private files information

To validate the two certificates:

- In a command line, type:

```
voradmin mfa remote-config get [<privateKeyFile> <certificateFile>]
```

Example

```
voradmin mfa remote-config get private-key.pem cert.pem
```

Response

```

sha256 of key file:
dcb8eXXXXa92ac5dff34aXXXXab3811245aXXXXc204733bbeat43f4846274674

sha256 of certificate file:
3e2eec5bXXd357d14f5c0047d36aXXXXXXXXfc87f2a74ca3b5c2c2627XXxe6db4

certificate:

```

Using Remote Authentication for Multifactor Authentication

To login and use Multifactor Authentication from a remote endpoint:

- User must open a browser and enter a valid URL with the format: `https://<cte-hostname>:<mfa login port>/login`.

Note

When launched from the Etray application on a CTE agent, the browser is launched with the required URL automatically in the URL field.

Administrator Tasks for Multifactor Authentication

Using the Proper Filter

Note

The Multifactor Authentication feature **requires** the CTE VMLFS driver. This driver **must** be running in order for Multifactor Authentication to work.

- All new installations of 7.3.0.x contain this driver. Type `fltmc` to verify. A table displays listing all current drivers.

Filter Name	Num	Instances	Altitude	Frame
WdFilter		4	328010	0
storqosflt		0	244000	0
wcifs		0	189900	0
vmifs		4	142900	0
FileCrypt		0	141100	0
luafv		1	135000	0
npsvctrig		1	46000	0
Wof		1	40700	0

- Agents upgraded from 7.2.0, and previous versions, may be using the vmfiltr driver. If the agent ran the vmfiltr driver, then when you upgrade to 7.3.0, it will start with the vmfiltr driver. If the previous agent ran the vmifs driver, then when you upgrade to 7.3.0, it will start the vmifs driver. Type the following to switch to the vmifs driver:

```
voradmin config enable vmifs
```

User Authentication

Authentication is provided for the entire client and is enforced the first time a user opens a file. After the initial file opening, the user can perform read/writes to the file.

To authenticate, a user can login to MFA from the Windows system tray:

1. Click on the CTE icon in the System Tray.
2. Select **Multi-Factor Authentication > Authenticate**.

3. Login in to access the STA OIDC template.

After you log in, a message displays confirming your authentication and your access to the GuardPoint.

4. Close the Window to continue.

Note

If you logout, you disable your access to the GuardPoint.

Voradmin Commands

voradmin mfa status

Displays the MFA information for a user.

Syntax

```
voradmin mfa status
```

Example

```
C:\Windows\system32>voradmin mfa status
```

Response

```
User \dram is allowed access.  
MFA enabled guardpath(s) (Number of paths: 2):  
C:\cm\gp2  
C:\cm\gp1
```

voradmin mfa config

Displays configuration information.

Syntax

```
voradmin mfa config
```

Response

```
HostMfaEnable is set.  
MFA enabled guardpath(s) (Number of paths: 2):  
C:\cm\gp2  
C:\cm\gp1  
MFA access allowed users(s) (Number of users: 2):  
  Users\dram  
  NT AUTHORITY\SYSTEM  
MFA Exempt-List: (Number of entries: 1)  
  user: "system", group: "", domain(s): "NT AUTHORITY"  
OIDC configuration:  
  login-port : 5560  
  notification-port : 5562  
  client-id : 6653gd25-e1c7-4257-6034-46c77ffc8cb6  
  url : https://idp.eu.safenetid.com/auth/realms/1UWUA52A8A-STA
```

voradmin mfa check-connection

Allows the admin user to check the connection to the OIDC provider.

Syntax

```
voradmin mfa check-connection <name_of_OIDC-configuration-url>
```

Example

```
C:\Windows\system32>voradmin mfa check-connection https://idp.eu.safenetid.com/auth/realms/1UWUA60A8A-STA/.well-known/openid-configuration
```

Response 1: Success

```
Connection ok to https://idp.eu.safenetid.com/auth/realms/1UWUA60A8A-STA/.well-known/openid-configuration
```

Response 2: Failure

```
Connection failed to https://idp.eu.safenetid.com/auth/realms/1UWUA60A8A-STA/.well-known/openid-configuration-bad
```

voradmin mfa update-ports

Allows the administrator to update the OIDC ports.

- Updating the ports restarts the CipherTrust Transparent Encryption Multifactor Authentication application. Users must login to Multifactor Authentication again after the ports are updated.

Warning

If the OIDC-login-port is changed, then the redirect-URI for the OIDC application at the Multifactor Authentication provider must also be changed. It is specified in the format: `http://127.0.0.1:<oidc-login-port>/auth/callback`. If redirect-URI is not changed, CipherTrust Transparent Encryption may fail to connect to the provider.

Syntax

```
voradmin mfa update-ports <oidc-login-port> <oidc-notification-port>
```

Example

```
C:\Windows\system32> voradmin mfa update-ports 8000 8075
```

Response

```
Updated OIDC ports
```

voradmin mfa set-auth-expiry

Allows the admin to set an authentication expiry time.

Note

Changing authentication expiry clears all existing MFA logins. Users must login again.

Syntax

```
voradmin mfa set-auth-expiry <time interval in minutes (specify 0 to disable expiry time)>
```

Example

```
C:\Windows\system32> voradmin mfa set-auth-expiry 5
```

Response

```
Authentication will expire every 5 minute(s).  
Re-authenticate for new settings.
```

voradmin mfa localhost-redirect-uri

You do not need to manually set a parameter for this command. If you use **set** it automatically uses `http://localhost:5590/auth/callback` as the redirect URI. If you use **unset** it automatically uses the default redirect URI for the MFA provider. This command is useful if an MFA provider does not allow 127.0.0.1 as the redirect URI.

Syntax

```
voradmin mfa localhost-redirect-uri <get|set|unset>
```

voradmin mfa domains-map

Domain mapping is generally applicable for use with all providers, though it is only required for Entra ID.

Syntax

```
voradmin mfa domains-map <get|set|unset> <domain1>:<domain2>
```

Example

```
voradmin mfa domains-map set thalesgroup.com:<localhost>.com
```

Response

```
Restart secfsd service to affect changes.
```

Note

You can map multiple domains using a comma in between domain names. For example:

```
voradmin mfa domains-map set <domain-1-onMFA-provider>:<domain-1-onHost>,<domain-2-onMFA-provider>:<domain-2-onHost>
```

voradmin mfa remote-config

Remote authentication allows a user to log into Multifactor Authentication through a machine other than a CTE client. This allows you to enable authentication from remote endpoints accessing CIFS shares, exported by a CTE agent.

Syntax

```
voradmin mfa remote-config [<get|set|unset>] [<privateKeyFile> <certificateFile>]
```

Options	Description
certificateFile	Presented to web browser during TLS communication to the web browser.
get	Displays the 'sha256' encryption for keys and certificates. It allows the customer to check for a valid key and certificate that they imported using the set option.
privateKeyFile	Used by the OIDC service for TLS communication with the web browser.
set	Imports the key and certificate in use by CTE.
unset	Disables the remote authentication for Multifactor Authentication and reverts back to local Multifactor Authentication authentication.

See [Remote Authentication for Multifactor Authentication](#) for more information.

Restarting SecFSD

Many Multifactor Authentication commands require restarting SecFSD to enable.

1. To stop secfsd, type:

```
net stop secfsd
```

2. To restart secfsd, type:

```
net start secfsd
```

Troubleshooting Multifactor Authentication

Error Message: Failed to exchange token

This error message occurs when there are multiple failed login attempts for MFA due to incorrect username or credentials.

Solution

Contact an administrator who controls access to the MFA provider. The administrator needs to unlock the user's account(s) to fix the problem.

User denied access to Multifactor Authentication

User is blocked from accessing Multifactor Authentication.

Solution

- Your Windows remote access system logon account name, and your Multifactor Authentication account name, **MUST** be the same.
- The MFA username, including the domain-name, (if provided, in the format domain\username), must exist on the MFA provider. If no domain is provided, CTE infers it as hostname\username.

"Unknown Certificate" warning from browser

When a remote user launches the browser for remote Multifactor Authentication, it generates a TLS handshake error for unknown certificate in the agent system log directory.

Solution

To prevent the **Unknown Certificate** warning from a browser when accessing a remote endpoint, an administrator must import the certificate configured for remote Multifactor Authentication, to the CTE agent in the endpoint and in the browser configuration.

Multifactor Authentication Client Profile Failed on CipherTrust Manager enrollment**

Switching existing Multifactor Authentication Client Profile using `register_host` failed on CipherTrust Manager enrollment.*

Work-around

- In CipherTrust Manager, change the existing Multifactor Authentication **Select MFA Exempted User Set** parameter to your new target user set

Choosing a Login Name Type

Currently, CipherTrust Transparent Encryption authenticates users with a User Principal Name (UPN). In Windows Active Directory, a UPN is the name of a system user. It is written in an email address format, for example: john.doe@domain.com.

The Security Account Manager (SAM) is a Windows database that stores user accounts and security descriptors for users on the local computer. The SAM Account Name is used to support clients and servers running earlier versions of the operating system, such as Windows NT 4.0, Windows 95, Windows 98, and LAN Manager.

Previously, CipherTrust Transparent Encryption only supported the UPN. Now, you can choose which login name you want your users to use. However, you must choose SAM Account Name or UPN. You cannot use both. By default UPN support is enabled on a host.

CipherTrust Transparent Encryption provides the following **voradmin** commands to change the Windows registry entries.

To enable SAM support:

1. Type the following command:

```
voradmin config usernamesupport samAccountName
```

2. Reboot the system for the changes to take affect.

To enable UPN support:

1. Type the following command:

```
voradmin config usernamesupport userPrincipalName
```

2. Reboot the system for the changes to take affect.

To get a status of the current support:

1. Type the following command:

```
voradmin config usernamesupport getCurrentNameSupport
```

2. Reboot the system for the changes to take affect.

Ransomware Protection

- [Setting up Ransomware Protection during Registration](#)
- [Use Cases for Ransomware Protection](#)

Ransomware Protection Overview

Compatibility

Operating System	CipherTrust Manager version
Ransomware Protection for Windows	v2.12 and subsequent versions
Ransomware Protection for Linux	v2.17 and subsequent versions

Overview

Ransomware is a type of malicious software that is designed to block access to a computer system until a sum of money is paid. CTE for supports detection of Ransomware and protection of sensitive data from Ransomware.

CTE Agent monitors volumes and looks for processes that perform suspicious behavior such as processes that try to encrypt files or open thousands of files. If a process displays suspicious behavior, then it is either audited, which means it is flagged in a log file, or it is blocked. The action taken is preconfigured by the user in the profile linked to the client.

Licensing

Ransomware Protection is supported with RWP-enabled CTE clients. A CTE for Ransomware Protection license must be activated on the CipherTrust Manager to register an RWP-enabled CTE client. Refer to [CTE Licensing Model](#) for details.

Protecting Non-Sensitive Data

Use the Ransomware Protection mode to protect systems that do not contain sensitive data, but have access to your network.

A use case of this scenario is when you have users with laptops who frequently use your network and access servers on it, but they do not have any sensitive data locally on their laptops. A system like this might belong to a salesperson who travels and frequently uses other networks to access the internet. When such users log on to your network, they access the sales network server and upload data to it. They could easily pick up a Ransomware from another network and accidentally upload it to your company's network. Using the Ransomware Protection mode would protect the data on the local volumes, mounted volumes, and the network servers from being infected with Ransomware.

Protecting Sensitive Data

The Ransomware Protection mode protects data on servers and endpoints from Ransomware attacks by auditing and blocking malicious IPs. Users can strengthen the security posture with CTE access and encryption policies and Ransomware protection for complete control on their data.

To protect sensitive data against Ransomware:

1. Ensure that the CTE Ransomware Protection license is activated and available on the CipherTrust Manager. Refer to [CTE Licensing Model](#) for details.
2. Install the CTE Agent with the Ransomware Protection capability enabled. The Ransomware Protection

support uses the same registration process as CTE clients. Refer to [Configuring CTE with CipherTrust Manager](#) for information on installing and configuring CTE Agents.

3. Configure the Ransomware Protection settings in the linked client profile. Refer to [Setting Ransomware Protection Configuration](#) for details.
4. Create a Ransomware Protection GuardPoint on a volume (Windows)|directory (Linux) and on the directory for Linux to be protected. Refer to the [Creating Ransomware GuardPoints](#) for details.

CTE Registration

During CTE registration with CipherTrust Manager, the following question displays:

```
If you are planning to use Ransomware Protection, type Y.
Do you want this host to have Ransomware protection support enabled on the server? (Y/N) [N]
```

CTE Ransomware Protection can support the following protection modes:

- **Filesystem protection (CTE)**

Allows you to protect and encrypt files with policies **without** Ransomware Protection.

- **Ransomware Protection (RWP)**

CTE is deployed to monitor volumes (Windows)|GuardPoints (Linux), for suspicious behavior from processes, and supports auditing or blocking of the processes.

- **Filesystem and Ransomware Protection (CTE-RWP)**

Protects GuardPoints from Ransomware and allows you to protect and encrypt CTE files with policies.

Use Ransomware Protection GuardPoints to monitor or block Ransomware access attempts to a protected GuardPoints on the CTE clients. Note that if the GuardPoint type is "Ransomware Protection Only", Ransomware Protection GuardPoint does not require any policy.

Locking the System after a Ransomware Attack

After enabling Ransomware Protection during installation, turn on the agent lock and the system lock in CipherTrust Manager. The Agent lock protects the CTE Agent files from modification and deletion. The System lock protects a system files from modification and deletion. Agent Lock automatically enables when System Lock enables. You can manually enable or disable the Agent Lock only when the System Lock is disabled.

Make sure that no one is currently accessing the Agent installation directories while applying the locks.

To apply the locks:

1. In CipherTrust Manager, open the **Transparent Encryption** application.
2. Click on the **Client Name** or **Client Group Name**.

3. On the lock bar, click **Agent Lock**.

4. Click **System Lock**.

5. Click **Apply**.

Windows Volume Shadow Copies

Ransomware Protection now detects and prevents deletion of Windows Volume Shadow Copies. The Volume Shadow Copy service is a built-in Windows feature that allows for the creation of backup snapshots of computer files, or disks, and often facilitates other commercial backup solutions. Most ransomware threats normally try to delete the volume shadow copies in order to prevent a healthy recovery from a Ransomware-infected system. Starting from CTE 7.7, deletion of volume shadow copies is prevented if CTE flags the presence of one or more malicious processes on the entire system. This will allow customers to recover their systems if infected by ransomware.

Reference Information

- [Setting Client Locks](#)

Disabling Ransomware Protection

To disable Ransomware Protection for all GuardPoints on the clients linked with a profile.

1. Open the **Transparent Encryption** application.
2. In the left pane, click **Settings > Profiles**.
3. Under **Name**, click the desired profile.
4. Expand **RANSOMWARE PROTECTION CONFIGURATION**.
5. Select the **Operation** to **Disable**.
6. Click **Update**.

Creating GuardPoints for Ransomware Protection

Steps to create GuardPoints on individual clients and client groups are similar. GuardPoints can be created on the GuardPoints tab of individual clients and client groups.

To create a Ransomware Protection GuardPoint:

1. In CipherTrust Manager, open the **Transparent Encryption** application.
2. Select the client or client group on which you want to create a GuardPoint.
 - Click an Ransomware Protection-enabled client under the **Client Name** column (**Clients > Clients**). These are the clients with either Ransomware Protection, or CTE Ransomware Protection, protection mode.
 - Click a client group under the **Client Group Name** column (**Clients > Client Groups**).
3. On the **GuardPoints** tab, click **Create GuardPoint**:

Note

Once Ransomware Protection is enabled during CTE registration, Ransomware Protection is applied to all GuardPoints.

Ransomware Protection is supported in 2 Protection Modes:

- **RWP**: In CipherTrust Manager, when creating a GuardPoint, you cannot assign a policy and type is automatically set to Ransomware Protection Only.
- **CTE-RWP**: On clients with **CTE RWP** mode, you can create a Ransomware Protection GuardPoint set to Ransomware Protection Only, as well as other types of GuardPoints that use policies as shown below. In Linux, Ransomware Protection is also available for other GuardPoints if the GuardPoints are set on a directory.

Status	Policy Name	Protected Path	Type	Client Group	Enabled	LEP Progress	Multistep Authentication
	ctm_rwp	\\mybookworms\c:\	Anti-Corruption		Yes	100%	
	ctm_rwp	\\mybookworms\c:\	Ransomware Protection Only		Yes	100%	

4. Specify the **Path** to be protected. This is a mandatory field. Options to specify the GuardPoint paths are:
 - **Enter/Browse Path**: Select this option, and enter the path by either typing or clicking the **Browse** button.

Note

- For **CTE Windows**, Ransomware Protection GuardPoints are applied at the volume level. Even if you specify the path of a folder or a file, the GuardPoint will be applied at the volume level.

- For **CTE Linux**, Ransomware Protection is applied at GuardPoint level.
- If you specify a network share, all of the network shares to be mounted subsequently will be protected.
- A CTE client administrator can configure protection of all existing GuardPoints, and those to be added to the client subsequently.
- A maximum of 200 GuardPaths can be specified using the **Enter/Browse Path** option.

Browse Method

- a. Click **Browse** to select the path by browsing the client file system. This method prevents typographical errors and verifies client availability. This is the recommended method to specify individual paths. Note that the client must be registered with CipherTrust Manager in order to browse its file system.
- b. In the **Enter Path** field, specify the path. Alternatively, in the **Select Path** field, select the path from the on-screen file system browser, and click **Select Path**.
- c. Click **Add**.

Manual Method

Alternatively, if you know the path, manually enter path in the given text box. Enter one path per line.

- **Upload CSV:** Select this option and click **Browse** to upload the CSV file containing the list of one or more paths. This is the recommended method to specify a large number of paths in one step.

Note

If a manually entered path does not yet exist, check that you entered the path correctly. The CipherTrust Manager does not parse manually entered paths for correct syntax.

5. Click **Create**. A message appears prompting to confirm the reuse of these GuardPoint settings on another path.
 - Click **Yes** to use the same settings on another path. The Use Settings on Another Path dialog box is displayed. Perform the following steps:
 - a. In the **Enter Path** field, specify the path. Alternatively, in the **Select Path** field, select the path from the on-screen file system browser, and click **Select Path**.
 - b. Click **Add Path**. The newly added path appears under the Paths list on the left. Similarly, add as many

paths as required.

c. Click **OK**.

- Click **No** if you do not want to use the same settings on another path.

6. Check the GuardPoint status, type:

```
secfsd -status guard
```

Guarding Data on CIFS Servers and Clients

The Common Internet File System (CIFS) is a well-known and widely-deployed distributed file sharing protocol for Windows. *NIX (Unix/Linux-like operating systems) offer support, to share a directory with Windows, via SAMBA.

Note

This topic is **not** about CTE Live Data Transformation.

You can guard data on a CIFS share:

- On the Server side of the share (WIN and *NIX)
- On the client side (WIN client only)

Guarding on the Windows SERVER side of a share

Guarding on the server side is supported for a local Windows volume drive (i.e. E: or local directory (i.e. E:\gp)). After which you can share the CIFS share out to another Windows server or client. **Do not** guard the share on the server side and then also on the client side. This will lead to double encryption and other problems.

Guarding on the Windows CLIENT side of a Share

You can guard server share on the client side, independent of the server side. The server side can be Windows or *NIX. For either the server or client side OS, the GuardPoint must be a File System that CipherTrust Transparent Encryption supports guarding, which is most typically a native FS.

PROS

- Data sent over the channel is encrypted by the agent, above any channel protocol encryption.
- GuardPoint policy sees the processes on the host accessing files.

CONS

- More agents required, one per client, than guarding on the server side.

Proxy GuardPoint

Guarding on a client, and then exporting that client to another server, is not supported.

Guarding on the *NIX Server side of a Samba share

Guarding on a mounted CIFS/SAMBA share on *NIX is not supported. Use NFS to guard on the client side.

Whenever you are creating a GuardPoint on a CIFS share, you have two options.

1. Install CipherTrust Transparent Encryption agent on the CIFS server. Then create a GuardPoint on the network share. Have users connect remotely from their systems to the network share.
2. Install the CipherTrust Transparent Encryption agent on all remote user computers and again create a GuardPoint on the network share.

Note

- When creating a GuardPoint, do not use the share mount point `\<serverName>\share$`. You must create the GuardPoint on a sub-folder of the mount point `\<serverName>\share$\folder1`
- In the policy, you must create a **UserSet** for remote users accessing the network share. This UserSet must be linked to the ProcessSet for `ntoskrnl.exe` (Windows Only). Then grant the user Permit and Apply_key permissions.

- If a user that is logging in with `UserPrincipalName` (xyzuser@thales.com) is accessing the share folder, then the `UserSet` must contain the UPN. If the remote user logs on with a `sAMAccountName`(jharriman), then the `UserSet` must contain the `sAMAccountName`.

Special Cases for CTE Policies

This following section describes a CTE-specific configuration task related to configuring policies in the key manager.

Behavior of Hard Links Inside and Outside of GuardPoints (Windows)

When using hard links on Windows, all the hard links to a file must be within the boundary of a GuardPoint and must use the same key. The following scenarios provide additional details:

- If hard links to the same file are inside a GuardPoint and outside a GuardPoint, the effect on the file depends on what process accesses which hard link first. If the hard link within the GuardPoint is opened first, the file is transformed. If the hard link outside the GuardPoint is opened first, the file won't be transformed.
- If hard links to the same file exist in different GuardPoints with different keys, the file will be corrupted.
- If hard links to the same file exist in the same GuardPoint but with different keys, such as if folder-based rules are used, there will be a conflict in the key.

Security Rule Ordering for Policies

If you want to enforce restrictions when guarding NFS/CIFS shares using an LDT or standard policy with a **CBC-CS1** key, note the following:

CipherTrust Transparent Encryption embeds the LDT and/or IV (initialization vector) attributes in the first 4K of files for NFS/CIFS shares guarded with an LDT or standard policy with a **CBC-CS1** key. Embedding CipherTrust Transparent Encryption attributes increases the actual file size by 4K. CTE hides that extra 4K when reporting the file size to users, or processes, that access the file with the Apply Key effect.

If you need the actual file size, or read/write access on the embedded header, for backup/restore processes for example, then you need a rule that permits access without Apply Key.

LDT Policies

Example 1: Permits Backup and Restore

A policy that allows backup and restore of encrypted data, clear-text access to certain processes, and denies access to all others:

Order	Resource Set	User Set	Process Set	Action	Effect	Browsing	
1				key_op	permit:applykey	No	
2			backup	all_ops	permit:audit	Yes	
3			authorized-processes	all_ops	permit:audit:applykey	Yes	
4				all_ops	deny:audit	Yes	

Rule	Purpose
1	Default LDT rule required for LDT policies.
2	Allows for processes in the backup Process Set to access the real file size and backup the CipherTrust Transparent Encryption attributes along with the encrypted file data.
3	Allows for processes in the authorized-processes Process Set to access the clear-text data, but it hides the additional 4K from the CipherTrust Transparent Encryption attribute.
4	Denies all other processes access to the data.

Example 2: Permits access to certain Processes

A policy that only allows certain processes clear-text access but allows all others to see the OS file attributes.

Order	Resource Set	User Set	Process Set	Action	Effect	Browsing	
1				key_op	permit:applykey	No	
2			authorized-processes	all_ops	permit:audit:applykey	Yes	
3				f_md_audit_md_read_r...	permit:audit	Yes	
4				all_ops	deny:audit	Yes	

Rule	Purpose
1	Default LDT rule required for LDT policies.
2	Allows for processes in the authorized-processes Process Set to access the clear-text data.
3	Allows for processes not in the authorized-processes Process Set to read the OS file and directory attributes. Note: Processes that match this rule obtain the file size with the 4K header. If a process that is not in the authorized-processes Process Set needs the file size without the header, then the Apply Key must be present in the Effect or you will need an additional rule granting Apply Key to that specific process. That rule must be defined before this rule.
4	Denies processes not in the authorized-processes

Rule	Purpose
	Process Set from reading any data from the files.

Standard Policies

Example 1: Permits access to certain Processes

A policy that allows backup and restore of encrypted data, clear-text access to certain processes, and denies access to all others:

Order	Resource Set	User Set	ProcessSet	Action	Effect	Browsing	
1			backup	all_ops	permit,audit	Yes	...
2			authorized-processes	all_ops	permit,audit,applykey	Yes	...
3				all_ops	deny,audit	Yes	...

Rule	Purpose
1	Allows for processes in the backup Process Set to access the real file size and backup the CipherTrust Transparent Encryption attributes along with the encrypted file data.
2	Allows for processes in the authorized-processes Process Set to access the clear-text data, but it hides the additional 4K from the CipherTrust Transparent Encryption attribute.
3	Denies all other processes access to the data.

Example 2: Permits access to certain Processes

A policy that only allows certain processes clear-text access but allows all others to see the OS file attributes.

Order	Resource Set	User Set	ProcessSet	Action	Effect	Browsing	
1			authorized-processes	all_ops	permit,audit,applykey	Yes	...
2				f_rd_attr_rd_sec,d_r...	permit,audit	Yes	...
3				all_ops	deny,audit	Yes	...

Rule	Purpose
1	Allows for processes in the authorized-processes Process Set to access the clear-text data.
2	Allows for processes not in the authorized-processes Process Set to read the OS file and directory attributes. Note: Processes that match this rule obtain the file

Rule	Purpose
	size with the 4K header. If a process that is not in the authorized-processes Process Set needs the file size without the header, then the Apply Key must be present in the Effect or you will need an additional rule granting Apply Key to that specific process. That rule must be defined before this rule.
3	Denies processes not in the authorized-processes Process Set from reading any data from the files.

For more information, see [Adding Security Rules](#) in the CipherTrust Manager documentation.

Enhanced Encryption Mode

This section describes the enhanced AES-CBC-CS1 encryption mode for keys. It contains the following topics:

- [Compatibility](#)
- [Disk Space](#)
- [Encryption Migration](#)
- [File Systems Compatibility](#)
- [FileTable Support on Windows](#)
- [Using the AES-CBC-CS1 Encryption Mode in CM](#)
- [Exceptions and Caveats](#)
- [Best Practices for AES-CBC-CS1 Keys and Host Groups](#)

The AES-CBC-CS1 encryption is superior to the existing AES-CBC mode because it uses a unique and unpredictable (random) IV (initialization vector) generated for each individual file. The per-file IV object is generated only at file creation time. It is stored as file metadata.

Note

AES-CBC-CS1 encryption does not require any additional license.

Security Improvements

	AES-CBC	AES-CBC-CS1
Unique IV per-file	No	Yes
IV predictability	Yes	No

File System Support

	AES-CBC	AES-CBC-CS1
Local FS	NTFS/ReFS	NTFS/ReFS
Remote FS	CIFS	No support
Block Device Support (secdm)	Fully supported	No. When a policy contains a key with CBC-CS1 encryption mode, the guarding fails on the CipherTrust Manager, and an error message displays.

Compatibility

- Starting with VTE for Windows version 6.1.0, CTE is backward compatible with, and fully supports, the existing AES-CBC mode for both new and existing datasets.
- Starting with VTE for Windows version 6.1.0, CTE fully supports AES-CBC-CS1 encryption for LDT and offline data transformation on CTE Windows environments.

Versions of VTE prior to version 6.1.0 are not backwards compatible with AES-CBC-CS1 encryption. On these earlier versions, attempting to guard a device using a policy containing an AES-CBC-CS1 key will fail.

- Protected hosts supporting AES-CBC-CS1 encryption can be added to host groups.

Difference between AES-CBC and AES-CBC-CS1

The two encryption modes are completely different from a file format standpoint.

- AES-CBC-CS1 encryption only applies to file system directories; AES-CBC encryption applies to both files and block devices.

Note

- If you attempt to use an AES-CBC-CS1 key to guard a block device or partition, the guarding fails with an error reported on the CipherTrust Manager, similar to: Raw or Block Device (Manual and Auto Guard) GuardPoints are incompatible with Policy "policy-xxx" that contains a key that uses the CBC-CS1 encryption mode."
- While AES-CBC-CS1 encryption is supported on both Linux and Windows environments, the file formats are incompatible. An encrypted file created with a specific AES-CBC-CS1 key on Windows cannot be read on Linux, even if that specific key were to be used and vice versa.

- AES-CBC-CS1 uses cipher-text stealing to encrypt the last partial block of a file whose size is not aligned with 16 bytes.
- Each file encrypted with an AES-CBC-CS1 key is associated with a unique and random base IV.

- AES-CBC-CS1 implements a secure algorithm to tweak the IV used for each segment (512 bytes) of a file.

Disk Space

Files encrypted with AES-CBC-CS1 keys consume additional disk space in contrast to files encrypted with AES-CBC keys. This is because AES-CBC-CS1 encryption requires file IVs to be created and persistently stored in contrast to AES-CBC encryption which does not consume any additional disk storage.

Therefore, administrators need to plan and provision additional disk capacity prior to deploying AES-CBC-CS1 encryption.

	AES-CBC	AES-CBC-CS1
Local Windows FS	No change to file size. No ADS allocation.	Extra 4KB allocation (at minimum) in the form of an embedded header per file. With CTE guarding enabled, file size expansion is hidden.

Encryption Migration

You can use either LDT or offline dataxform to:

- Transform data encrypted by AES-CBC to AES-CBC-CS1 and vice versa.
- Transform AES-CBC-CS1 encrypted data to clear contents and vice versa.

File Systems Compatibility

On Windows, you can use AES-CBC-CS1 keys to guard currently supported file systems.

Note

The remote file system must have enough extra space to store the extra 4K bytes of the embedded header.

Storing Metadata

AES-CBC-CS1 encrypted files on Windows store the base IV (initialization vector) of a file in a Windows ADS (Alternate Data Streams) associated with the file. The size required for saving the CS1 key depends on the allocation size of the file system. If the allocation size is set to 4k, then the new IV will require 4K of extra space on the disk. You can run the `fsutil fsinfo` tool to find out the allocation size of the file system.

The AES-CBC-CS1 key is supported on the following file systems:

- **NTFS:** Supported on all Windows platforms that are supported by CTE.
- **REFS:** Supported on Windows 2012 R2 and later.

- **CIFS:** Supported if the backend storage for the CIFS share is Windows-based storage.

Note

Some network storage servers do not support multiple ADS associated with a file.

Compatibility

	AES-CBC	AES-CBC-CS1
Local FS (Windows)	No change	Alternate Data Streams
NTFS file system	Supported	Supported
Azure File Share	Supported	Not supported with a standard policy on a system with a VMFILTR driver.

Note

AES-CBC-CS1 encrypted files on CTE Windows are not compatible with AES-CBC-CS1 encrypted files on CTE Linux. Do not create a policy on Linux that uses AES-CBC-CS1 keys if access to the same NFS GuardPoint is required by both Windows and Linux LAN clients.

Base IV file

To get the value of the base IV, type:

```
voradmin secfs iv get <file-name>
```

Note

The base IV of a file is protected. It cannot be set/modified/removed by commands and applications. However, if a GuardPoint is unguarded, the files in the GuardPoint are no longer protected. An adversary can then corrupt the content of the files, as well as the IVs.

AES-CBC-CS1 depends on the physical file system's support for extended attributes in a manner similar to the CipherTrust Transparent Encryption Live Data Transformation feature.

Missing IV file

If the IV for a file is missing, or CTE is unable to read the IV, then CTE denies access to the file. This access

denied message may trigger an application to display an error message. This message may vary from application to application.

FileTable Support on Windows

The CBC-CS1 key does not support FileTables. This is because FileTables do not support alternate data streams. The CS1 key requires the ability to write the per-file IV into an alternate data stream on each file.

Using the AES-CBC-CS1 Encryption Mode in CM

When you create a key in CTE, you enable Encryption Mode by selecting CTE Key Properties. See *Creating a New Key* in the [Managing Policies](#) chapter in the [CTE Administrator Guide](#).

Exceptions and Caveats

Note the following when using AES-CBC-CS1 keys.

Guarding Existing Files Without Data Transformation

You must convert an existing file with clear text through offline data transformation or LDT. If you do not transform the file, then after you guard using an AES-CBC key, the file displays garbled characters.

If you use an AES-CBC-CS1 key, access to the file is blocked with an I/O error.

Best Practices for AES-CBC-CS1 Keys and Host Groups

In a host group, do not deploy policies associated with AES-CBC and AES-CBC-CS1 keys unless all hosts are running VTE for Windows version 6.1.0 or CTE version 7.0.0 or later.

Utilities for CTE Management

Thales provides a variety of utilities that augment the standard Windows utilities. This combination of tools helps administrators manage CTE. The following utilities are described in this section:

- [Agent Health Return Codes](#)
- [agentinfo \(Java version\)](#)
- [Backup](#)
- [voradmin secfs Commands](#)
- [vmsec](#)
- [vmutil](#)

Agent Health Return Codes

The `agenthealth.ps` utility validates:

- Super-user privilege
- CTE Agent installation
- CTE registration to key manager
- CTE processes/modules that are running
- Available disk resources:
- Current GuardPoints: Tests if the agent can reach the GuardPoints
- CTE log directory resource status

This directory contains pending CTE log files for upload. This utility reports the size and number of pending files for upload. These text files are logs that contain vmd/SecFS information. They are regenerated whenever secfs restarts. If the number of files is unexpectedly large, this can indicate a problem.

Agent Health Check Script

The Agent health check script (`agenthealth.ps1`) is located in `C:\Program Files\Vormetric\DataSecurityExpert\agent\shared\bin\`

To run the `Agenthealth` check script:

1. Run the power shell command to enable self-signing for the system.

Before running agent-health script make sure power shell command has enough privileges to execute the Powershell script. Some Windows operating systems have default execution policy set as `restricted`.

Use the Powershell command `Set- Execution-policy Remote Signed` to change the execution policy if needed.

2. Open the `Power shell` prompt as administrator.
3. Type:

```
.\agenthealth.ps1
```

System Response

```
Log file is at log\agent_health.log
Checking super user privilege..... OK
Vormetric Agent installation..... OK
```

```

Vormetric policy directory..... OK
Registration to server..... OK
Kernel drivers are loaded..... OK
VMD is running..... OK
SECFSD is running..... OK
rhat26130.qa1.com is resolvable.....K.....OK
rhat26130.qa1.com port 8446 is reachable..... OK
rhat26130.qa1.com port 8447 is reachable..... OK
Can communicate to at least one server..... OK
VMD is listening on port 7024..... OK
Time of last update from server      2016-12-01      14:39:49.038
Checking available disk space..... OK
Checking logging space ..... OK
    Log directory is ""
    File system for log data is "/", 32G free (17% full)
    Log directory contains 2 of maximum 200 files (1% full)
    Log directory contains 1 of maximum 100 Mbytes used (1% fu
ll)
Testing access to C:\GP2..... OK

```

agentinfo Utility

The **agentinfo** utility collects system logs, CTE agent logs, CTE agent trace information, and system information for diagnostic purposes. All this information is saved in the destination path and compressed into a zip file. The **agentinfo** utility is available as an **agentinfo.js** Java command and as an **agentinfo.ps1** PowerShell command.

agentinfo Utility (Java version)

The **agentinfo.js** utility is a JavaScript file. You can open it in a text editor to see specific functions.

The **agentinfo.js** support collection scripts reside in the following path on systems where the CTE agent is installed.

To run the **agentinfo** script on Windows, navigate to one of the following folders:

```

C:\Program
Files\Vormetric\DataSecurityExpert\agent\vmd\bin
or
C:\Program
Files\Vormetric\DataSecurityExpert\agent\shared\bin

```

Then run the following script:

```
agentinfo.js
```

agentinfo Utility (PowerShell version)

The PowerShell version of `agentinfo` supports several parameters.

PowerShell version agentinfo parameters

- **Directory** - Specify the directory where all the collection information is saved. By default, this information is saved in the current directory.
- **ZipFile** - Specify the name of the compressed file, where all the collected information will be archived. By default, this information is saved in the current directory.
- **LogFile** - Specify the name of the files where verbose logs will be saved. By default, this information is saved in the current directory.

Examples for using agentinfo utility (PowerShell version)

To save all the collection information in `"c:\AgentLogs"` folder, run the following command:

```
.\agentinfo.ps1 -Directory 'C:\AgentLogs'
```

To save all the collected information in `"c:\AgentLogs"` folder and verbose logs in `"c:\temp\AgentInfo.log"`, run the following command:

```
.\agentinfo.ps1 -Directory 'C:\AgentLogs' -LogFile 'c:\temp\AgentInfo.log'
```

To save all the collected information in `"c:\AgentLogs"` folder, verbose logs in `"c:\temp\AgentInfo.log"`, and create the `"AgentInfo.zip"` archive file, run the following command:

```
.\agentinfo.ps1 -Directory 'c:\AgentLogs' -LogFile 'c:\temp\AgentInfo.log' -ZipFile 'C:\temp\AgentInfo.zip'
```

Note

PowerShell 5.1 or later is required. Use the `$PSVersionTable.PSVersion` command to confirm which PowerShell version you are using.

Backup Utility

When a backup is performed, certain files and directories may be protected against access. Therefore, those files and directories are not written to the backup repository. These include files located in Data Transformation GuardPoints or files in GuardPoints with appropriate policies. Additionally, the following files are locked by default by CTE agent:

```
/opt/vormetric/DataSecurityExpert/agent/secfs/.sec/.access
/opt/vormetric/DataSecurityExpert/agent/secfs/.sec/etc/*
/opt/vormetric/DataSecurityExpert/agent/secfs/.sec/pem/*
```

The following describes how to bypass the issue for multiple scenarios:

Agent is installed in the default location

1. Stop SecFS, type:

```
/etc/vormetric/secfs stop           //Linux

/etc/rc.d/rc2.d/S99secfs stop      //AIX
```

2. Run the backup application with the desired arguments.
3. Restart SecFS, type:

```
/etc/vormetric/ start
```

Using a backup image to install to other agents or restore to a different system

Note

When the image is used to reinstall the system, the agent will automatically start at system boot and will attempt to connect to the key manager to which it was originally registered.

To prevent multiple systems with the same agent ID, you must uninstall CTE from the system before running the backup application. The restore/install from the backup will not have an agent running.

1. Uninstall the agent, type

```
/opt/vormetric/DataSecurityExpert/agent/secfs/bin/uninstallsfs
```

2. Run the backup application with the desired arguments.
3. Re-install CTE agent.

Performing a backup while the agent is running

Before running the backup application, add the files that are protected by the agent to the exclusion rules to

exclude them from the backup:

```
/opt/vormetric/DataSecurityExpert/agent/secfs/.sec/.access
/opt/vormetric/DataSecurityExpert/agent/secfs/.sec/etc/*
/opt/vormetric/DataSecurityExpert/agent/secfs/.sec/pem/*
```

The GuardPoint policy may implement access restrictions which would also cause the backup application to generate error messages. These GuardPoint/directories will also need to be added to the exclusion rule method to exclude them from the backup. Alternatively, you can temporarily unguard them while the backup application is running.

If the CTE agent reports a status of incomplete in the backup application and does not start properly, or partially starts but generates error messages at system boot time, then uninstall and reinstall the agent. The restore/clone image contains everything needed to uninstall the agent. Use the following command to perform this operation:

```
/opt/vormetric/DataSecurityExpert/agent/secfs/bin/uninstallsf
```

Backing up Databases after Encryption

After encrypting a database, CipherTrust Transparent Encryption cannot make a backup of the database. Both scheduled and manual backup fail. The problem was the user's policy. A policy used in this scenario must follow a few rules.

With a CBC_CS1 key, a guarded file is modified to have a 4096 byte header holding key information. When an **Apply Key** effect is specified, the CipherTrust Transparent Encryption code adjusts the length and file offset for this header. Without an **Apply Key** effect, the size and access of the offset include the CBC_CS1 header.

Thales recommends that you modify the first rule of your policy. Remove the action entry for `f_rd_att` from the first rule and add a new rule before it:

```
**action**: f_rd_att

**effect**: Permit, Apply Key
```

Policy processing starts with the first rule and continues until a matching rule is found. The effect for the matching rule is then applied.

For the `f_rd_att` action, this results in the secfs code including the CBC_CS1 key header and adjusts the file size value. Without the Apply Key effect, the file size includes the CBC_CS1 header size and the file appears as 4096 bytes larger than its real size.

voradmin secfs Commands

The `voradmin secfs list` and `voradmin secfs status` commands display GuardPoint and policy information on the host.

voradmin secfs List Commands

The `voradmin secfs list` command has the following options:

voradmin secfs list Options

Guardpoints	Displays all the GuardPoints on the host.
Policy	Displays all the policies used on the host.
logger	Displays the logging details on the host.
Status	Displays the authentication settings on the host.

For example, to view all the GuardPoints on the host, type:

```
voradmin secfs list guardpoints
Guard Point:      1
Policy ID:        16553
Policy name:      ES-Standard-Policy
Directory:        esg-disk1-demo
Type:             rawdevice
Status:           guarded

Guard Point:      2
Policy ID:        18857
Policy name:      Accounting-IT-Access-Policy
Directory:        G:\Data
Type:             local
Status:           guarded

Guard Point:      3
Policy ID:        18985
Policy name:      LDT-Policy
Directory:        C:\LDT-Folder
Type:             local
Status:           guarded
```

To view just the policies in use on the host, you would enter:

```
voradmin secfs list policy
Policy:           1
Policy name:      LDT-Policy
Type:             LDT

Policy:           2
Policy name:      ES-Standard-Policy
Type:             ONLINE

Policy:           3
Policy name:      Accounting-IT-Access-Policy
Type:             ONLINE
```

voradmin secfs status Commands

The `voradmin secfs status` command has the following options:

voradmin secfs status Options

keys	Displays the current status of the keys on the host.
lock	Displays the status of any system or agent locks on the host.
crypto	Displays the encryption modes that are supported.

For example:

```
voradmin secfs status keys
```

Encryption keys are available

```
voradmin secfs status lock
```

FS Agent Lock: Disabled System Lock: Disabled

```
voradmin secfs status crypto
```

AES CBC, CBC_CS1, XTS modes are supported

Encryption key protection is supported

vmsec Utility

The `vmsec` utility allows you to manage the security aspect of the CTE Agent on the host. On Windows the `vmsec` utility is `<windows-agent-install-dir>\vmd\bin\vmsec.exe`. The default path is:

```
C:\Program Files\Vormetric\DataSecurityExpert\agent\vmd\bin\vmsec.exe
```

vmsec Syntax

check_install	Verifies that the kernel component is running. This command checks CTE services and reports if any of the services are not running.
challenge	Initiates challenge-response on the host. This command displays a CTE Agent password challenge string and enter the response string when the key manager is not network accessible.
status	Displays kernel configuration.
vmdconfig	Displays the vmd configuration.
check_hwenc	Determines whether this system supports hardware crypto.
hwok	Reports status of hardware signature.

<code>passwd [-p passwd]</code>	Enters the host password when the key manager is not network accessible. User can unlock the GuardPoints with this password.
<code>version</code>	Displays the CTE version.

Displaying the CTE Challenge String

In addition to using `vmsec challenge` on Windows, you can also right-click the tray icon and select **Challenge...-> Response**. The *CTE Challenge/Response* window opens.

If no challenge string is displayed, the host password is static. If a challenge string displays, contact a Administrator for the response string.

Using the CTE Challenge String

When communication with the CipherTrust Manager is unavailable, the agent pauses on access to guarded directories. The agent waits for communication to be restored or a challenge/response to be issued and completed. The agent notifies the user of this condition and requests the challenge/response with log messages in `dmesg` and `vmd.log` in five minute intervals.

vmutil

Usage

```
vmutil <options> <operations>
```

Options

Option	Function	Description
<code>-a</code>	<code>--agent <name></code>	Specify agent type (vmd or pkcs11)
<code>-d</code>	<code>--extdir <string></code>	Specify location of external certificate and key set
<code>-e</code>	<code>--error <string></code>	Specify one or more errors for state report
<code>-h</code>	<code>--help</code>	Display help and exit
<code>-l</code>	<code>--loglevel <level></code>	Specify log output level (debug, info, warn, error or fatal)
<code>-f</code>	<code>--force enabled</code>	Force option for delete host operation
<code>-v</code>	<code>--version</code>	Display program version and exit

Operations

Operation	Description
certexpiry	Report the certificate expiration date for this agent
deletehost	Delete this client from the server
renewcerts	Renew certificate set for this agent
reportstate	Report agent state and error conditions to server
unregister	Unregister this agent/client from the server
updatecerts	Update external certificate and key set for this agent/client

Upgrading CTE on Windows

This chapter describes how to upgrade an existing VTE for Windows host to CipherTrust Transparent Encryption (CTE) for Windows and contains the following sections:

- To Upgrade in Windows Silently
- CTE Scheduled Upgrade
- Workaround for MSI CTE Typical, Silent, and Scheduled Upgrades
- Upgrading CTE Agents in an LDT Communication Group from 7.4.0 to 7.5.0 and post 7.5.0

Silent Upgrade

If you have already installed CTE on a Windows computer and want to upgrade it silently, use the appropriate command below for the type of installation binary that you are using.

Note

The protected host must be able to connect to the CipherTrust Manager that it is registered to or the upgrade will fail.

Upgrade using self-extracting .exe

```
vee-fs-7.8.0.75-win64.exe /s /v" /qn"
```

Upgrade using MSI

```
msiexec.exe /i vee-fs-7.8.0.75-win64.msi /qn REINSTALLMODE=voums REINSTALL=ALL
```

Before upgrading using MSI, you must rename the installation file to the name of the previously used MSI installation file. See [Workaround for MSI CTE Typical, Silent, and Scheduled Upgrades](#) for more information.

Note

For all types of upgrades, including interactive (GUI-based) and scheduled upgrades, the protected host must be able to connect to the CipherTrust Manager that it is registered to or the upgrade will fail.

Verify the Windows Installation

After running a silent install, verify the installation by checking CTE processes.

1. In the system tray, right-click the CipherTrust Lock icon.
2. Select **Status**. Review the information in the Status window to confirm the correct CTE are installed and registered.

Resolving Problems that Prevent Silent Install

If you encounter problems using MSI or self-extracting `.exe` silent install commands, first check the syntax of the command. To further investigate installation issues, you can use Microsoft diagnostics software:

- For desktop versions of Windows: [Microsoft Diagnostics Troubleshooting Wizard](#)
- For server versions of Windows: [Microsoft Automatic Troubleshooting Services \(MATS\)](#)

Refer to the Microsoft documentation on the linked pages for more information. See the *Compatibility Matrix for CTE Agent with Data Security Manager* for a list of versions of Windows that are supported for use with CTE.

CTE Scheduled Upgrade

Scheduled upgrade allows you schedule an upgrade of the CTE agent to occur after the next time the server hosting the agent reboots normally. Scheduled upgrade can minimize CTE service interruptions. Also, scheduled upgrade can reduce coordination issues in organizations where the security roles are separated.

Prerequisites

The following prerequisites are mandatory for a successful upgrade of a CTE agent node:

1. Install all Microsoft update patches before scheduling a CTE Agent upgrade.
2. Make sure that your Windows version is Windows Server 2008 R2 and subsequent versions. The CTE scheduled upgrade feature is not compatible with previous versions.
3. For all types of upgrades, including interactive (GUI-based) and scheduled upgrades, the CTE client must be able to connect to the CipherTrust Manager to which it is registered.

4. When upgrading from a CipherTrust Transparent Encryption version that is prior to v7.1, you must **first** upgrade to v7.1 before scheduling an upgrade to subsequent versions from v7.1.

If you are upgrading CTE agents in an LDT Communication Group, the following prerequisites are also mandatory for a successful upgrade:

1. Disable the GuardPoints on the nodes to be upgraded:
 - a. Go to the CipherTrust Manager UI.
 - b. In the GuardPoint window, click the ellipsis on the right side of a GuardPoint and select **disable** to disable the GuardPoint.
 - c. Repeat the steps for all of the GuardPoints on the nodes to be upgraded.
2. Stop CTE Services on the nodes to be upgraded:
 - a. Go to **Control Panel > Services (local)**.
 - b. Select **secfsd**.
 - c. Select **Stop the Service**.

Scheduling a CTE Upgrade on the Command Line

To schedule CTE to upgrade the next time the system reboots, type:

```
voradmin upgrade schedule <CTE setup executable path> UPGRADE_NO_CIFSGP=Yes
```

Note

You must set the **UPGRADE_NO_CIFSGP** variable to **yes** after ensuring that all CIFS GuardPoints are disabled. This is mandatory. The upgrade fails if any CIFS GuardPoints are enabled. The **UPGRADE_NO_CIFSGP** variable checks that LDT CIFS GuardPoints are disabled, or not present, in v7.5.0 and subsequent versions. For v7.4.0 and previous versions, it cannot verify the GuardPoint status.

Self-extracting .exe Example

```
voradmin upgrade schedule C:\<Release.build-number>\vee-fs-7.8.0.75-win64.exe UPGRADE_NO_CIFSGP=Yes
```

Minor MSI Upgrades Only (Patches)

1. Before running `voradmin upgrade schedule`, check and remove any existing MSI packages from `C:\ProgramData\Vormetric`.

2. Type:

```
voradmin upgrade schedule C:\<Release.build-number>\vee-fs-7.8.0.75-win64.msi  
MINOR_UPGRADE=Yes REINSTALL=ALL REINSTALLMODE=vomus UPGRADE_NO_CIFSGP=Yes
```

System Response

```
Creating and installing service to upgrade. CTE agent will be upgraded on next  
reboot.
```

Alternative MSI Method

1. Rename the package named: `vee-fs-7.8.0.75-win64.msi` to the previous install package name, ex: `vee-fs-7.8.0.75-win64.msi`
2. Type:

```
voradmin upgrade schedule C:\vee-fs-7.8.0.75-win64.msi REINSTALL=ALL REINSTALL  
MODE=vomus UPGRADE_NO_CIFSGP=Yes
```

Major MSI Installations

For a major MSI upgrade, the command is the same as that for the `.exe` file.

- Type:

```
voradmin upgrade schedule <CTE MSI installer path> UPGRADE_NO_CIFSGP=Yes
```

Example

```
voradmin upgrade schedule C:\vee-fs-7.8.0.75-win64.msi UPGRADE_NO_CIFSGP=Yes
```

Warning

If you have scheduled an upgrade on reboot and the system crashes or is not shutdown gracefully, you must restart the system again to upgrade the agent.

Scheduling a CTE Upgrade Interactively (self-extracting .exe only)

When you open the self-extracting .exe CTE installation binary and a version of CTE is already installed, you have the option of upgrading immediately or initiating a scheduled upgrade. See the procedure below for details. This is an alternative to scheduling an update on the command line using `voradmin` (see [Scheduling a CTE](#)

Upgrade on the Command Line).

1. Move the self extracting `.exe` CTE installation binary to the computer on which you want to initiate the scheduled upgrade.
2. Double-click the self extracting `.exe` CTE installation binary to run it.
3. Click through the standard initial dialog boxes like the license dialog box.
4. On the **UPGRADE - Install now or Later** dialog box, click **Schedule Upgrade on next reboot** and then click **Next**.
5. Click **Schedule** on the confirmation dialog box.

The next time the computer reboots, the upgrade will occur.

This interactive method of scheduling an update is not available for MSI CTE installation binaries. You must use the `voradmin` command line scheduled upgrade method.

Show Scheduled CTE Upgrades

To display all scheduled CTE agent upgrades, type:

```
voradmin upgrade show
```

System Response

```
Current version:      6.0.3.12
Target upgrade version: 6.0.3.15
Upgrade on reboot:    Enabled
```

Cancel a Scheduled CTE Upgrade

To cancel/cleanup a scheduled CTE agent upgrade, type:

```
voradmin upgrade cancel
```

System Response

```
CTE agent upgrade canceled successfully.
```

Workaround for MSI CTE Typical, Silent, and Scheduled Upgrades

When performing an upgrade, Windows Installer Package (MSI) expects the name of the installation binary to be the same as the binary that you used to install CTE. Because Thales includes the software version and build number in the binary file name, you must rename the installation binary to the name of the previously used MSI installation binary before upgrading using MSI. This applies to any MSI CTE upgrade method: typical (interactive), silent upgrade, and scheduled upgrade. If the name does not match the previous binary file name, the upgrade

will fail with error code 1316.

For example, let's say that you installed the CTE Agent using the following installation file:

```
vee-fs-7.8.0.75.47-win64.msi
```

If you used this binary to install or upgrade CTE, the next time you want to upgrade CTE the installation binary that you download from Thales might have the following file name:

```
vee-fs-7.8.0.75.66-win64.msi
```

To upgrade successfully using MSI, you would need to rename the new installation binary to the previous file name of `vee-fs-7.8.0.75.47-win64.msi` before upgrading.

Finding The Name Used For A Previous MSI Installation or Upgrade

If you want to upgrade CTE using an MSI installation binary but don't know the file name that you used during the previous installation or upgrade, you can look it up by using one of the following methods on the computer where you installed CTE:

MSI File Name Lookup Method 1: PowerShell

Run the following command in PowerShell:

```
(Get-WmiObject Win32_Product | where { $_.Name -match "CipherTrust Transparent Encryption" }).PackageName
```

Rename the new CTE setup installation binary to the file name output from the PowerShell command and proceed with the upgrade.

MSI File Name Lookup Method 2: Windows Registry

Find the following registry entry:

```
HKEY_LOCAL_MACHINE\SOFTWARE\Classes\Installer\Product\  
905CB36BF7940894995701C86901D14F
```

Rename the new CTE installation binary to the file name in the registry and proceed with the upgrade.

Uninstalling CTE from Windows

Considerations

- The CTE Agent must be removed from the Windows host before the host is removed from the key manager with which it is registered.

- Database applications like DB2 and Oracle can lock the user space while they run. If the uninstall fails because a GuardPoint is in use, determine which applications are using the files in the GuardPoint and stop them. Then uninstall again.

Procedure

1. Stop any application from accessing files in the GuardPoint.
2. In the key manager with which this host is registered, do the following:
 - Decrypt any data you want to use after uninstall. After the CTE Agent software is removed, access to data is no longer controlled. If data was encrypted, it will remain encrypted. If decrypted or copied out of the GuardPoint, the data is visible as clear text.

This decryption must be done on every GuardPoint on the host if you want to access all existing data on the host.

- Make sure the Agent and System locks have been disabled for the host.
- Thales recommends that you remove all GuardPoints from the host before you uninstall the CTE Agent.

Do not remove the host from the key manager yet.

3. Log on to the host as with system administrator privileges.
4. Use one of the following methods to uninstall the CTE Agent:
 - Use the standard Windows Add/Remove program utility from the Control Panel to remove the CTE software.
 - If you installed the CTE Agent using the MSI file, you can uninstall it using the command line with:

```
msiexec.exe /x <Installation_executable> /qn` command.
```

For example:

```
:::yaml
msiexec.exe /x vee-fs-7.8.0.75-win64.msi /qn
```

5. Reboot the system when prompted.
6. Remove the host record from the key manager.

Troubleshooting and Best Practices

Windows Systems

CTE will not register with the CipherTrust Manager

- If there is a firewall between the CipherTrust Manager and CTE, configure **vmd.exe** as a firewall exception on CipherTrust Manager for Windows. Otherwise, the CipherTrust Manager is unable to browse CTE.
- If using a Windows XP or Windows 2003 system Firewall, select ****Control Panel > Windows Firewall > Exceptions > Add Program... **** and browse for **vmd.exe**. The default location is

```
C:\Program Files\Vormetric\DataSecurityExpert\agent\vmd\bin\vmd.exe
```

- If using a Windows 7 system Firewall, select **Control Panel > System and Security > Windows Firewall > Allowed Programs...** click **Change settings**, click **Allow another program** and browse for **vmd.exe**. The default location is

```
C:\Program Files\Vormetric\DataSecurityExpert\agent\vmd\bin\vmd.exe
```

CTE with NFSv4: Permission denied error

You may see a permission denied error if you try to access files on an NFSv4 file system that is guarded by CTE.

CTE imposes a restriction on NFSv4 file systems to prevent write-only permissions from being set on individual files. You can work around this restriction by configuring read and write permissions on the same files.

You can also add a policy that allows write permissions.

This restriction applies only in the case of files resident in guarded NFSv4 file systems.

McAfee VirusScan Enterprise + Antispyware Enterprise

You must install McAfee AV software **before** installing CTE agent. If CTE is installed first, McAfee cannot initialize and all attempts to scan fail.

CipherTrust Transparent Encryption

CTE Agent Windows Integration Guides

You can integrate CTE with the following applications:

- [Integrating Imperva File Activity Monitoring \(FAM\) with CTE Windows](#)
- [Using CTE with Microsoft SQL](#)
- [CTE with Microsoft DFS\(R\)](#)
- [Secure Start](#)
- [Exchange DAG](#)
- [Storage Spaces Direct](#)
- [Using CTE with Quantum StorNext](#)
- [Setting up Microsoft DPM with CTE](#)

Solutions Guides

Solutions guides have been moved to the [Use Cases](#) section.

Using CTE with Microsoft SQL AlwaysOn and SQL File Tables

This section discusses using CTE with Microsoft SQL with standard and LDT policies. It contains the following topics:

- [Boot Order for MSSQL with CTE for Windows](#)
- [Using CTE \(Standard Policy\) with Microsoft SQL](#)
- [Using CTE \(LDT Policy\) with Microsoft SQL](#)

Boot Order for MSSQL with CTE for Windows

Prerequisite

Setting the Proper Boot Order for SQL Server

CipherTrust Transparent Encryption **must** always boot up **prior** to Microsoft SQL starting. If MSSQL starts prior to CTE starting, it does not function properly. You can set this as a dependency in the Windows services. To set this dependency:

1. Open the command prompt and run it as an Administrator.
2. Modify the value of the service entry, type:

```
sc config MSSQLSERVER depend=secfsd/vmd
```

To validate the dependency:

1. Open the Services.
2. Navigate to MSSQLSERVER service.
3. Click **Properties** > **Dependencies**. Under dependencies, it lists the two CTE services on which MSSQLSERVER is dependent.

Using CTE with Microsoft SQL

- Using CTE with SQL

- Using CTE with SQL FileTables
- Installing CTE on Microsoft SQL AlwaysOn
- Data Transformation (Encryption in place)
- Copy/Restore
- SQL Server Policy Tuning

Using CTE with SQL

You must stop the SQL service before guarding the SQL DB. When this occurs, the SQL Server replication may become unsynchronized. When restarting, it may take a brief period of time for the SQL Server replication to resynchronize with the other node. The SQL Server issues a warning against any attempted failovers during that brief period.

Note

Minimizing the duration for which the SQL Server service is stopped is beneficial for reducing the resynchronization period.

Using CTE with SQL FileTables

SQL FileTables allows you to store files and documents in special tables in the SQL Server called FileTables, but access them from Windows applications as if they were stored in the file system, without making any changes to your client applications. For some of the use cases, you can use FileTables with CTE.

Considerations

- The CTE Agent must be installed on the same server where the FileTables reside. If the FileTables reside on your SQL server, then you should install the CTE Agent on your SQL server.
- If multiple servers access the SQL FileTables:
 - Install CTE agent on all of the servers.
 - Protect all of the FileTable folders with the same CTE policy.

Caution

Accessing the FileTable without CTE may corrupt the data.

- When you create a new FileTable, alter, or drop FileTables, this may require applying a new GuardPoint.

-
- Every FileTable has a separate FileTable Folder so you must apply separate GuardPoints for each FileTable.
 - You must apply a unique GuardPoint to each VNN path.

For example, if you configure two FileTables on an SQL Server, then the remote SQL administrator system must apply one GuardPoint to each configured VNN name.

- Guarding on a VNN name is similar to guarding a network path with CTE.
- If you want to access the FileTables from multiple remote systems, you must install CTE agent on those systems and apply the GuardPoints.
- In the scenario where all remote systems guard the file tables of a Virtual Network Name (VNN) path with CTE LDT over CIFS, and no such GuardPoints exist on the file tables server, then **do not** make any SQL Server backups of the file tables database during Live Data Transformation. If an SQL Server backup is made during LDT rekey, then it is possible that a file in the File Tables directory could be backed up in an incorrect state.

Advantages

- System administrator cannot see the data locally on the SQL server because no CTE Agent is installed on the SQL server.
- The data transferring between servers is also encrypted.

Supported FileTables Use Cases

CTE supports the following FileTables use cases:

CTE Data Transformation of existing files in FileTables

Configuration guidelines:

1. Install CTE agent on the remote server.
2. Create a new FileTable, or Identify the FileTable folder for the existing FileTable.
3. Create an offline Data Transformation policy and apply to the GuardPoint on the FileTable folder.
4. Run the Dataxform utility to transform the data.

Protect files in SQL FileTables with CTE

Configuration guidelines:

1. Install CTE agent on the remote server.
2. Create a new FileTable, or Identify the FileTable folder for the existing FileTable.

3. Create a production policy and apply the GuardPoint on the FileTable folder.
4. Once the GuardPoint is active, you can use the file table to load and access files.

Protect files with SQL AlwaysOn Availability Groups with CTE

When the database that contains the FILESTREAM, or FileTable data, belongs to an AlwaysOn availability group, the FILESTREAM and FileTable functions accept or return virtual network names (VNNs) instead of computer names.

Configuration guidelines:

1. Install CTE agent on the remote server.
2. Create a new FileTable, or Identify the virtual network names (VNNs) for the existing FileTable.
3. Create a production policy and apply the GuardPoint to the VNN name
4. Once the GuardPoint is active, you can use the FileTable to load and access files.
5. When you enable FILESTREAM on an instance of SQL Server, it creates an instance-level share to provide access to the FILESTREAM data. Access this share by using the computer name in the following format:

```
\\<computer_name>\<filestream_share_name>
```

6. In an AlwaysOn availability group, the computer name is virtualized by using a Virtual Network Name, (VNN). When the computer is the primary replica in an availability group, and databases in the availability group contain FILESTREAM data, then SQL creates a VNN-scoped share to provide access to the FILESTREAM data. Applications that use the file system APIs have to use the VNN-scoped share, which has a path in the following format:

```
\\<VNN>\<filestream_share_name>
```

Install CTE on remote systems and guard the SQL Server VNN names

In this use case, CTE is installed on the SQL administrator system (a separate system from where the SQL Server resides) and a GuardPoint is applied to the VNN name.

Unsupported FileTables Use Cases

CTE does not support the following use cases:

1. Install CTE agent on the SQL Server and locally apply the GuardPoint on the SQL Server storage.
2. Access FileTables with Transact-SQL.

3. Access FileTables with File I/O APIs on the SQL server. Perform all file I/O on the remote system running the CTE agent.

Installing CTE on Microsoft SQL AlwaysOn

This section describes how to implement CTE with Microsoft SQL AlwaysOn in a variety of configurations for primary and secondary replica servers, and assumes that you have a basic understanding of Microsoft SQL database.

You may want to keep the primary server decrypted to serve all users, and use the secondary database for running reports or backups.

- If the database is encrypted, then the Volume Shadow copy-related backups will snapshot and backup encrypted protected data.
- Administrators with the `apply_key` permission can run a query and pull down reports from the secondary database server without affecting the performance of the primary database server.
- The secondary server could be in a remote Data Recovery location. You may want to secure it with encryption.
- LDT is supported with SQL AlwaysOn. See [Using LDT with SQL AlwaysOn](#) for more information.

Methods for Initial Encryption

There are multiple methods for performing the initial encryption of the databases. Decide on which of the following methods best fits your environment. For more information on transforming data, see the *CTE-Live Data Transformation with Data Security Manager*.

- Data Transformation – Encrypt data in place
- Backup and Restore to a GuardPoint
- Copy and paste the data into a GuardPoint

Configuration 1

- Databases on primary server and secondary replica servers require encryption
- Database name and location of secondary replica server are the same as the primary server

To perform the procedure:

1. Perform a full backup of the primary database.
2. Change the primary database to offline mode.
3. Confirm the creation of a data transformation and/or standard policy.
4. Guard the folder containing the primary database files with that policy:
 - a. If using 'Encrypt data in place' as the selected method of encryption, execute the data transformation and

then apply the standard policy.

- b. If using the 'Copy/Restore ' method of encryption, apply the standard policy on an empty folder/device.
5. On the secondary server, create a new folder to store the replicated database.

Note

The folder name and the path must be the same as the primary server.

6. Guard the folder with the standard policy.
7. Perform step 4 above for additional secondary server(s).
8. Put the primary database back into online mode.
9. Setup SQL AlwaysOn High Availability group to perform FULL Data Synchronization.

This copies the primary database and replicates it to secondary replica servers.

10. Verify that the databases in the secondary server are in "Synchronized" mode.

Configuration 2

- Database on the primary server does not require encryption, but the secondary replica database requires it
- Database names and locations for the secondary replica servers are the same as the primary server

To perform the procedure:

1. Perform a full backup of the primary database.
2. Confirm the creation of a data transformation and/or standard policy.
3. On the secondary server, create a new folder to store the replicated database.

Note

The folder name and the path must be the same as the primary server.

4. Guard the folder with the standard policy.
5. Perform step 3 & 4 above for additional secondary server(s).

6. Setup SQL AlwaysOn High Availability group to perform **FULL Data Synchronization**.

This copies the primary database and replicates it to secondary replica servers.

7. Verify that the databases in the secondary server are in “Synchronized” mode.

Configuration 3

- Databases on the primary and secondary replica servers require encryption
- Database name is the same, but the location of the secondary replica server is in a different location from that of the primary server

To perform the procedure:

1. Perform a full backup of the primary database.
2. Change the primary database to offline mode.
3. Confirm the creation of a data transformation and/or standard policy.
4. Guard the folder containing the primary database files with that policy:
 - a. If using 'Encrypt data in place' as the selected method of encryption, execute the data transformation and then apply the standard policy.
 - b. If using the 'Copy/Restore ' method of encryption, apply the standard policy on an empty folder/device.
5. On the secondary server, create a new folder to store the replicated database.

Note

The folder name and the path must be the same as the primary server.

6. Guard the folder with the encryption policy.
7. From secondary server, perform the restore to the primary database.
 - a. Select the options **Restore with norecovery** and **Relocate all files to folder**.
 - b. Specify the path of the new folder from step 5.
8. Repeat steps 4 & 5 above for any additional secondary server(s).
9. Setup SQL AlwaysOn High Availability group to perform **JOIN ONLY Data Synchronization**.

This joins the secondary database to the SQL Always High Availability Group. It also establishes replication of

new data and logs from the primary to the secondary replicated server.

10. Verify that the databases in the secondary server are in **Synchronized** mode.

Configuration 4

- Database on the primary server does not require encryption, but the secondary replica database requires encryption
- Database name is the same, but the location on the secondary replica server is in a different location than that of the primary server

To perform the procedure:

1. Perform a full backup of the primary database.
2. Confirm the creation of a data transformation and/or standard policy.
3. On the secondary server, create new folder to store the replicated database.
4. Guard the folder with the standard policy.
5. From secondary server, perform restore the primary database:
 - a. Select the options **Restore with norecovery** and **Relocate all files to folder**.
 - b. Specify the path of the new folder from step.
6. Setup SQL AlwaysOn High Availability group to perform **JOIN ONLY Data Synchronization**.

Joins the secondary database to the SQL Always HA Group. It also establishes replication of new data and logs from the primary to the secondary replicated server.

7. Verify that the databases in the secondary server are in **Synchronized** mode.

Configuration 5

Following is an alternative method for protecting data in a MS SQL Server AlwaysON environment.

To perform the procedure:

1. Shut down SQL services completely, on the secondary node.

Note

It is important to shut down the secondary node first, in order to keep the assignments the same.

2. Shut down SQL services completely on the primary node.
3. Create GuardPoints, using Data Transformation policies, on the directories containing the databases to be encrypted in the primary node.

Note

Perform encrypt-in-place encryption on each directory.

4. Create GuardPoints, using Data Transformation policies, on the directories containing the databases to be encrypted in the secondary node.

Note

Perform encrypt-in-place encryption on each directory.

5. Delete the GuardPoints, using Data Transformation policies, from the primary node.
6. Create GuardPoints, using operational policies, on the four directories in the primary node.
7. Delete GuardPoints, using Data Transformation policies, from the secondary node.
8. Create GuardPoints, using operational policies, on the four directories in the secondary node.
9. Activate SQL services on the primary node.
10. Activate SQL services on the secondary node.

Data Transformation (Encryption in place)

For more information on transforming and encrypting data-in-place, see the [CTE Agent: Data Transformation Guide](#).

Copy/Restore

For more information on transforming data using the copy and replace method, see the [CTE Agent: Data Transformation Guide](#).

SQL Server Policy Tuning

In this section, you created and defined a process set for SQL Server that grants certain executables, in this case, `sqlservr.exe`, unrestricted access to the database files. The need may arise to allow other executables, and/or users, access to the files.

You can grant this access by:

- Adding to the existing process set
- Creating a new one

The best option depends on the access requirements. The key decision is whether or not to select the **Apply Key** effect along with **Permit** or not. Omitting **Apply Key** on a security rule that still contains **Permit** allows the specified user or process to access to the data, but does not apply the encryption key, so therefore only shows them the data in its encrypted, cypher-text format. This is useful for anti-virus or backup software that may need to scan or copy the file, but does not necessarily need to see the contents.

Using LDT with Microsoft SQL

- Using LDT with SQL AlwaysOn
- Using LDT with SQL FILESTREAM
- Guarding SQL Server FileTable databases with LDT

Using LDT with SQL AlwaysOn

To guard a directory with an LDT (Live Data Transformation) policy, you must temporarily close all of the files in that directory. In an SQL Server AlwaysOn environment, this may entail temporarily stopping the SQL Server service on the node that is being guarded. Once the directory is guarded, then you can start the SQL Server service immediately.

It is important to remember that the SQL Server AlwaysOn replication standard operating procedures.

- If one SQL Server service is taken offline for any reason, then once it is brought back on line, it takes the SQL Server a moment to re-synchronize the database nodes.
- The longer that secondary service was down, and the more inserts/updates and deletes that occurred on the still active node during that downtime, then the longer the synchronization period takes.
- During that synchronization period, any attempted fail over results in the SQL Server warning that data loss may occur if the fail over continues. However, once the SQL Server has completed re-synchronizing that secondary node, then any fail over is safe and does not result in loss of data.

Using LDT with SQL FILESTREAM

The following section is for guarding an SQL Server FileStream database with an LDT policy. If the database contains FileTables directories instead, then follow the instructions in [Using CTE with SQL FileTables](#).

Creating a policy for LDT

To guard an SQL Server FileStream Database with an LDT policy, create an appropriate policy on CipherTrust Manager.

1. In a web browser, navigate to the URL of the CipherTrust Manager you want to use and log in with

CipherTrust Manager Administrator credentials.

2. If the client you want to protect is registered to the default domain (root), proceed to the next step. If you need to change to a different domain, do the following:
 - a. In the top menu bar, click the domain/user name (default: **root/admin**) on the right-hand side.
 - b. Select **Switch Domains**, then select the domain in which the client is registered.
 - c. The logged in user now shows the new domain name/user name.

3. In the CipherTrust Manager Applications Page, open the **CTE** application.
4. In the left-hand menu bar on the Clients page, click **Policies**.
5. Click **Create Policy**. CipherTrust Manager displays the Create Policy Wizard.
6. On the General Info page, set the following options:

Field	Description
Name	A unique name for the policy. Make sure you use a name that is descriptive and easy to remember so that you can find it quickly when you want to associate it with a GuardPoint. For example: LDT-Policy-West
Policy Type	Select Live Data Transformation.
Description	A user-defined description to help you identify the policy later. For example: LDT policy for the West Coast

Field	Description
	Datcenter.
Learn Mode	Learn Mode provides a temporary method for disabling the blocking behavior of CTE/LDT policies. While useful for quality assurance, troubleshooting, and mitigating deployment risk, Learn Mode is not intended to be enabled permanently for a policy in production. This prevents the policy Deny rules from functioning as designed in the policy rule set. Ensure that the policy is properly configured for use in Learn Mode. Any Security Rule that contains a Deny effect must have Apply Key applied as well. This is to prevent data from being written in mixed states, resulting in the loss of access or data corruption. Apply Key will have no effect when combined with a Deny rule unless the policy is in Learn Mode.

7. Click **Next**.
8. On the Security Rules page, define the security rules you want to use.

CipherTrust Manager automatically adds a default security access rule with an action of **key_op** and the effects **Permit** and **Apply Key**. This rule permits key operations on all resources, without denying user or application access to resources. This allows it to perform a rekey operation whenever the encryption key rotates to a new version. This rule is required by LDT, so you cannot edit it, move it, or delete it.

- a. If no process other than SQL Server's process needs access to clear data, then after the default security rule, create a security rule with:

Policy Element	Value
Process set	<code>path-to-sqlservr.exe</code>
Action	<code>all_ops</code>
Effect	<code>permit,apply key</code>

- b. The SQL Server process set for the second security rule should specify the path to `sqlservr.exe`, and optionally, select to sign that process when adding that process to the process set.

Create Process Set - Add Process

1 General Info 2 Add Processes 3 Confirmation

Add Process > Create Process

Add processes to the process set.

Directory

C:\Program Files\Git

Select

File

Git-cmd.exe

Signature

signsqlservr

Select

RWP Exempted Resource

RWP Exempted Resource

Select

Back

Add

- a. Create a third security rule:

Rule	Value	Note
Action	All_ops	
Effect	Permit, audit	Needed if each operation occurring on the database outside of <code>sqlservr.exe</code> will be audited.

9. On the Create Key Rule page, click **Create Key Rule** and enter the following information:

Field	Description
Resource Set	If you want to select a resource set for this key rule, click Select and either choose an existing resource set or create a new one. Resource sets let you specify which directories or files will either be encrypted with the key or will be excluded from encryption with this key.
Current Key Name	Click Select to choose an existing key or create a new one.

Field	Description
	If the data has not yet been encrypted, select clear_key . Otherwise select the name of the non-versioned key that is currently being used to encrypt the data.
Transformation Key Name	Click Select to choose an existing versioned key or to create a new one. CTE uses the versioned key specified in this field to encrypt the data in the GuardPoint. If the data is currently encrypted, CTE decrypts it using the key specified in the Current Key Name field and re-encrypts it using the key specified in this field.

Note

LDT now supports dynamic resource sets. This means that you can alter the resource set, and the policy will pick up the changed resource set and apply it. However, make sure that you **do not** mix encryption keys in your edited resource set. This will cause corruption.

When you are done specifying key rules, click **Next**.

Create a GuardPoint

1. Navigate to and select the directory containing *.mdf, *.ndf and *.ldf database files to guard.

- On the SQL Server, take the database offline so that CTE Agent can guard the database.

When the CTE Etray on the agent turns green, that indicates that the directory is now guarded. You can now bring the database back online.

- On the Confirmation page, review the information you entered and click **Save** when you are ready to save the policy.

Within a minute after the directory is guarded, either before or after the database is brought back online, LDT begins encrypting the files in the directory, including the database files (*.mdf, *.ndf and *.ldf), and any

other files in that directory or subdirectory. This LDT encryption activity includes all of the files in the the FileStream subdirectories in that guarded parent directory.

As the LDT activity is transparent, the database can be brought back online before or after this activity occurs. CipherTrust Manager will periodically update with the LDT percentage progress:

Verify Successful Encryption

To verify that the FileStream files are encrypted on a disk, open a file outside of SQL Server, using notepad or any desired application. Issue an SQL query to verify if `sqlservr.exe` is reading the decrypted data:

The screenshot shows a SQL query being executed in SQL Server Enterprise Manager. The query is `select * from Archive1.dbo.Records`. The results are displayed in a table with columns Id, SerialNumber, and Chert. The file explorer shows a directory containing several files with names like `0000002c-0000012c-0002`. A Notepad window is open, showing the decrypted content of one of the files, which is `new E=8w|`.

Id	SerialNumber	Chert
1	1	0x536569736D69632044617465
2	2	0x536569736D69632044617465
3	3	0x536569736D69632044617465
4	4	0x536569736D69632044617465

Once LDT completes, the status on CipherTrust Manager for that GuardPoint changes to **rekeyed**.

Backup an SQL FileStream Database

To backup a FileStream database using SQL, use SQL normally, however, if the backup file target location is outside of the guarded database directory, then that backup target location should be guarded as well. When utilizing SQL to backup a database, since `sqlservr.exe` is the process that creates the backup file and performs all of the database backups, the backup is encrypted inline and on disk for those writes when writing to that guarded backup directory. The backup includes the FileStream files in that backup.

Restore an SQL FileStream Database

To restore a FileStream database, restore the database as usual from a backup that was created either before, or after, the database was guarded by a LDT policy. (This is possible because LDT stores file metadata on each file, indicating if it is encrypted or not.) This is not supported though when guarding with a standard policy since no file metadata is stored on files for a standard policy. For a standard policy, any backup being restored, from within a guarded directory, needs to have been created after that directory was guarded with that standard policy. Otherwise, any older, unencrypted clear backup file needs to be outside of the guarded directory.

Conclusion

As `sqlservr.exe` is the only process that reads the decrypted data, avoid mixing accesses to SQL Server database backups across guarded directories and non-guarded directories. For example: If you use SQL to backup a database to a guarded directory, then outside of SQL Server, use explorer to copy that backup from the guarded directory to a non-guarded directory. Then using SQL to restore that backup results in undecipherable data being returned to `sqlservr.exe`. No corruption would occur, as the `sqlservr.exe` process would simply recognize that the file is not in SQL Server backup format and thus immediately fail to restore it. Copying the file back into a GuardPoint and then restoring it it would resolve the issue.

Guarding SQL Server FileTable databases with LDT

There are specific steps for guarding an SQL FileTables database which **must not** be deviated from to correctly and safely guard the FileTables directory.

The following steps are for the scenario where all of the remote systems, installed with CTE, are guarding the FileTables Virtual Network Name (VNN) directory, as well as the FileTables server.

Note

The remote agent, the LDT primary, encrypts the files in the VNN, but it does not encrypt the actual database. As well, all remote agents perform transparent encryption/decryption on the VNN. But the agent running on the SQL Server does not perform any encryption at all, not for LDT, or for the transparent encryption/decryption. It strictly provides access control.

The benefit of this scenario is access to the files in the VNN path are transmitted across the encrypted LAN, and the files on the FileTables server cannot be decrypted.

Even though the FileTables server does not decrypt the files, it must still have CTE installed and guarding the real path to prevent the SQL Server from backing up the FileTables files during LDT transformation.

Prerequisite

Create a CIFS connection with CIFS credentials that LDT will use:

1. Log on to CipherTrust Manager.
2. In the left nav-bar, click **Access Management > Connections**.
3. Select **+ Add Connection**.
4. In the **Select Connection Type**, click **More**.
5. From the **Select Connection** dropdown, select **CIFS/SMB** and click **Next**.
6. In the **General Info** section, enter the **Name** and **Description** for the connection and click **Next**.
7. In the Configure Connection page, enter valid values for:
 - **Host**: IP or FQDN of the SMB share server.
 - **Port**: The port where the SMB service is running on the host.

Note

The *Host* and *Port* fields must be specified together. If *Host* and *Port* are not specified while creating a connection, these fields cannot be added later.

- **Username**: Username to access the SMB share.
- **Password**: Password to access the SMB share.
- **Domain**: Workgroup or domain under which the username is configured. It is an optional field.
- (Optional) Click **Test Credentials** to validate the connection. If the test is successful, the status is **OK**, else the status is **Fail**.

Note

The *Host*, *Port*, and *Test Credentials* fields are mandatory for testing the connection credentials.

8. Click **Add Connection**.

Setup

1. Install [CTE agent for Windows](#) on the FileTables server and register the CTE clients to the CipherTrust Manager.
2. During registration, you **must** select Access Only to prevent this system's LDT from rekeying the files unsynchronized with the other systems.
3. Configure the FileTables server to treat all local GuardPoints as header-based. This is required because SQL Server FileTables technology does not support NTFS Alternate Data Streams (ADS), therefore, each file must contain a header for that file's LDT metadata for storage. Open the CLI with administrator privileges and type:

```
voradmin ldt header add 1 <path-to-GP>
```

Where

- Path is case sensitive
- Path only needs to be a partial matching substring of any part of that path

Example

```
voradmin ldt header add 1 FileTables
```

- This would match `e:\GPFileTables2`, but not `e:\GPfiletables2`
4. Use the following commands to list or delete the header information:

```
voradmin ldt header list
voradmin ldt header delete 1
```

5. Create a **DESKTOP_PRESENCE** file in the virtual network path. Type the following in the command line:

```
mkdir <VNN FileTable directory path>\.vorm_lgs

echo desktop > <VNN FileTable directory path>\.vorm_lgs\DESKTOP_PRESENCE
```

6. Create a policy for the FileTables server that prevents any local user, or any SQL Server, from accessing the clear data once it is encrypted.
 - For this scenario, no security rule can have apply key.
 - You **must** use the same encryption key for the policy used to guard the SQL FileTable Server, and the policy used to guard the VNN/FileTable directory from the ClientGroup.

7. Guard the real path that the SQL Server uses with that policy:

Example: If the database `.mdf` file is located at `e:\db4filetable`, then guard `E:\db4filetable`

8. Right-click on the database and take it offline. Select to drop the connections.
9. If necessary, restart the SQL Server instance to ensure all files are closed in each path to be guarded.
10. Once guarded successfully on the FileTables server, bring the SQL Server database back online.
11. Install CTE on each remote server that will access the VNN. During registration, **select the same Client Group** and **the same Communication Group** for each remote server.
12. You can also install CTE and register it as access-only on some systems. Those systems will not be able to access files that are actively being rekeyed, but they will reduce LDT cross-system communication traffic during rekey.
 - See [Configuring LDT for CIFS shares \(with LDT AccessOnly nodes\) Mapped to Multiple IP addresses](#) for more information.
13. Create a policy that each remote CTE agent will use:
 - a. Set up the security rules per customer's required access control for the Virtual Network Path (VNN). Grant users access to clear data

User set/Process Set Action: permit, apply key

- b. In the Client Group, guard the `Virtual_Network_Name/FileTable_directory` with that policy, and select the CIFS connection created as a prerequisite. Example:

```
VNN: \\192.168.93.89\FileTableShared\FileTableDB8\FileTableTb_Dir8_2
```

At this point, the Virtual Network Name paths should be accessible and return clear data from each remote system. Additionally, Live Data Transform should begin transforming the files accessed through the VNN on a remote primary agent automatically selected to perform LDT.

Accessing the files directly on the FileTables server itself, or querying the FileTables files through SQL, will return

the raw data of the file. This will include the LDT header followed by encrypted data.

SQL Server backups will backup the encrypted FileTables files with the database.

1. Once LDT has completed transforming the data, create a new database backup. Any restore operation should be performed from that new backup. If an older backup needs to be restored, then you must unguard and regard the VNN/FileTable directory GuardPoint from the client group once the older backup is restored, to recreate CTE metadata files in the GuardPoint.
2. LDT should be completed, or paused, before performing any restore of the database.

Unsupported FileTables Use Cases

CTE does not support the following use cases:

1. Install CTE agent on the SQL Server and locally apply the GuardPoint on the SQL Server storage.
2. Access FileTables with Transact-SQL.
3. Access FileTables with File I/O APIs on the SQL server. Perform all file I/O on the remote system running the CTE agent.

Integrating Imperva File Activity Monitoring (FAM) with CTE Windows

Software Requirements

Software	Minimum Version Required
CipherTrust Transparent Encryption	7.8.0.75
CipherTrust Manager	2.19 or subsequent versions

Overview of FAM on CTE agents

File Activity Monitoring (FAM) catalogs, monitors, and secures unstructured data (files). Unstructured data refers to any data that is not stored in databases. You can find these files locally, on the network, or in the cloud. FAM provides insights into data location, ownership, access history, permissions, protection, sharing, and sensitivity, enabling informed decisions about data protection.

For more information on FAM, see the [Introduction to the File Activity Monitoring User Guide](#)

CTE agents enabled with both File System Encryption and FAM capabilities can perform file system monitoring and audit file operations, as per the requirements of the Data Security Fabric (DSF) policies.

Scope of FAM on CTE host

Enabling FAM will also monitor activity on files outside of CTE GuardPoints.

Note

FAM will **not** monitor activity on RWP-enhanced files with CTE Ransomware Protection feature enabled

File Monitoring

The CTE agents monitor and audit user and application access to all files. Monitoring is not limited to files inside of CTE GuardPoints. Files outside of CTE GuardPoints are also monitored, except for those in the following directories:

Linux

```
/dev
/roc
/sys
/media
/opt/vormetric
/CTE-custom-install-location
```

Windows

```
\BOOT
\Windows
\Program Files*
\Users\*\APPDATA\ROAMING\MICROSOFT\WINDOWSAPPDATA\ROAMING\MICROSOFT\WINDOWS*
\Users\*\APPDATA\LOCAL\MICROSOFT\*
\Users\*\APPDATA\LOCAL\TEMP\*
\Users\*\APPDATA\LOCAL\PACKAGES\*
\Users\*\APPDATA\LOCAL\GOOGLE\CHROME\*
\PROGRAMDATA\MICROSOFT\*
\PROGRAMDATA\DELL\*
```

Also excluded from monitoring:

- VSS volumes
- DFSR private folders
- CSV volumes
- File operations performed by:
 - CTE internal processes
 - Thales Data Discovery and Classification processes
 - CTE-managed internal system operations
 - Metadata files

FAM Policies vs CTE Policies

FAM policies, which are similar to CTE policies with respect to security rules, allow you to monitor activity on specific data locations and/or by specific users. FAM policies only allow audit rules to specify/filter the content to be monitored. They do not impact access to the file.

Note

FAM policies are associated with the entire client, as compared to CTE policies which are limited to a particular GuardPoint path.

Performance Impact of FAM on CTE

File activity monitoring and audits consume system resources. This can potentially affect the performance of system and critical applications running on CTE agents. You can reduce the performance impact on the DSF management console by modifying the monitoring rules of the FAM policy applied to the CTE agent. For example:

- File operations, such as reading file attributes, are operations that are performed very frequently by applications and system utilities.
- If the CTE GuardPoint has policy rules with audit enabled, then with FAM also enabled, there may be additional overhead/performance impact due to the additional FAM policy evaluation and logging. However, the policy has no impact on file access/permissions.

Adjustments in the FAM policy to reduce, or eliminate highly frequent operations, can decrease the impact of FAM. Consult the FAM documentation for information on adjusting the FAM policy.

Enabling FAM on CTE Agent

You can enable FAM on CTE agent during CTE registration, or through the API.

Enable during Registration

After installing CTE, you enable FAM when registering, or re-registering, to CipherTrust Manager. During registration, you are prompted with the following two questions:

```
Do you want this host to have Filesystem encryption support enabled on the server? (Y/N) [Y]: Y
```

```
Do you want this host to have File Activity Monitoring support enabled? (Y/N) [N]: Y
```

Make sure that you answer **Y** to both questions.

Restart Secfs

For CipherTrust Manager v2.19 on **Linux**, post registration, you **must** restart **secfs**. This is **not** required for

CipherTrust Manager v2.20 and subsequent versions. To restart secfs:

1. Type:

```
/etc/vormetric/secfs stop
```

2. Type:

```
/etc/vormetric/secfs start
```

Enable through the CM API

You can enable FAM on CTE, post registration:

- As part of the CTE upgrade on reboot process.
- Through the CM API available for CM 2.20 and subsequent versions. See the API documentation available through the CipherTrust Manager software.
- Through the DSF management console. Refer to DSF documentation for more information.

Disabling FAM on CTE

- For CipherTrust Manager v2.19, you cannot completely disable FAM once enabled. However, you can remove the FAM policy associated with the client to temporarily disable FAM audit logging/monitoring.
- For CipherTrust Manager v2.20, you can disable FAM on CTE agent through the DSF management console or through the CM API. Refer to DSF documentation for disabling FAM on CTE agents.

Voradmin Support for FAM

The **voradmin** utility allows you to gather statistics and administer CTE on a host/client. It has slightly different syntax and command capabilities depending on whether the host/client is running in Linux or Windows. The voradmin command provides minimal support for FAM administration on CTE agents. You can check the state of FAM and the FAM policy name applied to the CTE host.

The following command reports the state of FAM, the FAM policy name applied to the CTE host, and the DSF GW configuration for forwarding FAM audits to the DSF GWs.

```
voradmin fam show config
```

FAM Output when policy not applied

Example

```
# voradmin fam show config
```

Response

```
FAM_STATE   : DISABLED
FAM_POLICY  : Not Applied
```

FAM Output when policy applied

Example

```
# voradmin fam show config
```

Response

```
FAM_STATE   : ACTIVE
FAM_POLICY  : fam-all-ops-policy
```

Limitation

- File path names included in the FAM audits that are generated from file operations performed inside Linux containers, or namespaces, under **chroot** enforcement, are relative to the directory created by the **chroot**, or container, as the root directory.
- CTE enforces a limit of 128 characters in the FAM policy names. FAM audits resulting from policies exceeding this limit, will have the policy name trimmed to the this limit.

CTE with Microsoft DFSR

The Microsoft Distributed File System Replication (DFSR) service is a multi-master replication engine used to keep folders synchronized on multiple servers. Using CTE with DFS(R) requires a unique configuration to make sure that all folders within a GuardPoint are only encrypted once, and that all sources to which those folders are replicated can access the proper encryption key to read the encrypted data.

This section contains the following topics:

- [Overview](#)
- [Terms and Topology](#)
- [Configure DFS\(R\)](#)
- [CTE Configuration Workflow](#)
- [Creating Required DFS\(R\) Policy Components](#)
- [Using the Standard/Offline Encryption Method](#)
- [Using the LDT Encryption Method](#)

- [Troubleshooting](#)

For more information about DFS(R), see the Microsoft DFS(R) documentation at [Distributed File System Replication](#).

Overview

This section details the CipherTrust software suite and will act as an operational (run book) guide for managing the CipherTrust security environment. It contains the steps to configure CTE agent on a Windows Server host running Microsoft Distributed File System (DFS) with Replication.

Microsoft introduced the Distributed File System in Server 2003 as a value-add for customers seeking low-cost data resiliency across high-latency, low-bandwidth WAN links. DFS is a free feature included with all subsequent versions of Windows Server software. DFS uses a namespace architecture where nested data folders use a replication service to synchronize similar data directories on 2 or more servers. Architects choose this model to ensure fault tolerance, preserve active uptime and to improve access performance by spreading the workload across many servers: client requests are routed to the nearest DFS folder for a given namespace. CTE began supporting DFS(R) starting with Windows 2012 R2 and continues to do so through Windows 2022 and subsequent versions.

Use this document for guidance on encrypting DFS data depending on how it is currently deployed. It contains a number of scenarios, often highlighting important configuration considerations applicable for the project. Before encrypting any DFS data, however, Thales Support assumes that the customer has made a backup of the latest production data, has a good understanding of their own DFS(R) deployment and has a fully-developed encryption plan.

The information listed here details best practices and tool sets when using encryption for DFS data. It starts by defining the terms and layouts for this technology and ends by reviewing common problems that may compound DFS(R) encryption and troubleshooting tips.

CTE Encryption Methods

CTE supports two encryption methods:

- **Standard offline data transformation**

Where the data is **unavailable** while it is being encrypted or rekeyed.

- **Live Data Transformation**

Where the data is encrypted and rekeyed in the background while it remains **accessible to users**. This method requires a separate license for the LDT feature.

While DFS(R) policies have some unique required components, the basic policy and GuardPoint creation process is identical to non-DFS(R) environments. For details about offline data transformation, see the [CTE Data Transformation Guide](#). For details about LDT, see the [CTE Live Data Transformation with CipherTrust Manager](#).

Considerations with DFS(R)

If you are using CTE in a DFS(R) environment, keep in mind the following:

- You should always back up your data prior to beginning the encryption process and you should have a full backup of the data in the hub server before you restore a spoke.

- You cannot place a GuardPoint *anywhere* on the boot drive, so if your DFS(R) replication point is currently `C:\`, or a directory under `C:\` such as `C:\data\`, you need to move that data and its replication point to a new volume on the server before you can encrypt it.

Note

Make sure that all GuardPoints are at, or above, the level of the DFS(R) replication point. For example:

- If the replication point is `D:\`, the CTE GuardPoint must also be at `D:\`. Adding a GuardPoint on a directory in `D:\`, such as `D:\data\`, fails.
- If the replication point is `D:\data\`, you can add a GuardPoint at `D:\data\` or `D:\`, but you *cannot* add a GuardPoint on a subdirectory of `D:\data\` such as `D:\data\HR-files\`.
- If you are backing up your DFS data, make sure that your backup software is not backing up the archive bit. File replication is triggered by file version change or a modified time stamp. As such, there is a chance that updating the archive bit may cause issues that trigger a replication storm, which will then put a heavy encryption load on the servers.
- When you set a replication point, Microsoft automatically creates a private directory called `<dir name>\DfsrPrivate` that resides with that replication point. For example, if the replication point is set on `D:\`, the private directory would be `D:\DfsrPrivate`. If the replication point is set on `D:\data\`, the private directory would be `D:\data\DfsrPrivate`.

How this private directory must be handled depends on the the encryption method that you are using.

- For **Standard** encryption, you must guard the private directory with the same policy that you use for the main GuardPoint. If the GuardPoint is at the root of the volume (for example, `D:\`), this happens automatically. But if you are guarding a specific directory, such as `D:\data\`, you need to create a second GuardPoint using the same policy on `D:\data\DfsrPrivate`.
- For **LDT**, you must guard the private directory with the same policy that you use for the main GuardPoint, even if the GuardPoint is at the root level. (For example, you must have a GuardPoint for both `D:\` and `D:\DfsrPrivate\`.) In addition, you must exclude this directory from LDT processing.
- The policy you specify for a DFS(R) GuardPoint **cannot** contain a resource set in any of the key rules included in the policy. All files in the guarded directory, and its subdirectories, must be encrypted with the same encryption key **without exception**. Additionally, if you rekey the GuardPoint, all files must be rekeyed with the same encryption key.
- If you want to change from one encryption key to an entirely different encryption key (as opposed to rekeying the data with a new version of the existing key), you must decrypt the data and remove all existing GuardPoints so that you have a clean environment. Then you can start the CTE encryption process over from the beginning.

Caution

You cannot change from one encryption key to another if any of the existing data is still encrypted with the old key. If you attempt to do so, you may encounter data replication errors and you may need to delete the entire volume and recreate it.

- When CTE encrypts data on a node, the encrypted data must be replicated to other nodes in the configuration. This may result in increased replication activity on the network.

Terminology and Topology

DFS(R) uses a compression algorithm known as remote differential compression (RDC). RDC detects changes to the data in a file and enables DFS Replication to replicate only the changed file blocks instead of the entire file. DFS(R) uses a database engine that keeps track of all file deltas and is used when reconciling replicated data across servers.

Term	Definition
DFS Namespace	A central namespace through which you can see a unified view of the shared folders that are included in the DFS.
DFS Namespace Server	The server that hosts the DFS Namespace. DFS Namespace Root is the top level of the DFS namespace. The namespace root and the DFS namespace use the same name.
DFS Folder	A folder presented to a client within the DFS namespace, but below the DFS root. A DFS folder can exist on the same server that is hosting the DFS root, but it is not required. DFS folders commonly represent file system resources located on other servers.
DFS Tree	A DFS tree is a reference to the DFS hierarchy. The tree starts with the DFS root, and contains all of the DFS folders defined within the root.
Replicated folder	A folder that stays synchronized on each member. As the data changes in each of the replicated folders, the changes replicate across connections between all members of the replication group.

In order to use DFS(R), administrators designate a namespace on a namespace server. Folders nested within the namespace contain all of the data that is distributed across many servers.

The **Tools** folder, in the preceding graphic, is part of a replication group composed of two servers, known as members, which participate in the replication of one or more replicated folders.

Creating multiple replicated folders in a single replication group simplifies the process of deploying replicated folders because the topology, schedule, and bandwidth throttling for the replication group are applied to each replicated folder. You can administer DFS(R) by using DFS Management, the DFS(R) Admin and DFS(R) diag commands, or scripts that call WMI. The connections between all members form the replication topology.

DFS(R) Topology

How you deploy CTE in a DFS(R) environment depends on the topology you have chosen for your DFS(R) configuration. Microsoft offers several topology options for DFS(R):

Hub and Spoke

In this configuration, there is a central server (an explicitly-designated hub) whose content is replicated on multiple satellite servers (the spokes). While each spoke server has a two-way communication channel with the hub server, none of the spoke servers can communicate with each other. If the data changes on one spoke server, that server communicates the changes back to the hub server and the hub server initiates the data replication on all of the other spoke servers.

This configuration allows you to encrypt servers one at a time, starting with the hub and then moving outwards to the spokes. This type of topology tends to be very efficient, but the problem with it is that if the initial master fails, then all replication ceases to function until it is online again. This topology is typically used for WANs that consist of faster network connections between major computing hubs and slower links connecting branch offices.

Full Mesh

A full mesh topology allows every replica to replicate with every other replica. In this configuration, data replication can be initiated by any server on all of the other servers. The advantage of using this topology is that replication continues functioning even if a server drops off-line. Users see no interruption in service. Deploying this model is useful for maintenance operations and satisfies data resiliency. The disadvantage to using this method is that it can result in an excessive amount of replication traffic.

As of Windows 2012, Microsoft added support for more than 5 replicas in a set. In addition, DFS(R) now supports multiple Namespaces: good for encrypting different namespaces with different AES keys (when required for “fencing” requirements).

In this configuration, you must stop the replication service while you encrypt the data on all servers in the mesh. You cannot restart the replication service until the initial encryption has completed on all servers.

No Topology

This option allows for creating a replication group without defining any replication topology. This means administrators may create their own custom replication topology later on.

Configure DFS(R)

Note

The following instructions were written for Windows 2016. If you are using a subsequent version, steps may differ slightly. See [Distributed File System Replication](#) for more information.

1. Launch the Server Manager applet.
2. Select **Tools > DFS Management**.
3. Right-click on Replication and select **New Replication Group ...**

4. For replication group, select **Multipurpose Replication Group**. Then click **Next**.
5. Enter a Replication Group name and the Domain name. Click **Browse** to select the domain. Then click **Next**.
6. In the Replication Group Members window, click **Add** and enter all of the DFS(R) replication group member servers. Then click **Next**.

7. Select the replication topology. Then click **Next**.
8. Set the replication schedule. Then click **Next**.

9. In the Primary Member section, select the Primary DFS(R) node. Then click **Next**.
10. In Folders to Replicate, click **Add**.
11. Click **Browse** and navigate to the folder on the primary node to place under DFS(R) replication.
12. Once the path is set, click **Permissions**.

13. Change the permissions or keep the existing folder permissions. Click **OK**.
14. On the local path for other members, click **Edit**.
15. Click **Browse** and select the target replication folder on the replication group member.

Note

If the path is different from the Primary member, then you cannot use CipherTrust Client Groups. You must set GuardPoints separately on individual member nodes.

16. Browse the folder structure for the member node and select the target replication folder. Click **OK**.

17. If the target replication folder displays correctly, click **OK** to continue. If it does not, click **Browse** and reset the folder.
18. Review the configuration and click **Create** if it all looks correct.

19. Click **Close** for a successful DFS(R) deployment.

Configure Namespace

DFS(R) namespace allows you to access the data remotely, through a network share path. For CipherTrust Transparent Encryption, it must have a policy that has a security rule that contains a user set. The user set must include privileged users linked to the process `ntoskrnl.exe`. This provides additional security for sensitive data protected on a DFS(R) folder.

1. In the DFS management tool, right-click on Namespace and select **New Namespace...**

2. Click **Browse** and search for the replication group member to host the namespace.
3. Select the node that will host the DFS(R) Namespace. Click **OK** and **Next**.
4. Enter a name for the Namespace and click Next.
5. Accept the default for the Domain-based namespace and click **Next**.

6. Review the settings and click **Create** to create the Namespace.

7. After a successful outcome, click **Close**.

Install the DFS(R) Role and Features

Consult the Microsoft documentation to install DFS by using Server Manager

Stopping and Starting the DFS Services

When setting up the topology, you will have to start and stop the DFS services. Following are the steps to stop and start the DFS services on a DFS management node. On all the nodes in a DFS(R) topology, there are two services running:

- DFS Namespace Service
- DFS Replication Service

Both of these services must be stopped before you can apply a CTE GuardPoint successfully:

1. Right-click on the start menu and click **Run**.

2. Type `services.msc` and hit enter. This launches the Services Management Console.
3. Locate the DFS Namespace and DFS Replication Services.
4. Select each one individually and click Stop.

CTE Configuration Workflow

In order to configure CTE with DFS(R), you must complete the following tasks:

1. Make sure you have a valid backup of the data you intend to encrypt.
2. Identify the volumes or folders you intend to encrypt.
3. Select an encryption method and make sure you understand how to create and deploy CTE GuardPoints using that encryption method. For details, see one of the following documents:
 - [CTE Data Transformation Guide](#)
 - [CTE-Live Data Transformation with CipherTrust Manager](#)
4. Create a DFS(R) Process Set and User Set for the policy. For details, see [Creating Required DFS\(R\) Policy Components](#).
5. Create the policies and GuardPoints you need to protect your data, using the process appropriate to the

selected encryption method. For details, see one of the following:

- [Using the Standard Encryption Method](#)
- [Using the LDT Encryption Method](#)

6. Consider configuring all nodes within a DFS topology under a single [CipherTrust Client Group](#)

Creating Required DFS(R) Policy Components

DFS(R) uses two services to for the replication process, `dfsrs.exe` and `ntoskrnl.exe` that must be associated with the NT AUTHORITY user. In order to do this, you need to create a process set and a user set that must then be combined into a security rule in the policy.

Note

Once you create these components, you can use them in any number of policies for both standard and LDT GuardPoints.

1. Log into the CipherTrust Manager Console and switch to the correct domain.
2. Launch the **Transparent Encryption** application.
3. In the left-hand menu bar, expand **Policies** and select **Policy Elements**.
4. Create a process set for the required DFS(R) processes:
 - a. Click **Process Sets**.
 - b. Click **Create Process Set**.
 - c. In the **Name** field, enter a name for this process set. In this example, we will use DFS(R)-Processes.
 - d. Click **Next**.
 - e. Enter the first DFS(R) process:
 - In the **Directory** field, enter `C:\Windows\System32\`.
 - In the **File** field, enter `dfsrs.exe`.
 - f. Click **Next**.
 - g. Below the table, click **Add Another Process**:
 - In the **Directory** field, enter `\SystemRoot\System32\`.
 - In the **File** field, enter `ntoskrnl.exe`.

h. Click **Next**. The process set should look like this:

Directory	File	Signature	
C:\Windows\System32\	dfsrs.exe		...
\SystemRoot\System32\	ntoskrnl.exe		...

Back Add Another Process Save

i. Click **Save** to save the process set.

5. Create the user set for the required **NT AUTHORITY** user:

a. Click **User Sets** tab.

b. Click **Create User Set**.

c. In the **Name** field, enter a name for the user set. In this example we will use **Local_NT_AUTHORITY**.

d. Click **Next**.

e. Click the **Manually Add Users** tab.

f. In the **uname** field, enter **SYSTEM**.

g. In the **OS domain** field, enter **NT AUTHORITY**.

h. Click **Next**. The user set should look like this:

uname	UID	gname	GID	OS domain	
SYSTEM				NT AUTHORITY	Remove

i. Click **Save** to save the user set.

j. Optionally, create another user set for other authorized users in the namespace. For example, you may want to add the "Administrator" user in each of the domains that are part of the namespace. You can create as many separate user sets as required.

6. Create the mandatory security rule for DFS(R):

The first security rule in a standard policy is for the DFS(R) process set (created in the previous section). This rule allows the DFS(R) processes to access the data and manage the replication under **DfsrPrivate** folder. The minimum permissions must be:

Rule	Permissions	Description
Process Set	DFS(R)_service	Contains the process <code>dfsrs.exe</code> and <code>ntoskrnl.exe</code>
Action	all_ops	Allows all read/write operations
Effect	Permit	Allows data to be copied/moved/replaced as encrypted

- When you have finished created the required components, you can use the components to create the appropriate policy for your chosen encryption method.

Using the Standard Encryption Method

If you want to encrypt your data using the standard (offline) encryption method, you need to create two different policies. The first policy is the initial encryption policy that specifies the symmetric key that you want to use to encrypt the data for the first time. The second is the production policy that you want to use for day-to-day operations on the encrypted data.

The initial encryption must be done while the volume or directory is offline, and users and applications must be prevented from accessing the data until the entire encryption process has finished. Once this initial encryption has been completed, any new or changed data in the GuardPoint will be automatically encrypted as it is added.

Note

If you want to encrypt the data without restricting access during the encryption process, you can use the LDT feature. For details, see [Using the LDT Encryption Method](#).

To use the standard encryption method:

- Make sure that you have created the required policy components for DFS(R) as described in [Creating Required DFS\(R\) Policy Components](#).
- Create the initial encryption and production policies as described in [Creating Standard Policies for DFS\(R\)](#).
- Create the GuardPoints that you want to use. The GuardPoint creation method depends on your DFS(R) topology. For details, see one of the following:
 - [Creating Standard GuardPoints with the DFS\(R\) Hub and Spoke Topology](#)
 - [Creating Standard GuardPoints with the DFS\(R\) Full Mesh Topology](#)

Creating Standard Policies for DFS(R)

If you are using the standard (offline) data encryption option, you need to create two policies, a data transformation policy that is used for the initial encryption and a standard policy that is used for day-to-day access of the encrypted data. The initial encryption policy is identical to the one you use for any standard GuardPoint. It is the standard policy that has DFS(R)-specific requirements.

How you create policies for DFS(R) depends on the key manager that you are using.

Procedure Using CipherTrust Manager

1. Log into the CipherTrust Manager Console and switch to the correct domain, if required.
2. Select **Keys** and select a symmetric key to use to encrypt the data, or create a new key to use for the DFS(R) namespace.
3. Launch the **Transparent Encryption** application.
4. In the left-hand menu bar, click **Policies**.
5. To create the **initial data encryption** policy, click **Create Policy** and enter the following information.

Note

The following example assumes you are using **dataxform** to encrypt the data in place. If you are using the copy or restore encryption method, create your initial data transformation policy as described in the [CTE Data Transformation Guide](#)

- a. In the **Name** field, enter a name for the policy. This example uses **DFS(R)-Std-Initial**.
- b. In the **Policy Type** field, select **Standard**.
- c. Enable the **Data Transformation** option.

Name *

DFSR-Std-Initial

Policy Type

Standard

Description

Learn Mode: ☐

Data Transformation: ☒

- d. Click **Next**.
- e. On the Security Rules page, make sure there is a security rule with the action **key_op** and the effect **permit, applykey**. If CipherTrust Manager did not add this security rule automatically, go back to the General Info page and make sure that the **Data Transformation** option is enabled.
- f. On the Security Rules page, click **Create Security Rule** and add another security rule that prevents any other process from accessing the data while it is being encrypted:
 - In the **Action** field, click **Select** and choose **all_ops**.
 - In the **Effect** field, click **Select** and choose **Deny**.

When you are done, click **Add** to save the security rule.

Resource Set	User Set	Process Set	Action	Effect	Browsing
			key_op	permit,applykey	Yes
	Local_NT_AUTH	DFSR-Processes		permit,applykey	Yes

- g. Click **Next**.
- h. On the Key Rules page, click **Create Key Rule**. In the **Current Key Name** field, click **Select** and choose **clear_key**.

Resource Set	Current Key Name	
	clear_key	...

Caution

In a DFS(R) environment, you must apply the initial encryption policy on unencrypted data **ONLY** (the current key must be set to clear_key). If your data is already encrypted, you must decrypt it and completely remove the existing GuardPoint before re-encrypting the data with a new key from scratch. For details, see [Considerations with DFS\(R\)](#).

- i. Click **Add** to save the key rule.
- j. Click **Next**.
- k. On the Data Transformation page, click **Create Data Transformation Rule**. In the **Transformation Key Name** field, click **Select** and choose the symmetric key you want to use for data transformation.
- l. Click **Add** to save the data transformation rule.

Resource Set	Transformation Key Name	
	DFS(R) Standard-Key	...

- m. Click **Next**.
 - n. Verify the policy information and click **Save** to save the initial encryption policy.
6. To create the **production policy**, click **Create Policy** and enter the following information.
- a. In the **Name** field, enter a name for the policy. This example uses **DFS(R) -Std-Policy**.
 - b. In the **Policy Type** field, select **Standard**.
 - c. Click **Next**.
 - d. On the Security Rules page, click **Create Security Rule** and add the following security rule:
 - In the **User Set** field, click **Select** and choose the user set you created that contains NT AUTHORITY. For details, see [Creating Required DFS\(R\) Policy Components](#).
 - In the **Process Set** field, click **Select** and choose the process set you created that contains the required DFS(R) processes `dfsrs.exe` and `ntoskrnl.exe`.
 - In the **Effect** field, click **Select** and choose **Permit**.

e. Click **Add**.

Resource Set	User Set	Process Set	Action	Effect	Browsing
*	Local_NT_AU...	DFS-R-Processes		permit,audit	Yes

f. Add any other security rules you need to your policy. When you have added all your security rules, click **Next**.

g. On the Key Rules page, click **Create Key Rule**. In the **Current Key Name** field, click **Select** and choose the symmetric key you used to encrypt the data in the initial data encryption policy.

Resource Set	Key Name
	DFS-R-Standard-Key

h. Verify the policy information and click **Save** to save the production policy.

7. To allow the system and users to access the metadata on files and folders under the DFS(R) path, you can include the metadata rule. Apply Key is not required because the metadata files and folders is never encrypted.

Rule	Permissions	Description
Action	f_rd_attr,f_rd_sec,d_rd,d_rd_attr,d_rd_sec	Allows all metadata read operations
Effect	Permit	Allows metadata to read files and folders.

8. When you have both policies ready, you can create the required DFS(R) GuardPoints as described in [Creating Standard GuardPoints with the DFS\(R\) Hub and Spoke Topology](#) or [Creating Standard GuardPoints with the DFS\(R\) Full Mesh Topology](#).

DFS(R) GuardPoint Considerations

Remember the following when configuring GuardPoints on protected data. Doing so ensures reliable replication of guarded data:

1. A GuardPoint may not be placed on any replicated folder on the BOOT drive. If the replication point is currently **C:**, consider moving it to another volume on the server (any non-BOOT drive) and use DFS utilities to re-populate any new namespace or target folder configurations. Then apply a GuardPoint to the replicated folder (dataxform or st_policy).
2. When a GuardPoint is not applied to an entire drive, ensure a sub-folder in the GuardPoint, named DFS(R) private, is also guarded with the same policy that is applied to the VDS GuardPoint. DFS(R) private is a hidden sub-folder immediately below the DFS(R) GuardPoint that is auto-generated when you configure a

folder as a DFS(R) GuardPoint. DFS(R) keeps intermediate configuration/state files in this sub-folder. The data in this folder constitutes an unstructured matchup of all data (and their deltas) organized in the DFS folders. Objects therein do not resemble their logical counterparts. Guarding this directory, however, is recommended, and will encrypt the data as intended.

Example

- If the DFS(R) GuardPoint, and the CTE GuardPoint are both `F:\data`, apply the same policy to `F:\data\DFS(R)` private that you applied to `F:\data`
- If the GuardPoint is `F:\data` and the DFS(R) pGuardPoint is `F:\data\data2`, apply the same policy to `F:\data\data2\DFS(R)` private that you applied to `F:\data`

Note

These rules apply only in situations in which the CTE GuardPoint and the DFS(R) GuardPoint are sub-directories. You do not need to guard the DFS(R) private sub-folder when the DFS(R) GuardPoint and the CTE GuardPoint are applied to the entire drive (e.g., both are the `F:\` drive).

3. A CTE GuardPoint must be the same as the DFS(R) GuardPoint configured on a folder, or the DFS(R) GuardPoint must be a sub-folder nested beneath the GuardPoint. Do not apply a GuardPoint on a sub-folder of the DFS(R) GuardPoint. Three consistency rules for Guardpoints on DFS folders:

DFS(R) GuardPoint	CTE GuardPoint	Works
<code>F:\</code>	<code>F:\</code>	Yes
<code>F:\data</code>	<code>F:\</code>	Yes
<code>F:\</code>	<code>F:\data</code>	No

Tip

- Administrators can accelerate replication completion by pre-populating target folders (seeding) with backup data.
- Always have a full backup of data in the hub node prior to restoring to a spoke.

Creating Standard GuardPoints with the DFS(R) Hub and Spoke Topology

Hub-and-spoke is the only topology that allows for encrypting the folders that need protection on each individual server, sequentially, starting with the Hub (think of it as the primary active node).

If you are using the hub and spoke DFS(R) topology, you should encrypt the data on the hub and then encrypt the data on the spokes. After you have encrypted the data on the hub server, you have two options for the data on the spoke servers:

- **Option 1: Delete the existing spoke server data and allow DFS(R) to replicate the encrypted hub data to all of the spoke servers.**

The advantage to this method is that you only need to encrypt the data on the hub. The disadvantage is that it will take time to replicate the data to all of the spoke servers.

- **Option 2: Encrypt each Spoke server using the same encryption process as you use on the hub server.**

The advantage to this method is that you do not need to wait for the full data replication process across the network. The disadvantage is that you must run the encryption process on all Spoke servers.

Prerequisites

- Make sure you have a valid backup of the data you plan to encrypt.
- Make sure you know what devices or directories you plan to protect.
- Make sure you understand how data transformation GuardPoints are created.
- Make sure you have an initial encryption and a production policy as described in [Creating Standard Policies for DFS\(R\)](#).

Note

The following procedures assume you are using `dataxform` to encrypt the data in place.

Procedure for Option 1: Use DFS(R) to Replicate the Encrypted Data

1. Disable user and application access to all devices and directories, on the hub server and all spoke servers, in the namespace, you intend to encrypt so that no users can add or change the data during the transformation process.

Note

You do *not* have to disable the namespace.

2. On the hub server:

- a. Stop the DFS(R) service.
- b. In your key manager, create the GuardPoints that you want to encrypt and apply the initial encryption policy to those GuardPoints.

Note

Make sure that all GuardPoints are at, or above, the level of the DFS(R) replication point. For example:

- If the replication point is `D:\`, the CTE GuardPoint must also be at `D:\`. Adding a GuardPoint on a directory in `D:\`, such as `D:\data\`, fails.
- If the replication point is `D:\data\`, you can add a GuardPoint at `D:\data\` or `D:\`, but you *cannot* add a GuardPoint on a subdirectory of `D:\data\` such as `D:\data\HR-files\`.

- Do not create GuardPoints for the `DfsrPrivate` directories yet.
- c. On the hub server, run the `dataxform` utility as described in the [CTE Data Transformation Guide](#).
 - d. After the data encryption process has completed, unguard the GuardPoints that use the initial encryption policy and guard them using the production DFS(R) policy.
 - e. If any of your GuardPoints are at the directory level, create a GuardPoint for the `<dir name>\DfsrPrivate` directory that goes with that GuardPoint. For example, If the GuardPoint is `D:\data\`, the private directory would be `D:\data\DfsrPrivate`. Make sure that you use the same production policy for the `DfsrPrivate` directory that you used for the main directory.

Warning

Do not start the DFS(R) service yet.

3. On each spoke server:
 - a. Stop the DFS(R) service on the spoke server.
 - b. Delete the data in all devices and directories that you added GuardPoints for on the hub server.
 - c. In your key manager, create the same GuardPoints on the spoke server that you created on the hub server, making sure that you apply the same standard policy to each GuardPoint on the spoke server that you applied on the hub server.

Make sure you also create the same `DfsrPrivate` GuardPoints on the spoke server that you created on

the hub server.

Note

Because the directories are empty, you do not need to use the initial encryption policy or the **dataxform** utility on the spoke servers. You can just guard the empty directory and the private directories directly using the production policy.

- a. **Start the DFS(R) service** on the spoke server.
4. Repeat the previous step for each spoke server in the configuration.
5. When every spoke server has the exact same production GuardPoints as the hub server, return to the hub server and do the following:
 - a. **Start the DFS(R) service** on the hub.
 - b. Force replication from the hub to the spokes.
6. When replication is complete for all spokes in the configuration, re-enable user and application access to the devices and directories that you encrypted.

Procedure for Option 2: Encrypt the Data on All Servers

1. Disable user and application access to all devices and directories that you intend to encrypt so that no users can add or change the data during the transformation process. This must be done on the hub server and all spoke servers in the namespace.

Note

You do not have to disable the namespace.

2. On the hub server:
 - a. Disable access to the hub server so that no one can change the data during the transformation process.
 - b. **Stop the DFS(R) service** on the hub.
 - c. In your key manager, create the GuardPoints that you want to encrypt and apply the initial encryption policy to those GuardPoints.
 - Make sure that all GuardPoints are at or above the level of the DFS(R) replication point.

-
- Do not create GuardPoints for the **DfsrPrivate** directories yet.
- d. Run the **dataxform** utility on the hub server as described in the [CTE Data Transformation Guide](#).
 - e. After the data encryption process has completed, unguard the GuardPoints that use the initial encryption policy and re-guard them using the production DFS(R) policy.
 - f. If any of your GuardPoints are at the directory level, create a GuardPoint for the **<dir name>\DfsrPrivate** directory that resides with that GuardPoint. For example, If the GuardPoint is **D:\data**, the private directory would be **D:\data\DfsrPrivate**. Make sure you use the same production policy for the **DfsrPrivate** directory that you used for the main directory.
 - g. [Restart the DFS\(R\) service](#) on the hub server.
3. On each spoke server:
 - a. Stop the DFS(R) service on the spoke server.
 - b. In your key manager, create the same GuardPoints on the spoke server that you created on the hub server. Make sure that you apply the same initial encryption policy to the GuardPoints on the spoke server that you applied on the hub server.
- Warning**

Do not create the **DfsrPrivate** GuardPoints yet.
- c. On the spoke server, run the **dataxform** utility.
 - d. After the data encryption process has completed, unguard the GuardPoints that use the initial encryption policy and re-guard them using the same production DFS(R) policy that you used for the corresponding GuardPoint on the hub server.
 - e. Create the same **DfsrPrivate** GuardPoints on the spoke server that you created on the hub server. Make sure that you use the same production policy for the **DfsrPrivate** directory that you used for the main directory.
 - f. Restart the DFS(R) service on the spoke server.
 - g. Re-enable user and application access to the spoke server.
4. Repeat the previous steps for each spoke server in the configuration.
 5. When data encryption is complete for all spokes in the configuration, re-enable user and application access to the devices and directories you encrypted.
-

Creating Standard GuardPoints with the DFS(R) Full Mesh Topology

If you are using the full mesh DFS(R) topology, you must restrict access to the data on all servers in the namespace until it has been encrypted on all servers in the namespace. That means the data will be inaccessible to users and applications until the encryption procedure has been completed on all servers.

Prerequisites

- Make sure you have a valid backup of the data you plan to encrypt.
- Make sure you know what devices or directories you plan to protect.
- Make sure you understand how data transformation GuardPoints are created.
- Make sure you have an initial encryption and a production policy as described in [Creating Standard Policies for DFS\(R\)](#).

Note

The following procedures assume you are using `dataxform` to encrypt the data in place.

Procedure

1. On **all** servers in the configuration:
 - Disable user and application access to all devices and directories you intend to encrypt so that no users can add or change the data during the transformation process.
 - [Stop the DFS\(R\) service.](#)
2. On one of the servers in the configuration:
 - a. In your key manager, create the GuardPoints that you want to encrypt and apply the initial encryption policy to those GuardPoints.

Note

Make sure that all GuardPoints are at, or above, the level of the DFS(R) replication point. For example:

- If the replication point is `D:\`, the CTE GuardPoint must also be at `D:\`. Adding a GuardPoint on a directory in `D:\`, such as `D:\data\`, fails.

- If the replication point is `D:\data\`, you can add a GuardPoint at `D:\data\` or `D:\`, but you *cannot* add a GuardPoint on a subdirectory of `D:\data\` such as `D:\data\HR-files\`.

- Do not create GuardPoints for the `DfsrPrivate` directories yet.

- Run the `dataxform` utility as described in the [CTE Data Transformation Guide](#).
 - After the data encryption process has completed, unguard the GuardPoints that use the initial encryption policy and re-guard them using the production DFS(R) policy.
 - If any of your GuardPoints are at the directory level, create a GuardPoint for the `<dir name>\DfsrPrivate` directory that goes with that GuardPoint. For example, If the GuardPoint is `D:\data\`, the private directory would be `D:\data\DfsrPrivate`. Make sure that you use the same production policy for the `DfsrPrivate` directory that you used for the main directory.
- Repeat the previous steps for each one of the servers in the configuration.
 - When you are finished, the production GuardPoints should be identical on every server in the namespace.
 - Restart the DFS(R) service on the each server in the namespace.
 - Re-enable user and application access to all devices and directories.

Using the LDT Encryption Method

If you want to encrypt your data using LDT, you need to create a Live Data Transformation policy and use that to create your GuardPoints. All encryption occurs in the background while users continue to access the data.

With LDT, the data will be automatically rekeyed periodically, based on the expiration date and the life span of the versioned key used to encrypt the data.

To use the LDT:

- Make sure you have created the required policy components for DFS(R) as described in [Creating Required DFS\(R\) Policy Components](#).
- Make sure that you have a versioned [encryption key](#).
- Create the LDT policy as described in [Creating a LDT Policy for DFS\(R\)](#).
- Create the GuardPoints you want to use as described in [Creating a LDT GuardPoint for DFS\(R\)](#).

Note

Make sure that all GuardPoints are at, or above, the level of the DFS(R) replication point. For example:

- If the replication point is **D:**, the CTE GuardPoint must also be at **D:**. Adding a GuardPoint on a directory in **D:**, such as **D:\data**, fails.
- If the replication point is **D:\data**, you can add a GuardPoint at **D:\data** or **D:**, but you *cannot* add a GuardPoint on a subdirectory of **D:\data** such as **D:\data\HR-files**.

5. Consider using [QoS](#) for optimal DFS(R) performance.

Creating an LDT Policy for DFS(R)

1. Log into the CipherTrust Manager Console and switch to the correct domain if required.
2. If you do not know which versioned key you want to use to encrypt the data, or you want to create a new key to use for the DFS(R) namespace, launch the Keys & Access Management application and locate an existing versioned key, or create a new versioned key. For details on creating a versioned key for LDT, see [Creating an Encryption key](#).
3. Launch the **Transparent Encryption** application.
4. In the left-hand menu bar, click **Policies**.
5. Click **Create Policy**.
6. Enter a name for the policy in the **Name** field.
7. In the **Policy Type** field, select **Live Data Transformation**.
8. Click **Next**.
9. On the Security Rules page, make sure there is a security rule with the action **key_op** and the effect **permit,applykey**. If CipherTrust Manager does not add this security rule automatically, go back to the General Info page and make sure that the policy type is set to **Live Data Transformation**.
10. On the Security Rules page, click **Create Security Rule** and add the following security rule:
 - In the **User Set** field, select the user set you created that contains **NT AUTHORITY**. For details, see [Creating Required DFS\(R\) Policy Components](#).
 - In the **Process Set** field, select the process set you created that contains the required DFS(R) processes **dfsrs.exe** and **ntoskrnl.exe**.
 - In the **Action** field, select **all_ops**.

- In the **Effect** field, select **Permit**.

11. When you are finished, click **Add** to save the security rule.

12. Add any other security rules that you need to your policy. When you are finished, click **Next**.

13. On the Key Rules page, click **Create Key Rule** and add the following key rule:

- In the **Current Key** field, select **clear_key**.

Caution

In a DFS(R) environment, you **must** apply the LDT policy on unencrypted data **ONLY** (the current key must be set to **clear_key**). If your data is already encrypted, you must decrypt it and remove the existing GuardPoints before re-encrypting the data with a new key.

- In the **Transformation Key** field, select the LDT versioned key that you want to use to encrypt the data.

14. When you are finished, click **Add** to save the key rule.

Resource Set	Current Key Name	Transformation Key Name	Exclusion Rule
	clear_key	DFSR-LDT-Key	No

15. Click **Next**.

16. Verify the policy information and click **Save** to save the LDT policy.

Creating a LDT GuardPoint for DFS(R)

Warning

Before you can create an LDT GuardPoint, you must set LDT to ignore the DFS(R) private directory that Microsoft automatically creates when you create a DFS(R) replication point. The private directory should **not** be encrypted by LDT.

1. Log into one of the DFS(R) servers in your network as an administrator.
2. For each GuardPoint that you intend to set up on the server, exclude the matching `DfsrPrivate` directory from the LDT process using the `voradmin ldt exlist add <guard path>` command.

For example, if you are going to guard `D:\data`, `G:\HR Files`, and the entire `F:` drive, you would use the following commands:

```
voradmin ldt exlist add D:\data\DfsrPrivate
voradmin ldt exlist add G:\HR Files\DfsrPrivate
voradmin ldt exlist add F:\DfsrPrivate
```

To make sure LDT is ignoring the proper directories, use the `voradmin ldt exlist get` command:

```
voradmin ldt exlist get
```

```
Live Data Transformation exclusion list. Following ${gp}s will be excluded from the Live Data Transformation.
```

```
G:\HR Files\DfsrPrivate
D:\data\DfsrPrivate
F:\DfsrPrivate
```

3. Reboot all of the LDT agent hosts before you create any LDT GuardPoints.
4. Repeat the previous steps on each server in your configuration before you create any LDT GuardPoints.
5. After you have excluded all `DfsrPrivate` directories on all servers from LDT processing, log into your key manager and set your LDT properties. When you begin the initial encryption, Thales recommends that you throttle the LDT processing speed with a CPU cap of 20%. You can increase this cap as more of the data is encrypted and there are fewer deltas between the DFS staging area and the production area.

To set the cap, launch the **CTE** application and create a Profile with the appropriate Quality of Service configuration parameters. Then make sure that all clients in the DFS(R) configuration use that profile.

6. Create the required LDT GuardPoints using the Live Data Transformation policy you created.

Create the same set of GuardPoints, using the same Live Data Transformation policies, on each server in the configuration. For example, if you set up the following GuardPoints for the first server:

Guard Path	LDT Policy Name
D:\data	LDT-Policy-Main
D:\data\DfsrPrivate	LDT-Policy-Main
F:\	LDT-Policy-Main
F:\DfsrPrivate	LDT-Policy-Main
G:\HR Files	LDT-Policy-HR
G:\HR Files\DfsrPrivate	LDT-Policy-HR

You must then set up the same six GuardPoints, using the same two LDT policies, on each server in the configuration.

CTE QoS Throttling and Rekey Scheduling

DFS(R) servers use a local database file for organizing and replicating file deltas. They employ many consistency checks, especially while processing large volumes of file changes. Furthermore, LDT requires a lot of system resources when encrypting target data for the first time. So consider throttling the encryption process for optimal DFS(R) performance. Best practice is to start low and increase steadily as the DFS staging areas shrink (fewer deltas).

QUALITY OF SERVICE CONFIGURATION

☐ Rekey by Rate

LDT QoS Rekey Rate (MB/s)

LDT Status Check Rate (in minutes)

☒ Rekey by CPU

☐ Cap CPU Allocation

CPU Percentage

QoS Schedules

LDT QoS Schedule: ANYTIME

Create New QoS Schedule

Name	Time Range
ANYTIME	Sunday 12:00 AM - Saturday 11:59 PM

The LDT Quality of Service can be controlled by either:

- Rekey Rate in MB/S
- Percentage of CPU usage
- Time schedule

Note

Rescheduling for off-hours and increasing CPU allocation are also best practices.

Troubleshooting

Common DFS(R) Configuration Mistakes

DFS(R) uses a staging area quota when processing replication tasks. If the allocated space is too small, performance is negatively impacted. An improperly sized staging area may also cause a replication loop among downstream nodes. Due to the intensive nature of encryption processing DFS data, you should evaluate your environment readiness. For more information about proper sizing techniques, see [How to Determine the Minimum Staging Area DFSR Needs for a Replicated Folder](#).

Review the following configuration mistakes as part of site readiness preparations:

Improper or Untested Seeding

To save downtime, administrators may choose to pre-seed new member replicas with DFS data before configuring all of the members in a replication group. In this manner, the initial synch consists of mostly delta changes rather than entire object transactions. See [Replacing DFSR Member Hardware or OS \(Part 2: Pre-seeding\)](#) for information on the advantages of pre-seeding.

Common issues include:

- ACL mismatch between source and target
- Changes were made to the files after they were copied to the new member
- No UAT testing was done to verify the pre-seeding process worked as expected

High DFS(R) Backlog

Customer DFS(R) deployments should be relatively up-to-date in replicating files across multiple nodes. High backlogs, especially over an extended period of time, mean that considerable amounts of data is out-of-sync. Unwanted conflict resolution may occur during these periods. Introducing encryption in this scenario would severely degrade performance and, likely require troubleshooting.

Hub Node – Single Point of Failure

The DFS primary active node is a single-point-of-failure in a Hub-and-Spoke topology. Fortunately, if the hub server goes down, all spoke servers retain the last-known-good data. All local changes are recorded locally and will not replicate until the primary node is back online. Spoke servers retain their own copies of their deltas and do not share them with others in the topology. You can confirm this risk, and confirm that offline backups are taken nightly to ensure optimal RTO (Recovery Time Objective).

Jet Database

DFS(R) maintains one Jet database per volume. As a result, placing all of your replicated folders on the same volume puts them all in the same Jet database. If that Jet database has a problem that requires repair or recovery of the database, all of the replicated folders on that drive are affected. It is better to spread replicated folders

around, using as many drives as possible to provide maximum uptime for the data.

Windows Server patch-level

Prepare for the deployment by checking for the latest software update for their DFS(R) servers. For replication, always make sure DFS(R) and NTFS are at least at the latest version listed. Proactively patching the DFS(R) servers is advisable, even if everything is running normally, as it will prevent your servers from being affected by a known issue.

DFS(R) as Backup

DFS(R) is not a bona fide backup solution. To be fully protected, customers must backup their data offline. DFS(R) was not designed as a backup solution. One of DFS(R)'s design goals is to be part of an enterprise backup strategy in that it gets your geographically distributed data to a centralized site for backup, restoration and archiving. Multiple members do offer protection from server failure; however, this does not protect your data from accidental deletions. Encrypting customer data should never occur without a full backup.

Stopping DFS(R) Replication

Sometimes, you may need to temporarily stop replication. Changing the replication status has consequences. The proper method is to set the schedule to no replication for the Replication Group in question. The DFS(R) service must be running to be able to read updates in the journal. Additionally, do not stop the DFS(R) service for long periods of time (days, weeks). Doing so may cause a journal wrap to occur (if many files are modified, added, or deleted in the meantime). DFS(R) will recover from the journal wrap, but in large deployments, this takes a long time and replication does not occur, or happens very slowly, during the journal wrap recovery. Monitor and prepare the environment prior to encryption.

File System Policies

Do not configure file system policies on replicated folders. The file system policy reapplies NTFS permissions at every Group Policy refresh interval. This can result in sharing violations because an open file does not replicate until the file is closed.

Backup Software

Having DFS data on other servers helps protect the data against a catastrophic failure, but does nothing to protect against data corruption. If a file becomes corrupted, the corruption gets replicated to other targets. Because the data should be identical on each DFS replica, backing up only one of the replicas is usually sufficient. Thales recommends that you backup at least the primary active node or hub.

Another important consideration regarding the backup process is that it is very critical to configure the backup software to not update the archival bit. The reason for this is that file replication is triggered by file version change or a modified time stamp. Therefore, there is a chance that updating the archive bit may cause issues that trigger a replication storm.

Troubleshooting DFS(R)

Unexpected problems may arise while encrypting replicated DFS data. Following are some of the common tasks recommended when configuring CipherTrust Transparent Encryption with DFS(R).

Encrypted Files Under DFSRPrivate Folder

In situations where the LDT Exclusion Registry key was deleted, and the LDT rekeyed files are under the

DFSRPrivate folder, following are the steps to reverse this.

On all nodes:

1. Stop DFS(R) service first on both nodes.
2. Add `LDTEExclusionGPList` to `vmmgmt/Parameters` with the path to `DFSRPrivate` if not already there.
3. Unguard the `DFSRPrivate` GuardPoint.
4. Open the command line as an administrator.
5. Copy the `DFSRPrivate` directory to a temporary backup, type:

```
xcopy "E:\DFSRTTest\DFSRPrivate" c:\backupOfDFSRPrivate /E /Y /H /Q /O /K
```

6. Delete all files in the `DFSRPrivate`, type:

```
del /S /Q E:\DFSRTTest\DFSRPrivate
```

7. Guard `DFSRPrivate` again.
8. Restart the DFS(R) service
9. Test replication of new files.

Double Encryption

A common cause for data corruption is that the data may have become double-encrypted. This can happen if existing encrypted data is written into a GuardPoint because it gets encrypted a second time. You can check for this by copying the data out of the GuardPoint into a clear location with a user who has 'apply_key' rights. Next, mount a GuardPoint on top of the copied data in the clear location using the same policy as the original GuardPoint. If the data then becomes viewable inside that newly mounted GuardPoint, this means that the data was double-encrypted.

To recover the data:

1. Copy all of the double encrypted data into a clear location.
2. Unguard the original GuardPoint.
3. Copy the data back into the original location that is now unguarded.
4. Re-guard the original GuardPoint. Data should now be viewable in the original GuardPoint.

Logs

Always download and parse the domain logs before doing anything else. Note the timestamp of certain DFS(R)-related error messages and compare them against similar timestamped log entries on the DFS servers. You may also run `agenthealth` on the DFS server to gather more extensive detail of the domain information.

The **agentinfo** support collection script resides in one of the following paths on systems where CTE agent is installed, depending on version:

```
C:\program files\vormetric\DataSecurityExpert\agent\vmd\bin  
C:\program files\vormetric\DataSecurityExpert\agent\shared\bin
```

The customers DFS environment may detail a lot of issues related to encrypting data, especially in relation to replicated, malformed or open handled data.

Different Keys for Different Folders

You may require that some folders be encrypted with a different key from others, perhaps due to a required SLA. Fencing the data is an excellent method for keeping different enterprise data separate. Normally, DFS nests target folders under one namespace. To encrypt the data, you would use a single key applied to the operational policy. However, if you want to use many keys, target folders must exist under a separate namespace. Windows 2012 and subsequent versions support multiple namespaces. Plan accordingly, allocating resources where necessary and staging target folders appropriately. This is also known as root scalability.

CTE Client Groups

Another consideration is the folders that are under DFS(R) control. If the folders and volumes are identical on all nodes of the DFS topology (i.e. F:\Data) then it is considered best practice to configure all nodes within a DFS topology under a single CipherTrust Client Group. This ensures consistency when apply Guard Paths across the DFS topology.

To create a client group:

1. Open the CTE application.
2. Click **Clients > Client Groups**.
3. Click **Create Client Group**. The Create Client Group dialog box displays.
4. Enter the following:
 - Client Group name: **DFSR**
 - Password creation method: **Generate**
 - Cluster Type: **Non-Cluster**
 - Client profile: The DFSR profile you created
 - Communication Enabled: Slide to activate
5. Click **Next**.
6. On the Add Clients window, select **Client group members** and click **Next**.
7. Select **Inherit Client Group Settings** and click OK.
8. On the Add GuardPoint page, click **Create GuardPoint**.

9. Select the DFSR Policy in the Policy section. Click **Browse** to browse to the host, select the DFSR mount point and DfsrPrivate folder, then click **Create**.
10. Confirm that the GuardPoints are correct and click **Next**.
11. On the confirmation page, verify all is correct and then click **Create**.

Mixed DFS(R) Topologies with Client Groups

In those environments where the DFS(R) folders are different on the individual nodes, then the GuardPoints must be configured for each DFS(R) node. Client groups cannot be deployed as the guard paths on each node will be different. In these cases, Thales recommends stopping the DFS services on this node before guarding the path. For a full Mesh topology, all of the nodes must be transformed and guarded at the same time. The last step after guarding the data is to [Start the DFS\(R\) services](#).

Encrypt Active Directory Database with Secure Start

This section describes encrypting a Microsoft Active Directory (AD) with the Secure Start feature. It contains the following topics:

- [Secure Start Overview](#)
- [Prerequisites](#)
- [Encrypt by Moving the AD Service into a Guarded Directory](#)
- [Encrypt Data in Place with Offline Transformation](#)
- [Encrypt with an LDT Transformation Policy](#)
- [Configure the Time Out Failure](#)
- [Recover a Server After it Loses Connection to the Key Manager](#)
- [Other Use Cases](#)
- [Best Practices for Encrypting and Protecting the AD Service](#)

Secure Start Overview

Secure Start offers data protection for applications which start earlier in the boot sequence than VMD (Vormetric Daemon). For example, the Microsoft Active Directory (AD) system service starts very early in the boot sequence. To determine if another application qualifies, contact Thales technical support.

Note

- Secure Start is included with CTE. You do not have to purchase it separately.

- Secure Start is supported on Windows Server 2008 R2 and later versions.
- When Secure Start is enabled, communication with CipherTrust Manager is required for security. After the Windows boot process completes, the CTE agent attempts to communicate with CipherTrust Manager for 2 minutes. If CipherTrust Manager cannot be reached after 2 minutes, then the CTE Agent initiates a reboot of the system.
- The challenge/response or password feature is disabled with secure boot GuardPoints.
- When Secure Start is enabled, communication with CipherTrust Manager is required for security. After the Windows boot process completes, the CTE agent attempts to communicate with CipherTrust Manager for 2 minutes. If CipherTrust Manager cannot be reached after 2 minutes, then the CTE Agent initiates a reboot of the system.
- The challenge/response or password feature is disabled with secure boot GuardPoints.

There are three methods for encrypting the AD directory:

- Encrypt by Moving the AD Service into a Guarded Directory
- Encrypt Data in Place with Offline Transformation
- Encrypt with an LDT Transformation Policy

Prerequisites

Prior to using Secure Start to guard your AD database:

1. Backup your AD database:
 - a. Navigate to **Administrative Tools**.
 - b. Click **Windows Server Backup**.
 - c. Click **Action > Backup Once**.
 - d. Follow the instructions in the Backup Wizard to create a backup of the server in a local drive.

Note

When the backup operation completes, it saves the server backup in *<backup drive>:\WindowsImageBackup\<BackupComputerName>*.

2. Perform a system state backup.
3. Obtain the Microsoft DSRM (Data Services Restore Mode) password.
4. Ensure that your AD database is not in `c:\Windows\NTDS`.

Warning

Do not put your AD database in `c:\Windows` or `c:\Program files`. Secure Start cannot encrypt or decrypt any files in those folders.

Encrypt by Moving the AD Service into a Guarded Directory

You can move the AD service into a directory protected by a standard or LDT production policy. This method does not require the initial data transformation step. When you move the AD service into this directory, CTE immediately encrypts the data with either policy.

Note

This step occurs when the system is in DSRM mode, so users have no access to the AD service.

Create the AD GuardPath directory

Create the directory in which the AD service will reside.

1. Log in to the Active Directory Server in DSRM mode using the DSRM password. User ID is Administrator.
2. Create a folder to which you will move the AD database.

Apply Secure Start GuardPoints to a Directory with CipherTrust Manager

To apply Secure Start GuardPoints in **CM**:

1. In the CipherTrust Manager Applications Page, click **CTE > Clients > <clientName>**.
2. Click **Create GuardPoint**.
3. In the Policy field, select a policy.
4. Set Type to **Auto Directory**.
5. Click **Browse**, navigate to, and select, the folder that you just created for the AD database.

6. Select the option: **Secure Start**.
7. Click **Create**.
8. Click **No** to the question, "Would you like to use these GuardPoint settings on another GuardPoint with a different path?" because you are only guarding the AD database.

Verify the Secure Start GuardPoint with CLI

After the policy is pushed to the Active Directory Server, verify the GuardPoints.

To verify the GuardPoints, type:

```
voradmin ss verify <GuardPoint_path>
Successfully completed the command verify
Success from kernel -Successfully verified the secure start GP
```

Move the AD Database into the Secure Start GuardPoint

Move your AD database from the default location (c:\windows\NTDS) to this newly created protected folder. To move the AD database:

1. In DSRM mode, login using the DSRM password. User ID is Administrator.
2. Start NTDSUTIL utility, type:

```
activate instance ntds
```

- a. Type:

```
files
```

3. Type:

```
move db to \<GuardPoint>
```

4. Type:

```
move logs to \<GuardPoint>
```

5. Exit NTDSUTIL utility.
6. Reboot the system into normal mode. The Active Directory Services automatically starts after rebooting.

Note

This step occurs when the system is in DSRM mode, so users have no access to the AD service.

Encrypt Data in Place with Offline Transformation

Encrypting the AD database with a standard (production), or offline policy is very similar to encrypting other data with a standard (production), or offline policy.

The advantage to encrypting data in place is that it saves space. When you copy/move a directory into a guarded directory, you will need twice as much space to store the data because you leave a copy of the data in the original folder, as a precaution, until the original directory has been successfully moved and encrypted. Once the data is transformed, then you can delete the directory that contains the decrypted/clear data.

Using this method, you perform an Initial Data Transformation using the **dataxform** command line utility. During this transformation, access to the GuardPoint data is blocked. After initial transformation, you remove the initial policy, and then apply a production policy, so users can access the data.

Note

This step occurs when the system is in DSRM mode, so users have no access to the AD service.

If your AD service is installed in the default directory, **C:\Windows\NTDS**, you must move it to another directory before you can encrypt it. See [Encrypt by Moving the AD Service into a Guarded Directory](#) for more information.

To encrypt the data:

1. In DSRM mode, login using the DSRM password. User ID is Administrator.
2. Create and apply a **dataxform** policy to the GuardPoint directory.
3. Run the **dataxform** command.
4. Remove the **dataxform** policy on the GuardPoint and replace it with a production policy.
5. Reboot out of DSRM mode.

Encrypt with an LDT Transformation Policy

Encrypting the AD database with an LDT policy uses the same steps as encrypting with a standard production policy. The only difference is that you select an LDT policy instead of a standard one. See [Encrypt by Moving the AD Service into a Guarded Directory](#) for more information for more information.

Note

If your AD service is installed in the default directory, `C:\Windows\NTDS`, you must move it to another directory before you can encrypt it.

Configure the Time Out Failure

During the initial access to a Secure Start GuardPoint, the CTE agent sets a timer. The default duration is 30 seconds, but you can configure the duration. Minimum duration is one second, maximum duration is 300 seconds.

Data inside the GuardPoint is accessible without CipherTrust Manager connectivity until the timeout is reached. VMD service activates and makes a secure connection to the CipherTrust Manager. After the VMD makes a secure connection, the agent verifies that it is connected to correct CipherTrust Manager. If the VMD fails to connect to the CipherTrust Manager, the timeout is reached, and if AD is installed, the agent shuts down the system for data security purposes.

Note

In DSRM mode, when the timeout occurs, CTE removes the keys from memory. However, CTE does not shut down the system.

In normal mode, CTE shuts down the AD server. For any other application, or if AD is not installed, Secure Start does not shut down the server. However, the data inside the GuardPoint becomes inaccessible until CipherTrust Manager connectivity is restored, or you issue a challenge/response, or password. After the timer has expired, CTE denies any further access to the Secure Start GuardPoint.

1. To configure the timeout duration in seconds, use the `voradmin ss settimeout <timeout>` command. For example:

```
voradmin ss settimeout 220
Successfully completed the command settimeout
Successfully set the Secure Start timeout value to 220 seconds
```

2. To verify the timeout duration, type:

```
voradmin ss gettimeout
Successfully completed the command gettimeout
Secure Start timeout value is set to 220 Seconds
```

Recover a Server After it Loses Connection to the Key Manager

Prerequisites

Before rebooting your active directory servers, ensure that CipherTrust Manager connectivity is strong. If it is not strong, restore the CipherTrust Manager connectivity.

Note

When trying to fix a CipherTrust Manager connectivity issue, you can log in to DSRM mode. In DSRM mode, there is no requirement to increase the timeout, because in DSRM mode, the AD system does not shut down after timeout expires.

DSRM Mode

The first method for recovering a server relies on manual CipherTrust Manager connection troubleshooting:

1. Boot into DSRM mode.
2. Attempt to resolve why the server is not connecting to the CipherTrust Manager.
3. Fix that CipherTrust Manager connectivity issue.
4. Reboot into normal mode.

Other Use Cases

Using Secure Start GuardPoints, you can also secure an SQL Server on Microsoft Azure in certain scenarios. SQL system services in Azure also boot earlier in the boot sequence than the VMD (Vormetric Daemon) agent service.

Note

To determine if another application qualifies, contact Thales technical support.

Boot a Windows Server in Azure

To move and guard the AD database, you must boot the AD server into DSRM mode.

To boot a Windows Server 2012/2016 Domain Controller into DSRM remotely in Azure:

Note

The Windows Server 2012/2016 domain controller must be running and accessible through Windows Remote Desktop.

1. Establish a Remote Desktop session on the domain controller.
2. Open an command prompt as Administrator and type:

```
> bcdedit /set safeboot dsrepair
```

3. Reboot the domain controller. The Remote Desktop session disconnects.
4. Wait a few minutes, then establish a new Remote Desktop session. The domain controller will be running in DSRM.
5. To reboot into normal mode, open an command prompt as Administrator and type:

```
> bcdedit /deletevalue safeboot
```

6. Reboot the domain controller.

Best Practices for Encrypting and Protecting the AD Service

Thales recommends the following best practices when using Secure Start with an AD service.

Access Control with Secure Start

User can setup a restricted access control policy with encryption to prevent the unauthorized access of AD database files. The restricted policy with Secure Start:

- Prevents a rogue user from logging into the system, and moving or copying the AD database files to another directory and tampering with it.
- Denies permissions, after you setup and guard files, so that no one can move a file from the guarded directory. Plus it restricts any other unwanted/unnecessary process or users from tampering with AD files.
- Provides permission for an authorized user who needs access to AD services and files.

Creating a Minimal Policy Required for AD with Access Control

When creating a normal, strict policy for access control, you must allow access to the following processes and directories for Active Directory.

Processes

```

secfsd.exe (C:\Program
Files\Vormetric\DataSecurityExpert\agent\secfs\ sec\bin\)
lsass.exe (C:\Windows\System32\)
vds.exe (C:\Windows\System32\)
vssvc.exe (C:\Windows\System32\)
wbengine.exe (C:\Windows\System32\)
ntoskrnl.exe (C:\Windows\System32\)

```

Users

NT AUTHORITY\SYSTEM

To create a minimal policy:

1. Create a User Set named **AD_Minimum_User_Set** with the following parameters:

ID	Uname	osDomains
1	SYSTEM	NT AUTHORITY

2. Create a Process Set named: **AD_Process_Set** with the following parameters:

ID	Directory	Base Name
1	C:\Program Files\Vormetric\ DataSecurityExpert\agent\secfs\ sec\bin	secfsd.exe
3	c:\Windows\ System32\ntoskrnl.exe	
4	c:\Windows\System32\vds.exe	
5	c:\Windows\System32\vssvc.exe	
6	c:\Windows\ System32\wbengine.exe	
7	c:\Windows\System32\lsass.exe	

3. Create a Security rule set with the following parameters:

Order	User	Process	Action	Effect	Browsing
1	AD_Minimum_U ser_Set	AD_Process_S et	all_ops	Audit, Permit, Apply	key
2				Audit, Deny	Yes

Creating a Restricted Policy in DSRM Mode

Create the following policy for the initial transformation of an AD database in DSRM mode. The policy allows access to the local administrator.

In DSRM mode, you use the **NTDSUTIL** utility to perform maintenance for an Active Directory.

To create a restricted policy:

1. Create a User Set named **AD_Minimum_User_Set** with the following parameters:

ID	uname	osDomains
1	SYSTEM	NT AUTHORITY
2	Administrator	localhost

2. Create a Process Set named: **AD_Process_Set** with the following parameters:

ID	Directory	Base Name
1	C:\Program Files\Vormetric\DataSecurityExpert\agent\secfs\sec\bin	secfsd.exe
2	c:\Windows\System32\	ntdsutil.exe
3	c:\Windows\System32\	ntoskrnl.exe
4	c:\Windows\System32\	vds.exe
5	c:\Windows\System32\	vssvc.exe
6	c:\Windows\System32\	wbengine.exe
7	c:\Windows\System32\	lsass.exe

3. Create a Security rule with the following parameters:

Order	User	Process	Action	Effect	Browsing
1	AD_Minimum_User_Set	AD_Process_Set	all_ops	Audit, Permit, Apply key	Yes
2				Audit, Deny	Yes

Guard Directories

The best practice for guarding a directory with a Secure Start GuardPoint is to:

1. Create a directory.

2. Guard that directory with a standard production or LDT policy. Follow the steps in [Apply Secure Start GuardPoints to a Directory with CipherTrust Manager](#).
3. Move the AD service into that directory.

Perform Subsequent System State Backups

After you move an AD service into a guarded directory, or out of a guarded directory:

1. Perform another system state backup.
2. Save this subsequent backup to a different location.

Exchange DAG

This section describes encrypting email databases using Microsoft Exchange database availability group (DAG). It contains the following topics:

- [Exchange DAG Overview](#)
- [CTE Policies for Exchange DAG](#)
- [Encrypting with LDT in an Exchange DAG Environment](#)
- [Encrypting with a Standard CTE Policy in the Exchange DAG Environment](#)
- [Decrypting with LDT in an Exchange DAG Environment](#)

Exchange DAG Overview

A DAG is a high-availability (HA) and data-recovery feature of the Microsoft Exchange Server. A DAG, which can consist of up to 16 Exchange mailbox servers, automates recovery at the database level after a database, server or network failure. You can now use CTE for Windows to encrypt Exchange DAG mailboxes.

You can encrypt the Exchange databases with a standard (offline) policy or an CTE-Live Data Transformation (LDT) policy. In an offline policy, users cannot access the database during initial data encryption. With an LDT policy, CTE encrypts the data while users and applications are accessing the files. LDT is used for Initial data transformation as well as transparent encryption and decryption.

Note

For more information about LDT and standard data transformation, see *CTE-Live Data Transformation with CipherTrust Manager*, *CTE-Live Data Transformation with Data Security Manager*, or the *CTE Data Transformation Guide*.

Supported Use Cases for CTE in an Exchange DAG Environment

CTE has been tested by Thales in the following scenarios:

- Initial data transformation of Exchange databases using either CTE-Live Data Transformation or standard data transformation.
- Transparent encryption or decryption of the Exchange database on DAG nodes.
- Key rotation using an LDT policy.
- Adding a new node to the Exchange DAG Environment.

Thales has only tested an Exchange DAG environment with two nodes, however, Thales does **not** anticipate any issues with using more than two nodes.

Thales also tested the following Exchange DAG operations during the above scenarios:

- Failover/Failback of databases from one node to another node and making both databases active on each node.
- Adding new Databases to the existing nodes.

Unsupported Use Cases

The following scenarios are not supported:

- Using different encryption keys on Exchange DAG nodes; both nodes must use the same encryption key
- The encryption of Exchange Binaries.
- Using nodes in a different subnet, data center, or site. (Thales is not testing this scenario, but we do not believe it will cause any issues.)

CTE Policies for Exchange DAG

The CTE policies you need depend on the type of encryption you will be using.

- When you use LDT encryption, you only need to create one Live Data Transformation policy. This policy will be used for both the initial data encryption and guarding the data in production. LDT requires a versioned CBC or CBC_CS1 key in order to perform automatic key rotation.
- When you use standard encryption, you need to create two policies:
 - The **initial encryption** policy specifies the current encryption key (if any) and the encryption key you want CTE to use when it encrypts the data. This policy also denies access to any other process trying to access the GuardPoint.

You apply the initial encryption policy when you first create the GuardPoint, and you leave it in place until all

of the data has been encrypted. After that, you remove this policy from the GuardPoint.

- The **production policy** specifies the same encryption key as the initial encryption policy along with any security rules you want to use to protect your data in production. After the initial encryption has completed, you apply the production policy to the GuardPoint and allow users and applications to access the now-protected data.

Note

There are no special CTE policy requirements for Exchange DAG with either LDT or Standard encryption. Therefore, you can use the same policies in an Exchange DAG environment that you use for any other CTE-protected directory.

The only special requirement for Exchange DAG is the guard path you specify when you create the GuardPoint. You must guard the Mailbox directory only. Do not guard above or below the Mailbox directory. For details, see [Encrypting with LDT in an Exchange DAG Environment](#) or [Encrypting with a Standard CTE Policy in the Exchange DAG Environment](#).

How you create these policies depends on the key manager that you are using. For details, see one of the following:

- [Creating a Policy for LDT Encryption with CipherTrust Manager](#)
- [Creating Policies for Standard Encryption with CipherTrust Manager](#)

Creating a Policy for LDT Encryption with CipherTrust Manager

When you use LDT encryption, you only need to create one policy. This policy will be used for both the initial data encryption and guarding the data in production. LDT requires a versioned CBC or CBC_CS1 key in order to perform automatic key rotation. For details, see the *CTE-Live Data Transformation with CipherTrust Manager* guide for the version of CTE that you are using.

1. Log into CipherTrust Manager and launch the **CTE** application.
2. In the left-hand menu bar, click **Policies**.
3. Click **Create Policy**.
4. For **Name**, make sure you use a name that clearly designates this as an LDT policy. You will need to be able to find this policy name from the list of all available policies when you create the GuardPoint.
5. For **Policy Type**, select **Live Data Transformation**.
6. Click **Next** to go to the Security Rules page. CipherTrust Manager should have automatically added a security rule for **Action: key_op**, **Effect: permit, applykey**. If this security rule is not there, click **Back** and make sure you have selected **Live Data Transformation** in the **Policy Type** field.
7. Enter any other security rules you want to use based on your production environment requirements. You can add as many security rules as you need to define who should have access to the protected data.

For more information about the type of rules you may want to use, or ways to exclude some data from encryption, see the *CTE-Live Data Transformation with CipherTrust Manager* guide for the version of CTE that you are using.

8. When you are done specifying your security rules, click **Next** to go to the Key Rules page.
9. Click **Create Key Rule** and enter the following information:
 - In the **Current Key Name** field, click **Select** to specify the current encryption key used for the data. If the data is unencrypted, specify `clear_key` as the encryption key.
 - In the **Transformation Key Name** field, click **Select** to specify the versioned encryption key you want to use to encrypt the data. When you are done, click **Add**.

Tip

You can also create a new key at this point if desired. For details on creating an encryption key, see your CipherTrust Manager documentation.

For example:

Resource Set	Current Key Name	Transformation Key Name	Exclusion Rule
	<code>clear_key</code>	VersionedKey-AES256	No ***

10. Click **Next** to go to the Confirmation page.
11. Verify your selections and click **Save** to save the policy.

Creating Policies for Standard Encryption with CipherTrust Manager

When you use standard encryption, you need to create two policies:

- The *initial encryption* policy specifies the current encryption key (if any) and the encryption key you want CTE to use when it encrypts the data. This policy also denies access to any other process trying to access the GuardPoint.

You apply the initial encryption policy when you first create the GuardPoint, and you leave it in place until all of the data has been encrypted. After that, you remove this policy from the GuardPoint.

- The *production* policy specifies the same encryption key as the initial encryption policy along with any security rules you want to use to protect your data. After the initial encryption has completed, you apply the production policy to the GuardPoint and allow users and applications to access the now-protected data.

Creating the Initial Encryption Policy

1. Log into CipherTrust Manager and launch the **CTE** application.
2. In the left-hand menu bar, click **Policies**.
3. Click **Create Policy**.
4. For **Name**, make sure you use a name that clearly designates this as an initial-encryption policy and not a production policy. You will need to be able to find this policy name from the list of all available policies when you create the GuardPoint.
5. For **Policy Type**, select **Standard**.
6. Enable the **Data Transformation** check box.
7. Click **Next** to go to the Security Rules page. CipherTrust Manager should have automatically added a security rule for **Action: key_op**, **Effect: permit, applykey**. If this security rule is not there, click **Back** and make sure you have enabled the **Data Transformation** check box.
8. Click **Create Security Rule** and do the following:
 - a. In the **Action** field, select **all_ops**.
 - b. In the **Effect** field, select **deny**.
 - c. Click **Add** to return to the Security Rules page.

You should now have two security rules, as shown:

Resource Set	User Set	Process Set	Action	Effect	Browsing
			key_op	permit, applykey	Yes
			all_ops	deny	Yes

9. Click **Next** to go to the Key Rules page.
10. Click **Create Key Rule**.
11. In **Current Key Name**, click **Select** to specify the current encryption key used for the data. If the data is unencrypted, specify **clear_key** as the encryption key. When you are done, click **Add**. For example:

Resource Set	Current Key Name
	clear_key

Tip

You can also create a new key at this point if desired. For details on creating an encryption key, see your CipherTrust Manager documentation.

12. Click **Next** to go to the Data Transformation page.
13. Click **Create Data Transformation Rule**.
14. In the **Transformation Key Name** field select the encryption key you want to use to encrypt the data. This key must match the one specified in the production policy you intend to apply to the GuardPoint after the data has been encrypted. For example, if you want to encrypt the data with the key CS1_AES256, you would specify the following transformation rule:

Resource Set	Transformation Key Name
	CS1_AES256

15. Click **Next** to go to the Confirmation page.
16. Verify your selections and click **Save** to save the policy.

Creating the Production Policy

1. Launch the **CTE** application.
2. In the left-hand menu bar, click **Policies**.
3. Click **Create Policy**.
4. For **Name**, make sure you use a name that clearly designates this as a production policy and not an initial encryption policy. You will need to be able to find this policy name from the list of all available policies when you create the GuardPoint.
5. For **Policy Type**, select **Standard**.
6. Click **Next** to go to the Security Rules page. Enter the security rules you want to use based on your production environment requirements. You can add as many security rules as you need to define who should have access to the protected data.
7. When you are done, click **Next** to go to the Key Rules page.
8. Click **Create Key Rule**.
9. In **Key Name** field, click **Select** to specify the encryption key used to transform the data in the initial encryption

policy. When you are done, click **Add**. For example:

Resource Set	Key Name
	CS1-AES256

10. Click **Next** to go to the Data Transformation page.
11. Click **Create Data Transformation Rule**.
12. In the **Transformation Key Name** field select the encryption key you want to use to encrypt the data. This key must match the one specified in the production policy you intend to apply to the GuardPoint after the data has been encrypted. For example, if you want to encrypt the data with the key CS1_AES256, you would specify the following transformation rule:

Resource Set	Transformation Key Name
	CS1-AES256

13. Click **Next** to go to the Confirmation page.
14. Verify your selections and click **Save** to save the policy.

Encrypting with LDT in an Exchange DAG Environment

Prerequisites

Before you can start the LDT data encryption process, you need to:

- Create or identify the CTE policy you want to use for data encryption. LDT uses a single Live Data Transformation policy for both initial encryption and subsequent rekeys, so the policy you use should have all the access control rules you want to use for your data when it is in production. For details, see [CTE Policies for Exchange DAG](#).
- Set your Quality of Service (QoS) settings. QoS enables administrators to manage and control LDT impact to application workloads by monitoring and controlling the use of host system resources, such as memory or I/O utilization, during data transformation.

For details about using LDT, see *CTE-Live Data Transformation with Data Security Manager* or *CTE-Live Data Transformation with CipherTrust Manager* for the version of CTE that you are using.

Procedure

1. In the **Exchange Admin Center**, make Exchange node 1 the primary node.

Make node 1 the active node and move all of the databases to that node.

2. Make all of the databases active on node 1.
3. Suspend all databases on node 2. Wait for 2-3 minutes for the database to finish with replication so the database will be suspended.

Warning

Make sure that all of the Exchange services in node 2 are down and not accessing the Exchange databases. All Exchange Services must be stopped, all databases must be suspended, and all data replication between the nodes must be stopped. Any file access on the node during the encryption process could cause data corruption.

4. When you are certain that all Exchange DAG services have been suspended on node 2, create the GuardPoints you want to use on node 2 with the appropriate Live Data Transformation policy. When you create the GuardPoints:
 - Make sure you are guarding each host individually. Do not assign the GuardPoints using a Host or Client Group because you only want these GuardPoints to exist on node 2 at this point.
 - **Important:** When you specify the guard path, only guard the Mailbox Database. Do *not* guard at a higher or lower directory. For example:
 - **Correct:** C:\Program Files\Microsoft\Exchange Server\V15\Mailbox\Mailbox Database 1088388171\
 - **Incorrect:** C:\Program Files\Microsoft\Exchange Server\V15\Mailbox\Mailbox Database 1088388171\Inbox\ — This is *not* correct because it's below the mailbox database directory.
 - Make sure that **Secure Start** is on for the GuardPoints.

The following example shows two correctly-specified GuardPoints in CipherTrust Manager:

Status	Policy	Protected Path	Type	Client Group	T	Rekey Status	Enabled	T
Active	Datashield...	C:\Program Files\Microsoft\Exchange Server\V15\Mailbox\Mailbox Database 2035273564	directory_auto	-		N/A	Yes	—
Active	Datashield...	C:\Program Files\Microsoft\Exchange Server\V15\Mailbox\Mailbox Database 1088388171	directory_auto	-		N/A	Yes	—

Live data transformation on node 2 begins as soon as the GuardPoints become active on node 2.

5. Wait until LDT has finished transforming the data in all GuardPoints on node 2.
6. In the **Exchange Admin Center**, go to the Exchange Database tab and **Resume** all Passive database copy

on node 2.

7. Wait for the server to move to the healthy state. If it does not, wait for some more time for the Content Index state to change to Healthy.

Warning

It may take a few minutes for the Exchange Service to resync. Monitor the Exchange logs on the system and make sure that replication is working. Make sure that database replication finishes and databases are in a healthy state before proceeding.

8. In the **Exchange Admin Center**, move all of the databases from node 1 to node 2.

Now the databases on node 1 are mounted as passive. All databases on node 2 are mounted as active.

9. Create the same GuardPoints on node 1 that you created on node 2.

Warning

- Make sure that all GuardPoints on node 1 are identical to those on node 2.
- You must guard the same databases with the same Live Data Transformation Policy and the same encryption key on both nodes.

Encrypting with a Standard CTE Policy in the Exchange DAG Environment

Prerequisites

Before you can start the standard (offline) data encryption process, you need to:

- Decide if you will be using the copy/restore method or the *CTEdatasync* utility in order to perform the initial encryption. For details about these methods and their specific benefits and limitations, see the *CTE Data Transformation Guide* for the version of CTE that you are using.
- Create or identify the encryption key that you want to use for the initial data encryption.
- Create or identify the Standard policies that you want to use for the initial data encryption and for protecting the data in production after it has been initially encrypted. For details, see [Creating Policies for Standard Encryption with CipherTrust Manager](#).

Procedure

1. In the **Exchange Admin Center**, make Exchange node 1 the primary node.

This means that node 1 is mounted as the active node and node 2 is mounted as the passive node.

2. Make all of the databases active on Exchange node 1.
3. Go to the Exchange Database tab and suspend all database on node 2.

Make sure that all of the exchange database services in node 2 are down and not accessing the Exchange databases. This process can take several minutes.

Warning

Make sure that all of the Exchange services in node 2 are down and not accessing the Exchange databases. All Exchange Services must be stopped, all databases must be suspended, and all data replication between the nodes must be stopped. Any file access on the node during the encryption process could cause data corruption.

4. When you are certain that all Exchange DAG services have been suspended on node 2, create the GuardPoints you want to use on node 2 with the appropriate Standard data transformation policy that you want to use for the initial data encryption. When you create the GuardPoints:
 - Make sure you are guarding each host individually. Do not assign the GuardPoints using a Host or Client Group because you only want these GuardPoints to exist on node 2 at this point.
 - **Important:** When you specify the guard path, only guard the Mailbox Database. Do not guard at a higher or lower directory. For example:
 - **Correct:** C:\Program Files\Microsoft\Exchange Server\V15\Mailbox\Mailbox Database 1088388171\
 - **Incorrect:** C:\Program Files\Microsoft\Exchange Server\V15\Mailbox\Mailbox Database 1088388171\Inbox\ — This is *not* correct because it's below the mailbox database directory.
 - Make sure that **Secure Start** is on for the GuardPoints.

The following example shows two correctly-specified GuardPoints in CipherTrust Manager:

Status	Policy	Protected Path	Type	Client Group	T	Rekey Status	Enabled	T
Active	Default...	C:\Program Files\Microsoft\Exchange Server\V15\Mailbox\Mailbox Database 2035273564	directory_auto	-		N/A	Yes	—
Active	Default...	C:\Program Files\Microsoft\Exchange Server\V15\Mailbox\Mailbox Database 1089388171	directory_auto	-		N/A	Yes	—

- After all GuardPoints on node 2 have been enabled, run the `dataxform` utility for each GuardPoint:

```
dataxform --rekey --print_stat --gp <directory>
```

- After the data transformation is finished, unguard each mailbox on node 2, then re-guard each mailbox on node 2 with the appropriate Production policy.

Note

Use the same Key/Policy on both nodes.

- In the **Exchange Admin Center**, go to the Exchange Database tab and resume all databases on node 2.

After a few minutes, all nodes should become Healthy.

Warning

It may take a few minutes for the Exchange Service to resync. Monitor the Exchange logs on the system and make sure that replication is working. Make sure that database replication finishes and databases are in a healthy state before proceeding.

- In the **Exchange Admin Center**, try to move a database from node 1 to node 2. If the data move is successful this means that node 2 is mounted as the active node and node 1 is mounted as the passive node.
- Create the same GuardPoints on node 1 that you created on node 2. Make sure that all GuardPoints on node 1 are identical to those on node 2.

Warning

You must guard the same databases with the same Standard Policy and the same encryption

key on both nodes.

Decrypting with LDT in an Exchange DAG Environment

Prerequisites

- Make sure that the LDT state is set to REKEYED before unguarding.
- Make sure that all of the files inside the GuardPoint are at the same version of the key.
 - Run the LDT report to find the version:

```
voradmin ldt report <GuardPoint path> [<logfile>]
```

- Run the Key map report to find the version:

```
voradmin ldt key [report|map] <key_name, version> <GuardPoint path>
```

Procedure

1. Make sure that all of the Exchange services in node 2 are down and not accessing the Exchange databases.

Note

Suspension can take 2-3 Minutes.

2. In the **Exchange Admin Center**, make Exchange node 1 the primary node.

This means that node 1 is mounted as the active node and node 2 is mounted as the passive node.

3. Make all of the databases active on Exchange node 1.
4. Go to the Exchange Database tab and suspend all databases on node 2.
5. Unguard the database folders that you previously guarded on node 2.
6. Delete all of the metadata on all of the database folders on node 2, type:

```
voradmin ldt attr delete [<file name path> | <guard path>]
```

7. Guard with an LDT policy set for Encryption to Clear on node 2.

Note

You must clone the current version of the encryption key to use as the current key in the new LDT policy and `clear_key` as the transformation key.

8. Go to the Exchange Database tab and resume all databases on node 2.

Note

After a few minutes, the databases should become healthy automatically. If not, wait for the LDT process to decrypt the data. Make sure that all of the data is transformed back to clear and that the LDT state is set to **REKEYED**.

9. Move the database from node 1 to node 2.
10. Repeat this procedure for node 1.
11. After both nodes are rekeyed and transformed from encryption to clear, unguard them:
 - a. In the **Exchange Admin Center**, make Exchange node 1 the primary node.

This means that node 1 is mounted as the active node and node 2 is mounted as the passive node. 2. Make all of the databases active on Exchange node 1.
 - b. Go to the Exchange Database tab and suspend all databases on node 2.
 - c. Unguard the database folders that you previously guarded on node 2.

Warning

Always ensure that you are unguarding a passive node.

- d. Repeat this procedure for Node 1.

Storage Spaces Direct

This chapter describes how CTE integrates with Windows Storage Spaces Direct (S2D) hyper-converged clusters. It contains the following sections:

- S2D Overview
- Deployment Options
- Supported Use Cases

S2D Overview

S2D uses industry-standard servers with local-attached drives to create high-availability (HA) software-defined storage. S2D is included in Windows Server 2019 Data center and Windows Server 2016 Data center, both of which are supported by CTE.

S2D extends the stack of usable storage devices to storage devices such as SATA and SAS HDD's, SSD's and NVMe (Non-Volatile Memory Express) disks to create shared disk volumes. S2D supports clusters of a minimum of two nodes, and a maximum of 16 nodes and 400 drives. S2D aggregates the available storage into a Storage Pool.

The hyper-converged deployment option runs virtual machines on the servers providing the storage.

A complete description of the S2D product, and instructions on how to set up the S2D environment is available on the Microsoft website at <https://docs.microsoft.com/en-us/windows-server/storage/storage-spaces/storage-spaces-direct-overview>

Deployment Options

CTE supports S2D in a hyper-converged infrastructure where computing and storage components are in a single cluster as shown in the following figure.

Hyper-converged infrastructure

Hyper-converged with S2D and CTE virtual machines run on the servers providing the storage. In the following figure, CTE is installed inside 6 of the VMs to protect the data.

High-Level view of S2D

You can use all the capabilities of CTE to protect the data in the VMs in a S2D hyper-converged deployment. These capabilities are described in [Supported Use Cases](#).

Supported Use Cases

Thales tested only Hyper-converged deployments in the following scenarios.

- Initial Data Transformation of data using:
 - Live Data Transformation
 - Offline Data Transformation
- Transparent Encryption/Decryption of structure and unstructured data
- Key rotation using a Live Data Transformation policy

Using CTE with Quantum StorNext

This chapter describes how to configure CTE and Quantum StorNext devices to interoperate to allow CTE policies to apply to storage managed by Quantum StorNext.

This section contains the following topics:

- [Overview of using CTE with Quantum StorNext](#)
- [CTE and Quantum StorNext Compatibility](#)
- [Setting up CTE and Quantum StorNext Integration](#)

Overview of using CTE with Quantum StorNext

Quantum StorNext Fibre Channel-connected devices provide shared file access to third party storage for workstation clients and are optimized for simultaneous access to very large files such as video files. The Quantum StorNext file system is known as SNFS or by its older name, CVFS.

You can encrypt and control access to SNFS files with policies by installing CTE Agents on Windows clients that are configured for access to the SNFS file system. Some limitations apply to this integration, such as supported operating systems, supported SNFS features, concurrent read/write access by multiple clients, and GuardPoint settings (see the next section for more information about these limitations).

CTE and Quantum StorNext Compatibility

The following sections list the supported operating systems and CTE settings supported for use with Quantum StorNext file systems. Important unsupported configuration parameters are also listed.

Supported StorNext Server and Client Configurations

The CTE integration with SNFS file systems works only with certain SNFS versions, SNFS storage policies, and client operating systems.

Configuration parameter	Windows
StorNext (SNFS) operating system version	6.x
StorNext metadata controller (MDC) server OS type	Windows MDC supported
StorNext replication policy	Not supported
StorNext deduplication policy	Not supported
StorNext truncation	Supported
StorNext full and partial backup	Supported
StorNext expand file system	Supported
StorNext data migration	Supported
StorNext read-ahead cache	Disable for use with CTE
Client operating systems	Windows Server 2012 R2, Windows Server 2016
StorNext LAN client	DLC
StorNext mount method: locally mounted directory	Supported
StorNext mount method: CIFS	Not supported
StorNext mount method: NFS	Not supported

Supported GuardPoint and Key Settings for SNFS File Systems

When configuring CTE GuardPoints and keys for SNFS, keep in the mind the compatibility limitations listed in the following table.

Configuration element	Windows
Offline data transformation	Supported
Live Data Transformation (LDT)	Not supported
Key manager compatibility	See the <i>Compatibility Matrix for CTE Agent with Data Security Manager</i> or the <i>Compatibility Matrix for CTE</i>

Configuration element	Windows
	<i>Agent with Data Security Manager</i> for your CTE version
Guard unstructured data	Supported
Guard structured data	Not supported
GuardPoint type: Directory (including entire SNFS volume)	Supported
GuardPoint type: Raw device	Not supported
GuardPoint type: Block device	Not supported
GuardPoint mount option: manual guard	Not applicable
GuardPoint mount option: auto guard	Supported
GuardPoint mount option: automount	Not supported
AES-CBC key type	Supported
AES-CBC-CS1 key type	Not supported

Supported Concurrent Access Read/Write Scenarios

If you want to allow access by multiple clients (users) to CTE-protected SNFS files under the same GuardPoint, just read-only access is supported. StorNext file locking is not implemented in CTE, so there is currently no way to prevent concurrent conflicting writes to the same file. As a result, Thales does not support write access to the same GuardPoint from multiple clients.

To enable read access to the same GuardPoint from multiple clients, ensure that all clients are configured to use the same policy and key.

Configuration parameter	Windows
Read/write access from a single LAN client to a GuardPoint	Supported
Read/write access from two or more LAN clients to the same GuardPoint	Not supported
Read-only access from one, two, or more LAN clients to the same GuardPoint	Supported

Setting up CTE and Quantum StorNext Integration

For the most part, CTE integration with Quantum StorNext is the same as for any standard file system. The next section provides an overview of the steps involved in making CTE work with SNFS. Later sections provide more information about the steps that are new or differ significantly from a typical CTE setup.

Integration Task Overview

The table below provides an overview of the steps involved in setting up SNFS and CTE to work together. As noted in the table, some of these tasks are described in the documentation for your selected key manager. Some of these steps may need to be performed by other staff members at your organization if you have divided the

security administration duties as recommended by Thales and you don't have access to the key manager.

Task	Key configuration notes	For more information
Install and configure a Quantum StorNext MDC server for use with CTE	Disable the StorNext read-ahead cache. Only certain StorNext policies, features, and mount types are supported. See Supported StorNext Server and Client Configurations .	See Installing and Configuring a Quantum StorNext MDC Server for Use with CTE .
Install and configure Quantum StorNext clients for use with CTE	Only certain operating systems are supported. See Supported StorNext Server and Client Configurations .	See Installing and configuring Quantum StorNext DLC Clients for Use with CTE .
Create a domain for one or more SNFS hosts, or add them to an existing domain	No difference from standard CTE agent configuration.	See "Domain Management" in your key manager documentation.
Add the host to the key manager	No difference from standard CTE agent configuration.	See "Configuring Hosts and Host Groups" in your key manager documentation.
Install and register the CTE Agent on the host system	No difference in installation.	See Getting Started with CTE for Windows
Create encryption keys (optional)	AES-CBC-CS1 keys are not supported on Windows. See the note in Supported GuardPoint and Key Settings for SNFS File Systems .	See "Managing Keys" in your key manager documentation. For information about AES-CBC-CS1 keys, see Enhanced Encryption Mode .
Configure host groups containing one or more StorNext LAN clients (optional)	No difference from standard CTE agent configuration.	See "Configuring Hosts and Host Groups" in your key manager documentation.
Configure policies (including user, process, and resource sets) to control access or enable encryption	No difference from standard CTE agent configuration.	See "Configuring Policies" in your key manager documentation.
Configure one or more GuardPoints	Some GuardPoint settings are not supported. See Supported GuardPoint and Key Settings for SNFS File Systems .	See "Managing GuardPoints" in your key manager documentation

Installing and Configuring a Quantum StorNext MDC Server for Use with CTE

Install and configure a Quantum StorNext metadata controller (MDC) server using the [Quantum StorNext documentation](#) as a guide. The CTE integration works with Windows StorNext MDCs. Ensure that you configure the StorNext server to work with the settings supported by CTE as listed in [Supported StorNext Server and Client Configurations](#). For example, you must disable the StorNext read-ahead cache and only certain StorNext policies, features, and mount types are supported.

Installing and Configuring Quantum StorNext DLC Clients for Use with CTE

Install and configure Quantum StorNext DLC clients using the [Quantum StorNext documentation](#) as a guide. The CTE integration works with Windows StorNext DLCs.

Ensure that you configure DLC clients to work with the settings supported by CTE as listed in [Supported StorNext Server and Client Configurations](#). For example, only certain operating systems are supported.

Note

Just read-only access is supported if multiple StorNext LAN clients will access files in the same GuardPoint. For more information, see [Supported Concurrent Access Read/Write Scenarios](#).

Choosing a Mounting Method

There are two methods for mounting a StorNext file system on Windows in the StorNext Client Configuration application:

- Map to Drive Letter
- Map to Directory

Both methods are supported in CTE. If you mount the StorNext file system using the Map to Directory method, you must create the directory on the Windows computer before assigning that directory in the Client Configuration application. For example, the default Map to Directory folder is `C:\Mount\snfs1`. If you use that default, you must create `C:\Mount\snfs1` before mounting the StorNext file system in the Client Configuration application.

If you change mounting methods (drive letter to directory or vice versa), you may need to close and reopen Windows Explorer or reboot the computer for the change to take effect.

Installing the CTE Agent on Each StorNext LAN client

Install a CTE Agent on each computer that is set up as a StorNext LAN client and for which you want to set policies. For supported operating systems, see the table in [Supported StorNext Server and Client Configurations](#).

Use any installation method supported for your operating system. For details, see [Getting Started with CTE for Windows](#).

Setting up Microsoft DPM with CTE

Microsoft System Center Data Protection Manager (DPM) is a robust enterprise backup and recovery system that contributes to your BCDR (Business Continuity and Disaster Recovery) strategy by facilitating the backup and recovery of enterprise data. The DPM is a server-agent configuration setup. DPM agent is usually pushed over to the managed host by the DPM server. See [Data Protection Manager](#) for more information.

Prerequisite

If you are using LDT, create two new LDT policies. If you are not using LDT, create two new standard policies.

LDT No-View policy

1. In CipherTrust Manager, create a new LDT policy.
2. In that policy, create a process set called **DPM process** which contains the following directory and file:

Directory	File
C:\Program Files\Microsoft Data Protection Manager\DPM\bin	DPMRA.exe

3. Create a security rule for a noview key that contains the following criteria:

Order	Field	Value
1	Action	key_op
	Effect	permit, applykey
2	Process Set	DPM process
	Action	all_ops
	Effect	permit, audit
3	Action	all_ops
	Effect	permit, applykey, audit
4	Action	all_ops
	Effect	deny, audit

Note

Once you have the policy with the Process Set (No-View) rule applied, you can guard any directory, disk, or even a bare metal system backup and recovery, and the encrypted data is backed up.

LDT Open Policy

1. In CipherTrust Manager, create a new LDT policy.
2. Create a security rule for an open key, (where the backup job backs up decrypted data to clear format), that

contains the following criteria:

Order	Field	Value
1	Action	key_op
	Effect	permit, applykey
2	Action	all_ops
	Effect	permit, applykey, audit
3	Action	all_ops
	Effect	deny, audit

Note

If you use an open security rule, the backed up data is not encrypted. You can restore the backup job to a baseline directory. It is clear and readable.

Standard No-View Policy

1. In CipherTrust Manager, create a new standard policy.
2. In that policy, create a process set called **DPM process** which contains the following directory and file:

Directory	File
C:\Program Files\Microsoft Data Protection Manager\DPM\bin	DPMRA.exe

3. Create a security rule for a noview key, (where the backup job backs up the encrypted data), that contains the following criteria:

Order	Field	Value
1	Process Set	DPM process
	Action	all_ops
	Effect	permit, audit
2	Action	all_ops
	Effect	permit, applykey, audit
3	Action	all_ops

Order	Field	Value
	Effect	deny, audit

Note

Once you have the policy with the Process Set (No-View) rule applied, you can guard any directory, disk, or even a bare metal system backup and recovery, and the encrypted data is backed up.

Standard Open Policy

If you are not using LDT, create a standard policy:

1. In CipherTrust Manager, create a new standard policy.
2. Create a security rule for an open key, (where the backup job backs up decrypted data to clear format), that contains the following criteria:

Order	Field	Value
1	Action	all_ops
	Effect	permit, applykey, audit
1	Action	all_ops
	Effect	deny, audit

Note

If you use an open security rule, the backed up data is not encrypted. You can restore the backup job to a baseline directory. It is clear and readable.

Installing and Setting up CipherTrust Transparent Encryption

1. Copy dataset `E:\office2007_bk` folder to `E:\data` folder.
2. [Install Windows CTE agent](#) and register the host to your key manager.
3. Using the policy that you created in the Prerequisites section, guard the `to E:\data` folder

Installing and Configuring DPM

- Setup and configure [DPM v2022](#) for your Windows 2019 Server.

Setting up DPM

1. Start **System Center 2022 DPM Administrator Console**.
2. Add a DPM Storage pool volume:
 - a. Click **Management > Disk Storage > Add**.
 - b. Select an available volume (ex. F:) and click **OK**.
 - c. Click **Yes** to allow DPM to format the volume before adding it to storage pool.
3. Create a **Protection Group**.
 - a. Click **Protection > New** and click **Next**.
 - b. Select **Server** and click **Next**.
 - c. Select **All volumes > E:\data** and click **Next**.
 - d. Enter the **Protection group name** (ex. Protection Group 1) and click **Next**.
 - e. Click **Specify Short-term Goals** and click **Next**.
 - f. Choose **Replica Creation Method (Automatically or manual)** and click **Next**.
 - g. Select **Run a consistency check if a replica becomes inconsistent** or **Run a daily consistency check according to the following schedule** and click **Next**.
4. Click **Create Group**.
5. Set up **Recovery**:
 - a. Click **Recovery > Select Recover** and click **Next**.
 - b. In Review Recovery Selection, select **Recover to the original location** or **Recover to an alternate location** and then enter the alternate location in the field and click **Next**.
 - c. Select recovery type:
 - Create Copy
 - Skip
 - Overwrite

-
- d. Click **Recover** to start.

Validating Setup

1. Run **Windiff** to compare the original dataset **E:\office2007_bk** folder and recovery GuardPoint **E:\data** folder. Make sure that there is no data corruption.
2. View a text file from **E:\restore**. Make sure that you see cipher text.
3. Using the policy that you created in the Prerequisites section, guard the **E:\restore** folder.
4. View a text file from GuardPoint **E:\restore** folder and make sure that you see clear text.
5. Run **Windiff** again to compare GuardPoint **E:\data** folder and the recovery GuardPoint **E:\restore** folder. Make sure that there is no data corruption.
6. Update GuardPoint **E:\data** folder by adding, deleting or modifying a text file.
7. In **DPM**, click **Protection**, then right-click on **E:\data** and select **Create recovery point**.
8. Choose **Create a recovery point after synchronizing** and click **OK**.
9. Click **Recovery**, then right-click on **E:\data** and select **Show All Recovery Points**.
10. Select latest protection and click **Recovery > Select Recover** and click **Next**.
11. In Review Recovery Selection, select **Recover to the original location** or **Recover to an alternate location** and then enter the alternate location in the field. Click **Next**.
12. Select recovery type:
 - Create Copy
 - Skip
 - Overwrite
13. Click **Recover** to start.
14. Using the policy that you created in the Prerequisites section, guard the **E:\restore1** folder.
15. Run **Windiff** to compare the GuardPoint **E:\data** folder and recovery GuardPoint **E:\restore1\data** folder. Make sure that there is no data corruption.

CipherTrust Transparent Encryption

Version: v7.8.0 (latest)

Contents

CTE Terminology 3

CTE Terminology

The guide uses the following terminology:

Term	Description
CTE	CipherTrust Transparent Encryption is a suite of products that allow you to encrypt and guard your data. The main software component of CTE is the CTE Agent, which must be installed on every host whose devices you want to protect. Note: This suite was originally called Vormetric Transparent Encryption (VTE), and some of the names in the suite still use "Vormetric". For example, the default installation directory is <code>/opt/vormetric/DataSecurityExpert/agent/</code> for Linux and AIX, and <code>C:\Program Files\Vormetric\DataSecurityExpert\agent\</code> for Windows.
CTE Agent	The software that you install on a physical or virtual machine in order to encrypt and protect the data on that machine. After you have installed the CTE Agent on the machine, you can use CTE to protect any number of devices or directories on that machine.
key manager	An appliance that stores and manages data encryption keys, data access policies, administrative domains, and administrator profiles. Thales offers CipherTrust Manager - a key manager for use with CTE.
host / client	In this documentation, host and client are used interchangeably to refer to the physical or virtual machine on which the CTE Agent is installed.
GuardPoint	A device or directory to which a CTE data protection and encryption policy has been applied. CTE will control access to, and monitor changes in, this device and directory, encrypting new or changed information as needed.

CTE Components

The CTE solution consists of two parts:

- The *CTE Agent software* that resides on each protected virtual or physical machine (host). The CTE Agent performs the required data encryption and enforces the access policies sent to it by the *key manager*. The communication between the CTE Agent and the key manager is encrypted and secure.

After the CTE Agent has encrypted a device on a host, that device is called a GuardPoint. You can use CTE to create GuardPoints on servers on-site, in the cloud, or a hybrid of both.

- A *key manager* that stores and manages data encryption keys, data access policies, administrative domains, and administrator profiles. After you install the CTE Agent on a host and register it with a key manager, you

can use the key manager to specify which devices on the host that you want to protect, what encryption keys are used to protect those devices, and what access policies are enforced on those devices.

Thales offers CipherTrust Manager, next generation key manager that supports most CTE for Linux and Windows features, most CTE features on Linux and Windows, and all CTE features on AIX.

CipherTrust Manager can be set up as either a security-hardened physical appliance or a virtual appliance. It provides access to the protected hosts through a browser-based, graphical user interface as well as an API and a CLI.

CipherTrust Manager versions support all CTE for Linux features *except* for the following:

- Container Security

Support for these features will be included in future releases of the CipherTrust Manager.

CipherTrust Manager versions 2.7 and higher support all CTE for Windows features *except* for the following:

CipherTrust Transparent Encryption

Learn Mode Tool 3

Learn Mode Tool

The Learn Mode Policy Builder (**lmpb**) is an OpenSource Python-based tool for processing the CipherTrust Transparent Encryption Learn Mode audit logs and generating security policies. Learn Mode allows access to guarded paths while logging access details. This tool helps administrators understand the gap between the current policy and the required policy and suggests corrective changes. The CipherTrust Manager and file system administrators are advised to review the changes before pushing them to CipherTrust Manager.

Note

This is an unsupported tool. Users are free submit request for enhancements and bugs, but Thales will not treat them as escalations.

Prerequisite

To collect logs that can be processed by the Learn Mode tool, enable the Learn Mode toggle on the CipherTrust Manager GUI while creating a policy.

Using the Learn Mode Tool

The Tool is available from the Thales site [CipherTrust Transparent Encryption Git repository](#).

After you have the logs for Learn Mode, proceed as follows:

1. Clone the CipherTrust Transparent Encryption Git repository.

```
git clone https://github.com/thalescpl-io/CipherTrust_Transparent_Encryption.git
```

2. Navigate to the `learn-mode-policy-builder` directory.

```
cd CipherTrust_Transparent_Encryption/tools/learn-mode-policy-builder
```

3. View the common commands.

```
./lmpb -h
```

Sample Output

```
usage: lmpb [-h] [--logdir LOGDIR] {log,policy} ...
```

```
positional arguments:
  {log,policy}
    log          cte learn mode logs
    policy       learn mode policy updates

options:
  -h, --help          show this help message and exit
  --logdir LOGDIR     log directory, defaults to /var/log/vormetric
```

Log Related Commands

```
./lmpb --logdir /home/logs/logs/ubu0/ log
```

Sample Output

```
positional arguments:
  {status,process,report}
    status          logs status
    process         process logs
    report          print log report in text format

options:
  -h, --help          show this help message and exit
```

View the log status:

```
./lmpb --logdir /home/logs/logs/ubu0/ log status
```

- If unprocessed logs are present, output displays as follows:

Sample Output

```
Found 181 log files in /home/logs/logs/ubu0/ with unprocessed entries.
Total size of unprocessed entries is 326.62 MB
```

- If all log files are already processed, output displays as follows:

Sample Output

```
No new log entries in /home/logs/logs/ubu0/ since Mon Dec 5 17:34:39 2022
```

- For processing the unprocessed log files, run the command:

```
./lmpb --logdir /home/logs/logs/ubu0/ log process
```

Sample Output

```
Successfully parsed all log files
Other log entries: 9, saved to /tmp/lmskip.340576
Log output saved as JSON at /home/logs/logs/ubu0/output.json
```

- Input the `output.json` file to Splunk to visualize the data.

```
cat /home/logs/logs/ubu0/output.json | nc 10.171.56.220 6666
```

In the example above, the SPLUNK server is configured to listen on port 6666 for `json_no_timestamp` events. The IP address `10.171.56.220` is an example.

- For viewing the log report:

```
./lmpb --logdir /home/logs/logs/ubu0/ log report
```

Sample Output

The output will show all processes, accesses performed by them, and the directories over which they have been performed.

```
Process: [ /sdb/anom/vtebuild/_obj_fspem_64_perf_vor_klinux_5.4.0-48-generi
c/build/env/linux/5.4.0-48-generic/build/scripts/genksyms/genksyms ]
Access: [ write_app read_file_sec_attr read_attr ]
Files/dirs: 20
-----
1 /sdb/anom/vtebuild/_obj_fspem_64_perf_vor_klinux_5.4.0-48-generic/crypto/
sha2/.tmp_sha256.ver
2 /sdb/anom/vtebuild/_obj_fspem_64_perf_vor_klinux_5.4.0-48-generic/vmcore/
cfg/.tmp_vm_cfg_upd.ver
3 /sdb/anom/vtebuild/_obj_fspem_64_perf_vor_klinux_5.4.0-48-generic/vmcore/
cfg/.tmp_vm_cfg.ver
...
19 /sdb/anom/vtebuild/_obj_fspem_64_perf_vor_klinux_5.4.0-48-generic/vmcor
e/common/.tmp_hexbin.ver
20 /sdb/anom/vtebuild/_obj_fspem_64_perf_vor_klinux_5.4.0-48-generic/vmcor
e/ktctl/.tmp_vm_tc.ver
```

After the logs are processed by the Learn Mode policy builder tools, the following policy related commands can be run to list the existing policies or show updates recommended by the tool.

Policy Related Commands

```
./lmpb --logdir /home/logs/logs/ubu0/ policy
```

Sample Output

```
positional arguments:
  {list,show,upload}
  list                list policies with learn mode updates
  show                show learn mode policy updates
  upload              upload learn mode policy to CM

options:
  -h, --help          show this help message and exit
```

- List the policies with Learn Mode updates:

```
./lmpb --logdir /home/logs/logs/ubu0/ policy list
```

Sample Output

```
Policies with learn mode updates:

audit
```

- Show Learn Mode policy updates:

```
./lmpb --logdir /home/logs/logs/ubu0/ policy show
```

Sample Output

```
User sets:
  audit-uset-0
    [ audit ]
  audit-root-uset-1
    [ root ]

Process sets:
  audit-group-pset-0
    [ /sdb/anom/vtebuild/_obj_pem_64_perf_vor_ulinux_ubuntu20/mk/generate_messages_h.pl
      /usr/bin/dh_installdeb /usr/bin/dh_testroot /usr/lib/rpm/check-files /usr/lib/gcc/x86_64-linux-gnu/9/collect2 /usr/bin/ar /sdb/anom/vtebuild/_obj_fspem_64_perf_vor_klinux_5.4.0-48-generic/build/env/linux/5.4.0-48-generic/build/scrip
```

```

ts/mod/modpost /usr/bin/make /bin/gzip /usr/bin/fakeroot
...]

audit-group-pset-1
[ /bin/mount /bin/df /bin/chmod /usr/bin/make /bin/bash /bin/sh /usr/bin/fa
keroot /usr/bin/updatedb.mlocate /bin/ls ]

Resource sets:
audit-rset-0
[ /sdb/anom* ]

Security rules:
Rule 0
  User set      audit-root-uset-1
  Process set   audit-group-pset-1
  Resource set  audit-rset-0
  Action        d_chg_att,d_rd_att,d_rd_sec,f_rd,d_rd
  Effect        permit,applykey
Rule 1
  User set      audit-uset-0
  Process set   audit-group-pset-0
  Resource set  audit-rset-0
  Action        f_ren,d_chg_att,f_rm,d_rmdir,f_cre,d_rd_att,f_chg_sec,writ
e,f_rd_sec,d_rd_sec,f_rd_att,f_chg_att,f_wr,f_wr_app,f_rd,d_mkdir,d_rd
  Effect        permit,applykey

```

- Policies can be viewed based on users or processes. By default, it is user-based.

```
./lmpb --logdir /home/logs/logs/ubu0/ policy show --type user
```

- The output of policy show in this case will be sorted, based on user sets. This is the default setting for policy show command.

```
./lmpb --logdir /home/logs/logs/ubu0/ policy show --type process
```

- The output of policy show in this case will be sorted, based on process sets.

Sample Output

```

  Process set   audit-which-pset-26
  Resource set  audit-rset-2
  Action        d_rd_att
  Effect        permit,applykey
Rule 11
  User set      audit-root-uset-1
  Process set   audit-ls-pset-57
  Resource set  audit-rset-0
  Action        d_rd_att,d_rd,d_rd_sec
  Effect        permit,applykey
...

```

Uploading Policy to CipherTrust Manager

- To upload the policy to the CipherTrust Manager, run the command:

```

./lmpb --logdir /home/logs/logs/ora policy upload --policy-name LEARNMODE --typ
e user --upload-name learn-mode-policy --cmaddr IP-ADDR-OF-CM --username admin
--password PASSWORD

```

The above command will upload a policy to the CipherTrust Manager with modifications on top of the original policy suggested by the Learn Mode policy builder tool. Note that the above command will fail if the original policy is not found on the specified CipherTrust Manager.

CipherTrust Live Data Transformation

Zero-Downtime Encryption and Key Rotation

Apply encryption and access controls to files, volumes and Hadoop environments without taking applications offline

- Meet compliance requirements for encryption and access control without taking applications offline
- Expand encryption implementations with minimal impact on application operations and users
- Reduce the impact and cost of implementing encryption by eliminating encryption and rekeying downtime
- Accelerate recovery of data encrypted with older keys

The challenge: implementing and maintaining encryption with minimal application impact

In the face of escalating threats and compliance mandates, data encryption has become a best practice component integral to layered IT security strategies. For many, two critical barriers to the adoption of encryption with existing databases, files, and big data implementations have been:

A database protected with CipherTrust Transparent Encryption and Live Data Transformation enables non-disruptive initial encryption and simplified, more-compliant encryption key rotations. Users continue to work as usual while encryption is in process.

- **Initial encryption time.** With a large dataset, the process of initially converting from clear-data text to ciphertext has typically meant that applications using the data must be taken off-line during the initial conversion process. Even when state-of-the-art cloning and synchronization techniques are used, there is substantial downtime. For mission critical applications required to run with “five nines” of uptime, this can result in failure to meet SLAs, operational disruptions, and loss of revenue.
- **Downtime caused by re-keying of data sets.** Best practices and compliance regimes frequently require encrypted data be re-keyed with a new encryption key at specified intervals. This operation typically requires a large maintenance window, and results in the same disruption level as initially encrypting the data. The result is IT, compliance, and security teams face tough decisions about the balance between security, availability, uptime, and levels of compliance.

The solution: CipherTrust Live Data Transformation extension for CipherTrust Transparent Encryption

Customers have relied on CipherTrust Transparent Encryption for over a decade. It eliminates many of the challenges associated with implementing encryption in an enterprise. CipherTrust Transparent Encryption breaks down data security silos, encrypts both structured databases and unstructured files, centralizes key management across the enterprise, and provides privileged user access controls and detailed data access audit logs that integrate with major Security Information and Event Management (SIEM) systems.

CipherTrust Transparent Encryption operates with minimal disruption, effort, and cost. Its transparent architecture enables security organizations to implement encryption without changing application, networking, or storage architectures.

CipherTrust Live Data Transformation builds on these advantages, offering patented capabilities that deliver breakthroughs in availability, resilience, and efficiency.

Delivering patented capabilities for deploying and maintaining encryption without downtime

- **Zero-downtime encryption deployments.** CipherTrust Live Data Transformation enables administrators to encrypt data with minimal downtime or any disruption to users, applications, or workflows. Users need to plan minimal application downtime to configure Live Data Transformation policies, after which applications continue to work with no downtime while encryption is in progress.
- **Seamless, non-disruptive key rotation.** To address compliance requirements and best practices, Live Data Transformation enables organizations to perform key rotation without having to duplicate data or take associated applications offline.

Key features

CipherTrust Transparent Encryption agents operate on Windows and Linux servers that store or access any data that needs to be secured and controlled. CipherTrust Live Data Transformation is enabled in the CipherTrust Manager by applying a license for each agent on which it will operate. CipherTrust Live Data Transformation licenses can be enabled at any time, at which point users can secure their mission-critical data without any disruption or maintenance windows.

Live Data Transformation includes features to assure that its operation is transparent to users and applications independent of the size and scale of the deployment:

- **CPU resource management.** Encrypting large data sets can require significant CPU resources for an extended time. Live Data Transformation provides sophisticated CPU management rules to enable administrators to balance resources between encryption and other CPU operations upon which users depend. For example, a resource management rule can define that, during business hours, encryption can consume up to 10% of system CPU, reserving the balance of 90% for users. Then, the rule can define that on nights and weekends, encryption can consume 70%, when there are lower user demands on CPU resources. And encryption and re-keying processes can be manually paused and resumed as desired.
- **Versioned backups and archives.** With key versioning management, CipherTrust Live Data Transformation ensures efficient backup and archive recovery to enable more immediate access. In a data recovery operation, archived encryption keys, recovered from the CipherTrust Manager, are automatically applied to an older data set. Restored data is encrypted with the current cryptographic keys.
- **Resiliency.** By storing encryption metadata with the target files or database volumes, CipherTrust Live Data Transformation is resilient in the face of storage failures, system issues, or network downtime. Any interrupted encryption process will seamlessly recover without having to have the entire process restarted. This architecture ensures that data is never corrupted, no matter how, when, or where a failure occurs, and, scales with the size of the file system, rather than being limited by design.

About Thales

The people you rely on to protect your privacy rely on Thales to protect their data. When it comes to data security, organizations are faced with an increasing number of decisive moments. Whether the moment is building an encryption strategy, moving to the cloud, or meeting compliance mandates, you can rely on Thales to secure your digital transformation.

Decisive technology for decisive moments.

CipherTrust Live Data Transformation

Zero-Downtime Encryption and Key Rotation

Apply encryption and access controls to files, volumes and Hadoop environments without taking applications offline

- Meet compliance requirements for encryption and access control without taking applications offline
- Expand encryption implementations with minimal impact on application operations and users
- Reduce the impact and cost of implementing encryption by eliminating encryption and rekeying downtime
- Accelerate recovery of data encrypted with older keys

The challenge: implementing and maintaining encryption with minimal application impact

In the face of escalating threats and compliance mandates, data encryption has become a best practice component integral to layered IT security strategies. For many, two critical barriers to the adoption of encryption with existing databases, files, and big data implementations have been:

- **Initial encryption time.** With a large dataset, the process of initially converting from clear-data text to ciphertext has typically meant that applications using the data must be taken off-line during the initial conversion process. Even when state-of-the-art cloning

A database protected with CipherTrust Transparent Encryption and Live Data Transformation enables non-disruptive initial encryption and simplified, more-compliant encryption key rotations. Users continue to work as usual while encryption is in process.

and synchronization techniques are used, there is substantial downtime. For mission critical applications required to run with “five nines” of uptime, this can result in failure to meet SLAs, operational disruptions, and loss of revenue.

- **Downtime caused by re-keying of data sets.** Best practices and compliance regimes frequently require encrypted data be re-keyed with a new encryption key at specified intervals. This operation typically requires a large maintenance window, and results in the same disruption level as initially encrypting the data. The result is IT, compliance, and security teams face tough decisions about the balance between security, availability, uptime, and levels of compliance.

The solution: CipherTrust Live Data Transformation extension for CipherTrust Transparent Encryption

Customers have relied on CipherTrust Transparent Encryption for over a decade. It eliminates many of the challenges associated with implementing encryption in an enterprise. CipherTrust Transparent Encryption breaks down data security silos, encrypts both structured databases and unstructured files, centralizes key management across the enterprise, and provides privileged user access controls and detailed data access audit logs that integrate with major Security Information and Event Management (SIEM) systems.

CipherTrust Transparent Encryption operates with minimal disruption, effort, and cost. Its transparent architecture enables security organizations to implement encryption without changing application, networking, or storage architectures.

CipherTrust Live Data Transformation builds on these advantages, offering patented capabilities that deliver breakthroughs in availability, resilience, and efficiency.

CipherTrust Transparent Encryption and Live Data Transformation are available for sale to the U.S. Federal Government exclusively through Thales Trusted Cyber Technologies.

Delivering patented capabilities for deploying and maintaining encryption without downtime

- **Zero-downtime encryption deployments.** CipherTrust Live Data Transformation enables administrators to encrypt data with minimal downtime or any disruption to users, applications, or workflows. Users need to plan minimal application downtime to configure Live Data Transformation policies, after which applications continue to work with no downtime while encryption is in progress.
- **Seamless, non-disruptive key rotation.** To address compliance requirements and best practices, Live Data Transformation enables organizations to perform key rotation without having to duplicate data or take associated applications offline.

Key features

CipherTrust Transparent Encryption agents operate on Windows and Linux servers that store or access any data that needs to be secured and controlled. CipherTrust Live Data Transformation is enabled in the CipherTrust Manager by applying a license for each agent on which it will operate. CipherTrust Live Data Transformation licenses can be enabled at any time, at which point users can secure their mission-critical data without any disruption or maintenance windows.

Live Data Transformation includes features to assure that its operation is transparent to users and applications independent of the size and scale of the deployment:

- **CPU resource management.** Encrypting large data sets can require significant CPU resources for an extended time. Live Data Transformation provides sophisticated CPU management rules to enable administrators to balance resources between encryption and other CPU operations upon which users depend. For example, a resource management rule can define that, during business hours, encryption can consume up to 10% of system CPU, reserving the balance of 90% for users. Then, the rule can define that on nights and weekends, encryption can consume 70%, when there are lower user demands on CPU resources. And encryption and re-keying processes can be manually paused and resumed as desired.
- **Versioned backups and archives.** With key versioning management, CipherTrust Live Data Transformation ensures efficient backup and archive recovery to enable more immediate access. In a data recovery operation, archived encryption keys, recovered from the CipherTrust Manager, are automatically applied to an older data set. Restored data is encrypted with the current cryptographic keys.
- **Resiliency.** By storing encryption metadata with the target files or database volumes, CipherTrust Live Data Transformation is resilient in the face of storage failures, system issues, or network downtime. Any interrupted encryption process will seamlessly recover without having to have the entire process restarted. This architecture ensures that data is never corrupted, no matter how, when, or where a failure occurs, and, scales with the size of the file system, rather than being limited by design.

About Thales Trusted Cyber Technologies

Thales Trusted Cyber Technologies, a business area of Thales Defense & Security, Inc., protects the most vital data from the core to the cloud to the field. We serve as a trusted, U.S. based source for cyber security solutions for the U.S. Federal Government. Our solutions enable agencies to deploy a holistic data protection ecosystem where data and cryptographic keys are secured and managed, and access and distribution are controlled. For more information, visit www.thalestct.com

CipherTrust Transparent Encryption

Ensure the protection of sensitive data with advanced data-at-rest encryption, robust access controls, and comprehensive audit logging for data access. Achieve compliance and adhere to best practices with a reliable hardware-accelerated encryption solution that secures files, volumes, and connected cloud storage across physical, virtual, and cloud environments.

Challenge: Securing Sensitive Data Across Changing Environments and Increasing Threats

Safeguarding sensitive data requires much more than just securing a data center's on-premises databases and files. The typical enterprise today uses three or more IaaS or PaaS providers, along with fifty or more SaaS applications, big data environments, container technologies, and their own internal virtual environments and private clouds.

To further complicate the problem, cyberattacks have grown in sophistication and power. New compliance and regulatory mandates around protection of sensitive information keep on coming, and existing regulations have become more stringent. SAS PCE Enterprise IAM can seamlessly integrate with existing infrastructure and applications, minimizing disruptions and ensuring smooth operations.

Solution: CipherTrust Transparent Encryption

CipherTrust Transparent Encryption delivers data-at-rest encryption with centralized key management, privileged user access control, and detailed data access audit logging that helps organizations meet compliance and best practice requirements for protecting data, wherever it resides. The FIPS 140-3 L1 certified CipherTrust Transparent Encryption agent resides at the operating file-system or device layer, and encryption and decryption is transparent to all applications that run above it. CipherTrust Transparent Encryption provides rich access controls, which allow organizations to determine who can access data, when they can access it, and what type of access they have.

Key Requirements for Securing Sensitive Data-at-Rest:

- **Compliance and best practices:** Meet encryption, access control, and data access logging requirements with a proven, hardware-accelerated encryption solution. Secure files, volumes, and linked cloud storage, while enabling detailed access controls and audit logging across physical, virtual, and cloud environments.
- **Simple, scalable deployment:** Easily deploy a solution that scales across multiple clouds, on-premises, big data, and container environments. Centralized key management, encryption,

and access policies ensure streamlined operations.

- **Privileged user access control:** Protect sensitive data by enabling administrators to continue their work while preventing unauthorized access by potential threats among users and groups.

- **Actionable security insights:** Utilize detailed, actionable security event logs to gain valuable insights into file access activities and quickly detect and stop potential threats.
- **Broad platform support:** Secure both structured and unstructured data across Linux, FreeBSD, AIX, and Windows systems. Extend transparent encryption and access controls to data stored in S3 buckets.
- **No downtime for encryption and re-keying:** Use the Live Data Transformation connector to eliminate downtime during initial encryption and re-keying processes. This unique feature sets CipherTrust Transparent Encryption apart from other solutions.

Key Features

Transparent data protection: Continuously enforces file-level encryption that protects against unauthorized access by users and processes and creates detailed data access audit logs of all activities without requiring changes to applications, infrastructure, systems management tasks, or business practices.

Seamless and easy to deploy: CipherTrust Transparent Encryption agents are deployed on servers at the file system or volume-level and support both local disks as well as cloud storage environments, such as Amazon S3 and Azure Files.

Define granular access controls: Apply granular, least-privileged user access policies that protect data from external attacks and

misuse by privileged users. Specific policies can be applied by users and groups from systems, LDAP/Active Directory, Hadoop and containers. Controls also include access by process, file type, time of day, and other parameters.

High-performance hardware accelerated encryption: CipherTrust Transparent Encryption only employs strong, standard-based encryption protocols, such as the Advanced Encryption Standard (AES) for data encryption and Elliptic Curve Cryptography (ECC) for key exchange. Encryption overhead is minimized using the AES hardware encryption capabilities available in modern CPUs.

Comprehensive security intelligence: Identify and stop threats faster with detailed data access audit logs that not only satisfy compliance requirements, but also enable data security analytics.

In addition, security intelligence logs and reports streamline compliance reporting and speed up threat detection using leading security information and event management (SIEM) systems.

Broadest system and environment support: The agent is available for a broad selection of Windows, Linux, and AIX platforms, and can be used in physical, virtual, cloud, Kubernetes and big data environments, regardless of the underlying storage technology.

Advanced Security Benefits

Integration with cloud and container environments: Protects data in dynamic cloud and container environments.

Key rotation: Automatically rotates encryption keys to enhance security.

Data destruction: Ensures sensitive data is permanently erased when no longer needed.

Zero-downtime data transformation: Live Data Transformation option eliminates the downtime required for initial encryption and scheduled rekeying operations. This patented technology allows for databases or files to be encrypted or re-keyed with a new encryption key while the data is in use without taking applications off-line.

SAP HANA and teradata qualified: SAP and Teradata have qualified CipherTrust Transparent Encryption with SAP HANA and Teradata database respectively to deliver data encryption, key management, privileged user access control, and granular file access audit logs

CipherTrust transparent encryption userspace: Provides scalable and robust file encryption solution based on Linux FUSE that is not affected by kernel upgrades on Linux servers.

Solution Architecture

Deployment consists of CipherTrust Transparent Encryption connectors and CipherTrust Manager appliances. Policy and key management is centralized at the CipherTrust Manager. The CipherTrust Manager is available as a FIPS 140-2 Level 1 or FIPS 140-2 Level 3 with HSM compliant appliance.

Data-at-rest security wherever it resides

Benefits of CipherTrust Transparent Encryption:

Enhanced Data Security:

Data-at-rest encryption: Protects sensitive data from unauthorized access, even if the underlying storage is compromised.

Centralized key management: Manages encryption keys securely, reducing the risk of key exposure.

Privileged user access control: Controls access to encrypted data, even for privileged users, ensuring data confidentiality.

Improved Compliance:

Detailed data access audit logging: Provides a comprehensive audit trail, helping organizations meet compliance requirements such as PCI DSS, HIPAA/HITECH, and GDPR.

Strong data protection: Enhances overall data security posture, reducing the risk of data breaches and regulatory fines.

Operational Efficiency:

Transparent encryption: Encrypts data without requiring changes to applications or user workflows, minimizing disruption to business operations.

Scalability: Easily scales to protect large volumes of data across diverse environments, simplifying management.

Flexible deployment: Supports various deployment options to adapt to different use cases.

Additional Benefits:

Integration with cloud and container environments: Protects data in dynamic cloud and container environments.

Key rotation: Automatically rotates encryption keys to enhance security.

Data destruction: Ensures sensitive data is permanently erased when no longer needed.

By leveraging these benefits, CipherTrust Transparent Encryption empowers organizations to safeguard their sensitive data, meet compliance obligations, and maintain operational efficiency.

CipherTrust Data Security Platform

CipherTrust Transparent Encryption is part of the CipherTrust Data Security Platform. Featured in Gartner's Market Guide to Data Security Platforms, CipherTrust Data Security Platform is an integrated set of data-centric solutions that remove complexity from data security, accelerate time to compliance, and secure cloud migrations.

The CipherTrust Platform unifies data discovery, classification, data protection, and centralized management for keys and secrets into a single platform. This results in fewer resources dedicated to security operations, ubiquitous compliance controls, and significantly reduced risk across your business.

About Thales

Today's businesses and governments depend on the cloud, data and software to deliver trusted digital services. That is why the most recognized brands and organizations around the world rely on Thales to help them protect sensitive information and software wherever it is created, stored, or accessed – from the cloud and data centers to devices and across networks. As the global leader in data security and software licensing, our solutions enable organizations to move to the cloud securely, achieve compliance with confidence, create more value from their software and deliver seamless digital experiences for millions of consumers every day.

CipherTrust Transparent Encryption

Challenge: securing sensitive data across changing environments and increasing threats

Safeguarding sensitive data requires much more than just securing a data center's on-premises databases and files. The typical enterprise today uses three or more IaaS or PaaS providers, along with fifty or more SaaS applications, big data environments, container technologies, and their own internal virtual environments and private clouds.

To further complicate the problem, cyber-attacks have grown in sophistication and power. New compliance and regulatory mandates around protection of sensitive information keep on coming, and existing regulations have become more stringent.

Solution: CipherTrust Transparent Encryption

CipherTrust Transparent Encryption delivers data-at-rest encryption with centralized key management, privileged user access control, and detailed data access audit logging that helps organizations meet compliance and best practice requirements for protecting data, wherever it resides. The FIPS 140-2 compliant CipherTrust Transparent Encryption agent resides at the operating file-system or device layer, and encryption and decryption is transparent to all applications that run above it. CipherTrust Transparent Encryption provides rich access controls, which allow organizations to determine who can access data, when they can access it, and what type of access they have.

CipherTrust Transparent Encryption is available for sale to the U.S. Federal Government exclusively through Thales Trusted Cyber Technologies.

Securing sensitive data-at-rest wherever it resides

- Meet compliance and best practice requirements for encryption, access control, and data access logging using a proven hardware accelerated encryption solution, that secures files, volumes and linked cloud storage while enabling access control and data access audit logging in physical, virtual, and cloud environments.
- Deployment is simple, scalable and fast with centralized key management, encryption, and access policies that reach across multiple clouds, on-premises, and within big data, and container environments.
- Easily implement privileged user access controls to enable administrators to work as usual but protect against users and groups that are potential threats to data.
- Leverage detailed, actionable security event logs that provide unprecedented insight into file access activities to identify and stop threats faster.
- Broadest platform support in the industry. Protects structured and unstructured data accessed by Linux, AIX and Windows systems, as well as transparent encryption and access control for data residing in S3 buckets.

- Eliminate the downtime required for initial encryption and re-keying operations by adding the Live Data Transformation option. There is no other data encryption solution that offers this unique capability.

CipherTrust Transparent Encryption

Key advantages

Transparent data protection. Continuously enforces file-level encryption that protects against unauthorized access by users and processes and creates detailed data access audit logs of all activities without requiring changes to applications, infrastructure, systems management tasks, or business practices.

Seamless and easy to deploy. CipherTrust Transparent Encryption agents are deployed on servers at the file system or volume-level and support both local disks as well as cloud storage environments, such as Amazon S3 and Azure Files.

Define granular access controls. Apply granular, least-privileged user access policies that protect data from external attacks and misuse by privileged users. Specific policies can be applied by users and groups from systems, LDAP/Active Directory, Hadoop and containers. Controls also include access by process, file type, time of day, and other parameters.

High-performance hardware accelerated encryption. CipherTrust Transparent Encryption only employs strong, standard-based encryption protocols, such as the Advanced Encryption Standard (AES) for data encryption and Elliptic Curve Cryptography (ECC) for key exchange. Encryption overhead is minimized using the AES hardware encryption capabilities available in modern CPUs.

Comprehensive security intelligence. Identify and stop threats faster with detailed data access audit logs that not only satisfy compliance requirements, but also enable data security analytics.

In addition, security intelligence logs and reports streamline compliance reporting and speed up threat detection using leading security information and event management (SIEM) systems.

Broadest system and environment support. The agent is available for a broad selection of Windows, Linux, and AIX platforms, and can be used in physical, virtual, cloud, container, and big data environments, regardless of the underlying storage technology.

Advanced security

Zero-downtime data transformation. Live Data Transformation option eliminates the downtime required for initial encryption and scheduled rekeying operations. This patented technology allows for databases or files to be encrypted or re-keyed with a new encryption key while the data is in use without taking applications off-line.

Advanced access controls for big data (Hadoop). When implemented in Hadoop environments, access controls are extended to Hadoop users and groups.

SAP HANA qualified. SAP has qualified CipherTrust Transparent Encryption with HANA v2.0 to deliver data encryption, key management, privileged user access control, and granular file access audit logs.

CipherTrust Transparent Encryption UserSpace. Provides scalable and robust file encryption solution based on Linux FUSE that is not affected by kernel upgrades on Linux servers.

Solution architecture

Deployments consist of CipherTrust Transparent Encryption agents and CipherTrust Manager appliances. Policy and key management is centralized at the CipherTrust Manager. The CipherTrust Manager is available as a FIPS 140-2 level 1, 2 or 3 compliant appliance.

CipherTrust Data Security Platform

CipherTrust Transparent Encryption is part of the CipherTrust Data Security Platform. The CipherTrust platform unifies data discovery, classification, data protection, and provides unprecedented granular access controls, all with centralized key management. This simplifies data security operations, accelerates time to compliance, secures cloud migrations, and reduces risk across your business. You can rely on Thales CipherTrust Data Security Platform to help you discover, protect and control your organization's sensitive data, wherever it resides.

About Thales Trusted Cyber Technologies

Chapter 1: Introduction

This document details the CTE Linux performance using the Oracle TPCC benchmark.

Summary of Activity

This test used the industry wide OLTP benchmark standard Transaction Processing Performance Council (TPC-C) (<http://www.tpc.org/tpcc/detail5.asp>), which was executed using the HammerDB benchmark tool (<https://hammerdb.com/>). A baseline benchmark on an unguarded schema was first created and then compared against a benchmark run on the same schema protected by a CTE GuardPoint.

For establishing the baseline, several combinations of numbers of warehouses and number of virtual users was tried in order to arrive at a combination that provided optimum saturation, which was 500 warehouses driven by 125 virtual users.

The common approach was used to benchmark both SecFS as well as SecVM performance, using Oracle with filesystem and ASM storage respectively.

The test systems and the benchmarking system were hosted on a dedicated VMware ESX server which had no other machines. The benchmark tablespaces only used SSD storage. All benchmark runs were conducted for an hour after first rebooting the test machines. The details of the test systems are in the appendices.

Terminology

- **Redo logs**

A set of files used by Oracle to perform recovery in case of failures. These files store all changes made to the database as they occur. When the redo log files reach maximum capacity, they can be archived through an Oracle tunable parameter. However, this affects performance, so Thales did not archive log files while we were conducting the benchmark testing.

- **Undo logs**

These files contain information which can be used by Oracle to save the changes made during a transaction.

- **Temporary tablespace**

Used by Oracle for storing temporary data which is generated when SQL statements perform sort operations.

Chapter 2: Methodology

The HammerDB benchmark tool was used for carrying out the performance evaluation. A baseline benchmark on an unguarded schema was first created, and then compared against, a benchmark run on the same schema protected by a CTE GuardPoint.

For establishing the baseline, several combinations of numbers of warehouses, and numbers of virtual users, were tried in order to arrive at a combination that provided optimum saturation.

The common approach was used to benchmark both SecFS, as well as SecVM performance, using Oracle with a file system and ASM storage, respectively.

About TPC-C

As an OLTP system benchmark, the TPC-C simulates a complete environment where a population of terminal operators executes transactions against a database. The TPC policies allow for derivations of TPC benchmark standards that comply with the TPC fair use rules. TPROC-C is the OLTP workload implemented in HammerDB derived from the TPC-C specification with modifications to make running HammerDB straightforward and cost-effective on any of the supported database environments. The rest of the content of this section has been excerpted from the HammerDB documentation available at <https://hammerdb.com/docs/ch03s05.html>.

The TPROC-C schema is shown below. Note how the number of rows in all of the tables, apart from the ITEM table which is fixed, is dependent upon the number of warehouses used to create the schema.

The workload is defined by a mix of 5 transactions selected at random according to the balance of the percentage value shown as follows:

1. **New-order:** Receive a new order from a customer: 45%
2. **Payment:** Update the customers balance to record a payment: 43%
3. **Delivery:** Deliver orders asynchronously: 4%
4. **Order-status:** Retrieve the status of customers most recent order: 4%
5. **Stock-level:** Return the status of the warehouses inventory: 4%

For the benchmark comparison, the GuardPoints were always applied to the TPCC tablespace. In one scenario, the redo logs, the temporary tablespace and the undo tablespace were in cleartext. In another scenario, the temporary and undo table space, as well as the redo logs, were guarded.

Metrics

The benchmark provides the transactions per minute (TPM) counter, which is used to compare the baseline with guarded schemas.

Chapter 3: ASM Storage

Only TPCC tablespace guarded

The TPM metric comparison is as follows:

	Baseline	CTE	Drop
Average TPM	258141.3	247410	4.2
Median TPM	261897	250164	4.5

This graph compares the TPM for 60 minutes.

The following table compares the IO metrics for the duration of the benchmark run. These figures only compare the IO numbers for the TPCC tablespace.

	Baseline	CTE	Drop
Read Requests/second	19,994.64	18,891.42	5.83
Read/second	156.30	147.66	5.85

	Baseline	CTE	Drop
Write Requests/second	14,449.41	12,605.30	14.62
Writes/second	185.73	171.62	8.22

Conclusion

Based on the average TPM comparison of the baseline vs the guarded benchmarks, with the redo logs, undo tablespace, temporary tablespace and TPCC tablespace guarded, the performance drop is 5.6% when the database uses ASM storage (using SecVM).

Appendix A: Tools Used

The following tools were used in this testing:

Infrastructure

The benchmark was conducted on a dedicated ESX (ProLiant DL360 Gen10) with the following hardware:

- CPU: 48 CPUs x Intel(R) Xeon(R) Gold 6252 CPU @ 2.10GHz
- Memory: 255.68 GB

The tablespace used in the benchmark, the redo logs, and the undo and temporary tablespace, were created on SSD storage. The ESX had three virtual machines, namely the Oracle server, the benchmark slave, and a Jenkins master. For the details of the resources allotted to the Oracle server, see ["Machine Details" below](#).

Machine Details

Oracle Server Details

This section lists the most significant details of the Oracle server for the filesystem as well as the ASM benchmark systems:

Filesystem Storage

- **File server:** Red Hat Enterprise Linux release 8.3
- **Kernel:** 4.18.0-240.el8.x86_64
- **CPU count:** 8
- **Memory:** 32 GB
- **Filesystem:** XFS

ASM Storage

- **File server:** Red Hat Enterprise Linux release 8.4
- **Kernel:** 4.18.0-305.17.1.el8_4.x86_64
- **CPU count:** 8
- **Memory:** 32 GB

Application versions

- **Oracle:** Oracle Database 19c Enterprise Edition Release 19.0.0.0.0 – Production, Version 19.3.0.0.0
- **File system IO options:** setall
- **CTE:** 7.1.1.30
- **CipherTrust Manager:** 2.4.0.6018
- **Key Type:** AES 256 (CBC)

Other systems

HammerDB client

- **File server:** Ubuntu 20.04.2 LTS
- **Kernel:** 5.4.0-80-generic
- **CPU count:** 4
- **Memory:** 16 GB
- **Filesystem:** XFS
- **HammerDB:** 4.1

Jenkins

- **File server:** CentOS Linux 8 (Core)
- **Kernel:** 4.18.0-193.6.3.el8_2.x86_64
- **CPU count:** 1
- **Memory:** 4 GB
- **Filesystem:** XFS

CipherTrust Transparent Encryption

CTE Agent for Linux Advanced Configuration and Integration Guide

Release 7.0.0

Document Version 2

September 28, 2020

The bottom half of the page features a dark blue background with abstract geometric shapes. On the left, there is a large, bright blue triangle pointing upwards. Below it, a smaller, darker blue triangle points upwards. In the bottom left corner, there is a blue circle with a dotted pattern. The right side of the page has a vertical gradient from dark blue at the top to a lighter blue at the bottom, with a dotted pattern at the very bottom.

Thales hereby disclaims all warranties and conditions with regard to the information contained herein, including all implied warranties of merchantability, fitness for a particular purpose, title and non-infringement. In no event shall Thales be liable, whether in contract, tort or otherwise, for any indirect, special or consequential damages or any damages whatsoever including but not limited to damages resulting from loss of use, data, profits, revenues, or customers, arising out of or in connection with the use or performance of information contained in this document.

Thales does not and shall not warrant that this product will be resistant to all possible attacks and shall not incur, and disclaims, any liability in this respect. Even if each product is compliant with current security standards in force on the date of their design, security mechanisms' resistance necessarily evolves according to the state of the art in security and notably under the emergence of new attacks. Under no circumstances, shall Thales be held liable for any third party actions and in particular in case of any successful attack against systems or equipment incorporating Thales products. Thales disclaims any liability with respect to security for direct, indirect, incidental or consequential damages that result from any use of its products. It is further stressed that independent testing and verification by the person using the product is particularly encouraged, especially in any application in which defective, incorrect or insecure functioning could result in damage to persons or property, denial of service or loss of privacy.

Preface	17
The CTE Agent Documentation Set	17
Document Conventions	17
Typographical Conventions	17
Notes, tips, cautions, and warnings	18
Sales and Support	19
 Chapter 1: Overview of CTE	 20
CTE Terminology	20
CTE Components	20
How to Protect Data with CTE	21
 Chapter 2: Getting Started with CTE for Linux	 22
Installation Workflow	22
Additional Considerations	22
Tracking and Preventing Local User Creation	22
Restricted Directories	23
Restricted Mode	23
Linux Package Installation	24
Installing the Unsigned RPM Package	25
Installing the Signed RPM Package with Yum	25
Installing the Signed RPM Package Manually	26
Installing CTE with No Key Manager Registration	27
Configuring CTE for Linux with CipherTrust Manager	28
Installation Overview	28
Installation and Registration Options	28
Installation Method Options	28
Hardware Association (Cloning Prevention) Option	28
Installation Prerequisites	28
Recommendations and Considerations	29
Network Setup Requirements	29
Port Configuration Requirements	29
Interactive Installation on Linux	29
Before You Begin	29
Silent Installation on Linux	32
Guarding a Device with CipherTrust Manager	34
Access the CipherTrust Manager Domain	34
Create an Encryption Key	34

Create a Standard Policy	36
Create a GuardPoint	38
Configuring CTE for Linux with a DSM	39
Installation Overview	39
Installation Prerequisites	39
Recommendations and Considerations	40
Network Setup Requirements	40
Host Name Resolution Requirements	40
Port Configuration Requirements	40
One-way Communication Option	41
Determining Kernel Compatibility With CTE	41
Installation and Registration Options	42
Installation Method Options	42
CTE Registration Method Options	42
Hardware Association (Cloning Prevention) Option	42
CTE Linux Installation Checklist	43
Interactive Installation on Linux	43
Installing CTE and Registering Using the Certificate Fingerprint	44
Installing CTE and Registering Using the Shared Secret Registration Method	47
Silent Installation on Linux	51
Silent Installation on Linux Using the Shared Secret Registration Method	51
Silent Installation on Linux Using the Fingerprint Registration Method	53
Registering CTE with the Shared Secret Registration Method After Installation is Complete	56
Registering CTE with the Fingerprint Registration Method After Installation is Complete	58
Guarding a Device with the DSM	61
Access the DSM Domain	62
Create an Encryption Key	62
Create a Standard Policy	62
Create a GuardPoint	63
Chapter 3: Special Cases for CTE Policies	65
More Information About Configuring CTE Policies	65
Re-Signing Executable Files on Secfs GuardPoints	65
Re-Enabling Automatic Signing for Host Settings	66
Restricting Access Overrides from Unauthorized Identities	66
Chapter 4: Concise Logging	68
Overview of Concise Logging	68
Using Concise Logging	68

Considerations	68
Configuring Concise Logging for CTE Clients or Client Groups with CipherTrust Manager	69
Configuring Global Concise Logging with the DSM	69
Configuring Concise Logging for a Registered Host with the DSM	69
Chapter 5: Enhanced Encryption Mode	70
Compatibility	70
Difference between AES-CBC and AES-CBC-CS1	71
Disk Space	71
Encryption Migration	71
File Systems Compatibility	71
File System Requirements	72
Samba Share	72
Storing Metadata	72
Missing IV file	73
HDFS	73
Backups	73
Container Compatibility	74
Using the AES-CBC-CS1 Encryption Mode in DSM	74
Using the AES-CBC-CS1 Encryption Mode in CM	74
Exceptions and Caveats	74
Best Practices for AES-CBC CS1 Keys and Host Groups	75
Chapter 6: CTE and systemd	76
Overview of CTE and systemd	76
Linux Distributions that Support CTE and systemd	76
CTE Agent Control Changes on systemd	76
CTE Configuration Changes Required on systemd	77
About systemd Dependency Changes for Unit Configuration Files	78
Location of Application Unit Configuration Files	79
Adding Dependencies to systemd Unit Configuration Files	79
Adding Applications to the secfs-fs-barrier.service File	79
Adding Dependencies to the saslauthd.service File	80
Supported Use Cases	80
Manually Stop 3rd Party Applications on a Live System	81
Chapter 7: Utilities for CTE Management	82
secfsd Utility	82
secfsd syntax	82

secfsd Examples	83
Display GuardPoint Information	83
Display GuardPoint Information in a Different Format	84
Display Host Settings	84
Display Key Status	84
Display Lock Status	84
Display CTE Log Status	85
Display Applied Policies	85
Display CTE Process Information	85
Display CTE Version Information	85
Manually Enable a GuardPoint in DSM	85
Manually Enable a GuardPoint in CipherTrust Manager	86
secfsd and Raw Devices	86
vmsec Utility	86
vmsec Syntax	87
vmsec Examples	87
Display CTE Challenge String	87
Display CTE Status	87
Entering a Password	87
Display Kernel Status	88
Display CTE Build Information	89
Display Contents of Conf files	89
Binary Resigning	89
Enable Automatic Signing for Host Settings	90
Restricting Access Overrides from Unauthorized Identities	91
Using Advanced Encryption Set New Instructions (AES-NI)	91
vmd utility	92
Syntax	92
Display the Installed Version	92
agenthealth Utility	92
The Agent health check script	92
agentinfo Utility (Java version)	93
check_host Utility	93
check_host Syntax	94
register_host Utility	94
fsfreeze and xfs_freeze	94
Restrictions	94
Platform Restrictions	94
Target Restrictions	95
File System Restrictions	95

LDT Restrictions	95
Offline Data Transformation Restrictions	95
Chapter 8: Installing CTE on Hadoop	96
Overview	96
Overview of CTE on HDFS	96
HDFS Administrator:	96
DSM Security Administrator:	97
HDFS Administrator:	97
Implementing CTE on HDFS	97
CTE on HDFS Implementation Assumptions	97
Configure the HDFS NameNodes	97
Create an Encryption Zone in HDFS Name Space for AWS EMR	98
Using the Original Information from HDFS	99
Create a HDFS Host Group and Host Group GuardPoint	99
Take a DataNode Offline and Perform Data Transformation	101
Implementing CTE on HDFS on a Single Host	102
Adding a New DataNode to a CTE-protected HDFS	103
CTE Installed on the Cluster Nodes Before Ambari Installs Hadoop	103
HDFS Upgrade with CTE	104
Upgrading one node at a time	104
Upgrade CTE with CTE-LDT in an HDFS Cluster	104
Rolling Upgrades	104
Configure the Hadoop Cluster for CTE	106
Create a Vormetric Configuration Group	106
Update the Hadoop-env Template with CTE Settings	107
Modify the HDFS IOCTL	107
Change the HDFS File Rename Check	107
User Information Push	107
Create Kerberos Principal for CTE	108
Uninstalling CTE for the Hadoop Cluster	108
CTE Installation and Configuration	108
Installing and Configuring CTE on an HDFS Node	109
Modifying host settings for HDFS hosts on the DSM	109
Simple Modification	109
Using Kerberos	110
Modifying Host Group for HDFS NameNodes HA on DSM	110
Configuring Hadoop to Use CTE	111
Verify secfsd is Running with Hadoop Environment	111
HDFS Name Cache	111

Enabling CTE on HDFS	112
Deleting Metadata in HDFS when Migrating Out of LDT	112

Chapter 9: Using CTE with Oracle 114

Oracle RAC ASM and ASMLib	114
Using CTE with an Oracle RAC ASM	114
ASMLib	114
Important ASM Commands and Concepts	114
Rebalancing Disks	114
Mapping Raw Devices	115
Checking Rebalance Status	115
Determining Best Method for Encrypting Disks	116
Online Method (No Application / Database Downtime)	116
Offline Method (Backup the DB)	116
General Prerequisites	117
Setup	117
Modify the UDEV Rules	117
Altering ASM_DISKSTRING on ASM	117
Specific Prerequisites	118
Establishing a Starting Point	118
The Importance of Device Mapping	118
Important Note about Raw Devices on UNIX	118
Oracle RAC ASMLib Multi-Disk Online Method	119
Assumptions	119
About Oracle RAC ASM Raw Devices	119
When Not Using ASMLib	119
Devices using Raw Bindings	119
Multipath I/O Devices	120
Standard Devices	120
Consistent Naming of Devices across RAC Nodes	120
Oracle RAC ASM Multi-Disk Online Method	120
Checking for Space	120
Adding a Disk to the Diskgroup	121
Troubleshooting	121
Oracle RAC ASM Multi-Disk Offline Method (Backup/Restore)	122
Troubleshooting	122
Surviving the Reboot and Failover Testing	123
Preparing for Failover Testing with ASMLib	123
CTE Load Order and Startup Scripts	123
Failover Testing	123

Issues with Device Mapper and Invalid Guard Path	123
Basic Troubleshooting Techniques	123
Verifying Database Encryption	124
Option 1	124
Option 2	125
Option 3	125
Chapter 10: Configuring Support for SAP HANA	126
Overview	126
Customizing CTE for SAP HANA in HA Mode	126
Using SAP HANA with LDT	128
Setting Memory Allocation	128
Chapter 11: Container Security	129
Installing Docker Automatically	129
Container Security Overview	129
Container Terminology	129
Docker Containers with CTE	130
CTE: Virtual Machine versus Docker	130
Using the CTE Agent	130
Docker containers in custom paths won't start after CTE agent is installed	131
Set the Docker Storage Driver	131
Change the Storage Driver	132
Administering the Docker Host	132
Creating Policies	132
Adding Security Rules	133
Create Resource Set	133
Create User Set	133
Create Process Set	134
Enable Docker through Host Settings	135
CTE Docker GuardPoints	135
Image-based GuardPoints	135
Container-based GuardPoints	136
GuardPoints for Docker Containers	136
Creating GuardPoints	136
Viewing GuardPoints	136
Data Security for Docker Images and Containers	137
Setting up an image based GuardPoint	137
Setting up a Container-Based GuardPoint	138

Setting up a GuardPoint for an Exported Docker Volume	139
Configuring Audit Logging	139
Configure Docker Log Settings	139
Searching for Docker Log Messages	140
Generating Reports	140
System Level Reports	140
Domain Level Reports	140
RedHat OpenShift Containers with CTE	141
Using the CTE Agent	141
CTE: Virtual Machine versus OCP	141
Set the OpenShift Storage Driver	141
Administering the OpenShift Host	141
Enable OpenShift through Host Settings	141
CTE OCP GuardPoints	141
Types of GuardPoints	141
Image-based GuardPoints	142
Container/POD-based GuardPoints	142
Creating GuardPoints	142
Viewing GuardPoints	142
Data Security for OpenShift Images and Containers	142
Setting up an Image-based GuardPoint	142
Setting up a POD-based GuardPoint	142
Setting up a GuardPoint for an exported OCP volume	142
Configuring Audit Logging	142
Generating Reports	142
Creating an OCP Project in CLI with API Commands	143
Creating an OCP Project with a Template	143
Deploying an OCP Project	143
Available OpenShift commands	144
Available OPC Options	144
Container secfsd Utilities	145
Chapter 12: NetApp Snapshot Directory	146
Overview	146
Accessing snapshots	146
Enabling Snapshots	146
Dataxform Considerations	146
Best Practices	147

Chapter 13: Using CTE with Quantum StorNext	148
Overview of using CTE with Quantum StorNext	148
CTE and Quantum StorNext Compatibility	148
Supported StorNext Server and Client Configurations	148
Supported GuardPoint and Key Settings for SNFS File Systems	149
Supported Concurrent Access Read/Write Scenarios	149
Setting up CTE and Quantum StorNext Integration	150
Integration Task Overview	150
Installing and Configuring a Quantum StorNext MDC Server for Use with CTE	151
Installing and configuring Quantum StorNext DLC Clients for Use with CTE	151
Ensuring that the StorNext SNFS File System Starts Before secfs	151
Installing the CTE Agent on Each StorNext LAN client	151
Stop secfs Before Upgrading StorNext LAN Clients	152
 Chapter 14: Using CTE with McAfee Endpoint Security for Linux Threat Prevention	 153
Supported McAfee Versions and Linux Operating Systems	153
Ensuring Correct McAfee Service Startup Order	153
Ensuring Correct McAfee Service Startup Order in systemd	153
Ensuring Correct McAfee Service Startup Order Manually	154
Updating McAfee	154
Virus Scanning Behavior Differences for CIFS and NFS GuardPoints	154
 Chapter 15: Using CTE with Trend Micro Deep Security Software	 155
Supported Deep Security Versions and Linux Operating Systems	155
Ensuring Correct Deep Security Service Startup Order	155
Ensuring Correct Deep Security Service Startup Order in systemd	155
Ensuring Correct Deep Security Service Startup Order Manually	156
Updating Deep Security	156
 Chapter 16: CTE COS for Amazon S3	 157
Overview	157
Supported operations	158
Limitations	158
Multi-part Upload Restrictions	159
System and Software Requirements	159
Client Software Requirements	159
CTE COS S3 Installation Overview	159
Install Required Linux Packages	160

Install CTE	160
Configure the AWS CLI to use the COS Root CA Certificate	161
Configure the AWS CLI Network Proxy	161
Configure CTE COS S3	162
Setting the Default Chunk Size	162
Optionally Configure a CTE COS S3 Role for Guarded Buckets	163
Secure an S3 Bucket with the CTE COS S3 Role	166
Disable the CTE COS S3 Role for an S3 Bucket	166
Guard an AWS Bucket	167
Create a CBC_CS1 Key in DSM	167
Create the Cloud Object Storage (COS) policy in DSM	168
Creating GuardPoints in a Host	169
Additional COS Proxy Root CA Certificate Information	170
Protecting Python Programs with CTE	172
Benefits of Using PyInstaller with CTE	172
Getting PyInstaller	172
Example Usage	172
Chapter 17: CTE-Efficient Storage for Linux	174
Introduction to CTE-Efficient Storage	174
Requirements and Considerations	174
CTE-Efficient Storage Enhanced Storage Arrays	175
Storage Arrays Compatible with CTE-Efficient Storage	175
Sharing Encryption Keys	175
Storage Array Registration	176
Efficient Storage Device Header and CTE Private Region	176
Device Size	176
DSM Domain Enabled for KMIP	177
ES GuardPoint Encryption Keys	177
Key Attributes - Example	178
KMIP Key Object	179
Policy Requirements for ES GuardPoints	179
Guarding an Efficient Storage Device on Linux	180
Requirements for Efficient Storage GuardPoints on Linux	180
Register the Host with DSM	181
Initialize Linux Efficient Storage Devices	182
Initialize a New Linux Device	182
Initialize and Resize an Existing Linux Device	183
Guard the Linux Device with an ES GuardPoint	184
Data Relocation on Existing Linux Devices	186

Data Transformation on Existing Linux Devices	186
Example of Creating an ES GuardPoint on an Existing Linux Device	187
Guarding a CTE-Efficient Storage Device with Multiple IO Paths on Linux	189
Linux System and ES GuardPoint Administration	189
voradmin ESG Commands on Linux	189
Viewing Device Status and the ES Header on Linux	189
File System Mount Points on Linux	190
Auto Mount Options for File System Devices on Linux	190
Linux System Utilities for Signing	191
Changing the Encryption Key on Linux ESG Devices	192
Creating a New DSM Policy for Key Rotation	192
Prepare an ES GuardPoint for Rekey	193
Resizing Guarded Efficient Storage Devices	194
Example: Resizing a Linux Device	195
Use Cases involving Efficient Storage GuardPoints	196
Use Case 1: Single Encryption Key	196
Use Case 2: Device-Level GuardPoints	196
Use Case 3: Directory-Level GuardPoints	197
Challenges with Root Access on Linux	199
Use Case 4: Using CTE-Efficient Storage with LVM	204
Alerts and Errors on Linux	205
Encryption key on device has not been made available	205
Specified policy disagrees with metadata set on the Guard Path	205
Device has not been configured for Efficient Storage	205
Device not resized for guarding as Efficient Storage	206
Data transformation failed	206
Data transformation in progress	206
Device <device-name> is configured to guard as Efficient Storage GuardPoint	206
Device <device-name> is configured as Efficient Storage GuardPoint	206
GuardPoint for device <device-name> still guarded on DSM	206
Failed to open device <device-name>, error Device or resource busy	207
Device <device-name> is not configured as Efficient Storage	207
Abort! Error: Could not stop secfs, secvm device(s) busy	207
Abort! Error: Could not unmount file systems	207
A dependency job for esg.mount failed. See 'journalctl -xe' for details	207
ESG-ALERT: IO error on header for [GuardPoint]	207
ESG-ALERT: Data transformation failure on [GuardPoint]	207
ESG-INFO: Data transformation complete on [GuardPoint]	208
ESG-ALERT: Failed to resize <device-name>	208
FSADM-ALERT: ESG required Signature Set for system utilities may have to be resigned	208

File System is not automatically mounted after IDT completes	208
Chapter 18: CipherTrust InPlace Data Transformation for Linux	209
Introduction to CipherTrust InPlace Data Transformation (IDT)	209
Requirements for IDT-Capable GuardPoints	209
The CTE Private Region and IDT Device Header	210
CTE Private RegionLocation	210
Device Size	211
IDT-Capable GuardPoint Encryption Keys	211
Key Attributes - Example	212
Policy Requirements for IDT-Capable GuardPoints	213
Guarding an IDT-Capable Device on Linux	214
Initializing an IDT-Capable Device	215
Initialize a New Linux Device	215
Initialize a Linux Device with Existing Data	216
Guard the Linux Device with an IDT-Capable GuardPoint	218
Data Relocation and Transformation on Existing Linux Devices	220
Example of Creating an IDT-Capable GuardPoint on an Existing Linux Device	221
Changing the Encryption Key on Linux IDT-Capable Devices	222
Guarding an IDT-Capable Device with Multiple IO Paths on Linux	225
Viewing Device Status and the IDT Device Header	225
Linux System and IDT-Capable GuardPoint Administration	226
voradmin IDT Commands on Linux	226
File System Mount Points on Linux	226
Auto Mount Options for File System Devices on Linux	226
Linux System Utilities for Signing	227
Resizing Guarded IDT Devices	228
Use Cases Involving IDT-Capable GuardPoints	228
Alerts and Errors on Linux	228
Encryption key on device has not been made available	228
Specified policy disagrees with metadata set on the Guard Path	229
Device has not been configured for IDT-Capable or Efficient Storage	229
Device not resized for guarding as IDT-Capable or Efficient Storage	229
Data transformation failed	229
Data transformation in progress	229
Device <device-name> is configured to guard as Efficient Storage GuardPoint	229
Device <device-name> is configured as Efficient Storage GuardPoint	230
Device <device-name> is configured to guard as IDT-Capable GuardPoint	230
Device <device-name> is configured as IDT-Capable GuardPoint	230
GuardPoint for device <device-name> still guarded on DSM	230

Failed to open device <device-name>, error Device or resource busy	230
Device <device-name> is not configured as IDT-Capable	230
Abort! Error: Could not stop secfs, secvm device(s) busy	231
Abort! Error: Could not unmount file systems	231
A dependency job for idt.mount failed. See 'journalctl -xe' for details	231
ESG/IDT-ALERT: IO error on header for [GuardPoint]	231
ESG/IDT-ALERT: Data transformation failure on [GuardPoint]	231
ESG/IDT-INFO: Data transformation complete on [GuardPoint]	231
ESG/IDT-ALERT: Failed to resize <device-name>	231
FSADM-ALERT: ESG/IDT required Signature Set for system utilities may have to be resigned ..	231
File System is not automatically mounted after IDT completes	232
Chapter 19: CTE with Teradata Database Appliances	233
IDT-Capable GuardPointsand Teradata Database Appliances	233
Requirements and Considerations	233
Location of the CTE Private Region	233
Metadata File Access and Teradata Clusters	234
Additional Requirements and Considerations	234
Guarding a Teradata Database Device	235
Install CTE on the Teradata Database Appliance	235
Identify the Devices to Be Guarded	236
Select the Initial Configuration Method	237
Initialize and Guard the Database Devices Using the Standard Initialization Method	237
Guard the Devices as IDT-Capable GuardPoints	238
Viewing Device and Data Transformation Status	240
Initialize and Guard the Teradata Database Devices Using the Backup/Restore Method	240
Changing the Encryption Key on Teradata Devices	243
Access Rules to Apply on the Teradata Database Appliance	244
Replication of IDT Metadata Files Across Members of a Clique	248
Specific Issues to Consider	248
General PCL Error	248
Offline Node in Clique During Data Transformation	249
Adding a New Node to a Clique	249
Interoperability with Host Groups	249
Best Practices	250
Using a of Host Group to Guard Metadata Directories	250
Using a Host Group for Guarding Teradata Devices in a Clique	250
Best Practice for Preparation for Initial Data Transformation or Rekey	251
Uninstalling CTE from the Teradata Cluster	251
Alerts and Errors	252

General Errors	252
IDT-TD-ALERT: Node <node name> did not respond to pcl command	253
IDT-TD-ALERT: Node <node name> failed to perform voradmin task	253
IDT-TD-ALERT: Failed to find clique for disk <device>	253
IDT-TD-ALERT: Failed to move or rename IDT-Capable metadata file on remote nodes	253
IDT-TD-ALERT: Failed to get GuardPoint status on remote nodes	253
Operation Errors	253
IDT-TD-ALERT: Failed to distribute IDT-Capable metadata file to remote nodes	253
IDT-TD-WARNING: Failed to delete IDT-Capable metadata file on remote nodes	254
IDT-TD-ALERT: Failed to complete rekey on remote nodes	254
 Chapter 20: Upgrading CTE on Linux	255
Upgrading CTE	255
Scheduled Upgrade Feature	256
Warnings for CTE for Linux	256
Using the Scheduled Upgrade Feature	256
Performing a Manual Upgrade When an Upgrade is Already Scheduled	257
Voradmin Commands for the Scheduled Upgrade Feature	258
 Chapter 21: Uninstalling CTE from Linux	260

Preface

The CTE Agent for Linux Advanced Configuration and Integration Guide provides information about advanced installation, configuration, and integration options for CTE for Linux.

The CTE Agent Documentation Set

The following guides are available for CTE Agent:

- *CTE Agent for Linux Quick Start Guide*
- *CTE Agent for Linux Advanced Configuration and Integration Guide*
- *CTE Agent for Windows Quick Start Guide*
- *CTE Agent for Windows Advanced Configuration and Integration Guide*
- *CTE Agent for AIX Installation and Configuration Guide*
- *CTE-Live Data Transformation with Data Security Manager*
- *CTE-Live Data Transformation with CipherTrust Manager*
- *Compatibility Matrix for CTE Agent with CipherTrust Manager*
- *Compatibility Matrix for CTE Agent with Data Security Manager*
- *Compatibility Matrix for CTE Agent for AIX with CipherTrust Manager*
- *Compatibility Matrix for CTE Agent for AIX with Data Security Manager*
- *Release Notes for CTE for Linux Version 7.0.0.47*
- *Release Notes for CTE for Windows Version 7.0.0.47*
- *Release Notes for CTE for AIX Version 7.0.0.11*

Document Conventions

The document conventions describe common typographical conventions and important notice and warning formats used in Thales technical publications.

Typographical Conventions

This section lists the common typographical conventions for Thales technical publications.

Table 3-1: Typographical Conventions

Convention	Usage	Example
bold regular font	GUI labels and options.	Click the System tab and select General Preferences.
<i>bold italic monospaced font</i>	variables or text to be replaced	https://<Token Server name>/admin/ Enter password: <Password>
<code>regular monospaced font</code>	Command and code examples XML examples	Example: session start iptarget=192.168.253.102

Table 3-1: Typographical Conventions (continued)

Convention	Usage	Example
<i>italic regular font</i>	GUI dialog box titles	The <i>General Preferences</i> window opens.
	File names, paths, and directories	<i>/usr/bin/</i>
	Emphasis	<i>Do not</i> resize the page.
	New terminology	<i>Key Management Interoperability Protocol (KMIP)</i>
	Document titles	See <i>CTE Agent for Linux Advanced Configuration and Integration Guide</i> for information about CipherTrust Transparent Encryption.
quotes	File extensions Attribute values Terms used in special senses	"js", ".ext" "true" "false", "0" "1+1" hot standby failover

Notes, tips, cautions, and warnings

Notes, tips, cautions, and warning statements may be used in this document.

A Note provides guidance or a recommendation, emphasizes important information, or provides a reference to related information. For example:

Note

It is recommended to keep tokenization keys separate from the other encryption/decryption keys.

A tip is used to highlight information that helps you complete a task more efficiently, such as a best practice or an alternate method of performing the task.

Tip

You can also use Ctrl+C to copy and Ctrl+P to paste.

Caution statements are used to alert you to important information that may help prevent unexpected results or data loss. For example:

CAUTION

Make a note of this passphrase. If you lose it, the card will be unusable.

A warning statement alerts you to situations that can be potentially hazardous to you or cause damage to hardware, firmware, software, or data. For example:

WARNING

Do not delete keys without first backing them up. All data that has been encrypted with deleted keys cannot be restored or accessed once the keys are gone.

Sales and Support

If you encounter a problem while installing, registering, or operating this product, please refer to the documentation before contacting support. If you cannot resolve the issue, contact your supplier or Thales Customer Support.

Thales Customer Support operates 24 hours a day, 7 days a week. Your level of access to this service is governed by the support plan arrangements made between Thales and your organization. Please consult this support plan for further information about your entitlements, including the hours when telephone support is available to you.

For support and troubleshooting issues:

- <https://supportportal.thalesgroup.com>
- (800) 545-6608

For Thales Sales:

- <https://cpl.thalesgroup.com/>
- CPL_Sales_AMS_TG@thalesgroup.com
- (888) 267-3732

Chapter 1: Overview of CTE

CTE includes several unique utilities to help you encrypt and manage your data. It also integrates with several third-party platforms such as Oracle, Teradata Database Appliances, and Amazon S3.

This document describes the installation and advanced configuration options for CTE, as well as detailed information about how to integrate CTE with the supported third-party products.

CTE Terminology

The CTE documentation set uses the following terminology:

Term	Description
CTE	CipherTrust Transparent Encryption is a suite of products that allow you to encrypt and guard your data. The main software component of CTE is the CTE Agent, which must be installed on every host whose devices you want to protect. Note This suite was originally called Vormetric Transparent Encryption (VTE), and some of the names in the suite still use "Vormetric". For example, the default installation directory is <code>/opt/vormetric/DataSecurityExpert/agent/</code>.
CTE Agent	The software that you install on a physical or virtual machine in order to encrypt and protect the data on that machine. After you have installed the CTE Agent on the machine, you can use CTE to protect any number of devices or directories on that machine.
key manager	An appliance that stores and manages data encryption keys, data access policies, administrative domains, and administrator profiles. Thales offers two key managers for use with CTE, the Vormetric Data Security Manager (DSM) and CipherTrust Manager.
host / client	In this documentation, host and client are used interchangeably to refer to the physical or virtual machine on which the CTE Agent is installed. The difference comes from the key manager you are using. The DSM refers to the machines as hosts, while the CipherTrust Manager refers to them as clients.
GuardPoint	A device or directory to which a CTE data protection and encryption policy has been applied. CTE will control access to, and monitor changes in, this device and directory, encrypting new or changed information as needed.

CTE Components

The CTE solution consists of two parts:

- The *CTE Agent software* that resides on each protected virtual or physical machine (host). The CTE Agent performs the required data encryption and enforces the access policies sent to it by the *key manager*. The communication between the CTE Agent and the key manager is encrypted and secure.
After the CTE Agent has encrypted a device on a host, that device is called a *GuardPoint*. You can use CTE to create GuardPoints on servers on-site, in the cloud, or a hybrid of both.
- A *key manager* that stores and manages data encryption keys, data access policies, administrative domains, and administrator profiles. After you install the CTE Agent on a host and register it with a key manager, you can use the key manager to specify which devices on the host that you want to protect, what encryption keys are used to protect those devices, and what access policies are enforced on those devices.

Thales offers two key managers that work with CTE:

- CipherTrust Manager, Thales's next generation key manager that supports most CTE for Linux features.
- The *Vormetric Data Security Manager* (DSM), Thales's legacy key manager that supports all CTE for Linux features.

Both key managers can be set up as either a security-hardened physical appliance or a virtual appliance. Both provide access to the protected hosts through a browser-based, graphical user interface as well as an API and a CLI. Thales recommends that you use the CipherTrust Manager unless you need a feature that is only supported by the DSM, as described below.

The CipherTrust Manager currently supports all CTE for Linux features *except* for the following:

- Container Security
- CTE-Efficient Storage
- CipherTrust InPlace Data Transformation
- CTE with Teradata Database Appliances

Support for these features will be included in future releases of the CipherTrust Manager.

For details about any of these features, see the *CTE Agent for Linux Advanced Configuration and Integration Guide*.

You must select one and only one key manager per host or host group. While you could have some hosts registered with a CipherTrust Manager and some registered with a DSM, you cannot have the same host registered to both a CipherTrust Manager and a DSM.

Note: For a list of CTE versions and supported operating systems, see the *Compatibility Matrix for CTE Agent with CipherTrust Manager* and the *Compatibility Matrix for CTE Agent with Data Security Manager*.

How to Protect Data with CTE

CTE uses policies created in the associated key manager to protect data. You can create policies to specify file encryption, data access, and auditing on specific directories and drives on your protected hosts. Each GuardPoint must have one and only one associated policy, but each policy can be associated with any number of GuardPoints.

Policies specify:

- Whether or not the resting files are encrypted.
- Who can access decrypted files and when.
- What level of file access auditing is applied when generating fine-grained audit trails.

A Security Administrator accesses the DSM or CipherTrust Manager through a web browser. You must have administrator privileges to create policies using either key manager. The CTE Agent then implements the policies once they are pushed to the protected host.

CTE can only enforce security and key selection rules on files inside a guarded directory. If a GuardPoint is disabled, access to data in the directory goes undetected and ungoverned. Disabling a GuardPoint and then allowing unrestricted access to that GuardPoint can result in data corruption.

Chapter 2: Getting Started with CTE for Linux

This chapter describes how to install CTE for Linux, register it with your selected key manager, and then create a simple GuardPoint on the protected host. It contains the following sections:

Installation Workflow	22
Linux Package Installation	24
Installing CTE with No Key Manager Registration	27
Configuring CTE for Linux with CipherTrust Manager	28
Configuring CTE for Linux with a DSM	39

Installation Workflow

In order to install and configure CTE, you need to perform the following high-level tasks:

1. Select which key manager you want to use. The Vormetric Data Security Manager and the CipherTrust Manager have different requirements and support different features, so you must make this decision first. For details, see ["CTE Components" on page 20](#).
2. If you want to include the CTE Agent software with the Linux distribution files, see ["Linux Package Installation" on page 24](#).
3. If you want to install the CTE Agent without registering with a key manager, see ["Installing CTE with No Key Manager Registration" on page 27](#). However, you cannot protect any data on the host until it has been registered. Otherwise, set up your systems according to the requirements of the selected key manager. For details, see one of the following:
 - ["Configuring CTE for Linux with CipherTrust Manager" on page 28](#)
 - ["Configuring CTE for Linux with a DSM" on page 39](#)
4. Create your policies, encryption keys, and GuardPoints using the selected key manager. For an example, see one of the following:
 - ["Guarding a Device with CipherTrust Manager" on page 34](#).
 - ["Guarding a Device with the DSM" on page 61](#).

Additional Considerations

The following sections describe some of the things to keep in mind when configuring CTE.

Tracking and Preventing Local User Creation

CTE allows you to track attempts to change user authentication files using the host settings `audit` and `protect`. This includes, but is not limited to user creation, modification, and deletion, or to deny users.

- The `audit` setting is set to on by default. It audits access to the system credential files but does not prevent account creation.
- The `protect` setting both audits and prevents local user account creation. You must manually enable the `protect` setting for tracking and prevention of local user account creation.

You can tag the following files with either `audit` or `protect`. If you tag a file with both options, CTE uses the `protect` setting.

- `/etc/passwd`
- `/etc/group`
- `/etc/shadow`
- `/etc/gshadow`

Notes

- You do not have to restart CTE after applying or removing these host settings.
- To see the audit messages in the DSM, you must use DSM version 6.x or later. Audit messages are not available in DSM versions 5.x and earlier.

Restricted Directories

Linux does not allow you to guard the following directories:

- `<secfs install root>/agent/secfs/`
- `/etc`
- `/tmp`
- `/usr`
- `/usr/lib`
- `/usr/lib/pam`
- `/var/log/vormetric`

Linux does not allow you to guard the following directories and all of their subdirectories:

- `<install root>/agent/secfs/bin`
- `<secfs install root>/agent/vmd`
- `/etc/vormetric`
- `/etc/pam.d`
- `/etc/security`
- `/usr/lib/security`
- `/etc/rc*`

Restricted Mode

CAUTION

If you install or upgrade in restricted mode, you cannot revert to unrestricted mode without uninstalling CTE.

You can install CTE in restricted mode. This mode prevents any user other than `root` from accessing the following directories:

- `/var/log/vormetric`
- `/opt/vormetric/DataSecurityExpert`

Restricted Mode also prevents non-`root` users from running the following utilities:

- `agenthealth`
- `agentinfo`
- `check_host`
- `register_host`
- `secfsd`
- `vmd`
- `vmsec`
- `voradmin`

Key Agents and Restricted Mode

- On systems where CTE is installed in restricted mode, you cannot install a key agent (pkcs11) or CipherTrust TDE Key Management.
- On systems where a key agent (pkcs11) or CipherTrust TDE are already installed, you cannot install CTE in restricted mode.

Restricted Mode Installation

To install in restricted mode, use the `-r` option.

```
# ./vee-fs-<release>-<build>-<system>.bin -r
```

For example:

```
# ./vee-fs-7.0.0-47-rh8-x86_64.bin -r
```

RPM Installation

If installing from an RPM directly, prior to installation, type:

```
# export VOR_RESTRICTED_INSTALL_MODE=yes
```

Upgrade in Restricted Mode

The upgrade mode is the same as the installation mode.

Linux Package Installation

This section describes how to access the Linux RPM installation package so that the CTE Agent installation integrates with the distribution software. To access the Linux RPM file, you can:

- Extract the RPM file from the CTE Agent install bin file. This is the easiest method, but the files in the package are not signed and therefore cannot be verified. For details, see ["Installing the Unsigned RPM Package" on the next page](#).
- Download the package from the Yum repository. If you use Yum, the files in the package are signed and the signatures are automatically verified when the package is installed. For details, see ["Installing the Signed RPM Package with Yum" on the next page](#).
- Manually download the RPM package outside of Yum and manually verify the package signatures. For details, see ["Installing the Signed RPM Package Manually" on page 26](#).

CAUTION

Do not use package installation for SUSE Linux. Instead, use the interactive or silent installation.

Installing the Unsigned RPM Package

The CTE installation `bin` files contain the unsigned native packages. Extract them by running the `bin` file with the `-e` flag.

1. Log on to the host system as root and copy or mount the installation file to the host system.
2. Extract the RPM file using the following command:

```
# ./vee-fs-<release>-<build>-<system>.bin -e
```

For example:

```
# ./vee-fs-7.0.0-47-rh8-x86_64.bin -e
```

Contents extracted.

```
# ls *rpm
```

```
vee-fs-7.0.0-47-rh8-x86_64.rpm
```

3. To start the installation using the RPM file, use the following command:

```
# rpm -ivh vee-fs-7.0.0-47-rh8-x86_64.rpm
```

4. Follow the prompts to install and register CTE.

For details about the installation and registration process, see the appropriate installation procedure.

- If you are going to register the system with a CipherTrust Manager, see ["Configuring CTE for Linux with CipherTrust Manager" on page 28](#).
- If you are going to register the system with a Vormetric Data Security Manager (DSM), see ["Configuring CTE for Linux with a DSM" on page 39](#).

Installing the Signed RPM Package with Yum

Note

Before you can download and install the package using the Yum repository, you must contact Thales Customer Support to get the username and password for the package repository on which the package resides.

1. Create the repository file, `/etc/yum.repos.d/Vormetric-VTE.repo`, with the following contents:

```
[vormetric-vte]
releasever=REL_VERSION
name=Vormetric VTE Packages $releasever - $basearch - Source
baseurl=https://USER:PASSWORD@packages.vormetric.com/vte/VERSION/rhel-$releasever/
gpgkey=https://packages.vormetric.com/pub/PKG-GPG-KEY-vormetric
enabled=1
gpgcheck=1
repo_gpgcheck=1
sslverify=1
```

where:

- **REL_VERSION** is the the version of RHEL that you are running. This would be `rhel-6`, `rhel-7`, or `rhel-8`.
- **USER:PASSWORD** is the username and password for the CTE package repository you obtained from Thales Customer Support.
- **VERSION** is the CTE release version number. For example, `7.0.0`.

2. Clean up the Yum cache directory:

```
# yum clean all
```

3. Use Yum to install the CTE binary. For example, if the cte binary name is vee-fs-7.0.0-.x86_64, you would enter:

```
# yum install vee-fs-7.0.0-.x86_64
```

Note: The first time you install CTE through Yum, you will be asked to import the GPG key. Make sure that you download this key or the install will fail. For example:

```
vormetric-vte/7Server/signature | 198 B 00:00:00
Retrieving key from https://packages.vormetric.com/pub/PKG-GPG-KEY-vormetric
Importing GPG key 0x628536B7:
  Userid      : "Vormetric (PKG-GPG-KEY) <support@vormetric.com>"
  Fingerprint: 7cb5 4f55 40d4 1b63 bf91 c896 f00a 13b0 6285 36b7
  From        : https://packages.vormetric.com/pub/PKG-GPG-KEY-vormetric
Is this ok [y/N]: y
```

4. Follow the prompts to install and register CTE.

For details about the installation and registration process, see the appropriate installation procedure.

- If you are going to register the system with a CipherTrust Manager, see ["Configuring CTE for Linux with CipherTrust Manager" on page 28](#).
- If you are going to register the system with a Vormetric Data Security Manager (DSM), see ["Configuring CTE for Linux with a DSM" on page 39](#).

Installing the Signed RPM Package Manually

If you want to manually verify the signed version of the CTE RPM package, you can download the public key from the Thales package repository and manually verify the rpm signature.

1. Import the public key from the Thales package repository:

```
# rpm --import https://packages.vormetric.com/pub/PKG-GPG-KEY-vormetric
# rpm -qa gpg-pub*
gpg-pubkey-628536b7-56f9887b : Imported CTE GPG public key.
gpg-pubkey-fd431d51-4ae0493b
```

2. Verify the signature of the package using the `rpm -Kv` command.

```
# rpm -Kv vee-fs-7.0.0-.x86_64.rpm
vee-fs-7.0.0-.x86_64.rpm:
  Header V4 DSA/SHA1 Signature, key ID 628536b7: OK
  Header SHA1 digest: OK (ed3d33dca580c66c70961cfee143e9877a09544c)
  MD5 digest: OK (95273b36ef1c205a7cea444e14bef15f)
  V4 DSA/SHA1 Signature, key ID 628536b7: OK
```

The output should show that the keys match is OK.

3. To start the installation using the RPM file, use the following command:

```
# rpm -ivh vee-fs-7.0.0-.x86_64.rpm
```

4. Follow the prompts to install and register CTE.

For details about the installation and registration process, see the appropriate installation procedure.

- If you are going to register the system with a CipherTrust Manager, see ["Configuring CTE for Linux with CipherTrust Manager" on page 28](#).
- If you are going to register the system with a Vormetric Data Security Manager (DSM), see ["Configuring CTE for Linux with a DSM" on page 39](#).

Installing CTE with No Key Manager Registration

The following procedure installs the CTE Agent on the host but does not register it with a key manager. You cannot protect any data on the host until the CTE Agent is registered with one of the supported key managers. For a comparison of the available key managers, see ["CTE Components" on page 20](#).

1. Log on to the host where you will install the CTE Agent as `root`. You cannot install the CTE Agent without `root` access.
2. Copy or mount the installation file to the host system. If necessary, make the file executable with the `chmod` command.
3. Install the CTE Agent. A typical installation uses the following syntax:

```
# ./vee-fs-<release>-<build>-<system>.bin
```

For example:

```
# ./vee-fs-7.0.0-47-rh8-x86_64.bin
```

To install the CTE Agent in a custom directory, use the `-d <custom-dir>` option. For example:

```
# ./vee-fs-7.0.0-47-rh8-x86_64.bin -d /home/my-cte-dir/
```

Note: If possible, Thales recommends that you use the default directory `/opt/vormetric`.

To view all installer options, use the `-h` parameter. For example:

```
# ./vee-fs-7.0.0-47-rh8-x86_64.bin -h
```

4. The Thales License Agreement displays. When prompted, type `y` and press Enter to accept.

The install script installs the CTE Agent software in either `/opt/vormetric` or your custom installation directory and then prompts you about registering the CTE Agent with a key manager.

```
Welcome to the CipherTrust Transparent Encryption File System Agent
Registration Program.
```

```
Agent Type: CipherTrust Transparent Encryption File System Agent
Agent Version: 7.0.0.47
```

```
In order to register the CipherTrust Transparent Encryption File System Agent
with a Vormetric Data Security Manager
```

- 1) you must know the host name of the machine running the DSM (the host name is displayed on the Dashboard window of the Management Console), and
- 2) unless you intend to use the 'shared secret' registration method, the agent's host machine must be pre-configured on the DSM as a host with the 'Reg. Allowed' checkbox enabled for this agent type on the Hosts window of the Management Console.

```
In order to register with a CipherTrust Manager you need a valid registration
token from the CM.
```

```
Do you want to continue with agent registration? (Y/N) [Y]:
```

5. Type `n` and press Enter to end the installation procedure without registering the CTE Agent with either key manager.

When you are ready to register the CTE Agent with a key manager, see one of the following:

- ["Configuring CTE for Linux with CipherTrust Manager" on the facing page](#)
- ["Configuring CTE for Linux with a DSM" on page 39](#)

Configuring CTE for Linux with CipherTrust Manager

This section describes how to install and configure CTE on Linux systems that you plan to register with a CipherTrust Manager. If you want to register CTE with a Vormetric Data Security Manager (DSM), see ["Configuring CTE for Linux with a DSM" on page 39](#).

Installation Overview

The installation and configuration process when you are using CTE with a CipherTrust Manager consists of three basic steps:

1. Gather the information needed for the install and set up your network as described in ["Installation Prerequisites" below](#).
2. Install CTE on the protected host as described in ["Interactive Installation on Linux" on the next page](#) or ["Silent Installation on Linux" on page 32](#).
3. Register the protected host with CipherTrust Manager and make sure that they can communicate with each other. Registration can be done as part of the initial installation or at any point after the CTE Agent has been installed.

Installation and Registration Options

CTE provides the following installation and registration options. The options you choose determine the information you need to supply during the actual install procedure.

Installation Method Options

There are two methods for installing CTE on Linux platforms:

- **Typical:** Most common and recommended type of installation. Use this method for installing the CTE Agent on one host at a time. See ["Interactive Installation on Linux" on the next page](#).
- **Silent:** Create pre-packaged installations by providing information and answers to a set of installation questions. Use silent installations when installing on a large number of hosts. See ["Silent Installation on Linux" on page 32](#).

Hardware Association (Cloning Prevention) Option

CTE's hardware association feature associates the installation of CTE with the machine's hardware. When enabled, hardware association prohibits cloned or copied versions of CTE from contacting the key manager and acquiring cryptographic keys. Hardware association works on both virtual machines and hardware clients.

You can enable hardware association during CTE registration process. You can disable hardware association by re-running the registration program.

To verify if hardware association (cloning prevention) is enabled on a Linux host, on the command line enter the following:

```
cat /opt/vormetric/DataSecurityExpert/agent/vmd/etc/access
```

If you see `usehw:true`, then hardware association is enabled. If you see `usehw:false`, it's disabled.

Installation Prerequisites

This section lists the tasks you must complete, and the information you must obtain, before installing CTE.

Recommendations and Considerations

- The host on which you want to install CTE *must* support AES-NI hardware encryption. If it does not, any attempt to install or upgrade CTE to release 7.0.0 or later will fail.
- Thales recommends that you install CTE in the default location.
- Do not install CTE on network-mounted volumes such as NFS.
- Make the Installation root directory `/opt` a real directory. If `/opt` is a symlink, you **must** use the `-d` option to specify the installation directory, which must be a real directory.

For example:

```
# ./vee-fs-7.0.0-47-rh8-x86_64.bin -d /home/hello/
```

- Ensure read/write permission is granted to other users accessing your shared resource.

Network Setup Requirements

- The IP addresses, routing configurations, and DNS addresses must allow connectivity of the Linux system on which you plan to install CTE to the CipherTrust Manager. After the Linux system is registered as a client with the CipherTrust Manager, the client must be able to poll the CipherTrust Manager in case there are any changes to the encryption keys, policies, or GuardPoints.
- If the system is a virtual machine, the VM must be deployed and running.

Port Configuration Requirements

If a protected client must communicate with the CipherTrust Manager through a firewall, see the CipherTrust Manager documentation to determine which of the ports must be opened through the firewall.

The default port for communication between the CipherTrust Manager and the CTE Agent is 443. If this port is already in use, you can set the port to a different number during the CTE Agent installation.

Interactive Installation on Linux

The Linux typical install is an interactive script that asks you a series of questions during the installation. You can also install CTE using a silent installer which pre-packages the install information. This allows you to install CTE on a large number of hosts. (For more information, see ["Silent Installation on Linux" on page 51](#)).

After you install CTE, you are prompted to register it immediately with a key manager. CTE must be registered with a key manager before you can protect any of the devices on the host. However, you may postpone the registration if you plan to register CTE later.

Note

Do not install CTE on network-mounted volumes like NFS.

Before You Begin

Make sure you have the following information from the CM Administrator:

- The registration token for the CipherTrust Manager with which you plan to register the CTE Agent.
- The name of the profile you intend to assign to the client if you want to use a profile other than the default client profile.
- Optionally, the name of the host group you want this client to be a part of.

Procedure

1. Log on to the host where you will install the CTE Agent as `root`. You cannot install the CTE Agent without `root` access.
2. Copy or mount the installation file to the host system. If necessary, make the file executable with the `chmod` command.

3. Install the CTE Agent. A typical installation uses the following syntax:

```
# ./vee-fs-<release>-<build>-<system>.bin
```

For example:

```
# ./vee-fs-7.0.0-47-rh8-x86_64.bin
```

To install the CTE Agent in a custom directory, use the `-d <custom-dir>` option. For example:

```
# ./vee-fs-7.0.0-47-rh8-x86_64.bin -d /home/my-cte-dir/
```

Note: If possible, Thales recommends that you use the default directory `/opt/vormetric`.

To view all installer options, use the `-h` parameter. For example:

```
# ./vee-fs-7.0.0-47-rh8-x86_64.bin -h
```

4. The Thales License Agreement displays. When prompted, type `y` and press Enter to accept.

The install script installs the CTE Agent software in either `/opt/vormetric` or your custom installation directory and then prompts you about registering the CTE Agent with a key manager.

```
Welcome to the CipherTrust Transparent Encryption File System Agent
Registration Program.
```

```
Agent Type: CipherTrust Transparent Encryption File System Agent
Agent Version: 7.0.0.47
```

```
In order to register the CipherTrust Transparent Encryption File System Agent
with a Vormetric Data Security Manager
```

- 1) you must know the host name of the machine running the DSM (the host name is displayed on the Dashboard window of the Management Console), and
- 2) unless you intend to use the 'shared secret' registration method, the agent's host machine must be pre-configured on the DSM as a host with the 'Reg. Allowed' checkbox enabled for this agent type on the Hosts window of the Management Console.

```
In order to register with a CipherTrust Manager you need a valid registration
token from the CM.
```

```
Do you want to continue with agent registration? (Y/N) [Y]:
```

5. Enter `y` to continue with the registration process. The install script prompts you to enter the host name or IP address of the CipherTrust Manager with which you want to register CTE. For example:

```
Do you want to continue with agent registration? (Y/N) [Y]: y
```

```
Please enter the primary key manager host name: 10.3.200.141
```

```
You entered the host name 10.3.200.141
```

```
Is this host name correct? (Y/N) [Y]: y
```

6. Enter the client host name when prompted.

Please enter the host name of this machine, or select from the following list.

```
[1] sys31186.qa.com
[2] 10.3.31.186
```

Enter a number, or type a different host name or IP address in manually:
What is the name of this machine? [1]: **2**
You selected "10.3.31.186".

7. Enter the CipherTrust Manager registration token, profile name, host group and host description. If you omit the profile name, CipherTrust Manager associates the default client profile with this client.

Please enter the registration token: **12345**
Please enter the profile name for this host: **My-Profile**
Please enter the host group name for this host, if any:
Please enter a description for this host: **West Coast Datacenter server 5**

```
Token           : 12345
Profile name     : My-Profile
Host Group       : (none)
Host description : West Coast Datacenter server 5
Are the above values correct? (Y/N) [Y]: Y
```

8. At the hardware association prompt, select whether you want to enable the hardware association feature (for details, see ["Hardware Association \(Cloning Prevention\) Option" on page 28](#)). The default is **y** (enabled):

It is possible to associate this installation with the hardware of this machine. If selected, the agent will not contact the key manager or use any cryptographic keys if any of this machine's hardware is changed. This can be rectified by running this registration program again.
Do you want to enable this functionality? (Y/N) [Y]: **Y**

9. At the LDT prompt, specify whether you want this client to use CipherTrust Transparent Encryption - Live Data Transformation (CTE-LDT).

Do you want this host to have LDT support enabled on the server? (Y/N) [N]: **Y**

10. At the Cloud Object Storage (COS) prompt, specify whether you want this client to use CTE COS.

Do you want to configure this host for Cloud Object Storage? (Y/N) [N]:

11. CTE finishes the installation and registration process.

```
Generating key pair for the kernel component...done.
Extracting SECFS key
Generating EC certificate signing request for the vmd...done.
Signing certificate...done.
Enrolling agent with service on 10.3.200.141...done.
Successfully registered the CipherTrust Transparent Encryption File System Agent with the
CipherTrust Manager on 10.3.200.141.

Installation success.
```

12. In CipherTrust Manager, change the client password using the manual password creation method. This password allows users to access encrypted data if the client is ever disconnected from the CipherTrust Manager. For details on changing the password, see the CipherTrust Manager documentation.

Silent Installation on Linux

This section describes how to perform a silent (unattended) installation of the CTE on a single host. The silent installation automates the installation process by storing the answers to installation and registration questions in a separate file that you create. You can also use the silent installation to install CTE on multiple hosts simultaneously.

The silent install method installs CTE on the host, and registers the host with the CipherTrust Manager you specify in the silent installation file.

Prerequisites

Make sure you have the following information from the CM Administrator:

- The registration token for the CipherTrust Manager with which you plan to register the CTE Agent.
- The name of the profile you intend to assign to the client if you want to use a profile other than the default client profile.
- Optionally, the name of the host group you want this client to be a part of.

Procedure

1. Log on as an administrator to the host where you will install CTE.
2. Create a parameter file and store it on your system, or copy an existing file from another location. The file can contain any of the following parameters:

Parameter	Description
SERVER_HOSTNAME	Required if you want to register CTE with a CipherTrust Manager.
REG_TOKEN	The registration token for the CipherTrust Manager with which you plan to register this client. Required for registration.
HOST_PROFILE	Specifies the client profile in the CipherTrust Manager that will be associated with this client. If this value is omitted, the CipherTrust Manager uses the default client profile.
TMPDIR	Specifies a custom temporary directory that the installer can use during the installation process. If this value is omitted, the installer uses the default temporary directory.
HOST_DOMAIN	Specifies the domain name with which this CTE Agent will be associated.
HOST_GROUP	Specifies the optional client group with which this client will be associated.
AGENT_HOST_NAME	FQDN of the host on which the CTE Agent is being installed. If this value is not specified, the installer uses the host's IP address.
PKCS11_PASSWORD	The administrative password for the CTE Agent. Required if the CTE Agent is being registered with a CipherTrust Manager. This password allows users to access encrypted data on the client if it is disconnected from the CipherTrust Manager.
AGENT_USEIP	Use the IP address of the protected host instead of host name. Used when <code>-agent</code> is not supplied.

Parameter	Description
HOST_DESC	Specifies a description for the host. This description is displayed in the DSM. If an entry for this host already exists in the DSM and the host already has a description, CTE does <i>not</i> overwrite the existing description even if this option is specified.
AGENT_HOST_PORT	Specifies the port number this CTE Agent should use.
USEHWSIG	Set this value to 1 when you want to associate this installation with the machine hardware for cloning prevention.
ENABLE_LDT	Set this value to 1 to automatically enable and register CTE-LDT (Live Data Transformation) during silent install.

The following example contains just the required information for registration with CipherTrust Manager. In this case, the client will be registered with the CipherTrust Manager using its IP address instead of its host name:

```
SERVER_HOSTNAME=Key-Mgmt-Server.example.com
REG_TOKEN=12345
PKCS11_PASSWORD=ClientAdminP@$$w0rd
```

The following example specifies the required registration information, adds a host name and description, and enables hardware association and CTE-LDT. In this case, the client will be registered with the CipherTrust Manager using its host name instead of the IP address:

```
SERVER_HOSTNAME=DSM-Server.example.com
REG_TOKEN=12345
PKCS11_PASSWORD=ClientAdminP@$$w0rd
AGENT_HOST_NAME=myagent.example.com
HOST_DESC="West Coast Server 12"
USEHWSIG=1
ENABLE_LDT=1
```

- Copy or mount the CTE installation file to the host system. The installation file is in the format `vee-fs-<release>-<build>-<system>.bin`.

- Run the installer using the following syntax:

```
# ./vee-fs-<release>-<build>-<system>.bin [-d <custom-dir>] -s <install-file>
```

where:

- `-d <custom-dir>` is an optional parameter that specifies the installation directory for CTE. If you omit this parameter, CTE is installed in `/opt/vormetric/DataSecurityExpert/agent/`.
- `-s <install-file>` indicates that you want to install silently using the installation options file `<install-file>`

For example, if the installation options file is called `/tmp/unattended.txt`, you would enter:

```
# ./vee-fs-7.0.0-47-rh8-x86_64.bin -s /tmp/unattended.txt
```

- Verify the installation by checking CTE processes on the host:
 - Run `vmc -v` to check the version of CTE matches that just installed.
 - Run `vmsec status` to display CTE kernel status.
 - Look at the log files in `/var/log/vormetric`, especially `install.fs.log.<date>` and `vorvmd_root.log`.
- In CipherTrust Manager, change the client password using the manual password creation method. This password allows users to access encrypted data if the client is ever disconnected from the CipherTrust Manager. For details on changing the password, see the CipherTrust Manager documentation.

Guarding a Device with CipherTrust Manager

After you register a client with a CipherTrust Manager, you can create as many GuardPoints on the client as you need. These GuardPoints can protect an entire device or individual directories.

In order to guard a device or directory, you need to use the CipherTrust Manager Console to:

1. Access the CipherTrust Manager domain in which the client is registered.
2. Identify or create an encryption key that CTE will use to encrypt the data on the device or directory.
3. Identify or create a policy for the device or directory that specifies the access controls and the encryption keys to use for the device or directory.
4. Assign a GuardPoint to the device or directory.

The following example creates a simple policy and uses it to guard a directory on a registered client. For all of the following procedures, you must be logged into the CipherTrust Manager Console as a CipherTrust Manager Administrator, and you must be in the domain with which the client is registered.

For details about any of these procedures or the options for domains, encryption keys, policies, and GuardPoints, see the CipherTrust Manager documentation.

Access the CipherTrust Manager Domain

1. In a web browser, navigate to the URL of the CipherTrust Manager Console you want to use and log in with CipherTrust Manager Administrator credentials.
2. If the client you want to protect is registered to the default domain (root), proceed to ["Create an Encryption Key" below](#). If you need to change to a different domain, do the following:
 - a. In the top menu bar, click the user name **root/admin** on the right-hand side.
 - b. Select **Switch Domains**, then select the domain in which the client is registered.
 - c. The logged in user now shows the new domain name/user name.

Create an Encryption Key

1. In the Applications page of the CipherTrust Manager Console, select **Keys & Access Management**.
2. Above the Key table, click **Create a New Key**.
3. In the **Key Name** field, add a name for the key. This name must be unique. For example, Simple-Key.
4. In the **Key Metadata > Groups for Key sharing** section, do the following:

- a. In the **Search** box, type "cte".
- b. Add CTE Admins and CTE Clients to the key sharing groups by clicking the green **Add** button. The **Key Shared?** check box is automatically selected and the **Add** button changes to a **Remove** button.
- c. Below the Groups table, click the **CTE Key Properties** check box.

CipherTrust Manager displays the following options for CTE keys:

- **CTE Versioned:** Specify whether the key is versioned. By default, the key is set as versioned.
For a standard policy, you should clear this check box. If you do not, the key will *not* appear in the keys list when you add the key rule to the standard policy.
- **Persistent on Client:** Specify whether the key is stored in persistent memory on the client.
When the check box is selected, the key is downloaded and stored (in an encrypted form) in persistent memory on the client.
When the check box is left clear, the key is downloaded to non-persistent memory on the client. Every time the key is needed, the client retrieves it from the CipherTrust Manager. This is the default setting.
- **Encryption Mode:** Encryption mode of the key. The options are:
 - CBC
 - CBC CS1
 - XTS

Encryption using the XTS and CBC CS1 keys is known as enhanced encryption. For details, see the *CTE Agent for Linux Advanced Configuration and Integration Guide*.

5. In the Key Behaviors section at the bottom of the page, clear the **Prevent this key from being exported** check box. If the key cannot be exported, the key will not appear in the keys list when you add the key rule to the policy.

6. Click **Create**. The new key appears in the Keys table.

Create a Standard Policy

1. In the Applications page of the CipherTrust Manager Console, select the **CTE** application.
2. In the sidebar on the Clients page, click **Policies**.
3. Click **Create Policy**. CipherTrust Manager displays the Create Policy Wizard.
4. On the General Info page, set the following options:

Field	Description
Name	A unique name for the policy. Make sure you use a name that is descriptive and easy to remember so that you can find it quickly when you want to associate it with a GuardPoint. This example uses "Simple-Policy".
Policy Type	The type of policy you want to create. In this example, we will create a Standard policy.
Description	A user-defined description to help you identify the policy later. For example: Standard policy for new GuardPoints
Learn Mode	Learn Mode provides a temporary method for disabling the blocking behavior of CTE/CTE-LDT policies. While useful for quality assurance, troubleshooting, and mitigating deployment risk, Learn Mode is not intended to be enabled permanently for a policy in production. This prevents the policy Deny rules from functioning as designed in the policy rule set. Ensure that the policy is properly configured for use in Learn Mode. Any Security Rule that contains a Deny effect must have Apply Key applied as well. This is to prevent data from being written in mixed states, resulting in the loss of access or data corruption. Apply Key will have no effect when combined with a Deny rule unless the policy is in Learn Mode.
Data Transformation	If you select Standard as the policy type, also select the the Data Transformation option to tell CTE that you want to change the current encryption key used on the data in the GuardPoint, or that you want to encrypt clear-text data for the first time. This option is only displayed for Standard policies.

When you are done, click **Next**.

5. On the Security Rules page, define the security rules you want to use.

CipherTrust Manager automatically adds a default security access rule with an action of `key_op` and the effects `Permit` and `Apply Key`. This rule permits key operations on all resources, without denying user or application access to resources. This allows it to perform a rekey operation whenever the encryption key rotates to a new version. This rule is required by CTE-LDT, so you cannot edit it, move it, or delete it.

To add additional security rules, click **Create Security Rule** and enter the requested information. For details about adding security rules, see the CipherTrust Manager documentation.

For this example, click **Create Security Rule** and:

- Set Action to `all_ops`.
- Set Effect to **Permit** and **Audit**.

When you are done, click **Next**.

6. On the Create Key Rule page, click **Create Key Rule** and enter the following information:

Field	Description
Resource Set	If you want to select a resource set for this key rule, click Select and either choose an existing resource set or create a new one. Resource sets let you specify which directories or files will either be encrypted with the key or will be excluded from encryption with this key.
Current Key Name	Click Select to choose an existing key or create a new one. If the data has not yet been encrypted, select clear_key . Otherwise select the name of the non-versioned key that is currently being used to encrypt the data. In this example, select clear_key .
Transformation Key Name	Click Select to choose an existing versioned key or to create a new one. CTE uses the versioned key specified in this field to encrypt the data in the GuardPoint. If the data is currently encrypted, CTE decrypts it using the key specified in the Current Key Name field and re-encrypts it using the key specified in this field.

When you are done, click **Next**.

7. On the Data Transformation page, click **Create Data Transformation Rule** and enter the following information:

Field	Description
Resource Set	If you want to select a resource set for this key rule, click Select and either choose an existing resource set or create a new one. Resource sets let you specify which directories or files will either be encrypted with the key or will be excluded from encryption with this key.
Transformation Key Name	Click Select to choose an existing key or to create a new one. CTE uses the key specified in this field to encrypt the data in the GuardPoint. If the data is currently encrypted, CTE decrypts it using the key specified in the Current Key Name field and re-encrypts it using the key specified in this field. For this example, select the key Simple-Key you created in "Create an Encryption Key" on page 34 .

When you are done, click **Next**.

8. Click **Next**.

- On the confirmation page, review the information for the policy and click **Save**.

Create Policy

General Info Security Rules Key Rules Data Transformation Rules Confirmation

Review the provided policy details.

General Info

Name: Create Policy
Policy Type: Standard
Description: Standard policy for new GuardPoints

Security Rules

Resource Set	User Set	Privilege Set	Action	Effect	Browsing
			key_for	perm:allow	Yes
			all_obj	perm:allow	Yes

Key Rules

Resource Set: Current Key Name: data-key

Data Transformation Rules

Resource Set: Transformation Key Name: encrypt-key

Back Save

Create a GuardPoint

- Stop all applications that are accessing the device you want to protect. In this example, we are going to protect the following directories with the same policy and encryption key:
 - /dir/hr/files
 - /dir/accounting/files
 - /dir/shared/hr
 - /dir/shared/accounting

Tip: If you want to encrypt data without taking the device offline, you must use CipherTrust Transparent Encryption - Live Data Transformation.

- In the Applications page of the CipherTrust Manager Console, select the **CTE** application.
- In the Clients table, click on the name of the client you want to protect.
- Above the GuardPoints table, click **Create GuardPoint**.
- In the Create GuardPoint page:
 - In the **Policy** field, select the policy you created earlier.
 - In the **Type** field, select the type of device. You can guard a directory or a raw/block device. For this example, select **Auto Directory**.
 - In the **Path** field, enter the directories you want to protect with this policy or click **Browse** to select them from a explorer window.

If you want to enter multiple paths, put each path on its own line. For example:

- d. Click **Create**.
- e. If you want to use the same policy and GuardPoint type on another path, click **Yes** when prompted. Otherwise, click **No**. For this example, click No.

The CipherTrust Manager pushes the GuardPoint configuration to the client and CTE immediately begins transforming the data in the specified folders from clear-text to cipher-text.

6. When the data transformation has finished, applications can resume accessing the now-protected data.

Configuring CTE for Linux with a DSM

This section describes how to install and configure CTE on Linux systems that you plan to register with a Vormetric Data Security Manager (DSM). This process requires actions from two roles:

- The *agent installer* or *host administrator* who uses these instructions to install and configure the CTE Agent on each Linux host whose data you want to protect.
- The DSM Administrator, who adds hosts to the DSM database using the FQDN or the IP address.

Installation Overview

The installation and configuration process for CTE with a DSM consists of three basic steps:

1. Gather the information needed for the install and set up your network as described in ["Installation Prerequisites" below](#).
2. Select the installation options you want to use as described in ["Installation and Registration Options" on page 42](#).
3. Install CTE on the protected host as described in ["Interactive Installation on Linux" on page 43](#) or ["Silent Installation on Linux" on page 51](#).
4. Register the protected host with the DSM and make sure that they can communicate with each other. This process can be done as part of the initial installation or at any point after the CTE Agent has been installed.

Installation Prerequisites

This section lists the tasks you must complete, and the information you must obtain, before installing CTE.

Recommendations and Considerations

- The host on which you want to install CTE *must* support AES-NI hardware encryption. If it does not, any attempt to install or upgrade CTE to release 7.0.0 or later will fail.
- Thales recommends that you install CTE in the default location.
- Do not install CTE on network-mounted volumes such as NFS.
- Make the Installation root directory `/opt` a real directory. If `/opt` is a symlink, you **must** use the `-d` option to specify the installation directory, which must be a real directory.
For example:

```
# ./vee-fs-7.0.0-47-rh8-x86_64.bin -d /home/hello/
```
- Ensure read/write permission is granted to other users accessing your shared resource.

Network Setup Requirements

- The IP addresses, routing configurations, and DNS addresses must allow connectivity of the DSM(s) to all hosts where you install CTE.
- If the host is a virtual machine, the VM must be deployed and running.

Host Name Resolution Requirements

Host name resolution is the method of mapping a host name to an IP address. During this configuration process, enter either the FQDNs, or IP addresses, of your DSM and protected hosts. If you use FQDNs, your protected hosts must be able to resolve the DSM host names, and the DSM must be able to resolve its protected hosts.

Note

The exception to this requirement is if you plan to configure one-way communication between CTE and the DSM.

A Domain Name Service (DNS) server is the preferred method of host name resolution. If you use DNS, use the FQDNs for the DSM and hosts.

If you do *not* use a DNS, you can do one of the following:

- Use the IP addresses of the DSM and protected hosts.
- Add an entry in the `/etc/hosts` file on the DSM associated with the host. The administrator must use the CipherTrust CLI, and, in an HA environment, they must add an entry to *each* DSM in the cluster because entries in the `/etc/hosts` file are not replicated across the cluster.

Port Configuration Requirements

If a protected host must communicate with the DSM through a firewall, see the *DSM Administration Guide* to determine which of the ports must be opened through the firewall.

The default port for communication between the DSM and the CTE Agent is 7024. If this port is already in use, you can set the port to a different number during the CTE Agent installation.

One-way Communication Option

In some deployments, CTE might not be visible to the DSM through normal network communications. For example, when the host on which CTE is installed:

- is behind NAT.
- is behind a firewall.
- is not permanently connected to a communication channel to the DSM.
- is unable to resolve the host name to an IP address.

In these situations, CTE can initiate CTE-only communication to the DSM. This feature is called one-way communication and works by having CTE poll the DSM for any policy messages or changes, then downloading changes as required.

The downside of one-way communication is that the DSM cannot issue any queries to CTE. For example, the DSM Administrator cannot browse host directories or User IDs. To enable the full functionality of both CTE and the CipherTrust Manager, Thales recommends that you use two-way communication between them whenever possible.

Port Usage in One-Way Communications Mode

By default, polling from the agent host to the DSM when running in one-way communications mode uses HTTP via port 8080. If the CTE Agent is configured to use secure polling, then polling is performed using HTTPS via port 8448 (in suite B mode) or port 8445.

Determining Kernel Compatibility With CTE

As new Red Hat, SUSE, and Ubuntu Linux kernels are published, Thales regularly publishes new patch versions of CTE that are compatible with selected versions of these new kernels. Thales recommends that you check that the kernel on which you want to install CTE is verified to be compatible with CTE. CTE may appear to run correctly on an unsupported kernel. However, Thales strongly advises against running CTE on an unsupported kernel due to potential stability issues.

The table below describes several ways to verify that a kernel version is compatible with the version of CTE that you plan to install or are running. For more information, see the following sections.

Methods to check kernel compatibility with CTE

Kernel compatibility check method	How to check	Description
Compatibility Matrix for CTE Agent with Data Security Manager document	Download from Thales support site	Includes kernel compatibility and other types of compatibility such as file system, database, antivirus, and DSM version compatibility.
Automated kernel compatibility check during installation or upgrade	Kernel compatibility is checked during installation or upgrade	If an incompatible kernel is detected, a message is printed to the screen and logged to <code>syslog</code> .
Automated run-time kernel compatibility check	Kernel compatibility is checked when the CTE services start	If an incompatible kernel is detected, a message is logged to <code>syslog</code> .

Installation and Registration Options

CTE provides the following installation and registration options. The options you choose determine the information you need to supply during the actual install procedure, so you should decide what options you want to use before you start the installation.

Installation Method Options

There are two methods for installing CTE on Linux platforms:

- **Interactive:** Most common and recommended type of installation. Use this method for installing the CTE Agent on one host at a time. See ["Interactive Installation on Linux" on the next page](#).
- **Silent:** Create pre-packaged installations by providing information and answers to a set of installation questions. Use silent installations when installing on a large number of hosts. See ["Silent Installation on Linux" on page 51](#).

CTE Registration Method Options

You can register the protected hosts with a DSM using either the *Fingerprint method* or the *Shared Secret method*.

- **Fingerprint method** requires the DSM Administrator to add the FQDN, or IP address, of each protected host to the DSM before registering CTE.
During the registration, the DSM generates the certificate and passes it down to CTE along with the fingerprint. The security administrator must verify the fingerprint to make sure the certificate is valid.
- **Shared Secret method** requires the DSM Administrator to create a *shared secret* password—a case-sensitive string of characters—for auto-registering a domain or host group.
CTE installers use the shared secret to add and register protected hosts to the DSM for a domain or host group. The DSM Administrator can optionally add host names or IP addresses to the DSM. There is no need to verify that the protected host and DSM share valid certificates. You can add multiple protected hosts dynamically with a single shared secret password during CTE installation and registration.
After the DSM Administrator creates a shared secret for the domain or host group in which the new protected host will reside, obtain it and the validity period (one hour, day, week, or month) and register within that period.

Hardware Association (Cloning Prevention) Option

CTE's hardware association feature associates the installation of CTE with the machine's hardware. When enabled, hardware association prohibits cloned or copied versions of CTE from contacting the key manager and acquiring cryptographic keys. Hardware association works on both virtual machines and hardware hosts.

You can enable hardware association during CTE registration process. You can disable hardware association by re-running the registration program.

To verify if hardware association (cloning prevention) is enabled on a Linux host, on the command line enter the following:

```
cat /opt/vormetric/DataSecurityExpert/agent/vmd/etc/access
```

If you see `usehw:true`, then hardware association is enabled. If you see `usehw:false`, it's disabled.

CTE Linux Installation Checklist

Use the following table to verify prerequisites and collect the information you need for the installation.

Checklist item	Notes
Obtain the CTE Agent installation image from Thales. The format for the installation file names is: <code>vee-fs-<release>-<build>-<system>.bin</code> For example: <code>vee-fs-7.0.0-47-rh8-x86_64.bin</code>	
Get the Fully Qualified Domain Name (FQDN) of the DSM as shown on the DSM Dashboard.	
Get the IP address or FQDN of the host. If you are using the Fingerprint registration method, this must match exactly with the name specified in the DSM.	
Make sure you have the <code>root</code> user login credentials for the host. You must install CTE as <code>root</code> .	
If using Shared Secret registration, obtain the following from the DSM Administrator: • Shared secret password • Domain • Host group, if applicable • Description of the host (Optional)	
If using the Fingerprint registration method: • Ask the DSM Administrator to add the host to the DSM and check the Registration Allowed and Communication Enabled check boxes. • Get the EC CA certificate fingerprint as shown on the DSM Dashboard.	
Make sure the host can communicate with the DSM. For details, see "Host Name Resolution Requirements" on page 40 .	
Make sure the correct ports are open. For details, see "Port Configuration Requirements" on page 40 .	
Determine if you want to use the One-way communication option. For details, see "One-way Communication Option" on page 41 .	
Determine if you want to use the Hardware Association feature. For details, see "Hardware Association (Cloning Prevention) Option" on the previous page .	
Synchronize the host clock to the DSM clock.	
Determine your preferred DNS Server (if using FQDNs).	

Interactive Installation on Linux

The Linux interactive install is a standard interactive script that asks you a series of questions during the installation. You can also install CTE using a silent installer which pre-packages the install information. This allows you to install CTE on a large number of hosts. (For more information, see ["Silent Installation on Linux" on page 51](#)).

After you install CTE, you are prompted to register it immediately with a DSM. CTE must be registered with a DSM before you can protect any of the devices on the host. However, you may postpone the registration if you plan to register CTE later.

The procedure for installing CTE depends on the registration method you want to use. The available methods are described in ["CTE Registration Method Options" on page 42](#). After you have selected your registration method, you can use one of the following procedures:

- ["Installing CTE and Registering Using the Shared Secret Registration Method" on page 47](#)
- ["Installing CTE and Registering Using the Certificate Fingerprint" below](#)

Note

Do not install CTE on network-mounted volumes like NFS.

Installing CTE and Registering Using the Certificate Fingerprint

The following procedure describes how to install the CTE Agent on the host and then register the CTE Agent with a DSM using the Fingerprint registration method. For more information about the available registration methods, see ["CTE Registration Method Options" on page 42](#).

For other installation options, see ["Installing CTE and Registering Using the Shared Secret Registration Method" on page 47](#) and ["Installing CTE with No Key Manager Registration" on page 27](#).

Prerequisites

Make sure the DSM Administrator has added the the FQDN, or IP address, of this host to the domain in which you want to register the host. During the registration, the DSM generates the certificate and passes it down to CTE along with the fingerprint. You will then need to verify the certificate fingerprint as part of the registration procedure.

In the DSM Management Console, the entry for the host must have at least the **Registration Allowed Agents > FS** and **Communication Enabled** options selected.

When you register the host, the machine name you use must exactly match the one in the DSM.

Additionally, make sure you know the server name of the primary DSM as shown on the DSM Dashboard.

Note

If registration appears to freeze, verify that the DSM and CTE can communicate with each other over the network.

Procedure

1. Log on to the host where you will install the CTE Agent as `root`. You cannot install the CTE Agent without `root` access.
2. Copy or mount the installation file to the host system. If necessary, make the file executable with the `chmod` command.

3. Install the CTE Agent. A typical installation uses the following syntax:

```
# ./vee-fs-<release>-<build>-<system>.bin
```

For example:

```
# ./vee-fs-7.0.0-47-rh8-x86_64.bin
```

To install the CTE Agent in a custom directory, use the `-d <custom-dir>` option. For example:

```
# ./vee-fs-7.0.0-47-rh8-x86_64.bin -d /home/my-cte-dir/
```

Note: If possible, Thales recommends that you use the default directory `/opt/vormetric`.

To view all installer options, use the `-h` parameter. For example:

```
# ./vee-fs-7.0.0-47-rh8-x86_64.bin -h
```

4. The Thales License Agreement displays. When prompted, type `y` and press Enter to accept.

The install script installs the CTE Agent software in either `/opt/vormetric` or your custom installation directory and then prompts you about registering the CTE Agent with a key manager.

```
Welcome to the CipherTrust Transparent Encryption File System Agent
Registration Program.
```

```
Agent Type: CipherTrust Transparent Encryption File System Agent
Agent Version: 7.0.0.47
```

In order to register the CipherTrust Transparent Encryption File System Agent with a Vormetric Data Security Manager

- 1) you must know the host name of the machine running the DSM (the host name is displayed on the Dashboard window of the Management Console), and
- 2) unless you intend to use the 'shared secret' registration method, the agent's host machine must be pre-configured on the DSM as a host with the 'Reg. Allowed' checkbox enabled for this agent type on the Hosts window of the Management Console.

In order to register with a CipherTrust Manager you need a valid registration token from the CM.

```
Do you want to continue with agent registration? (Y/N) [Y]:
```

5. Enter **y** to continue with the registration process. The install script prompts you to enter the name of the DSM with which you want to register the host. This name must match the name shown in the **Server name** field in the **Management Summary** section on the DSM **Dashboard** page.

For example:

```
Do you want to continue with agent registration? (Y/N) [Y]: y
```

```
Please enter the primary key manager host name: dsm630-121079.i.vormetric.com
```

```
You entered the host name dsm630-121079.i.vormetric.com
```

```
Is this host name correct? (Y/N) [Y]: y
```

6. Enter the host name when prompted. This name must match the name used on the **Add Host** page of the DSM Management Console.

Please enter the host name of this machine, or select from the following list. If using the "fingerprint" registration method, the name you provide must precisely match the name used on the "Add Host" page of the Management Console.

```
[1] host14.i.example.com  
[2] Host-RHEL-14.i.example.com  
[3] 10.3.14.90
```

```
Enter a number, or type a different host name or IP address in manually:
```

```
What is the name of this machine? [1]: 3
```

```
You selected "10.3.14.90".
```

7. When prompted for the registration method, enter **F** for fingerprint registration:

```
Would you like to register to the DSM using a  
registration shared secret (S) or using fingerprints (F)? (S/F) [S]: F
```

8. At the hardware association prompt, select whether you want to enable the hardware association feature that prevents a clone of this machine from accessing keys in the DSM. The default is **y** (enabled):

It is possible to associate this installation with the hardware of this machine. If selected, the agent will not contact the key manager or use any cryptographic keys if any of this machine's hardware is changed. This can be rectified by running this registration program again.

```
Do you want to enable this functionality? (Y/N) [Y]: y
```

- At this point, the install script asks you about some of the optional CTE features you may want to enable, such as CTE-Efficient Storage, CTE-LDT, and docker support.

Note: Some of these features may require a separate license in the DSM.

For example:

Do you want this host to have docker support enabled on the server? (Y/N) [N]:

Do you want this host to have Efficient Storage support enabled on the server? (Y/N) [N]:

Do you want this host to have LDT support enabled on the server? (Y/N) [N]:

Do you want to configure this host for Cloud Object Storage? (Y/N) [N]:

- At this point, the install program generates certificate signing requests and lists the fingerprint of the EC (elliptic curve) CA (Certificate Authority) certificate. This fingerprint must match the one on the DSM Dashboard in the **Management Summary** section, **EC CA fingerprint** field.

The following is the fingerprint of the EC CA certificate.

Please verify that it matches the fingerprint shown on the Dashboard page of the Management Console. If they do not match, it can indicate an unsuccessful setup or an attack.

2F:9A:1C:DB:7E:B9:6C:63:D4:BA:D2:25:C6:7C:97:F1:E1:48:20:AE

Do the fingerprints match? (Y/N) [N]: **Y**

If the fingerprints match, enter **y**. The installer displays the fingerprint for the CTE Agent on the host and completes the installation:

The following is the fingerprint for this agent on this host.

Please verify that it matches the fingerprint shown for this host on the Edit Host window of the Management Console.

12:CF:64:A3:28:7E:2E:50:72:70:FF:8F:B2:79:5B:4F:40:1B:74:20

Successfully registered the CipherTrust Transparent Encryption File System Agent with the Vormetric Data Security Manager on dsm630-121079.i.vormetric.com.

Installation success.

- Verify with the DSM Administrator that the CTE fingerprint matches with the fingerprint shown for this host on the **Hosts > Hostname > Edit Host** window of the DSM Management Console. CTE is installed and registered.
- Verify the installation by checking the CTE processes on the host:
 - Run `vmd -v` to check the version of CTE.
 - Run `vmsec status` to display the CTE processes.
 - Look at the log files in `/var/log/vormetric/install.fs.log.<date>`, especially `vorvmd_root.log`.

Installing CTE and Registering Using the Shared Secret Registration Method

The following procedure describes how to install the CTE Agent on the Linux host and then register the CTE Agent with a DSM using the Shared Secret registration method. For more information about the available registration methods, see ["CTE Registration Method Options" on page 42](#).

For other installation options, see ["Installing CTE and Registering Using the Certificate Fingerprint" on page 44](#) and ["Installing CTE with No Key Manager Registration" on page 27](#).

Prerequisites

Make sure you know the following information from the DSM Administrator:

- The server name of the primary DSM as shown on the DSM Dashboard.
- The shared secret for the domain on the primary DSM with which you want to register the host.
- The name of the domain in the DSM with which you want to register the host.
- Optionally, the name of the host group in which this host should be included.

All of this information is case-sensitive and must exactly match the corresponding information in the DSM.

Note

If registration appears to freeze, verify that the DSM and CTE can communicate with each other over the network.

Procedure

1. Log on to the host where you will install the CTE Agent as `root`. You cannot install the CTE Agent without `root` access.
2. Copy or mount the installation file to the host system. If necessary, make the file executable with the `chmod` command.
3. Install the CTE Agent. A typical installation uses the following syntax:

```
# ./vee-fs-<release>-<build>-<system>.bin
```

For example:

```
# ./vee-fs-7.0.0-47-rh8-x86_64.bin
```

To install the CTE Agent in a custom directory, use the `-d <custom-dir>` option. For example:

```
# ./vee-fs-7.0.0-47-rh8-x86_64.bin -d /home/my-cte-dir/
```

Note: If possible, Thales recommends that you use the default directory `/opt/vormetric`.

To view all installer options, use the `-h` parameter. For example:

```
# ./vee-fs-7.0.0-47-rh8-x86_64.bin -h
```

4. The Thales License Agreement displays. When prompted, type **y** and press Enter to accept.

The install script installs the CTE Agent software in either `/opt/vormetric` or your custom installation directory and then prompts you about registering the CTE Agent with a key manager.

```
Welcome to the CipherTrust Transparent Encryption File System Agent
Registration Program.
```

```
Agent Type: CipherTrust Transparent Encryption File System Agent
Agent Version: 7.0.0.47
```

In order to register the CipherTrust Transparent Encryption File System Agent with a Vormetric Data Security Manager

- 1) you must know the host name of the machine running the DSM (the host name is displayed on the Dashboard window of the Management Console), and
- 2) unless you intend to use the 'shared secret' registration method, the agent's host machine must be pre-configured on the DSM as a host with the 'Reg. Allowed' checkbox enabled for this agent type on the Hosts window of the Management Console.

In order to register with a CipherTrust Manager you need a valid registration token from the CM.

Do you want to continue with agent registration? (Y/N) [Y]:

5. Enter **y** to continue with the registration process. The install script prompts you to enter the name of the DSM with which you want to register the host. This name must match the name shown in the **Server name** field in the **Management Summary** section on the DSM **Dashboard** page.

For example:

Do you want to continue with agent registration? (Y/N) [Y]: **y**

Please enter the primary key manager host name: **dsm630-121079.i.vormetric.com**

You entered the host name dsm630-121079.i.vormetric.com

Is this host name correct? (Y/N) [Y]: **y**

6. Enter the host name when prompted. If the Shared Secret registration in your DSM is configured to require an existing host entry, his name must match the name used on the **Add Host** page of the DSM Management Console.

Please enter the host name of this machine, or select from the following list. If using the "fingerprint" registration method, the name you provide must precisely match the name used on the "Add Host" page of the Management Console.

```
[1] host14.i.example.com
[2] Host-RHEL-14.i.example.com
[3] 10.3.14.90
```

Enter a number, or type a different host name or IP address in manually:
What is the name of this machine? [1]: **3**
You selected "10.3.14.90".

7. When prompted for the registration method, enter **s** for shared secret registration and then enter the required information about the domain, optional host group, and optional host description. For example:

Would you like to register to the DSM using a
registration shared secret (S) or using fingerprints (F)? (S/F) [S]: **S**

What is the registration shared secret?
Please enter the domain name for this host: **west-coast-domain**
Please enter the host group name for this host, if any:
Please enter a description for this host: **West Coast Data Center server 5**

```
Shared secret      : *****
Domain name       : west-coast-domain
Host Group        : (none)
Host description   : West Coast Data Center server 5
Are the above values correct? (Y/N) [Y]: Y
```

8. At the hardware association prompt, select whether you want to enable the hardware association feature that prevents a clone of this machine from accessing keys in the DSM. The default is **y** (enabled):

It is possible to associate this installation with the hardware of this machine. If selected, the agent will not contact the key manager or use any cryptographic keys if any of this machine's hardware is changed. This can be rectified by running this registration program again.
Do you want to enable this functionality? (Y/N) [Y]: **Y**

9. At this point, the install script asks you about some of the optional CTE features you may want to enable, such as CTE-Efficient Storage, CTE-LDT, and docker support.

Note: Some of these features may require a separate license in the DSM.

For example:

Do you want this host to have docker support enabled on the server? (Y/N) [N]:

Do you want this host to have Efficient Storage support enabled on the server? (Y/N) [N]:

Do you want this host to have LDT support enabled on the server? (Y/N) [N]:

Do you want to configure this host for Cloud Object Storage? (Y/N) [N]:

10. At this point the installation script completes the installation and indicates that it successfully registered the host with the DSM.

```
Generating certificate signing request for the kernel component...done.  
Signing certificate...done.  
Generating EC certificate signing request for the vmd...done.  
Signing certificate...done.  
Generating EC certificate signing request for the vmd...done.  
Signing certificate...done.  
Successfully registered the CipherTrust Transparent Encryption File System Agent with the  
Vormetric Data Security Manager on dsm630-121079.i.vormetric.com.
```

11. Verify the installation by checking the CTE processes on the host:

- Run `vmd -v` to check the version of CTE.
- Run `vmsec status` to display the CTE processes.
- Look at the log files in `/var/log/vormetric/install.fs.log.<date>`, especially `vorvmd_root.log`.

Silent Installation on Linux

This section describes how to perform a silent (unattended) installation of the CTE on a single host. The silent installation automates the installation process by storing the answers to installation and registration questions in a separate file that you create. You can also use the silent installation to install CTE on multiple hosts simultaneously.

The silent install method installs CTE on the host, and registers the host with the DSM you specify in the silent installation file.

For details, see one of the following procedures:

- ["Silent Installation on Linux Using the Shared Secret Registration Method" below](#)
- ["Silent Installation on Linux Using the Fingerprint Registration Method" on page 53](#)

Silent Installation on Linux Using the Shared Secret Registration Method

This section describes how to perform a silent (unattended) installation of the CTE on a single host. The silent installation automates the installation process by storing the answers to installation and registration questions in a separate file that you create. You can also use the silent installation to install CTE on multiple hosts simultaneously.

The silent install method installs CTE on the host, and registers the host with the DSM you specify in the silent installation file using the Shared Secret registration method. To register it using the Fingerprint registration method, see ["Silent Installation on Linux Using the Fingerprint Registration Method" on page 53](#).

Prerequisites

Make sure you know the following information from the DSM Administrator:

- The server name of the primary DSM as shown on the DSM Dashboard.
- The shared secret for the domain on the primary DSM with which you want to register the host.
- The name of the domain in the DSM with which you want to register the host.
- Optionally, the name of the host group in which this host should be included.

All of this information is case-sensitive and must exactly match the corresponding information in the DSM.

Note

If registration appears to freeze, verify that the DSM and CTE can communicate with each other over the network.

Procedure

1. Log on as an administrator to the host where you will install CTE.
2. Create a parameter file and store it on your system, or copy an existing file from another location. The file can contain any of the following parameters:

Parameter	Description
SERVER_HOSTNAME	Required if you want to register CTE with a DSM.
TMPDIR	Specifies a custom temporary directory that the installer can use during the installation process. If this value is omitted, the installer uses the default temporary directory.
SHARED_SECRET	Specifies the shared secret for the DSM. This value is required for shared secret registration.
AGENT_HOST_NAME	FQDN of the host on which the CTE Agent is being installed. If this value is not specified, the installer uses the host's IP address.
PKCS11_PASSWORD	The administrative password for the CTE Agent. This password allows users to access encrypted data on the host if it is disconnected from the DSM.
AGENT_USEIP	Use the IP address of the protected host instead of host name. Used when <code>-agent</code> is not supplied.
HOST_DESC	Specifies a description for the host. This description is displayed in the DSM. If an entry for this host already exists in the DSM and the host already has a description, CTE does <i>not</i> overwrite the existing description even if this option is specified.
AGENT_HOST_PORT	Specifies the port number this CTE Agent should use.
USEHWSIG	Set this value to 1 when you want to associate this installation with the machine hardware for cloning prevention.
ENABLE_LDT	Set this value to 1 to automatically enable and register CTE-LDT (Live Data Transformation) during silent install.
ENABLE_ES	Set this value to 1 to automatically enable and register CTE-Efficient Storage during silent install.
ENABLE_DOCKER	Set this value to 1 if you want to enable docker security on this host.
ONEWAY_COMMS	Set this value to 1 when CTE-initiated-only communication is required. Thales recommends that you use two-way communication between CTE and the key manager whenever possible.

Parameter	Description
CERT_FIELD_PARAM	If you are using CTE-Cloud Object Storage, this option specifies a custom certificate field values for the CTE COS Root CA Certificate.
SUBJECT_ALT_NAME_PARAM	If you are using CTE-Cloud Object Storage, this option specifies a custom Subject Alt Name for the CTE COS Root CA Certificate. You must also specify CERT_FIELD_PARAM to use this parameter.
STRONG_ENTROPY	Set this value to 1 to switch between /dev/random and /dev/urandom based on read speed.

The following example contains just the required information for Shared Secretregistration. In this case, the host will be registered with the DSM using its IP address instead of its host name:

```
SERVER_HOSTNAME=Key-Mgmt-Server.example.com
SHARED_SECRET=Shallac112345#
HOST_DOMAIN=My-Domain
```

The following example specifies the required registration information, adds a host name and description, and enables hardware association, CTE-Efficient Storage, and CTE-LDT. In this case, the host will be registered with the DSM using its host name instead of the IP address:

```
SERVER_HOSTNAME=DSM-Server.example.com
AGENT_HOST_NAME=myagent.example.com
SHARED_SECRET=Shallac112345#
HOST_DOMAIN=My-Domain
HOST_DESC="West Coast Server 12"
USEHWSIG=1
ENABLE_ES=1
ENABLE_LDT=1
```

3. Copy or mount the CTE installation file to the host system. The installation file is in the format `vee-fs-<release>-<build>-<system>.bin`.

4. Run the installer using the following syntax:

```
# ./vee-fs-<release>-<build>-<system>.bin [-d <custom-dir>] -s <install-file>
```

where:

- `-d <custom-dir>` is an optional parameter that specifies the installation directory for CTE. If you omit this parameter, CTE is installed in `/opt/vormetric/DataSecurityExpert/agent/`.
- `-s <install-file>` indicates that you want to install silently using the installation options file `<install-file>`

For example, if the installation options file is called `/tmp/unattended.txt`, you would enter:

```
# ./vee-fs-7.0.0-47-rh8-x86_64.bin -s /tmp/unattended.txt
```

5. Verify the installation by checking CTE processes on the host:
 - Run `vmd -v` to check the version of CTE matches that just installed.
 - Run `vmsec status` to display CTE kernel status.
 - Look at the log files in `/var/log/vormetric`, especially `install.fs.log.<date>` and `vorvmd_root.log`.

Silent Installation on Linux Using the Fingerprint Registration Method

This section describes how to perform a silent (unattended) installation of the CTE on a single host. The silent installation automates the installation process by storing the answers to installation and registration questions in a separate file that you create. You can also use the silent installation to install CTE on multiple hosts simultaneously.

The silent install method installs CTE on the host, and registers the host with the DSM you specify in the silent installation file using the Fingerprint registration method. To register using the Shared Secret registration method, see ["Silent Installation on Linux Using the Shared Secret Registration Method" on page 51](#).

Prerequisites

Make sure the DSM Administrator has added the the FQDN, or IP address, of this host to the domain in which you want to register the host. During the registration, the DSM generates the certificate and passes it down to CTE along with the fingerprint. You will then need to verify the certificate fingerprint as part of the registration procedure.

In the DSM Management Console, the entry for the host must have at least the **Registration Allowed Agents > FS** and **Communication Enabled** options selected.

When you register the host, the machine name you use must exactly match the one in the DSM.

Additionally, make sure you know the server name of the primary DSM as shown on the DSM Dashboard.

Note

If registration appears to freeze, verify that the DSM and CTE can communicate with each other over the network.

Procedure

1. Log on as an administrator to the host where you will install CTE.
2. Create a parameter file and store it on your system, or copy an existing file from another location. The file can contain any of the following parameters:

Parameter	Description
SERVER_HOSTNAME	Required if you want to register CTE with a DSM.
TMPDIR	Specifies a custom temporary directory that the installer can use during the installation process. If this value is omitted, the installer uses the default temporary directory.
AGENT_HOST_NAME	FQDN of the host on which the CTE Agent is being installed. If this value is not specified, the installer uses the host's IP address.
PKCS11_PASSWORD	The administrative password for the CTE Agent. This password allows users to access encrypted data on the host if it is disconnected from the DSM.
AGENT_USEIP	Use the IP address of the protected host instead of host name. Used when <code>-agent</code> is not supplied.
HOST_DESC	Specifies a description for the host. This description is displayed in the DSM. If an entry for this host already exists in the DSM and the host already has a description, CTE does <i>not</i> overwrite the existing description even if this option is specified.
AGENT_HOST_PORT	Specifies the port number this CTE Agent should use.
USEHWSIG	Set this value to 1 when you want to associate this installation with the machine hardware for cloning prevention.

Parameter	Description
ENABLE_LDT	Set this value to 1 to automatically enable and register CTE-LDT (Live Data Transformation) during silent install.
ENABLE_ES	Set this value to 1 automatically enable and register CTE-Efficient Storage during silent install.
ENABLE_DOCKER	Set this value to 1 if you want to enable docker security on this host.
ONEWAY_COMMS	Set this value to 1 when CTE-initiated-only communication is required. Thales recommends that you use two-way communication between CTE and the key manager whenever possible.
CERT_FIELD_PARAM	If you are using CTE-Cloud Object Storage, this option specifies a custom certificate field values for the CTE COS Root CA Certificate.
SUBJECT_ALT_NAME_PARAM	If you are using CTE-Cloud Object Storage, this option specifies a custom Subject Alt Name for the CTE COS Root CA Certificate. You must also specify <code>CERT_FIELD_PARAM</code> to use this parameter.
STRONG_ENTROPY	Set this value to 1 to switch between <code>/dev/random</code> and <code>/dev/urandom</code> based on read speed.

The following example contains just the required information for Fingerprint registration. In this case, the host will be registered with the DSM using its IP address instead of its host name:

```
SERVER_HOSTNAME=Key-Mgmt-Server.example.com
```

The following example specifies the required registration information, adds a host name and description, and enables hardware association, CTE-Efficient Storage, and CTE-LDT. In this case, the host will be registered with the DSM using its host name instead of the IP address:

```
SERVER_HOSTNAME=DSM-Server.example.com
AGENT_HOST_NAME=myagent.example.com
HOST_DESC="West Coast Server 12"
USEHWSIG=1
ENABLE_ES=1
ENABLE_LDT=1
```

3. Copy or mount the CTE installation file to the host system. The installation file is in the format `vee-fs-<release>-<build>-<system>.bin`.

4. Run the installer using the following syntax:

```
# ./vee-fs-<release>-<build>-<system>.bin [-d <custom-dir>] -s <install-file>
```

where:

- `-d <custom-dir>` is an optional parameter that specifies the installation directory for CTE. If you omit this parameter, CTE is installed in `/opt/vormetric/DataSecurityExpert/agent/`.
- `-s <install-file>` indicates that you want to install silently using the installation options file `<install-file>`

For example, if the installation options file is called `/tmp/unattended.txt`, you would enter:

```
# ./vee-fs-7.0.0-47-rh8-x86_64.bin -s /tmp/unattended.txt
```

5. Verify the installation by checking CTE processes on the host:
 - Run `vmd -v` to check the version of CTE matches that just installed.
 - Run `vmsec status` to display CTE kernel status.
 - Look at the log files in `/var/log/vormetric`, especially `install.fs.log.<date>` and `vorvmd_root.log`.

Registering CTE with the Shared Secret Registration Method After Installation is Complete

The following procedure describes how to register the CTE Agent after installation is complete. If you have not yet installed the CTE Agent, see ["Installing CTE and Registering Using the Shared Secret Registration Method" on page 47](#) or ["Installing CTE and Registering Using the Certificate Fingerprint" on page 44](#).

Prerequisites

Make sure you know the following information from the DSM Administrator:

- The server name of the primary DSM as shown on the DSM Dashboard.
- The shared secret for the domain on the primary DSM with which you want to register the host.
- The name of the domain in the DSM with which you want to register the host.
- Optionally, the name of the host group in which this host should be included.

All of this information is case-sensitive and must exactly match the corresponding information in the DSM.

Note

If registration appears to freeze, verify that the DSM and CTE can communicate with each other over the network.

Procedure

1. Log on to the host where you will install the CTE Agent as `root`. You cannot register the CTE Agent without `root` access.
2. Launch the CTE Registration script by running the `register_host` script. The default location is `/opt/vormetric/DataSecurityExpert/agent/vmd/bin`. For example:

```
# ./opt/vormetric/DataSecurityExpert/agent/vmd/bin/register_host
Welcome to the CipherTrust Transparent Encryption File System Agent
Registration Program.
```

```
Agent Type: CipherTrust Transparent Encryption File System Agent
Agent Version: 7.0.0.47
```

In order to register the CipherTrust Transparent Encryption File System Agent with a Vormetric Data Security Manager

- 1) you must know the host name of the machine running the DSM (the host name is displayed on the Dashboard window of the Management Console), and
- 2) unless you intend to use the 'shared secret' registration method, the agent's host machine must be pre-configured on the DSM as a host with the 'Reg. Allowed' checkbox enabled for this agent type on the Hosts window of the Management Console.

In order to register with a CipherTrust Manager you need a valid registration

token from the CM.

Do you want to continue with agent registration? (Y/N) [Y]:

3. Enter **y** to continue with the registration process. The install script prompts you to enter the name of the DSM with which you want to register the host. This name must match the name shown in the **Server name** field in the **Management Summary** section on the DSM **Dashboard** page.

For example:

Do you want to continue with agent registration? (Y/N) [Y]: **y**

Please enter the primary key manager host name: **dsm630-121079.i.vormetric.com**

You entered the host name dsm630-121079.i.vormetric.com

Is this host name correct? (Y/N) [Y]: **y**

4. Enter the host name when prompted. If the Shared Secret registration in your DSM is configured to require an existing host entry, his name must match the name used on the **Add Host** page of the DSM Management Console.

Please enter the host name of this machine, or select from the following list. If using the "fingerprint" registration method, the name you provide must precisely match the name used on the "Add Host" page of the Management Console.

```
[1] host14.i.example.com
[2] Host-RHEL-14.i.example.com
[3] 10.3.14.90
```

Enter a number, or type a different host name or IP address in manually:

What is the name of this machine? [1]: **3**

You selected "10.3.14.90".

5. When prompted for the registration method, enter **s** for shared secret registration and then enter the required information about the domain, optional host group, and optional host description. For example:

Would you like to register to the DSM using a
registration shared secret (S) or using fingerprints (F)? (S/F) [S]: **s**

What is the registration shared secret?

Please enter the domain name for this host: **west-coast-domain**

Please enter the host group name for this host, if any:

Please enter a description for this host: **West Coast Data Center server 5**

```
Shared secret      : *****
Domain name       : west-coast-domain
Host Group        : (none)
Host description   : West Coast Data Center server 5
Are the above values correct? (Y/N) [Y]: y
```

6. At the hardware association prompt, select whether you want to enable the hardware association feature that prevents a clone of this machine from accessing keys in the DSM. The default is **y** (enabled):

It is possible to associate this installation with the hardware of this machine. If selected, the agent will not contact the key manager or use any cryptographic keys if any of this machine's hardware is changed. This can be rectified by running this registration program again.
Do you want to enable this functionality? (Y/N) [Y]: **y**

7. At this point, the install script asks you about some of the optional CTE features you may want to enable, such as CTE-Efficient Storage, CTE-LDT, and docker support.

Note: Some of these features may require a separate license in the DSM.

For example:

Do you want this host to have docker support enabled on the server? (Y/N) [N]:

Do you want this host to have Efficient Storage support enabled on the server? (Y/N) [N]:

Do you want this host to have LDT support enabled on the server? (Y/N) [N]:

Do you want to configure this host for Cloud Object Storage? (Y/N) [N]:

8. At this point the installation script completes the installation and indicates that it successfully registered the host with the DSM.

Generating certificate signing request for the kernel component...done.
Signing certificate...done.
Generating EC certificate signing request for the vmd...done.
Signing certificate...done.
Generating EC certificate signing request for the vmd...done.
Signing certificate...done.
Successfully registered the CipherTrust Transparent Encryption File System Agent with the Vormetric Data Security Manager on dsm630-121079.i.vormetric.com.

9. Verify the installation by checking the CTE processes on the host:
 - Run `vmd -v` to check the version of CTE.
 - Run `vmsec status` to display the CTE processes.
 - Look at the log files in `/var/log/vormetric/install.fs.log.<date>`, especially `vorvmd_root.log`.

Registering CTE with the Fingerprint Registration Method After Installation is Complete

The following procedure describes how to register the CTE Agent after installation is complete. If you have not yet installed the CTE Agent, see ["Installing CTE and Registering Using the Certificate Fingerprint" on page 44](#) or ["Installing CTE and Registering Using the Shared Secret Registration Method" on page 47](#).

Prerequisites

Make sure the DSM Administrator has added the the FQDN, or IP address, of this host to the domain in which you want to register the host. During the registration, the DSM generates the certificate and passes it down to CTE along with the fingerprint. You will then need to verify the certificate fingerprint as part of the registration procedure.

In the DSM Management Console, the entry for the host must have at least the **Registration Allowed Agents > FS** and **Communication Enabled** options selected.

When you register the host, the machine name you use must exactly match the one in the DSM.

Additionally, make sure you know the server name of the primary DSM as shown on the DSM Dashboard.

Note

If registration appears to freeze, verify that the DSM and CTE can communicate with each other over the network.

Procedure

1. Log on to the host where you will install the CTE Agent as `root`. You cannot register the CTE Agent without `root` access.
2. Launch the CTE Registration script by running the `register_host` script. The default location is `/opt/vormetric/DataSecurityExpert/agent/vmd/bin`. For example:

```
# ./opt/vormetric/DataSecurityExpert/agent/vmd/bin/register_host
Welcome to the CipherTrust Transparent Encryption File System Agent
Registration Program.
```

```
Agent Type: CipherTrust Transparent Encryption File System Agent
Agent Version: 7.0.0.47
```

In order to register the CipherTrust Transparent Encryption File System Agent with a Vormetric Data Security Manager

- 1) you must know the host name of the machine running the DSM (the host name is displayed on the Dashboard window of the Management Console), and
- 2) unless you intend to use the 'shared secret' registration method, the agent's host machine must be pre-configured on the DSM as a host with the 'Reg. Allowed' checkbox enabled for this agent type on the Hosts window of the Management Console.

In order to register with a CipherTrust Manager you need a valid registration token from the CM.

Do you want to continue with agent registration? (Y/N) [Y]:

3. Enter `y` to continue with the registration process. The install script prompts you to enter the name of the DSM with which you want to register the host. This name must match the name shown in the **Server name** field in the **Management Summary** section on the DSM **Dashboard** page.

For example:

Do you want to continue with agent registration? (Y/N) [Y]: **y**

Please enter the primary key manager host name: **dsm630-121079.i.vormetric.com**

You entered the host name dsm630-121079.i.vormetric.com

Is this host name correct? (Y/N) [Y]: **y**

4. Enter the host name when prompted. This name must match the name used on the **Add Host** page of the DSM Management Console.

Please enter the host name of this machine, or select from the following list. If using the "fingerprint" registration method, the name you provide must precisely match the name used on the "Add Host" page of the Management Console.

```
[1] host14.i.example.com
[2] Host-RHEL-14.i.example.com
[3] 10.3.14.90
```

Enter a number, or type a different host name or IP address in manually:
What is the name of this machine? [1]: **3**
You selected "10.3.14.90".

5. When prompted for the registration method, enter **F** for fingerprint registration:

Would you like to register to the DSM using a
registration shared secret (S) or using fingerprints (F)? (S/F) [S]: **F**

6. At the hardware association prompt, select whether you want to enable the hardware association feature that prevents a clone of this machine from accessing keys in the DSM. The default is **y** (enabled):

It is possible to associate this installation with the hardware of this machine. If selected, the agent will not contact the key manager or use any cryptographic keys if any of this machine's hardware is changed. This can be rectified by running this registration program again.
Do you want to enable this functionality? (Y/N) [Y]: **y**

7. At this point, the install script asks you about some of the optional CTE features you may want to enable, such as CTE-Efficient Storage, CTE-LDT, and docker support.

Note: Some of these features may require a separate license in the DSM.

For example:

Do you want this host to have docker support enabled on the server? (Y/N) [N]:

Do you want this host to have Efficient Storage support enabled on the server? (Y/N) [N]:

Do you want this host to have LDT support enabled on the server? (Y/N) [N]:

Do you want to configure this host for Cloud Object Storage? (Y/N) [N]:

8. At this point, the install program generates certificate signing requests and lists the fingerprint of the EC (elliptic curve) CA (Certificate Authority) certificate. This fingerprint must match the one on the DSM Dashboard in the **Management Summary** section, **EC CA fingerprint** field.

The following is the fingerprint of the EC CA certificate.
Please verify that it matches the fingerprint shown on the Dashboard page of the Management Console. If they do not match, it can indicate an unsuccessful setup or an attack.

```
2F:9A:1C:DB:7E:B9:6C:63:D4:BA:D2:25:C6:7C:97:F1:E1:48:20:AE
```

```
Do the fingerprints match? (Y/N) [N]: Y
```

If the fingerprints match, enter **y**. The installer displays the fingerprint for the CTE Agent on the host and completes the installation:

The following is the fingerprint for this agent on this host.
Please verify that it matches the fingerprint shown for this host on the Edit Host window of the Management Console.

```
12:CF:64:A3:28:7E:2E:50:72:70:FF:8F:B2:79:5B:4F:40:1B:74:20
```

```
Successfully registered the CipherTrust Transparent Encryption File System Agent with the  
Vormetric Data Security Manager on dsm630-121079.i.vormetric.com.
```

```
Installation success.
```

9. Verify with the DSM Administrator that the CTE fingerprint matches with the fingerprint shown for this host on the **Hosts > Hostname > Edit Host** window of the DSM Management Console. CTE is installed and registered.
10. Verify the installation by checking the CTE processes on the host:
 - Run `vmd -v` to check the version of CTE.
 - Run `vmsec status` to display the CTE processes.
 - Look at the log files in `/var/log/vormetric/install.fs.log.<date>`, especially `vorvmd_root.log`.

Guarding a Device with the DSM

After you register a device with a DSM, you can create as many GuardPoints on the device as you need. These GuardPoints can protect the entire device or individual directories or files.

In order to guard a device, you need to use the DSM Management Console to:

1. Access the DSM domain in which the host is registered.
2. Identify or create an encryption key that CTE will use to encrypt the data on the device.
3. Identify or create a policy for the device that specifies the access controls and the encryption keys to use for the device.
4. Create a GuardPoint for the device.

The following example creates a simple policy with a single key rule and no access controls and uses it to guard several directories on a registered host. For all of the following procedures, you must be logged into the DSM Management Console as a DSM Administrator, and you must be in the domain with which the host is registered.

For details about any of these procedures or the options for domains, encryption keys, policies, and GuardPoints, see the *DSM Administration Guide*.

Access the DSM Domain

1. In a web browser, navigate to the URL of the DSM you want to use and log in with DSM Administrator credentials.
2. In the top menu bar of the DSM Management Console, select **Domains > Switch Domains**.
3. Select the domain with which the host you want to protect is registered and click **Switch to domain**.

Create an Encryption Key

1. In the top menu bar of the DSM Management Console, select **Keys**.
2. In the Key table, click **Add**
3. In the **Name** field, add a name for the key. This name must be unique. For example, Simple-Policy-Key.
4. Set any other desired options or use the defaults provided.
5. Click **Ok**.

Create a Standard Policy

1. In the top menu bar, select **Policies**.
2. In the Policy table, click **Add**.
3. In the Add Policy page:
 - a. Select a Policy Type. In this example, we will create a Standard policy.
 - b. Enter a name for the policy in the **Name** field. For example, Simple-Policy.
 - c. Enter a description for the policy in the **Description** field.
 - d. In the Key Selection Rules section, click **Add**.
 - e. In the Key field, click **Select**.
 - f. Select the key you created earlier and click **Select key**.
 - g. Click **Ok**.

4. Click **Ok** to create the policy.

Create a GuardPoint

1. Stop all applications that are accessing the device you want to protect. In this example, we are going to protect the following directories with the same policy and encryption key:
 - /dir/hr/files
 - /dir/accounting/files
 - /dir/shared/hr
 - /dir/shared/accounting

Tip: If you want to encrypt data without taking the device offline, you must use CipherTrust Transparent Encryption - Live Data Transformation.

2. In the top menu bar, click **Hosts**.
3. In the Hosts table, click on the name of the host you want to protect.
4. Click the **GuardPoints** tab.
5. In the GuardPoints table, click **Guard**.

6. In the Guard page:
 - a. In the **Policy** field, select the policy you created earlier.
 - b. In the Type field, select the type of device. You can guard a directory or a raw/block device. For this example, select **Directory (Auto Guard)**.
 - c. In the **Path** field, enter the directories you want to protect with this policy or click **Browse** to select them from a Windows-style explorer.

If you want to enter multiple paths, put each path on its own line. For example:

- d. Click **Ok**.

The DSM pushes the GuardPoint configuration to the host and CTE immediately begins transforming the data in the specified folders from clear-text to cipher-text.

7. When the data transformation has finished, applications can resume accessing the now-protected data.

Chapter 3: Special Cases for CTE Policies

This chapter describes some CTE-specific configuration tasks related to configuring policies in the DSM and contains the following sections:

More Information About Configuring CTE Policies	65
Re-Signing Executable Files on Secfs GuardPoints	65
Re-Enabling Automatic Signing for Host Settings	66
Restricting Access Overrides from Unauthorized Identities	66

More Information About Configuring CTE Policies

This chapter describes some special cases that apply only to CTE agent policy configuration. See the DSM Administration Guide for general information about configuring policies. The following chapters in the *DSM Administration Guide* pertain specifically to the information in this chapter:

- “Creating and Configuring Signature Sets”
- “Configuring Hosts and Host Groups”
- “Configuring Policies”

Re-Signing Executable Files on Secfs GuardPoints

If any of your existing VTE for Linux hosts are running VTE versions prior to version 6.1.2, an issue affects signed executables in Live Data Transformation policies. In these older VTE versions, any executable that is part of either a host setting or a Signature set, and resides in a GuardPoint that uses a Live Data Transformation policy will have a different SHA signature after every LDT key rotation. After each LDT key rotation, the host settings executables will no longer be authenticated, or the Signature Set policy rules that include those executables will no longer match them as expected. This problem occurred because VTE generated an SHA signature of the encrypted executable which changes after each key rotation. To work around these issues on these older VTE versions, the DSM Security Administrator must manually re-sign each affected executable after each key rotation. This workaround is *not* needed for any VTE for Linux release version 6.1.2 or later.

The SHA signature is created from the unencrypted executable. This new SHA signature does not change with a key rotation.

If upgrading or installing a new machine using the same signature sets that you used previously, do the following:

1. Install the current release of the CTE Agent. The previous signatures will be used until the next key rotation.
2. Before the next key rotation, the security administrator must resign the binaries.
3. Do not remove the old signatures on the DSM or CipherTrust Manager until all agents have been upgraded to the latest CTE release. Refer to the *DSM Installation and Configuration Guide* for information on how to perform a manual re-sign.
4. After all agents have been upgraded, then you can remove the old signatures.

Note

In previous releases, if the executable was in a GuardPoint protected directory, but was the same as an unguarded executable, the administrator could restrict only the guarded executable. In the current release of CTE, the unguarded executable matches the guarded executable with regards to policies.

Re-Enabling Automatic Signing for Host Settings

Starting with VTE for Linux release 6.0.2, VTE blocks automatic re-signing of the host settings. Some users may have established procedures for updating system software that are based on the assumption that restarting the `vmd` will generate new signatures when signed software is updated. This is no longer true. However, you can re-enable automatic re-signing if your environment requires it.

CAUTION

Re-enabling the automatic regeneration of signatures exposes a potential security vulnerability for CTE Agents. When enabled, host setting binaries are re-signed when CTE receives a push from the associated key manager. If an attacker were to replace a binary with a Trojan, and then force a push from the key manager by, for example, restarting the CTE Agent, CTE could generate a signature for the malicious binary and pass it.

To re-enable automatic re-signing for host settings:

1. Change to the directory where the `agent.conf` file resides. For example, type:

```
# cd /opt/vormetric/DataSecurityExpert/agent/vmd/etc/
```

2. Edit the `agent.conf` file.

3. Change or add the following line:

```
AUTO_RESIGN_HOST_SETTINGS=TRUE
```

Note: Previously this setting was known as `RE_SIGN_HOST_SETTINGS`. Starting with VTE for Linux 6.1.3, the attribute name is `AUTO_RESIGN_HOST_SETTINGS` as shown above.

4. Save your changes and exit the file.
5. Restart the `vmd` to set the changes. Type:

```
# /etc/vormetric/secfs restart
```

6. Type the following to verify that the host settings is set to true:

```
# vmsec vmdconfig
```

Restricting Access Overrides from Unauthorized Identities

In some setups, system administrators can use the host settings `> |authenticator|` feature with `su` to change identities and gain access to restricted data. Now, you can instruct CTE to not trust any authentication attempt performed by certain identities by assigning restricted users to a user shell that CTE can block from authenticating other processes.

Any executable path that is marked with a `|path_no_trust|` host setting marks the process, and all child processes, as not trusted. Non-trusted processes are treated as "User Not Authenticated" to prevent access on user-based policies.

CTE prevents overrides from other host settings authenticators, using the `|path_no_trust|` status. If a user runs the `su` command from a non-trusted shell, that new shell is still marked as `|path_no_trust|`, even if `|authenticator|/usr/bin/su` is specified in the host-settings. The `|path_no_trust|` feature overrides any and all authenticators under host settings.

To restrict access overrides in the DSM:

1. At the DSM Management Console, click **Hosts > Hosts**.
2. Click on an existing host name to edit the host.
3. Click **Host Settings** tab.

4. Add the following to the host settings:

```
|path_no_trust|<path of the binary>
```

For example:

```
|path_no_trust|/bin/ksh
```

The above example indicates that no process under the kshell executable will be authenticated.

5. Click **OK**.

To restrict access overrides in CipherTrust Manager:

1. In the CipherTrust Manager Applications Page, click **CTE > Clients**.
2. Click on an existing client name to edit the client.
3. Click **Client Settings** tab.

4. Add the following to the client settings:

```
|path_no_trust|<path of the binary>
```

For example:

```
|path_no_trust|/bin/ksh
```

The above example indicates that no process under the kshell executable will be authenticated.

5. Click **OK**.

Chapter 4: Concise Logging

This chapter contains the following sections:

Overview of Concise Logging	68
Using Concise Logging	68

Overview of Concise Logging

Thales's standard operational logging sends audit messages for each file system operation. An audit message is sent each time a file is opened, read, updated, or written. Thales's standard logging can generate high volumes of log data. Most of these messages might not be useful or required by security administrators to monitor file system activity on the system.

Concise Logging allows you to focus on relevant audit messages and important actionable messages, such as errors and warnings. It can eliminate the repetitive and less important audit messages generated by read and write activity on a file, reading and writing directory attributes, and other file system activity.

Concise Logging eliminates the following types of messages:

- Duplicate audit messages for each and every block read by the user or application. With Concise Logging, CTE only sends an audit message the *first* time a user or application performs a read/write activity. Subsequent read/write activity by that user or application is not logged.
- Audit messages that read the attributes, read the basic information of file-set attributes, and other event-based messages.
- Audit messages for directory open, read directory attributes, and directory close.

Using Concise Logging

You can enable and disable the Concise Logging option from the DSM or CipherTrust Manager for the following:

- All registered hosts in all domains; see ["Configuring Global Concise Logging with the DSM" on the next page](#).
- A host that has registered with the DSM; see ["Configuring Concise Logging for a Registered Host with the DSM" on the next page](#).

Considerations

- Concise Logging changes the set of log messages that are sent to Security Information and Event Management (SIEM) software systems. If this results in loss of data required for customer reports, then disable Concise Logging.
- Concise Logging is only supported by CTE `secfs`.
- Enable and disable Concise Logging on the host. CTE applies it to all GuardPoints and for all users on the host for which it is selected. There is no finer-grained control, such as per GuardPoint, user, or message type.
- When you enable this setting at the DSM level, it applies to all hosts in all domains, that are added to the DSM, but does not apply to any existing hosts. Hosts added after this setting is enabled inherit this setting. The default global setting is off.
- Do not use Learn mode with Concise Logging.

Configuring Concise Logging for CTE Clients or Client Groups with CipherTrust Manager

In CipherTrust Manager, when you create a Client Profile, you can select to Enable Concise Logging. Then, you can apply that Client Profile to a specific client, or to all clients in a Client Group. To enable Concise Logging, see the chapter *Managing Profiles* in the *CTE Administrator Guide*.

Configuring Global Concise Logging with the DSM

You can enable or disable Concise Logging at any time. The DSM controls the function. Any change in the Concise Logging is reflected on any newly registered hosts and their domains.

To configure global Concise Logging:

1. Log in to the DSM with System Admin privileges.
2. Click **System > Log Preferences**. Your system may contain multiple log tabs.
3. Click on a **Log** tab.
4. In the Duplicate Message Suppression Settings field, click **Enable Concise Logging**.
5. Click **Apply**.
6. Repeat steps for any other logs, as appropriate.

The host sends the following message after the administrator has enabled Concise Logging for an individual host:

```
DAO00821: Administrator "voradmin" updated Security Server configuration "Concise Logging Enabled" from "true" to "false".
```

Configuring Concise Logging for a Registered Host with the DSM

You can enable Concise Logging for a host after you have registered it with the DSM. Hosts that are added to the DSM after enabling Concise Logging inherit the global settings from the DSM. This setting can be customized at any time.

To enable Concise Logging on the DSM for a registered host:

1. Log into your host with DSM Security Administrator privileges.
2. Select the host that you would like to customize.
3. Select a **Log** tab.
4. In the Duplicate Message Suppression Settings, click **Enable Concise Logging**.
5. Click **Apply**.

After you enable or disable Concise Logging, CTE generates a log message to record that event:

```
[CGA] [INFO] [CGA3201I] [11/11/2016 10:57:18] Concise logging enable  
[CGA] [INFO] [CGA3202I] [11/11/2016 10:57:27] Concise logging disabled
```

Chapter 5: Enhanced Encryption Mode

This chapter describes the enhanced AES-CBC-CS1 encryption mode for keys. It contains the following sections:

Compatibility	70
Disk Space	71
Encryption Migration	71
File Systems Compatibility	71
Container Compatibility	74
Using the AES-CBC-CS1 Encryption Mode in DSM	74
Using the AES-CBC-CS1 Encryption Mode in CM	74
Exceptions and Caveats	74
Best Practices for AES-CBC CS1 Keys and Host Groups	75

The AES-CBC-CS1 encryption is superior to the existing AES-CBC mode because it uses a unique and unpredictable (random) IV (initialization vector) generated for each individual file. The per-file IV object is generated only at file creation time. It is stored as file metadata.

Note

AES-CBC-CS1 encryption does not require any additional license.

	AES-CBC	AES-CBC-CS1
Security Improvements		
Unique IV per-file	No	Yes
IV predictability	Yes	No
File System Support		
Local FS	EXT3/EXT4/XFS	EXT3/EXT4/XFS
Remote FS	NFS3/NFS4/CIFS	NFS3/NFS4
Block Device Support (sevm)	Fully supported	No. When a policy contains a key with CBC-CS1 encryption mode, the guarding fails on the DSM, and an error message displays.

Compatibility

- Starting with VTE for Linux version 6.1.0, CTE is backward compatible with, and fully supports, the existing AES-CBC mode for both new and existing datasets.
- Starting with VTE for Linux version 6.1.0, CTE fully supports AES-CBC-CS1 encryption for LDT and offline data transformation on CTE Linux environments.
Versions of VTE prior to version 6.1.0 are *not* backwards compatible with AES-CBC-CS1 encryption. On these earlier versions, attempting to guard a device using a policy containing an AES-CBC-CS1 key will fail.
- Protected hosts supporting AES-CBC-CS1 encryption can be added to host groups.

Difference between AES-CBC and AES-CBC-CS1

The two encryption modes are completely different from a file format standpoint.

- AES-CBC-CS1 encryption only applies to file system directories; AES-CBC encryption applies to both files and block devices.

Notes

- If you attempt to use an AES-CBC-CS1 key to guard a block device or partition, the guarding fails with an error reported on the DSM or CipherTrust Manager, similar to: Raw or Block Device (Manual and Auto Guard) GuardPoints are incompatible with Policy "policy-xxx" that contains a key that uses the CBC-CS1 encryption mode."
 - While AES-CBC-CS1 encryption is supported on both Linux and Windows environments, the file formats are incompatible. An encrypted file created with a specific AES-CBC-CS1 key on Windows cannot be read on Linux, even if that specific key were to be used and vice versa.
- AES-CBC-CS1 uses cipher-text stealing to encrypt the last partial block of a file whose size is not aligned with 16 bytes.
 - Each file encrypted with an AES-CBC-CS1 key is associated with a unique and random base IV.
 - AES-CBC-CS1 implements a secure algorithm to tweak the IV used for each segment (512 bytes) of a file.

Disk Space

Files encrypted with AES-CBC-CS1 keys consume additional disk space in contrast to files encrypted with AES-CBC keys. This is because AES-CBC-CS1 encryption requires file IVs to be created and persistently stored in contrast to AES-CBC encryption which does not consume any additional disk storage.

Therefore, administrators need to plan and provision additional disk capacity prior to deploying AES-CBC-CS1 encryption.

	AES-CBC	AES-CBC-CS1
Local Linux FS	No change to file size. No extended attribute allocation	Internal use of extended attribute per file. Extra 4KB increase in file size.
Remote Linux FS	No change to file size. No extended attribute allocation	Extra 4KB allocation in the form of an embedded header per file. With CTE guarding enabled, file size expansion is hidden.

Encryption Migration

You can use either LDT or offline dataxform to:

- Transform data encrypted by AES-CBC to AES-CBC-CS1 and vice versa.
- Transform AES-CBC-CS1 encrypted data to clear contents and vice versa.

File Systems Compatibility

On Linux, you can use AES-CBC-CS1 keys to guard currently supported file systems.

AES-CBC-CS1 encrypted files on Linux remote file systems like NFS and CIFS increase the file size compared to encrypted files on Linux local file systems which retain the original file size.

AES-CBC-CS1 encrypted files on Linux local file systems, in conjunction with LDT policies, can result in additional space consumption. Unlike the current AES-CBC encryption where encrypted files on all file systems, both remote or local, have the same file format, AES-CBC-CS1 encrypted file formats differ based on whether or not they were created on local or remote file systems.

AES-CBC-CS1 files on Linux remote file systems such as NFS and CIFS embed the IV in a 4K-byte header within the file. When these files are guarded, CTE masks the file header -- to applications and system utilities. The expanded file is only apparent when CTE guarding is disabled.

Note

The remote file system must have enough extra space to store the extra 4K bytes of the embedded header. You can run the following script in the GuardPoint to identify how much space to reserve before data transformation:

```
x=$(find . -type f | wc -l); y=$(echo "$x * 4 /1024" | bc); echo ${y}MB
```

File System Requirements

Unlike with AES-CBC encryption, files encrypted with AES-CBC-CS1 on remote file systems cannot be copied over to local file systems in the absence of CTE guarding. Similarly, AES-CBC-CS1 encrypted files on local file systems cannot be copied over to remote file systems in the absence of CTE guarding.

The fundamental reason for this incompatibility is the usage of extended attributes on local file systems to store the IV, in contrast to its storage as a part of the file metadata on remote file systems. This is why files cannot be transferred across these file system boundaries in the absence of CTE guarding.

	AES-CBC	AES-CBC-CS1
EXT3/EXT4 on RHEL6	None	EXT3/EXT4 must be mounted with <i>user_xattr</i> mount option
EXT3/EXT4 on other Linux distros	None	No limitation
XFS on Linux	None	No limitation
NFS v3,v4/CIFS on Linux	No limitation	No limitation

Samba Share

The remote Samba share server does not support ADS so you cannot use the CBC-CS1 key type on these GuardPoints.

Storing Metadata

AES-CBC-CS1 encrypted files on Linux store the base IV of a file in either the extended attributes or in the file metadata:

- On local FS (EXT3/EXT4/XFS), Linux saves it as an extended attribute associated with the file. The underlying file system requires that you mount it with the extended attribute mount option.
- On remote FS (NFS and CIFS), Linux saves it in the embedded header of the file.

To get the value of the base IV, type:

```
# voradmin secfs iv get <file-name>
```

Note

The base IV of a file is protected. It cannot be set/modified/removed by commands and applications. However, if a GuardPoint is unguarded, the files in the GuardPoint are no longer protected. An adversary can then corrupt the content of the files, as well as the IVs.

AES-CBC-CS1 depends on the physical file system's support for extended attributes in a manner similar to the CipherTrust Transparent Encryption - Live Data Transformation feature.

Missing IV file

If the IV for a file is missing, or CTE is unable to read the IV, then CTE denies access to the file. This access denied message may trigger an application to display an error message. This message may vary from application to application.

	AES-CBC	AES-CBC-CS1
Local Linux FS	No change	Internal extended attribute for each file
Remote Linux FS	No change	4KB embedded header for each file

HDFS

The AES-CBC-CS1 key is compatible with current Hadoop File System support.

Backups

Backups and other data protection utilities should take into account the extended attributes present in each AES-CBC-CS1 encrypted file on a Linux local file system to ensure that they are safely backed up. An AES-CBC-CS1 encrypted file whose IV is corrupted, renders the files to be corrupted and therefore unreadable. Hence all data protection software must preserve the file's extended attributes.

CTE Linux can inspect a file's IV using the following command:

```
# voradmin secfs iv get file
```

On Linux, the backup utility specified in the guarding policy should automatically backup/restore extended attributes as well. For example, you must use the options to preserve extended attributes when running `cp` or `rsync.normal`.

Due to the different file formats, the backup/restore across the local and remote file systems are not allowed. If you want to backup a GuardPoint from a local directory, you must restore it to a local directory. If a GuardPoint is backed up on a remote file system, you must restore it to a remote system.

	AES-CBC	AES-CBC-CS1
General backup utility requirement (all platforms)	Backup utility defined in guarding policy with clear view	Backup utility defined in guarding policy with clear view
Special requirement for backup/restore local fs on Linux	No	Backup utility must be run with user extended attribute enabled

	AES-CBC	AES-CBC-CS1
Special requirement for backup/restore remote fs on Linux	No	No
On Linux, backup local fs and restore to remote fs	Allowed	Not allowed, the restored files cannot be accessed with I/O error
On Linux, backup remote fs and restore to local fs	Allowed	Not allowed, the restored files cannot be accessed with I/O error

Container Compatibility

The CBC-CS1 key is compatible with current Docker and OpenShift support.

Using the AES-CBC-CS1 Encryption Mode in DSM

Deploy AES-CBC-CS1 encryption by using a symmetric agent key type created in the DSM:

1. In the DSM, click **Keys > Agent Keys > Keys**.
2. Click **Add**.
3. In the Encryption Mode dropdown, select **CBC-CS1**.
4. In the Algorithm dropdown, select **AES128** or **AES256** to create an AES-CBC-CS1 key.
5. Edit or create a policy that will use the AES-CBC-CS1 key. In this policy:
 - If you are using NFS, in the **Security Rules** section, add a security rule that specifies:
Action: `f_rd_att`
Effect: `Permit, Apply Key`
This security rule allows CTE to read the base IV value in the file's embedded header over NFS. This rule is not needed if you are not using NFS.
 - In the **Key Selection Rules** section, click **Add** and select the AES-CBC-CS1 key.
6. Click **OK** to save the policy.
7. Push the policy to the GuardPoints that you want to use this encryption key.

Using the AES-CBC-CS1 Encryption Mode in CM

When you create a key in CTE, you enable Encryption Mode by selecting CTE Key Properties. See *Creating a New Key* in the "Managing Policies" chapter in the CTE Administrator Guide.

Exceptions and Caveats

Note the following when using AES-CBC-CS1 keys.

Ensure User Extended Attributes are Enabled on RHEL 6

On RHEL6, EXT3/EXT4 are not mounted with user extended attributes enabled, by default. If a GuardPoint is on EXT3/EXT4, then remount EXT3/EXT4 with `user_xattr` as an option. Otherwise, guarding fails with the error "Extended attribute not enabled for GuardPoint."

Guarding Existing Files Without Data Transformation

You must convert an existing file with clear text through offline data transformation or LDT. If you do not transform the file, then after you guard using an AES-CBC key, the file displays garbled characters.

If you use an AES-CBC-CS1 key, access to the file is blocked with an I/O error.

Best Practices for AES-CBC CS1 Keys and Host Groups

In a host group, do not deploy policies associated with AES-CBC and AES-CBC CS1 keys unless all hosts are running VTE for Linux version 6.1.0 or CTE version 7.0.0 or later.

Chapter 6: CTE and systemd

CipherTrust Transparent Encryption (CTE) for Linux is integrated with the `systemd` framework. To ensure that applications start after the CTE agent starts at startup, you must modify `systemd`. This is also true when the CTE agent is started and stopped manually.

This chapter contains the following sections:

Overview of CTE and systemd	76
CTE Agent Control Changes on systemd	76
CTE Configuration Changes Required on systemd	77
Supported Use Cases	80

Overview of CTE and systemd

You can use `systemd` to configure dependent applications to start up or shut down in the proper order when CTE starts up or shuts down on a live system. If applications start before CTE starts, those applications may not be guarded. This applies to cases when you manually start or stop the system, such as when you upgrade CTE.

`systemd` replaces `init` in Linux as a system and service manager. Linux inherited `init` from the UNIX System V `init`. `systemd` . The file is a collection of daemons, libraries, and utilities to provide central management and configuration for certain Linux distributions (see "[Linux Distributions that Support CTE and systemd](#)" below). In addition to providing enhanced features and performance, `systemd` is backwards compatible with System V and Linux Standard Base `init` scripts.

Linux Distributions that Support CTE and systemd

The entries in the following table are Linux distributions that are compatible with CTE. The table shows which distributions implement `systemd`, and those that do not. See the *Compatibility Matrix for CTE Agent with CipherTrust Manager* or the *Compatibility Matrix for CTE Agent with Data Security Manager* for the Linux distributions and kernels supported with your CTE version and key manager.

Distributions that support systemd	Distributions that do not support systemd
RHEL 7 RHEL 8 SLES 12 SLES 15 Ubuntu 16.04 Ubuntu 18.04	RHEL 6 SLES 11

CTE Agent Control Changes on systemd

The commands to start, stop, restart, and check CTE status on `systemd` are shown in the following table.

Command	Command syntax for distributions that support systemd
Start	<code>/etc/vormetric/secfs start</code>
Restart	<code>/etc/vormetric/secfs restart</code>

Command	Command syntax for distributions that support systemd
Stop	<code>/etc/vormetric/secfs stop</code>
Check status	<code>/etc/vormetric/secfs status</code>

The normal states of CTE services on a system with one or more active GuardPoints is shown in the following list. It is normal for `secfs-init` and `secfs-fs` to be listed as active (exited).

- `secfs-init`: active (exited) state
- `secfsd`: active (running) state
- `vmd`: active (running) state
- `secfs-fs`: active (exited) state

Example

To check the status of CTE, type:

```
# /etc/vormetric/secfs status
```

System Response

```
secfs-init service: active (exited) since Tue 2017-09-26 09:04:21 PDT; 1 day 4h ago
secfsd service : active (running) since Tue 2017-09-26 09:04:21 PDT; 1 day 4h ago
vmd service : active (running) since Tue 2017-09-26 09:04:44 PDT; 1 day 4h ago
secfs-fs service : active (exited) since Tue 2017-09-26 09:04:45 PDT; 1 day 4h ago
```

CTE Configuration Changes Required on systemd

The following table is a high-level overview of the required changes in `systemd` unit configuration files to control the applications that must be in sync with CTE during system startup and shutdown.

Typical applications that require `systemd` changes include `postgres`, `httpd`, `mongodb`, `mysqld` and `mariadb`. For example, `mongodb` requires that CTE to be running before `mongodb` starts.

CAUTION

Configuring the dependencies as recommended here mean that whenever you stop CTE or if CTE stops unexpectedly, the dependent applications will automatically stop shortly before CTE stops. Be sure you understand the implications of this behavior on your production environment.

Task	For more information
Compile a list of your applications that use GuardPoints.	See the application examples above.
Shut down the applications that use GuardPoints.	"Adding Dependencies to systemd Unit Configuration Files" on page 79
Add the following lines to the <code>[Unit]</code> section of the <code>systemd</code> unit configuration file for each application: <code>After=secfs-fs-barrier.service</code> <code>BindsTo=secfs-fs-barrier.service</code>	"Adding Dependencies to systemd Unit Configuration Files" on page 79

Task	For more information
To the <code>Before=</code> line in the <code>[Unit]</code> section of the <code>secfs-fs-barrier.service</code> file, add the following: <code>saslauthd.service</code> An entry for each application you added to the <code>systemd</code> unit configuration file.	"Adding Applications to the <code>secfs-fs-barrier.service</code> File" on the next page
Add the following lines to the <code>[Unit]</code> section of the <code>saslauthd.service</code> configuration file: <code>BindsTo=secfs-fs-barrier.service</code> <code>After=secfs-fs-barrier.service</code>	"Adding Dependencies to the <code>saslauthd.service</code> File" on page 80
Force the system to read the changed <code>systemd</code> configuration files by typing <code>systemctl daemon-reload</code> .	"Adding Dependencies to the <code>saslauthd.service</code> File" on page 80
Restart the applications that you shut down to make these changes.	"Adding Dependencies to the <code>saslauthd.service</code> File" on page 80

About systemd Dependency Changes for Unit Configuration Files

The previous table describes the effect of the required unit configuration file changes that are described in the following sections. See the [systemd documentation](#) for more information about the `After=` and `BindsTo=` unit configuration options.

CAUTION

In some cases, the unit configuration file for an application other than CTE may be overwritten when the application is upgraded. After upgrading an application, verify that changes to that application's unit configuration file are still in place. Changes to the `secfs-fs-barrier.service` file are retained after you upgrade CTE.

The `secfs-fs-barrier.service` service ensures that CTE services and dependent applications start after CTE services and stop before CTE services as needed during system startup, shutdown, and when starting and stopping services on a live system. This special service manages the dependencies between applications and the `secfs-fs`, `secfs-init`, `secfsd`, and `vmtoolsd` services that make up the CTE agent:

File and Change	Purpose
File: Application-specific unit configuration file Add this line to <code>[Unit]</code> section: <code>After=secfs-fs-barrier.service</code>	In conjunction with the <code>BindsTo=</code> option, this option ensures that the application starts after the CTE agent on system startup.
File: Application-specific unit configuration file Add this line to <code>[Unit]</code> section: <code>BindsTo=secfs-fs-barrier.service</code>	If the CTE agent shuts down, the application also shuts down.
File: <code>secfs-fs-barrier.service</code> Add each application to the existing <code>Before=</code> line in the <code>[Unit]</code> section. Add <code>saslauthd.service</code> to the existing <code>Before=</code> line in the <code>[Unit]</code> section.	Ensure that the <code>secfs-fs-barrier.service</code> starts before the application services mentioned in the <code>Before=</code> line.

Location of Application Unit Configuration Files

To configure the proper startup order of services, modify the unit configuration file for applications that require CTE to be running. You must also modify the `secfs-fs-barrier.service` file. The location of these files varies between Linux distributions as described in the following table.

Distribution	Location of systemd unit configuration files
RHEL 7 RHEL 8 SLES 12 SLES 15	<code>/usr/lib/systemd/system/<application_name>.service</code>
Ubuntu 16.04 Ubuntu 18.04	<code>/lib/systemd/system/<application_name>.service</code>

Adding Dependencies to systemd Unit Configuration Files

If your system supports `systemd` (see ["Linux Distributions that Support CTE and systemd" on page 76](#)), before you can safely reboot your protected host or use the files in the GuardPoint, you must perform the following steps to set the proper CTE dependencies for your applications.

1. Compile a list of your applications that use GuardPoints.
2. Prepare users of those applications for the interruption in service required to make these changes.
3. Shut down each of the affected applications.
4. For each application, log in as root and open the unit configuration file for that application using a text editor such as `vi`. See the table above to determine the location of the `systemd` unit file.

For example, on RHEL 7, the unit configuration file for a hypothetical `exampled` application would be located in `/usr/lib/systemd/system/exampled.service`.

5. Locate the `[Unit]` area in the file and add the following two lines at the end of the `[Unit]` section:

```
After=secfs-fs-barrier.service
BindsTo=secfs-fs-barrier.service
```

For example, on RHEL 7, the `exampled` application unit configuration file might have the following existing `[Unit]` section:

```
[Unit]
Description=Example server
After=syslog.target
After=network.target
```

In this case, you would add the two new lines after `After=network.target`.

6. Save and close the unit configuration file.
7. Repeat steps 3–6 for each application.

Continue to ["Adding Applications to the secfs-fs-barrier.service File" below](#) to make necessary changes to `secfs-fs-barrier.service`.

Adding Applications to the secfs-fs-barrier.service File

After editing the `systemd` unit configuration file for each dependent application, you must also add each application to the `secfs-fs-barrier.service` file that is installed as part of CTE. The `secfs-fs-barrier.service` file ensures that CTE starts before dependent applications during boot and CTE stops before dependent applications when the

system is shut down.

1. As a root user, open the `secfs-fs-barrier.service` file in a text editor such as `vi`.
For example, on RHEL 7, the `secfs-fs-barrier.service` file is located in `/usr/lib/systemd/system/secfs-fs-barrier.service`.
2. Add `ssld.service` along with the names of the unit configuration files that you edited in the last section to the end of the “Before=” clause.
For example on RHEL 7, the `secfs-fs-barrier.service` file might contain the following before editing:

```
Before=postgresql.service httpd.service mongodb.service mongod.service mysqld.service mariadb.service nails.service
```

To add an entry for `ssld.service` and two custom application services called `example1.service` and `example2.service`, you would edit the `Before=` line to look like this:

```
Before=postgresql.service httpd.service mongodb.service mongod.service mysqld.service mariadb.service nails.service ssld.service example1.service example2.service
```
3. Save and close the `secfs-fs-barrier.service` file.

In the future, CTE will start before each application listed in the `Before=` line and those applications will stop before CTE stops.

Continue to the next section to make the necessary changes to `ssld.service`.

Adding Dependencies to the `ssld.service` File

The `ssld.service` must start after the `secfs-fs-barrier` service.

1. As a root user, open the `ssld.service` file in a text editor such as `vi`.
For example, on RHEL 7, the `ssld.service` file is located in `/usr/lib/systemd/system/ssld.service`.
2. Locate the `[Unit]` area in the file and add the following two lines at the end of the `[Unit]` section:

```
After=secfs-fs-barrier.service  
BindsTo=secfs-fs-barrier.service
```

For example, on RHEL 7, the `ssld.service` file might have the following existing `[Unit]` section:

```
[Unit]  
After=syslog.target  
After=network.target
```

In this case, you would add the two new lines after `After=network.target`.
3. Save and close the `ssld.service` file.
4. To force the system to re-read the `systemd` configuration files that you changed in this section and the previous section, type `systemctl daemon-reload`.
5. Start each application that you shut down to make the configuration changes.

Supported Use Cases

CTE supports the following use case.

Manually Stop 3rd Party Applications on a Live System

The applications must already be configured as dependencies in the unit configuration files using the `BindsTo` clause (required). For more information, see ["Adding Dependencies to systemd Unit Configuration Files" on page 79](#).

Use the following commands to stop CTE on a live system with dependent applications running.

```
$# systemctl stop secfs-fs
$# /etc/vormetric/secfs stop

Stopping the CipherTrust Encryption Expert File System Agent.
Stopping Live Data Transform processes (if any).
WARNING: Following dependent services will be stopped in order to stop secfs services.
isecesp.service
isectpd.service
mysql.service
These services are required to start manually.
Successfully stopped the Encryption Expert File System Agent.
```

WARNINGS

- The 3rd party application services using the `BindsTo` clause that automatically stop must be restarted manually after an upgrade.
- Only guard points that are busy due to 3rd party applications are freed using the new use case. Any guard point that is busy due to other I/O operations must be stopped manually.

Chapter 7: Utilities for CTE Management

Thales provides a variety of utilities that augment the standard Linux utilities. This combination of tools helps administrators manage CTE. The following utilities are described in this chapter:

secfsd Utility	82
vmsec Utility	86
Binary Resigning	89
Restricting Access Overrides from Unauthorized Identities	91
Using Advanced Encryption Set New Instructions (AES-NI)	91
vmd utility	92
agenthealth Utility	92
agentinfo Utility (Java version)	93
check_host Utility	93
register_host Utility	94
fsfreeze and xfs_freeze	94

secfsd Utility

The `secfsd` utility displays the following attributes of CTE:

- GuardPoints defined in the *GuardPoints* tab
- Authentication parameters defined in the *Host Settings* tab
- Lock status set by enabling **FS Agent Locked** and **System Locked**
- Web destination and SSL certificate for uploading log entries
- Policies applied in the **GuardPoints** tab
- Status of required processes (`secfsd` and `vmd`)
- Version of `secfs`

The `secfsd` utility is also used to mount GuardPoints for *Directory (Manual Guard)*. Normally, CTE automatically mounts the `secfs` file system when you apply a GuardPoint to a directory. On Linux, the `secfsd` utility is located in `<install_dir>/secfs/.sec/bin` and a symbolic link to this file is placed in `/usr/bin/secfsd`.

secfsd syntax

Command	Description
<code>-help</code>	display <code>secfsd</code> options
Status Options	
<code>-status guard [-v -tree]</code>	list all GuardPoints
<code>-status keys</code>	show current encryption key state
<code>-status auth</code>	list authentication settings
<code>-status lockstat</code>	show CTE lock status

Command	Description
-status logger	list logging details
-status policy	list configured policies
-status pslist	list protected processes
-status devmap	list guarded devices
Manual GuardPoint options	
-guard path [container ID]	manually guard path
-unguard path [container ID]	manually unguard path
Version option	
-version	list version of kernel module <code>secfs2</code>

secfsd Examples

Display GuardPoint Information

To display the GuardPoint paths, applied policies, policy type, and guard status, use the `secfsd -status guard` command. For example:

```
# secfsd -status guard
GuardPoint  Policy          Type          ConfigState  Status      Reason
-----
/opt/apl/lib allow AllOps_fs  local        guarded     guarded     N/A
/dev/sdb    watchaccess_rd  rawdevice    guarded     guarded     N/A
/dev/sdc    watchaccess_rd  manualrawdevice guarded     guarded     N/A
/dev/sdd    watchaccess_rd  manualrawdevice unguarded   not guarded Inactive
/opt/apl/tmp MSSQL00123      manual       unguarded   not guarded Inactive
```

Column	Description
GuardPoint	Full path of the GuardPoint.
Policy	Name of the policy applied to the GuardPoint.
Type	Can be local, automount, manual, raw device, or manual raw device. Configured in the GuardPoints tab.
ConfigState	Guard status of the GuardPoint, as recognized by the key manager. It can be guarded or unguarded.
Status	Current guard status, as recognized by CTE. State can vary.
Reason	Additional information about the status, if any.

Notes

- Config State and Status can vary. As an example, if you apply a GuardPoint and someone is currently working in the GuardPoint, the policy cannot be applied at that time. In this case, the ConfigState is guarded and the Status is not guarded.
- When the user removes an auto-mounted GuardPoint from CipherTrust Manager or the DSM, the CTE Agent is only deleted after the configured `autofs` timeout expires. This timeout does not start until the GuardPoint is free.

The timeout can be changed in the `auto.master` file on the host.

Display GuardPoint Information in a Different Format

To display the same information in a block format, use the `secfsd -status guard -v` command. For example:

```
# secfsd -status guard -v
GuardPoint: 1
  Policy:      allowAllOps_fs
  Directory:   /opt/apps/apps1/tmp
  Type:        local
  ConfigState: guarded
  Status:      guarded
  Reason:      N/A
GuardPoint: 2
  Policy:      allowAllRootUsers_fs
  Directory:   /opt/apps/apps1/lib
  Type:        local
  ConfigState: guarded
  Status:      guarded
  Reason:      N/A
```

Display Host Settings

To display the SHA2 hash signature for each protected host setting, use the `secfsd -status auth` command. For example:

```
# secfsd -status auth
/bin/su 3E765375897E04C39AB17D4C755F50A35195535B6747DBA28DF9BD4AA672DFF9
|authenticator|/usr/sbin/sshd 98FC599D459EDEA52A60AB394B394803B5DAB96B53148DC608732DDA6777FA1A
/usr/sbin/in.rlogind 5C9A0EDD8BF54AE513F039476D21B3032507CF957AA0CB28C368EB8AB6E684FB
/bin/login 0D2EE0B995A30AE382B4B1CA5104715FC8902F457D283BDABAAD857B09259956
/usr/bin/gdm-binary 363780522E3CCF9ABF559F059E437743F9F97BBB0EE85769007A464AD696BD1
/usr/bin/kdm BAD41BBCDD2787C7A33B5144F12ACF7ABC8AAA15DA9FDC09ECF9353BFCE614B5
```

Display Key Status

To display the status of CTE keys, use the `secfsd -status keys` command. For example:

```
# secfsd -status keys
Encryption keys are available
```

Display Lock Status

To display the status of CTE locks, use the `secfsd -status lockstat` command. For example:

```
# secfsd -status lockstat
FS Agent Lock: false
System Lock: false
```

The value is **true** if the lock is applied. The value is **false** if the lock is not applied. **System Lock** corresponds to **System Locked** in the *Host* window. **FS Agent Lock** corresponds to **FS Agent Locked** in the *Host* window.

Note

Before you upgrade, remove CTE software, or change operating system files, the status of FS Agent Lock and System Lock must be false.

Display CTE Log Status

To display the status of CTE log service, use the `secfsd -status logger` command. For example:

```
# secfsd -status logger
Upload URL: https://vmSSA06:8444/upload/logupload,https://vmSSA07:8444/upload/logupload, \
https://vmSSA05:8444/upload/logupload
Logger Certificate directory: /opt/vormetric/DataSecurityExpert/agent/vmd/pem
```

This command sequence returns the URL to which the log service sends log data. It also returns the directory that contains the CTE certificate. CTE uses the certificate to authenticate CTE when it uploads the log data to the DSM.

Display Applied Policies

To display the policies that are applied to CTE, use the `secfsd -status policy` command. For example:

```
# secfsd -status policy
Policy: enc-audit
Type: ONLINE
```

Display CTE Process Information

To display CTE processes, use the `secfsd -status pslist` command. This command shows the process number associated with each CTE process. To show the details about a specific CTE process, use the `ps -fp <process #>` command, where `<process #>` is the process number from the `secfsd -status pslist` command.

For example:

```
# secfsd -status pslist
Protected pid list:      739    731
# ps -fp 739
UID      PID   PPID  C   STIME      TTY  TIME   CMD
root    739     1     0  11:04:56    -   0:00 /opt/vormetric/ \
      DataSecurityExpert/agent/vmd/bin/vmd
```

Display CTE Version Information

To display CTE version information, use the `secfsd -version` command. For example:

```
# secfsd -version
version: 7.0.0.47
```

Manually Enable a GuardPoint in DSM

To manually enable a GuardPoint on a Linux host:

1. Click **Hosts > Hosts > <hostName> GuardPoints**
2. Click **Guard**.
3. In the Policy field, select a policy.

4. Set Type to **Directory (Manual Guard)**.
5. Click **Browse** and enter the GuardPoint path.
6. Click **OK**.
7. Log onto the system hosting CTE as the root user.
8. To manually enable the GuardPoint, use the `secfsd -guard <path>` command. For example:

```
# secfsd -guard /opt/apps/etc
secfsd: Path is Guarded
```

9. To verify the change, use the `secfsd -status guard` command. For example:

```
# secfsd -status guard
GuardPoint      Policy          Type    ConfigState    Status    Reason
-----
/opt/apps/etc   allowAllOps_fs  manual  guarded        guarded   N/A
```

Manually Enable a GuardPoint in CipherTrust Manager

To manually enable a GuardPoint on a Linux host:

1. Click **CTE > Clients > <clientName> GuardPoints**
2. Click **Create GuardPoint**.
3. In the Policy field, select a policy.
4. Set Type to **Manual Directory**.
5. Click **Browse** and enter the GuardPoint path.
6. Click **Create**.
7. Log onto the system hosting CTE as the root user.
8. To manually enable the GuardPoint, use the `secfsd -guard <path>` command. For example:

```
# secfsd -guard /opt/apps/etc
secfsd: Path is Guarded
```

9. To verify the change, use the `secfsd -status guard` command. For example:

```
# secfsd -status guard
GuardPoint      Policy          Type    ConfigState    Status    Reason
-----
/opt/apps/etc   allowAllOps_fs  manual  guarded        guarded   N/A
```

secfsd and Raw Devices

CTE only creates block devices. To display them, use the `ls -l /dev/secvm/dev` command. For example:

```
# ls -l /dev/secvm/dev
brw----- 1 root    system    38, 1 Jan 29 16:37 hdisk1
brw----- 1 root    system    38, 2 Jan 29 16:37 hdisk2
crw----- 1 root    system    38, 3 Jan 29 16:37 rhdisk1
crw----- 1 root    system    38, 4 Jan 29 16:37 rhdisk2
```

vmsec Utility

The vmsec utility allows you to manage security aspects of CTE on the host. On Linux hosts, the vmsec utility is located in:

/opt/vormetric/DataSecurityExpert/agent/vmd/bin/vmsec

vmsec Syntax

checkinstall	Show vmd kernel status
challenge	Enter the dynamic host password
vmdconfig	Display the vmd configuration
check_hwenc	Display kernel configuration
hwok	Report status of hardware signature
passwd [-p <password>]	Enter the static host password
version	Display CTE version

vmsec Examples

Display CTE Challenge String

To display a CTE password challenge string and enter the response string when the DSM is not network accessible, use the `vmsec challenge` command. For example:

```
# vmsec challenge
Contact the help desk at 1-800-555-1212 for response generation.
Your host name is "Host120" Your challenge is: HPTQ-ZYLK
Response -> IHFY-W7WG-PDAO-QKKQ
```

The contact information is configured in the DSM Management Console (Domains > Manage Domains) *Add Domain* window. Contact the DSM Administrator and give them the challenge string. The DSM Administrator will give you the response string. Enter the response string in the **Response** field and press **Enter**. You have 15 minutes to enter the response string.

Display CTE Status

This utility shows you if CTE is configured and running. If it is not running, you might need to start it manually.

To display CTE status, use the `vmsec checkinstall` command. For example:

```
# vmsec checkinstall
The kernel component is installed and running.
```

Entering a Password

To enter the CTE static host password, use the `vmsec passwd` command. For example:

```
# vmsec passwd
Please enter password:
OK passwd
```

To enter CTE static host password on the command line so you can specify it in a batch script, specify the password using the `-p` option. For example:

```
# vmsec passwd -p myPass123
OK passwd
```

Display Kernel Status

To display the kernel status, use the vmsec status command. For example:

```
# vmsec status
FILE_FORMAT=2

```

Display CTE Build Information

To see the CTE build version, use the `vmsec version` command. For example:

```
# vmsec version
Version 6
7.0.0
2020-03-17 15:15:23 (PDT)
Copyright (c) 2009-2020, Thales. All rights reserved.
```

Display Contents of Conf files

To display the contents of the `agent.conf` and `.agent.conf.defaults` files, use the `vmsec vmdconfig` command. For example:

```
# vmsec vmdconfig
appender_syslogdest_Syslog_Appender_0=127.0.0.1
VMSDK_AGENT_CONFIG_FILE=/opt/vormetric/DataSecurityExpert/agent/vmd/etc/agent.conf

...
appenders=Upload_Appender, File_Appender, Syslog_Appender_0
layouts=Upload_Layout, File_Layout, Syslog_Layout, Simple
CONNECT_TIMEOUT=180000
URL=https://srv.my.thales.com:8443
STRONG_ENTROPY=false
```

Binary Resigning

Note

The following issue applies to an existing VTE for Linux host registered with a DSM only. It does not apply to a CTE for Linux registered with CipherTrust Manager.

Prior to VTE for Linux version 6.1.2, any executable that is part of either a host setting or Signature Set, and that resides in a GuardPoint that uses a Live Data Transformation policy, will use a different signature for each LDT key rotation. The result is that the host settings binaries will no longer be authenticated, or the Signature Set policy rules will no longer trigger for those binaries. To prevent these issues, the security administrator must manually resign each affected binary after each key rotation.

Starting with VTE for Linux version 6.1.2, CTE includes binaries that are signed with a signature that does not change with a key rotation. The security administrator must do only one manual resigning after the first key rotation. After that, there is no longer a need to resign after each subsequent key rotation.

If you are installing a CTE Agent for the first time, there are no special steps if no signatures have been defined. The CTE Agent will sign using the new method.

If you are upgrading or installing a new machine using the same signature sets that you used previously, do the following:

1. Install the latest version of the CTE Agent. The previous signatures will be used until the next key rotation.
2. Before the next key rotation, the administrator resigns the binaries.
3. Do not remove the old signatures on the DSM until all VTE Agents have been upgraded to CTE version 7.0.0.47. For information on how to do a manual resign, see the *DSM Administration Guide*.
4. When all agents have been upgraded, remove the old signatures.

Note

In previous versions, if the binary was in a GuardPoint protected directory, but was the same as an unguarded binary, the administrator could restrict to only the guarded binary. With this change, the unguarded binary is now unrestricted. This means that if a user uses the unguarded binary and its SHA matches the guarded binary, it will now match as if it was the guarded binary.

Enable Automatic Signing for Host Settings

CTE blocks automatic re-signing of the host settings. Some users may have established procedures for updating system software based on the assumption that restarting the `vmd` will generate new signatures when signed software is updated. This process will not work with CTE unless you disable automatic signing.

To disable automatic signing:

1. Change to the directory where the `agent.conf` file resides. For example, type:

```
# cd /opt/vormetric/DataSecurityExpert/agent/vmd/etc/
```
2. Edit the `agent.conf` file.
3. Change or add the following line:

```
RE_SIGN_HOST_SETTINGS=TRUE
```
4. Save your changes and exit the file.
5. Restart the `vmd` to set the changes, type:

```
# /etc/vormetric/secfs restart
```
6. Type the following to verify that the host settings is set to true:

```
# vmsec vmdconfig
```

WARNING

Enabling the automatic regeneration of signatures exposes a potential security vulnerability for agents. When enabled, host setting binaries are resigned when it receives a push from the DSM. If an attacker were to replace a binary with a Trojan, and then force a push from the DSM by, for example, restarting the agent, CTE could generate a signature for the malicious binary and pass it to the kernel.

Restricting Access Overrides from Unauthorized Identities

In some setups, system administrators can use the host settings > `|authenticator|` feature with `su` to change identities and gain access to restricted data. You can instruct CTE to not trust any authentication attempt performed by certain identities by assigning restricted users to a user shell that CTE can block from authenticating other processes.

Any executable path that is marked with a `|path_no_trust|` host setting marks the process, and all child processes, as not trusted. Non-trusted processes are treated as "User Not Authenticated" to prevent access on user-based policies.

CTE prevents overrides from other host settings authenticators, using the `|path_no_trust|` status. If a user runs the `su` command from a non-trusted shell, that new shell is still marked as `|path_no_trust|`, even if `|authenticator|/usr/bin/su` is specified in the host-settings. The `|path_no_trust|` feature overrides any and all authenticators under host settings.

To restrict access overrides in **DSM**:

1. In the DSM Management Console, click **Hosts > Hosts**.
2. Click on an existing Host name to edit the host.
3. Click **Host Settings** tab.
4. Add the following to the host settings:

```
|path_no_trust|<path of the binary>
```

Example

```
|path_no_trust|/bin/ksh
```

The above example indicates that no process under the kshell executable will be authenticated.

5. Click **OK**.

To restrict access overrides in **CM**:

1. In the CM dashboard, click **CTE > Clients**.
2. Click on an existing Client name to edit the host.
3. Click **Client Settings** tab.
4. Add the following to the settings:

```
|path_no_trust|<path of the binary>
```

Example

```
|path_no_trust|/bin/ksh
```

The above example indicates that no process under the kshell executable will be authenticated.

5. Click **Apply**.

Using Advanced Encryption Set New Instructions (AES-NI)

To verify AES-NI hardware support, type:

```
# vmsec check_hwenc
```

Unlike the `-c algo` command above, CTE does not have to be running for this command to execute. This command displays one of the following messages to stdout:

```
"AES-NI hardware encryption is supported on this system."
```

"AES-NI hardware encryption is not supported on this system. Will default to software encryption."

vmd utility

The `vmd` utility displays CTE software version information.

The `vmd` utility is located in `/opt/vormetric/DataSecurityExpert/agent/vmd/bin` and a symbolic link to this file is placed in `/usr/bin/vmd`.

Syntax

`vmd [OPTIONS...]`

`-h` show utility syntax

`-v` display CTE version

`-f` runs `vmd` in the foreground

Display the Installed Version

To display the installed CTE version, type:

```
# vmd -v
Version 6
7.0.0.47
2020-09-20 11:09:40 (IST)
Copyright (c) 2009-2020, Thales.. All rights reserved.
```

agenthealth Utility

The `agenthealth` utility validates:

- Super-user privilege
- CTE Agent installation
- CTE registration to DSM Server
- CTE processes/modules that are running
- Available disk resources
- Current GuardPoints
- Tests if the agent can reach the GuardPoints
- CTE log directory resource status

This directory contains pending CTE log files for upload. This utility reports the size and number of pending files for upload. These text files are logs that contain `vmd/SecFS` information. They are regenerated whenever `secfs` restarts. If the number of files is unexpectedly large, this can indicate a problem.

The Agent health check script

By default, the `Agenthealth` script is installed in `/opt/vormetric/DataSecurityExpert/agent/vmd/bin`.

To run the `Agenthealth` check script, type:

```
# ./opt/vormetric/DataSecurityExpert/agent/vmd/bin/agenthealth
Checking for super-user privilege ..... OK
CipherTrust Agent installation ..... OK
CipherTrust policy directory ..... OK
Registration to server ..... OK
Kernel modules are loaded ..... OK
VMD is running ..... OK
SECFSD is running ..... OK
security.manager.com is resolvable ..... OK
security.manager.com port 8446 is reachable ..... OK
security.manager.com port 8447 is reachable ..... OK
security.manager.com is resolvable ..... OK
security.manager.com port 8446 is reachable ..... OK
security.manager.com port 8447 is reachable ..... OK
Can communicate to at least one server..... OK
VMD is listening on port 7024..... OK
Time of last update from server..... 2020-082-13 20:25:37.446
Checking available disk space..... OK
Checking logging space ..... OK
    Log directory is "/var/log/vormetric"
    File system for log data is "/", 32G free (17% full)
    Log directory contains 2 of maximum 200 files (1% full)
    Log directory contains 1 of maximum 100 Mbytes used (1% full)
Testing access to /ofx-fs1 ..... OK
Testing access to /gpl ..... Access denied as per policy
```

agentinfo Utility (Java version)

The `agentinfo` utility collects system and CTE configuration data. The `agentinfo` utility is used to take a configuration snapshot of the system that you will send to Thales Customer Support to debug an issue, (This section describes the Java version.)

The `agentinfo` utility is a Java Script file. You can open it in a text editor to see specific functions.

The `agentinfo` utility displays status information on the screen and outputs the results to a compressed tar file. The compressed tar file name format is `ai.<os_name_ver>.qa.com.tar.gz` and it is located in the current working directory.

To create an `agentinfo` file, type:

```
# /opt/vormetric/DataSecurityExpert/agent/vmd/bin/agentinfo
```

check_host Utility

If a CTE software installation fails during the certificate generation and exchange stage, use the `check_host` utility to list the network addresses for the host. The utility checks network interfaces, `/etc/hosts`, DNS, and so on, to compare, test, and evaluate possible addresses for the host, and weights them based upon their network efficiency. FQDNs are the most preferred and stand-alone IP addresses are the least preferred. Some applications, such as silent-mode installation, use `check_host` to determine the best host address to submit to the DSM during registration.

Run the `check_host` utility on a system that is hosting CTE to display available network host names, FQDNs, and IP numbers for the host.

Type:

```
# /opt/vormetric/DataSecurityExpert/agent/vmd/bin/check_host
```

check_host Syntax

```
check_host [[-h | -i | -a ] [-s name]] |  
-l name:port[,name:port] | -r name
```

-h	Print the best host name for this machine
-i	Print the best IP address
-a	Print all the host names and IP addresses
-s	The name of the server (optional hint)
-r	The name of the server for name resolution checks
-l	The name and port of the server for listening checks

register_host Utility

Use the `register_host` utility to create certificate requests, exchange certificates between the DSM and the host, and to register CTE on the DSM. After the host is registered, you can configure CTE, apply GuardPoints, or perform database backups. Run the `register_host` utility in text mode on a terminal window.

CAUTION

The default host registration timeout is 10 minutes. If the host is unable to reach the DSM within the allotted period because of an extremely slow network connection, set the `REGISTER_HOST_TIMEOUT` environment variable to extend the registration timeout. The variable value is an integer expressed in seconds. You might also have to extend the default TCP timeout.

fsfreeze and xfs_freeze

Users can freeze, snapshot, and unfreeze a file system with an SecFS GuardPoint using `fsfreeze|xfs_freeze` for both XFS and EXT3/4.

SecFS supports freezing with `fsfreeze|xfs_freeze` or by any other program issuing the same type of requests. Freezing SecFS results in freezing the underlying file system, as well as the primary file system.

Restrictions

There are restrictions for using `fsfreeze|xfs_freeze` support with CTE.

Platform Restrictions

The following platform restrictions occur with CTE and `fsfreeze|xfs_freeze`:

- CTE supports the `fsfreeze|xfs_freeze` utility for freezing SECFS GuardPoints on all Linux distributions for kernels ≥ 3.0 for Redhat, SLES, and Ubuntu platforms on EXT3/EXT4/XFS file systems. (Earlier Kernels do not contain the proper freeze_super VFS code).

Note

The existing behavior of using `fsfreeze|xfs_freeze` in the underlying XFS file system works for XFS only. We do not support `fsfreeze|xfs_freeze` on GuardPoints located on VxFS file systems.

`fsfreeze|xfs_freeze` is supported with Redhat 6 (2.6 kernel) only with XFS file system.

Target Restrictions

The expected target of the `fsfreeze|xfs_freeze` command is the path of the GuardPoint.

For example, if `/dev/sdb` is mounted as `ext4` on `/data` and CTE contains the GuardPoint: `/data/protected`, then the target of `fsfreeze` must be `/data/protected`, not `/data`.

Valid: `# fsfreeze -f /data/protected`

Not valid: `# fsfreeze -f /data`

File System Restrictions

The following file system restrictions occur with CTE and `fsfreeze|xfs_freeze`:

- If multiple GuardPoints exist on the same file system, you only need to freeze one.

For example, if `/dev/sdb` is mounted as `ext4` on `/data` and the CTE GuardPoints are `/data/protected1` and `/data/protected2`, then issuing:

```
# fsfreeze -f /data/protected1
```

freezes `/data/protected1`, `/data/protected2` and the underlying `ext4` file system.

CAUTION

Do not unguard a GuardPoint, or restart the CTE Agent, while the file system is frozen. The only action permitted on a frozen file system is taking a snapshot or backing up.

- If you try to freeze `/data/protected2` after freezing `/data/protected1`, it returns as busy
- If you are not permitted to freeze one GuardPoint, then you cannot freeze any GuardPoints

LDT Restrictions

- You cannot freeze a file system while it is undergoing an LDT rekey operation. If it detects a rekey, the freeze returns as busy
- You cannot start an LDT rekey on a frozen file system

Offline Data Transformation Restrictions

Do **NOT** use `fsfreeze|xfs_freeze` while an offline transform policy is in effect.

Chapter 8: Installing CTE on Hadoop

This chapter describes how to protect an HDFS cluster with CTE. It contains the following sections:

Overview	96
Implementing CTE on HDFS	97
Adding a New DataNode to a CTE-protected HDFS	103
HDFS Upgrade with CTE	104
CTE Installation and Configuration	108
Deleting Metadata in HDFS when Migrating Out of LDT	112

Overview

The Hadoop Distributed File System (HDFS) is a file system that supports large files and directory structures distributed across hundreds, or even thousands, of commodity DataNode hosts in a cluster. Previously, CTE could only protect directories and files on the *local file system* rather than the actual *HDFS* files and directories. Now, CTE can protect files and directories.

A DSM Administrator can:

- Define an encryption policy for HDFS files and directories in HDFS name space
- Selectively encrypt HDFS folders with different keys providing multi-tenancy support.
- Define user-based I/O access control rules for HDFS files in HDFS name space.

At the heart of an HDFS cluster is the *NameNode* that provides the framework to support a traditional hierarchical file and directory organization. The NameNode is a master server that manages the HDFS name space and regulates access to files by clients.

HDFS files are split into one or more data blocks that are distributed across *DataNode* hosts in a cluster. The NameNode maintains the namespace tree and the mapping of data blocks to DataNodes. To deploy CTE, install CTE on all the NameNode and DataNode hosts in a cluster.

Overview of CTE on HDFS

This section lists the high-level steps for implementing CTE protection on your HDFS. The process requires that the HDFS Administrator and DSM Security Administrator to work in tandem to complete separate tasks.

You can keep the HDFS cluster alive a active if you enable HDFS data replication and activate the nodes individually. Following are the high-level steps:

HDFS Administrator:

1. Compile a list directories specified by `dfs.datanode.data.dir`. If these directories do not already exist in the NameNode local file system, create them.
2. Pass the directory list to the DSM Security Administrator.
3. Ask DSM Security Administrator to:
 - a. Add the NameNode to the HDFS Host Group.
 - b. Create a GuardPoint for the HDFS Host Group on each of these directories.

DSM Security Administrator:

1. Create an HDFS host group to contain the HDFS nodes.
2. Create a host group GuardPoint on each of the datanode directories obtained from the previous step.
3. Add the NameNode to the HDFS Host Group.

HDFS Administrator:

1. For each DataNode, take the node offline and perform a data transformation.
2. Ask the DSM Security Administrator to add the DataNode to the host group. (After the DataNode is added to the host group, it can be brought online.)
3. Repeat this process until all of the nodes have been encrypted and added to the HDFS Host Group.
4. Modify the host group policies to protect specific HDFS files and directories, as needed.

Implementing CTE on HDFS

This section describes how to implement CTE protection on your HDFS NameNode or DataNode. If you enable HDFS data replication, protecting one node at a time allows you to maintain the HDFS cluster. When all the nodes are configured, you can create GuardPoints on specific HDFS files and directories.

These instructions require that the HDFS Administrator and DSM Security Administrator work in tandem to complete separate tasks.

Note

The instructions below assume that each NameNode and DataNode exist on their own separate host. If you have a NameNode and DataNode on the same host, see ["Implementing CTE on HDFS on a Single Host" on page 102](#).

CTE on HDFS Implementation Assumptions

- You have installed, configured and registered CTE on all of the NameNodes and DataNodes in the Hadoop cluster.
- The HDFS Administrator has knowledge and experience with HDFS and Ambari.
- The DSM Administrator has knowledge and experience with CTE.
- The two can work and communicate in tandem with each other.

Configure the HDFS NameNodes

The first step to implementing CTE on HDFS is for the **HDFS Administrator** to compile a list of the DataNode HDFS local file system directories, and create them on the NameNode local file systems. After this, the DSM Security Administrator must add the NameNodes to an HDFS Host Group:

1. Compile a list of directories specified by `dfs.datanode.data.dir`. Obtain this from `hdfs-site.xml` or using Ambari go to:
HDFS > Configs > Settings > DataNode > DataNode directories

2. If these directories do not already exist in the NameNode local file system, create them on each NameNode in your Hadoop cluster
3. Pass the following information to the DSM Security Administrator:
 - The directory list and instructions to create a GuardPoint for the HDFS Host Group on each of these directories.
 - Instructions to add the NameNodes IP addresses or host names to the HDFS Host Group.

Create an Encryption Zone in HDFS Name Space for AWS EMR

HDFS requires the following manual steps if you want to have an encryption zone in the HDFS name space for AWS EMR, (Elastic MapReduce).

1. Add the following properties to `hdfs-site.xml`.

Note: The default `.sec` folder is `/opt/vormetric/DataSecurityExpert/agent/secfs/.sec`.

```
<property>
  <name>dfs.vte.ioctl.lib</name>
  <value>vorhdfs</value>
</property>
<property>
  <name>dfs.vte.rename.check</name>
  <value>true</value>
</property>
<property>
  <name>dfs.vte.rename.check</name>
  <value>true</value>
</property>
<property>
  <name>dfs.vte.ioctl.device</name>
  <value><.sec folder name, up to the CTE installation location></value>
</property>
```

2. Save the file.
3. Restart HDFS NameNode and DataNode services.

Using the Original Information from HDFS

Update or add the following properties to `hdfs-site.xml` if you want CTE to use the original user information from HDFS.

1. Add the following properties to `hdfs-site.xml`.

```
<property>
    <name>dfs.block.access.token.enable</name>
    <value>true</value>
</property>
<property>
    <name>dfs.client.read.shortcircuit</name>
    <value>false</value>
</property>
<property>
    <name>dfs.vte.user.push</name>
    <value>true</value>
</property>
```

2. Save the file.
3. Restart HDFS NameNode and DataNode services.

Create a HDFS Host Group and Host Group GuardPoint

After configuring the NameNodes, the next steps in activating CTE on HDFS is for the DSM Security Administrator.

Create an HDFS Host Group to contain the HDFS nodes:

1. In the DSM Management Console, click **Hosts > Host Groups > Add**.
2. Enter a **Host Group Name** for the Hadoop cluster.
3. Select **HDFS Cluster** for the Cluster type.
4. (Optional) Enter a description and click **Ok**.

5. In the **Edit Host Group** page, click the HDFS tab.

6. For a Hadoop authentication configured as **Simple mode**, enter the NameNode URL information in the URL format: `hdfs://<host>:<port>`.

By default the port number is 8020. Check the HDFS configuration to verify this. HDFS HA cluster requires the URLs for both active and standby.

7. For Hadoop authentication configured as **Kerberos**, enter the NameNode URL information in the URL format: host name (not IP address).
8. Check the **Requires Kerberos Authentication** option and enter the following Kerberos information used for authentication:
 - **Kerberos Principal:** Unique identity to which Kerberos can assign tickets. Format is: `primary/instance@REALM`.
 - **Kerberos Realm:** Typically your domain name.
 - **KDC Host:** Hostname of your domain controller.
 - **Keytab File:** File containing pairs of Kerberos principals and encrypted keys.

9. You can create any policy you choose, but the example encryption policy, `hdfs-dev-enc`, uses the following rules:
- For the user set `hdfs-user`, the action is `all_ops`, the effect is `Audit, Apply Key, Permit`
 - For other users the action is `READ`, the effect is `Permit`.
 - For the resource set `hdfs-dev-data-1`, the key is `hdfs-dev-key-1`.
 - For the resource set `hdfs-dev-data-2`, the key is `hdfs-dev-key-2`.

10. If you haven't already done so, add the NameNode obtained from the HDFS Admin to the HDFS Host Group.

Note

Thales highly recommends Auto Guard for HDFS. You can use manual guards, but this might result in data corruption if some nodes in a running cluster are guarded, while other are not.

Take a DataNode Offline and Perform Data Transformation

The next step in activating CTE on HDFS is to switch a DataNode to offline and transform (encrypt) its sensitive data. Once the data is transformed, the HDFS Admin can add the DataNode to the HDFS Host Group. Then they can switch the DataNode back to online. Most of these procedures are completed by the **HDFS Administrator** although one is done by the **DSM Security Administrator**.

1. **HDFS Administrator:** Switch a DataNode to offline.
2. **HDFS Administrator:** Encrypt the files in the directories specified by `dfs.datanode.data.dir` (see ["Configure the HDFS NameNodes" on page 97](#)).

3. **DSM Security Administrator:** Create encryption keys and a data transformation policy to transform the data.

The following figure shows an example of a data transformation policy that transforms the Resource Set `hdfs-dev-data-1` from `clear_key` to `hdfs-dev-key-1`. It also transforms the Resource Set `hdfs-dev-data-2` from `clear_key` to `hdfs-dev-key-2`. Resource Set `hdfs-dev-data-1` consists of `/tmp/data1` and the Resource Set `hdfs-dev-data-2` consists of `/tmp/data2`.

4. **HDFS Admin:** After encrypting the data in those directories, ask the DSM Security Administrator to add the DataNode to the HDFS Host Group.
5. **DSM Security Administrator:** Add the DataNode host to the HDFS Host Group.
6. **HDFS Admin:** After the DataNode is added to the HDFS Host Group, bring the DataNode online.
7. Repeat this procedure for all the DataNodes in your HDFS cluster.

Implementing CTE on HDFS on a Single Host

It is possible, though not recommended, that an HDFS NameNode and DataNode exist as separate processes on the same host. If this is your deployment, use the following CTE deployment guidelines:

1. Configure the HDFS NameNodes (see ["Configure the HDFS NameNodes" on page 97](#)):

Note: The directories specified by `dfs.datanode.data.dir` already exist on the local file system so you do not have to create them.

2. Pass the following information to the DSM Security Administrator:
 - The `dfs.datanode.data.dir` directory list and instructions to create a GuardPoint for the HDFS Host Group on each of these directories.
 - Instructions to add the NameNodes IP addresses, or host names, to the HDFS Host Group.
3. Create an HDFS Host Group and Host Group GuardPoint (see ["Create a HDFS Host Group and Host Group GuardPoint" on page 99](#)):
 - a. DSM Security Administrator must create an HDFS Host Group to contain the HDFS nodes.
 - b. The DSM Security Administrator must create a GuardPoint for the Host Group on each of the directories specified by `dfs.datanode.data.dir`
4. Take the DataNode offline and perform a data transformation.
5. Add the NameNode/DataNode host to the Host Group.

Adding a New DataNode to a CTE-protected HDFS

Use the following procedure to add a new DataNode to a CTE-protected HDFS. If not followed, HDFS encrypted files could be exposed in cleartext.

Note

If you already have CTE installed on the cluster nodes before Ambari installs the Hadoop software, see ["CTE Installed on the Cluster Nodes Before Ambari Installs Hadoop"](#) below.

1. Install the HDFS client on the host. This option is available in Ambari when adding a new DataNode to the cluster.
2. Add the new node to DSM database and make sure that the host settings of the new node is the same as existing nodes in the cluster. See the *CTE Installation for Hadoop* chapter in the *CTE Installation and Configuration Guide*.
3. Install CTE on the new node, register to DSM, and run `config-hadoop.sh` to prepare the libraries. See the *Configuring Hadoop to use CTE* section in the *CTE Installation and Configuration Guide*.
4. Make sure that the data directories (specified in `dfs.datanode.data.dir` property) exist on the new node. They must have the same permission and ownership as the other existing nodes in the cluster. If necessary, create them.
5. Add the host to DSM HDFS Host Group that is guarding the cluster. This is important: do not rely on the DataNode to create the data directories as the data replication can occur before GuardPoints are in effect.
6. Add the DataNode service to the new node. Again this option is available through Ambari.
7. If using Kerberos, check that the keytab files are created correctly.
8. Start the DataNode service on the new node.
9. Execute some `hdfs dfs` shell commands to ensure that encryption/decryption of data works correctly.

CTE Installed on the Cluster Nodes Before Ambari Installs Hadoop

If CTE is already installed on the cluster nodes before Ambari installs the Hadoop software, Ambari can mistakenly pick up the `.sec` directory in configuration steps to store the HDFS data. Make sure the following properties do not contain the `.sec` directory:

- DataNode data directory
- NameNode data directory
- Secondary NameNode checkpoint directory
- Zookeeper directory
- `yarn.nodemanager.local-dirs`
- `yarn.nodemanager.log-dirs`
- `yarn.timeline-service.leveldb-timeline-store.path`
- `yarn.timeline-service.leveldb-state-store.path`

Note

This list is not exhaustive. Depending on the Hadoop ecosystem packages installed, there can be others.

HDFS Upgrade with CTE

To upgrade Hadoop from version 2.6.0 to version 2.7.0 and higher, configure CTE to integrate with the new HDFS instance.

Upgrading one node at a time

Once CTE is installed and configured on the node:

1. Upgrade Hadoop.
2. Make sure that HDFS services are shut down on the node.
3. Type:

```
/opt/vormetric/DataSecurityExpert/agent/secfs/hadoop/bin/config-hadoop.sh -i -y
```
4. Start HDFS services on the node.

Upgrade CTE with CTE-LDT in an HDFS Cluster

If you are using CTE-LDT with HDFS cluster, follow these steps when upgrading CTE, in order to maintain your CTE-LDT GuardPoints.

1. Suspend rekey on all data nodes.
2. Shutdown your namenodes/datanodes.
3. Upgrade CTE in the namenode first.

Note: Always upgrade namenodes before datanodes.

4. After CTE upgrade succeeds, type:

```
# config-hadoop.sh -i -y
```
5. On the Ambari admin console, start the namenode.
6. Verify that the CipherTrust java process successfully launched in the namenode. (You should not see an error message.) Type:

```
# ps -ef | grep java | grep vormetric
```
7. Check the DSM status. The DSM should show LDT rekeyed status.
8. Check the namenode status. It should display the GuardPoint status and match the state before upgrade. Type:

```
# secfsd -status guard
```

GuardPoint	Policy	Type	ConfigState	Status	Reason
/hadoop/hdfs/data	LDT_HDFS_Sanity	local	guarded	guarded	N/A
9. Repeat the above steps for all of the datanodes in the HDFS cluster.

Rolling Upgrades

Hortonworks Data Platform has introduced rolling upgrades to automate the Hadoop upgrade process (<http://bit.ly/2pQrFo3>). The upgrade process is controlled by the Upgrade Pack (<http://bit.ly/2rkutvF>) that is predefined and certified by Hortonworks.

To integrate CTE with the upgrade, you need to temporarily change the Ambari scripts before performing the rolling upgrades and then restore the scripts after the upgrades.

1. On Ambari server machine, type:

```
# cd /var/lib/ambari-server/resources/common-services/HDFS/2.1.0.2.0/package/scripts
```

2. Copy the `utils.py` file, type:

```
# cp utils.py utils.py.org
```

3. Using a text editor, add the following commands to `utils.py`:

```
if action == "start":
    if name == "namenode" or name == "datanode":
        Execute(format("/opt/vormetric/DataSecurityExpert/agent/secfs/hadoop/bin/c onfig-hadoop.sh
-i -h {hadoop_bin}/../ -j <java home> -p hdp -d", not_if=service_is_up, user=params.root_
user)
        # For Redhat 6.x, uncomment the following command
        # Execute(format("/etc/init.d/secfs secfsd restart"), not_if=service_is_up,
        user=params.root_user)
        # For Redhat 7.x, uncomment the following command
        # Execute(format("/etc/vormetric/secfs restart"), not_if=service_is_up, user=params.root_
        user)
        before
        Execute(daemon_cmd, not_if=service_is_up, environment=hadoop_env_exports
        The Java home of your HDFS instance should be used to replace <java home>:
        if action == "start":
            if name == "namenode" or name == "datanode":
                Execute(format("/opt/vormetric/DataSecurityExpert/agent/secfs/hadoop/bin/config-hadoop.sh -
                i -h {hadoop_bin}/../ -j <java home> -p hdp -d", not_if=service_is_up, user=params.root_
                user)
                # For Redhat 6.x, uncomment the following command
                # Execute(format("/etc/init.d/secfs secfsd restart"), not_if=service_is_up,
                user=params.root_user)
                # For Redhat 7.x, uncomment the following command
                # Execute(format("/etc/vormetric/secfs restart"), not_if=service_is_up, user=params.root_
                user)
                Execute(daemon_cmd,
                        not_if=service_is_up,
                        environment=hadoop_env_exports)
```

4. Type:

```
# ambari-server restart
```

5. Perform rolling upgrades.

6. During the upgrade process, many of the intermediate service status checks can fail. Skip over them by clicking on **Proceed to Upgrade**.

7. Click **Finalize** to complete the upgrade. If the active NameNode fails to activate due to the incompatible HDFS layout version, manually start the NameNode with '-upgrade' option to correct the layout version file.

```
# /var/lib/ambari-server/ambari-sudo.sh su hdfs -l -s /bin/bash -c 'ulimit -c unlimited ;
/usr/hdp/current/hadoop-client/sbin/hadoop-daemon.sh --config /usr/hdp/current/hadoop-
client/conf start namenode -upgrade'
```

8. If there are excessive under-replicated blocks, run the following command to isolate them and manually start the replication:

```
# su - <$hdfs_user>
# hdfs fsck / | grep 'Under replicated' | awk -F':' '{print $1}' >> /tmp/under_replicated_
files
# for hdfsfile in `cat /tmp/under_replicated_files`; do echo "Fixing
$hdfsfile :"; hadoop fs -setrep 3 $hdfsfile; done
```

9. Restart the HDFS services. Wait for the replication to complete and the NameNodes to exit safe mode.
10. When Hbase is restarted after upgrades, it tries to rename from:
`/apps/hbase/data/.tmp/data/hbase/namespace` to: `/apps/hbase/data/data/hbase/namespace`, which may cause key conflict if the GuardPoint is set incorrectly (for example, `/apps/hbase/data/data` is guarded, but not `/apps/hbase/data/.tmp`). This results in Hbase shutting down.
Before re-starting Hbase, make sure the GuardPoint policies on the Hbase files are set correctly to cover all Hbase-related files. A broader GuardPoint (`/apps/hbase/data` instead of just `/apps/hbase/data/data` and other folders) could fix this issue.
11. Check cluster upgrade by verifying the `hadoop version`.
12. Run a few mapreduce jobs and Hbase commands to make sure that the entire Hadoop stack is working properly.
13. Rename `utils.py.org` to `utils.py`

Configure the Hadoop Cluster for CTE

Configure the Hadoop cluster to use CTE before installing and configuring CTE on the nodes. Use Ambari to perform this configuration.

Create a Vormetric Configuration Group

The Vormetric Configuration Group will eventually contain all the hosts in your Hadoop cluster. At first you will create an empty group and later populate it with the hosts on which you will install and configure agents.

1. On Ambari, go to **HDFS > Configs > Manage Config Groups**.
2. Add a new configuration group *Vormetric*.
3. Make group *Vormetric* the current group.

Update the Hadoop-env Template with CTE Settings

1. Go to **HDFS > Configs > Advanced > Advanced hadoop env > hadoop env template**
2. Copy and paste the original `hadoop-env` templates into the Thales template and add the following two export lines to specify that the CTE Java agent is instrumented into NameNode and DataNode.

The screenshot shows a code editor with two panes. The top pane displays the original `hadoop-env` template content, including comments about Java 8 security requirements and the setting of `HADOOP_CLASSPATH`. The bottom pane shows the updated template with additional export lines for `HADOOP_NAMENODE_OPTS` and `HADOOP_DATANODE_OPTS` added at the bottom, before the `exit` command.

```
export HADOOP_NAMENODE_OPTS="-javaagent:/etc/vormetric/hadoop/jar/vormetric-hdfs-agent.jar=voragent ${HADOOP_NAMENODE_OPTS}"
export HADOOP_DATANODE_OPTS="-javaagent:/etc/vormetric/hadoop/jar/vormetric-hdfs-agent.jar=voragent ${HADOOP_DATANODE_OPTS}"
```

Modify the HDFS IOCTL

1. Go to **HDFS > Configs > Advanced > Custom hdfs-site**.
2. In the `dfs.vte.ioctl.lib` field, type: `vorhdfs`
3. In the `dfs.vte.ioctl.device` field, type:

```
# /opt/vormetric/DataSecurityExpert/agent/secfs/.sec
```

Change the HDFS File Rename Check

1. Go to **HDFS > Configs > Advanced > Custom hdfs-site**.
2. Set `dfs.vte.rename.check` to `true`

User Information Push

You only need this configuration if you want to use the original user information with HDFS operation for IO access check.

Note

It has a performance cost.

1. Go to **HDFS > Configs > Advanced > Advanced hdfs-site** and uncheck **HDFS Short-circuit read**.
2. Set **dfs.block.access.token.enable** to **true**.
3. Go to **HDFS > Configs > Advanced > Custom hdfs-site** and set **dfs.vte.user.push** to **true**.

Create Kerberos Principal for CTE

If Hadoop is configured in the secure mode with Kerberos enabled (`hadoop.security.authentication=Kerberos`), you need to create the Kerberos principal for CTE. Make the principal renewable with the `maxlife` property (Maximum ticket life) larger than 1 hour and smaller than 1 day, and Maximum ticket life smaller than Maximum renewable life (which by default is 7 days).

Configure the *keytab* file and principal with HDFS using these steps:

1. Go to **HDFS->Configs->Custom hdfs-site**
2. Set **dfs.vte.keytab.file**=<CTE keytab file>.
3. Set **dfs.vte.kerberos.principal**=<CTE principal name>.

CTE calls `kinit` to initialize the Kerberos ticket and renew the ticket once per hour. You can execute the following steps from the command line to verify that the Kerberos principal was created and configured for CTE correctly:

```
kinit -r 1440m -k -t <CTE keytab file> <CTE principle>
```

```
kinit -R
```

Uninstalling CTE for the Hadoop Cluster

This section explains how to remove CTE and restore the environment back to the non-CTE cluster environment. Thales recommends uninstalling the agent from HDFS nodes one by one, starting from the DataNode. Uninstall the agent from the NameNode last.

Follow the steps below:

1. Shut down one DataNode.
2. Perform the normal agent uninstall procedure
3. Go to Ambari, remove the DataNode host from the Vormetric Configuration Group.
4. Start the DataNode.
5. Delete the Vormetric Configuration Group from Ambari when agent is uninstalled from all DataNodes.
6. Repeat these steps for each DataNode.
7. Repeat these steps for each NameNode.

CTE Installation and Configuration

After configuring the Hadoop cluster for CTE:

1. Install and register CTE on the HDFS nodes.
 - You can do this to all the nodes at once, but the HDFS is unavailable during CTE installation and configuration.
 - You can also do this one node at a time. If you install and register CTE notes one at a time, you must start from NameNode, then DataNode, and always keep NameNode service up once NameNodes are configured.
2. In either case, add the FQDN of the node to the Vormetric Configuration Group, then proceed with agent installation and configuration. See ["Installing and Configuring CTE on an HDFS Node" below](#).
 - Modify the Host Group. See ["Modifying host settings for HDFS hosts on the DSM" below](#).
 - Configure CTE by running `config-hadoop.sh` on the HDFS node. See ["Configuring Hadoop to Use CTE" on page 111](#).
 - Review the `SecFS` configuration variables that support the HDFS name cache. ["HDFS Name Cache" on page 111](#).

Installing and Configuring CTE on an HDFS Node

1. Using Ambari, add the FQDN of the node to the Vormetric Configuration Group. See ["Create a Vormetric Configuration Group" on page 106](#).
2. Install, configure, and register CTE as described in the CTE Agent for Linux Quick Start Guide.
3. Modify the host settings for each node. See ["Modifying host settings for HDFS hosts on the DSM" below](#).

Modifying host settings for HDFS hosts on the DSM

The Hadoop service can start as root and then downgrade to an unprivileged user. If the unprivileged user is not authenticated by password, CTE flags the user as fake. CTE cannot allow a user to access a resource protected by a user rule when the user is faked, even if the user matches the permit rule. Because of this, modify DSM host setting as follows:

- On Ambari, go to **HDFS > Configs > Advanced > Advanced core-site** and find out if **hadoop.security.authentication** mode is set to **simple** (no authentication) or **Kerberos**.

Simple Modification

To use **simple**, ask the DSM Administrator to add the following lines to the Host Group in the DSM Management Console:

Note

`/usr/jdk64/jdk1.8.0_40/bin/java` is the Java executable used to launch the HDFS services. Change the Java `jdk` path to reflect your end-user environment.

```
|authenticator+arg=+class=org.apache.hadoop.hdfs.server.namenode.NameNode|  
|usr/jdk64/jdk1.8.0_40/bin/java|  
|authenticator+arg=+class=org.apache.hadoop.hdfs.server.datanode.DataNode|  
|usr/jdk64/jdk1.8.0_40/bin/java|
```

The entire host settings will look like this:

```
|authenticator|/usr/sbin/sshd
|authenticator|/usr/sbin/in.rlogind
|authenticator|/bin/login/
|authenticator|/usr/bin/gdm-binary
|authenticator|/usr/bin/kdm
|authenticator|/usr/sbin/vsftpd

|authenticator+arg+=class=org.apache.hadoop.hdfs.server.namenode.NameNode|usr/jdk64/jdk1.8.0_40/bin/java
|authenticator+arg+=class=org.apache.hadoop.hdfs.server.datanode.DataNode|usr/jdk64/jdk1.8.0_40/bin/java
```

Using Kerberos

To use **Kerberos**, ask the DSM Administrator to add the following two lines to the **Host Settings** in the DSM Management Console:

Note

`/usr/jdk64/jdk1.8.0_40/bin/java` and `/usr/lib/bigtop-utils/jsvc` are the Java executables used to launch the HDFS services. Change the versions accordingly to fit your environment.

```
|authenticator+arg+class=org.apache.hadoop.hdfs.server.namenode.NameNode|usr/jdk64/jdk1.8.0_40/bin/java
|authenticator+arg+class=org.apache.hadoop.hdfs.server.datanode.DataNode|usr/lib/bigtop-utils/jsvc
```

The entire Host Group will look like this:

```
|authenticator|/usr/sbin/sshd
|authenticator|/usr/sbin/in.rlogind
|authenticator|/bin/login/
|authenticator|/usr/bin/gdm-binary
|authenticator|/usr/bin/kdm
|authenticator|/usr/sbin/vsftpd

|authenticator+arg+=class=org.apache.hadoop.hdfs.server.namenode.NameNode|usr/jdk64/jdk1.8.0_40/bin/java
|authenticator+arg+=class=org.apache.hadoop.hdfs.server.datanode.DataNode|usr/lib/bigtop-utils/jsvc
```

Modifying Host Group for HDFS NameNodes HA on DSM

To enable high availability (HA) for your HDFS NameNodes, ask the DSM Administrator to add the following lines to the Host Group in the DSM Management Console

Note

`/usr/jdk64/jdk1.8.0_40/bin/java` is the Java executable used to launch the HDFS services. Change the Java jdk path to reflect your end-user environment.

```
|authenticator+arg+class=org.apache.hadoop.hdfs.qjournal.server.JournalNode|usr/jdk64/jdk1.8.0_40/bin/java
|authenticator+arg+class=org.apache.hadoop.yarn.server.applicationhistoryservice.ApplicationHistoryServer|usr/jdk64/jdk1.8.0_40/bin/java
|trust+arg+=class=org.apache.hadoop.hdfs.tools.DFSZKFailoverController|usr/jdk64/jdk1.8.0_40/bin/java
```

The entire Host Group for HA (in this example, with Kerberos) will look like this:

```
|authenticator|/usr/sbin/sshd
|authenticator|/usr/sbin/in.rlogind
|authenticator|/bin/login/
|authenticator|/usr/bin/gdm-binary
|authenticator|/usr/bin/kdm
|authenticator|/usr/sbin/vsftpd

|authenticator+arg+class=org.apache.hadoop.hdfs.server.namenode.NameNode|usr/jdk64/jdk1.8.0_40/bin/java
|authenticator+arg+class=org.apache.hadoop.hdfs.server.datanode.DataNode|usr/lib/bigtop-utils/jsvc
|trust+arg+class=org.apache.hadoop.hdfs.qjournal.server.JournalNode|usr/jdk64/jdk1.8.0_40/bin/java
```

```
|trust+arg+=class=org.apache.hadoop.yarn.server.applicationhistoryservice.ApplicationHistoryServer| \
/usr/jdk64/jdk1.8.0_40/bin/java
|trust+arg+=class=org.apache.hadoop.hdfs.tools.DFSZKFailoverController|/usr/jdk64/jdk1.8.0_40/bin/java
```

Configuring Hadoop to Use CTE

1. On the HDFS node, type:

```
# /opt/vormetric/DataSecurityExpert/agent/secfs/hadoop/bin/config-hadoop.sh -i.
```

HDFS prompts you for the following information:

- **Hadoop product name:** (i.e. *hdp*)
- **Hadoop product version:** (i.e. *2.6.0.2.2.0.0 2041*)
- **Path to JAVA_HOME used by Hadoop:** (i.e. */usr/jdk64/jdk1.8.0_40*)

Note: Alternatively, you can use the automated installation option:

```
/opt/vormetric/DataSecurityExpert/agent/secfs/hadoop/bin/config-hadoop.sh -i -p hdp
-v 2.6.0.2.2.0.0-2041 -j /usr/jdk64/jdk1.8.0_40 2.
```

2. Verify the configuration the using the `s` option:

```
# /opt/vormetric/DataSecurityExpert/agent/secfs/hadoop/ bin/config-hadoop.sh -s
Vormetric-Hadoop Configuration Status
PRODUCT_NAME=hdp- PRODUCT_VERSION=3.0.0.0-2557 HADOOP_HOME=/usr/hdp/current/hadoop-
client/sbin/..- HADOOP_VERSION=2.7.1 HADOOP_PRODUCT_VERSION=2.7.1.2.3.0.0-2557- HADOOP_
VERSION_MAJOR=2.7 LIBVORHDFS_
SO=/usr/hdp/current/hadoopclient/sbin/..//lib/native/libvorhdfs.so LIBHDFS_
SO=/etc/vormetric/hadoop/lib/libhdfs.so VORMETRIC_HADOOP=/etc/vormetric/hadoop-
#-----vormetric-----
export HADOOP_NAMENODE_OPTS="-javaagent:/etc/vormetric/hadoop/jar/vormetric-hdfs-
agent.jar=voragent ${HADOOP_NAMENODE_OPTS}"v6 . . . . 62 export HADOOP_DATANODE_OPTS="-

client/sbin/..//lib/native/libvorhdfs.so ...ok /etc/vormetric/hadoop/gen-vor-hadoop-
env.sh ...ok /etc/vormetric/hadoop/vor-hadoop.env ...ok
Looks ok
```

Verify secfsd is Running with Hadoop Environment

Use a text editor to view the `/etc/init/secfsd.upstart.conf` file. The file should contain `env` entries, type:

```
# cat /etc/init/secfsd.upstart.conf
```

HDFS Name Cache

Obtaining the HDFS file name from the NameNode is network intensive, so the map from HDFS block file name to HDFS file name is cached in a hash table. The following `secfs` configuration variables are used to support the hash cache. They are provided in case you need to tune the memory management of the name cache for better

performance.

hdfs_cache_entry: Default is 1,024,000, which could cover up to 125TB HDFS data because the default HDFS block size is up to 128MB (128MB * 1024000 = 125TB).

hdfs_cache_bucket: Default is 10240.

hdfs_cache_timeout: Default to 30 minutes.

hdfs_cache_interval: Default wake up interval for a worker thread to update the cache entry whose timeout has expired is 10 seconds.

On Linux, you can configure each secfs configuration variable in the following file:

```
# /opt/vormetric/DataSecurityExpert/agent/secfs/.sec/ conf/<variable name>
```

For example, you can configure the variable `hdfs_cache_entry`

```
../.sec/conf/hdfs_cache_entry
```

Note

Because HDFS rename is a metadata operation inside the HDFS NameNode and does not call into the local file system, the hash cache might contain expired data. The HDFS NameNode is coded to prevent renamed data from crossing a key boundary to prevent data corruption. However, other access checks based on the HDFS file name may give incorrect information if the name is expired. Understand this risk before using this feature.

Enabling CTE on HDFS

To enable CTE on your HDFS:

1. Restart CTE agent on the node.
 - For Redhat 6.x, type:

```
# /etc/init.d/secfs restart
```
 - For Redhat 7.x, type:

```
# /etc/vormetric/secfs restart
```
2. Restart the Hadoop Services in the cluster.

You can now create GuardPoints to protect your entire HDFS.

Deleting Metadata in HDFS when Migrating Out of LDT

In an HDFS deployment, if you migrate from an LDT to a non-LDT environment, the administrator must delete the LDT `mdstore` file.

In the following example:

`/hadoop/hdfs` is the mount point

`/hadoop/hdfs/data` is the guardpoint

To manage the migration:

1. In the DSM console, click **Host > Host Groups**.
2. Click `<host group name>`. The Edit Host Group - `<host group name>` window opens.
3. Click **GuardPoints**.
4. Select the appropriate HDFS directory with an LDT GuardPoint, and click **Unguard**.

5. Using the Ambari admin console, shutdown all NameNode/DataNode one by one. Ensure that no HDFS guardpoints are busy.
6. Ensure that no guardpoints are configured on any HDFS node in the cluster, type:

```
# secfsd -status guard
```

No guardpoints configured
7. On the node running secfs, type:

```
# voradmin ldt attr delete <guard path>
```

```
# voradmin ldt attr delete /hadoop/hdfs/data
```

LDT metadata has been removed from all files in guardpoint /hadoop/hdfs/data
8. On the system, verify that the metadata store has been removed from the secfs mount points, type:

```
# voradmin ldt rmstore <mount_point>
```

```
# voradmin ldt rmstore /hadoop/hdfs
```

Enter YES if /hadoop/hdfs does not include any guardpoints associated with an LDT policy -
>YES

MDS file /hadoop/hdfs/::vorm:mds:: has been removed.
9. Verify that the metadata store has been removed from the secfs mount points, type:

```
# ls -altr <mount_point>
```

```
# ls -altr /hadoop/hdfs
```

You should not see /hadoop/hdfs/::vorm:mds:: listed.
10. Repeat the above steps for each node in the HDFS cluster.

Chapter 9: Using CTE with Oracle

This chapter describes how to install and configure CTE on Oracle RAC ASM, Linux.

It contains the following sections:

Oracle RAC ASM and ASMLib	114
Oracle RAC ASMLib Multi-Disk Online Method	119
About Oracle RAC ASM Raw Devices	119
Oracle RAC ASM Multi-Disk Online Method	120
Oracle RAC ASM Multi-Disk Offline Method (Backup/Restore)	122
Surviving the Reboot and Failover Testing	123
Basic Troubleshooting Techniques	123

Oracle RAC ASM and ASMLib

This section describes how to install and configure CTE on an Oracle RAC ASM and ASMLib.

Using CTE with an Oracle RAC ASM

You can apply CTE when the Oracle DB is active or inactive. If you choose to use it while the Oracle DB is active, it eliminates any downtime. You can apply CTE during low volume traffic time frames. If you choose to use this option, then use the **rebalance** function of ASM. This allows you to:

1. Migrate data off of a disk so that it can be dropped/removed from a **Diskgroup**.
2. Apply CTE protection.
3. Add the disk back into the diskgroup.

CAUTION

If you drop a disk from an ASM diskgroup, then add it back to the diskgroup without cleanly wiping the disk, the ASM diskname will be corrupted. To avoid this problem, clear out the disk before you add it back to diskgroup. Example: `dd if=/dev/zero of=/dev/secvm/dev/mapper/asmdg-asmlv002 bs=32k`

ASMLib

ASMLib is an optional support library for the Automatic Storage Management feature of the Oracle Database. If the customer is using ASMLib, then management is performed through an Oracle ASM command line. Using this can be simpler than the setup required for standard ASM. The commands and details of the procedure differ as well.

Important ASM Commands and Concepts

Rebalancing Disks

When you drop/remove a disk from the diskgroup, it is important to apply the proper value for the power setting for rebalance and to use the `WAIT` command.

Example ASM Command:

```
SQL> ALTER DISKGROUP <DiskGroupName> DROP DISK <diskName> REBALANCE POWER 8 WAIT;
```

- The **rebalance** command moves the data off of the disk that you are removing from the diskgroup, distributing the data across the remaining DISKS.
- The **power** setting is a number from 1 to 11. It determines how much processing power is dedicated to the rebalance, versus normal operations. Unless the encrypting occurs during heavy traffic volume, the minimum value you should use is 6. Otherwise, consult the customer's DBA for the proper setting. An appropriate value to start with is 8.

Mapping Raw Devices

You can map raw devices for this configuration using:

- **Multipath I/O**

This is typically evident when the path for the mapped devices is set to: `/dev/mapper/<device-name>`.

- **Raw devices**

Some customers use raw devices to map a name like `raw3` to a specific device name. You usually find this mapping in a file called: `/etc/sysconfig/rawdevices`.

Note

It is important to understand how the device names are used and if they are the same across all of the RAC nodes.

- **EMC PowerPath**

If using EMC PowerPath then the device names are similar to the following: `/dev/emcpowerXXXX`.

When browsing the DSM through the local host, you cannot find Power Path devices. You must manually input the paths. The guarded disk names are prepended with: `/dev/secvm`.

Checking Rebalance Status

The `wait` command is very important when ASM performs a rebalance. When you specify `wait`, the command prompt does not display until all of the data is rebalanced and migrated off of the disk. If you do not specify `wait`, the command prompt returns immediately, and you must issue the following ASM command to check the status of the rebalance:

```
SQL> select * from v$asm_operation;
```

This command returns information about the:

- State
- Current power level
- Current amount rebalanced
- Estimated work until completion
- Rate
- Estimated minutes
- Any error codes

Note

It is highly recommended that you always specify the `wait` command when performing a **Drop Disk** with Rebalance. If it is not specified, ASM may prematurely release the disk, thereby allowing CTE to place a GuardPoint on the disk before the rebalance completes. This action may corrupt the data.

Oracle cautions against this issue:

CAUTION

The **ALTER DISKGROUP...DROP DISK** statement returns before the drop and rebalance operations complete. Do not reuse, remove, or disconnect the dropped disk until the **HEADER_STATUS** column in the **V\$ASM_DISK** view for this disk changes to **FORMER**. You can query the **V\$ASM_OPERATION** view to determine the amount of time remaining for the drop/rebalance operation to complete. For more information, refer to the *Oracle Database SQL Language Reference* and the *Oracle Database Reference*.

Determining Best Method for Encrypting Disks

A diskgroup can contain one or multiple disks. You must determine if the diskgroup contains enough disks and free space for encryption. If the diskgroup contains only one disk, or multiple disks but not enough free space, then you must use the **Offline** (backup/restore) method for encryption.

If the diskgroup contains more than one, you can use the **Online** (rebalancing) method. During rebalancing, additional disks allow for migrating data from the original disk so that it can be encrypted, added back into the diskgroup, and then migrated back to the source disk. Therefore, if the customer does not want to permanently add extra disks, they can add disks temporarily, just for rebalancing.

In general, once you have completed the initial setup for the operating system with which you are working, for both ASM or ASMLib, the high-level process is the same for applying CTE protection to raw devices and using them.

Online Method (No Application / Database Downtime)

Typically, when using the online method, follow these steps:

1. Make an ASM disk available for protection by either removing a disk from an existing diskgroup, or allocating a new disk.
2. Apply CTE encryption to the disk.
3. Add each protected disk to the diskgroup.
4. Restart the nodes and the failover test.
5. Repeat the previous steps for each disk in the diskgroup.

Offline Method (Backup the DB)

Typically, when using the offline method, follow these steps:

1. Backup the database.
2. Make an ASM disk available for protection by either removing a disk from an existing diskgroup, or allocating a new disk.
3. Stop the Oracle database.
4. Delete the diskgroup.
5. Apply CTE encryption to the disk.
6. Recreate the diskgroup.
7. Add the protected disk to the diskgroup.

8. Restart the nodes and the failover test.
9. Repeat the previous steps for each disk in the diskgroup.

General Prerequisites

Setup

- Verify that you have a current backup of the database
- Install and register CTE agents on all RAC node Hosts
- Create a **Host Group** and add all RAC node hosts as members
- Create an encryption key for the Oracle RAC Database / Application
- Create an Oracle policy using the proper encryption key

Note

If the raw device mappings for the disk(s) are **not** identical across all nodes in the RAC, then you cannot use a Host Group for managing the GuardPoint within the DSM. You **must** apply the GuardPoint to each Host individually. This is typically not optimal, as a Host Group is the most effective and consistent way to manage GuardPoints for Oracle RAC environments.

Modify the UDEV Rules

Note

This applies to RHEL 5 operating systems.

Update the UDEV rules to ensure that they recognize the CTE protected raw devices:

1. Edit the file `/etc/udev/rules.d/90-dm.rules`.
2. Find and comment out the following line by adding a hash tag (`#`) to the beginning of the line.

```
# KERNEL=="dm-[0-9]*", ACTION=="add", OPTIONS+="ignore_device"
```
3. Restart the UDEV rules by executing the following command:

```
# /sbin/start_udev
```

Note

The CTE guide states that a restart is usually required once the UDEV rules have changed. However, that would defeat the purpose of an online method for conversion to CTE. Using the above `start_udev` command removes the need to restart the Host. If this command does not work, then a system restart may be required.

Altering ASM_DISKSTRING on ASM

ASM uses the `asm_diskstring` setting to identify the path where ASM will attempt to locate available disks to use. If you are using device names when adding the disk, you must modify the string to include the path to SecVM.

1. To retrieve the `ASM_DISKSTRING` setting, type:

```
SQL> SHOW PARAMETER ASM_DISKSTRING
```

2. To modify the setting, type:

```
SQL> ALTER SYSTEM SET ASM_DISKSTRING='/dev/mapper/*', '/dev/secvm/dev/mapper/*';
```

Where the path added is the path to SecVM.

ASMLib manages the binding, not ASM. ASMLib creates ASMLib devices on the SecVM devices and presents it to ASM. ASM automatically recognizes the new device. This creates the need to alter diskstrings for ASM. In addition, Oracle ASM sees a new device created using ASMLib and Raw, by default.

For example:

Using Oracle ASMLib to bind the device:

```
# oracledisk createdisk <devicename> /dev/secvm/dev/<blockdev>
```

Using the raw command to bind the device:

```
# raw /dev/raw/rawN /dev/secvm/dev/<blockdev>
```

Specific Prerequisites

Establishing a Starting Point

In many production environments, you may find that it has been a very long time since the RAC nodes have had the services restarted or have been completely rebooted. This can result in a lack of understanding of the actual state of the RAC cluster and its ability to survive a reboot on its own, prior to installing CTE.

Restarts can uncover issues in the RAC environment that are unrelated to CTE. To avoid issues after a CTE installation, Thales recommends that you restart each RAC node **AFTER** CTE is installed and **PRIOR** to establishing any GuardPoints. This may not be feasible in a single node configuration. However, by doing so, CTE is installed but inactive, and you can ensure that the platform is in a workable state prior to getting started.

The Importance of Device Mapping

It is important to use device naming and mapping in a multi-node RAC configuration. Verify the device names to ensure that the disks are mapped to the same disks on each RAC node before applying any GuardPoints. Thales recommends that RAC nodes use the same device names across all nodes. If they do not match, then problems can occur.

If the RAC nodes use the same device names, use a Host Group to create GuardPoints. If they do not match, do not use a Host Group to create GuardPoints. Set them up independently on each Host.

Important Note about Raw Devices on UNIX

In general, raw devices are created as either character or block mode devices. Any I/O performed on character devices is non-buffered, while I/O on block devices is buffered and performed in defined block sizes (that is, 4K bytes).

While the Oracle documentation for using ASM with raw devices indicates that you can use either character or block devices, **CTE REQUIRES a block device for guarding.**

Notes

- Attempting to apply a GuardPoint on a character device that *does not* have a corresponding block device may result in a GuardPoint that never encrypts data. The status of the GuardPoint never shows as guarded.
- The WebUI does not support browsing for the character devices. You would need to manually paste the name into the WebUI.

Oracle RAC ASMLib Multi-Disk Online Method

The online method describes how to remove, protect and add disks to a diskgroup.

Assumptions

Using the Online Method assumes that there is enough free space in the diskgroup so that you can drop/remove, protect and then add the disk back into the diskgroup.

Note

During the initial investigation, you may want to ensure that you have the correct raw device name for each disk that you plan on protecting. Before making any changes to the ASM configuration, obtain the definitive device names for each disk by running the following from the command prompt:

```
# oracleasm querydisk -p <diskName>
```

To add the disk to the diskgroup using the online method and make it ready for use:

1. Open a terminal session on both RAC Nodes.
2. On **RAC Node 1**, perform the following:
 - a. On the ASM, type the following to remove a disk for the diskgroup.

```
SQL> ALTER DISKGROUP <diskGroupName> DROP DISK <diskName> REBALANCE POWER 11 WAIT;
```

- b. Delete the disk from ASM, type:

```
# oracleasm deletedisk <diskName>
```

- c. Verify that the disk is deleted from the ASM and therefore, it is not listed, type:

```
# oracleasm listdisks
```

Note

If you are planning to apply a GuardPoint to a raw device that is currently in an ASM diskgroup, you must remove and delete the disk from the diskgroup before you apply the GuardPoint. ASMLib will not see the guarded disk if you skip this step. When deleting the disk, make sure that the deletion completes before continuing.

About Oracle RAC ASM Raw Devices

When Not Using ASMLib

Before starting the CTE implementation, investigate how the customer is using raw devices for their ASM configuration.

Devices using Raw Bindings

Typically, a device that uses a raw binding looks like the following to ASM:

```
/dev/raw/raw1
```

If the device is mapped this way, you must locate where the mapping is performed. Typically, you can find this in the following configuration file:

```
/etc/sysconfig/rawdevices
```

The underlying binding could be to either a **standard device** name or a **multipath** I/O device name. Either way, you must find where the bind commands are run so that you can modify them for SecVM.

Note

If raw bindings are in use, then typically no changes are needed for the `asm_diskstring`. Because the binding to the actual device is created through the `bind` command, locate where the binding occurs and change the binding to SecVM.

Multipath I/O Devices

Devices using multipath I/O are typically found with the name:

```
/dev/mapper/mpath1
```

Generally, when using multipath I/O, you create SecVM on the multipath device name.

Note

If you use multipath I/O devices in the ASM configuration to add its disk, you must modify the `asm_diskstring` parameter to include the `/dev/secvm/dev/*` path.

Standard Devices

In many cases the ASM configuration may be using plain device names, like the following:

```
/dev/sda1
```

Note

If you use standard device names in the ASM configuration to add a disk, you must modify the `ASM_DISKSTRING` parameter to include the `/dev/secvm/dev/*` path.

Consistent Naming of Devices across RAC Nodes

As previously stated, if the raw device mappings for the disk(s) are **NOT** identical across all nodes in the RAC, then you **CANNOT** use a Host Group and you **MUST** apply the GuardPoints to each Host individually. This is typically NOT optimal, as a Host Group is the most effective way to manage an Oracle RAC environment.

Oracle RAC ASM Multi-Disk Online Method

Performing encryption with the online rebalancing method requires sufficient free space to allow the drop of the largest ASM disk.

Checking for Space

In the Oracle system, use the following commands to check for available disk space:

1. Check total free space in the disk group:

```
SQL> SELECT name, free_mb, total_mb, free_mb/total_mb*100 as percentage FROM v$asm_diskgroup;
```

NAME	FREE_MB	TOTAL_MB	PERCENTAGE
DATA	7	2109	.331910858

2. Check individual ASM disk size and usage:

```
SQL> select a.name DiskGroup, b.disk_number Disk#, b.name DiskName, b.total_mb, b.free_mb, b.path, b.header_status FROM v$asm_disk b, v$asm_diskgroup a where a.group_number (+) =b.group_number order by b.group_number, b.disk_number, b.name
```

DISKGROUP	DISK#	DISKNAME	TOTAL_MB	FREE_MB	PATH	HEADER_STATUS
DATA	0	DATA_0000	1874	1273	/dev/oracleasm/disks/ATA3	MEMBER
DATA	1	DATA_0001	1992	608	/dev/oracleasm/disks/ATA4	MEMBER
DATA	3	DATA_0003	117	0	/dev/oracleasm/disks/ATA2	MEMBER
	0	DATA_ENC_0000	109	28	/dev/oracleasm/disks/ATA1_ENC	MEMBER

Adding a Disk to the Diskgroup

Using the Online Method assumes that there is enough free space in the diskgroup so that you can drop/remove a disk, protect it with CTE, and then add it back into the diskgroup.

To add the disk to the diskgroup:

1. Open a terminal session on both RAC Nodes.

2. On **RAC Node 1**, on the ASM, remove the disk from the disk group, type.

```
SQL> ALTER DISKGROUP <diskGroupName> DROP DISK <diskName> REBALANCE POWER 11 WAIT;
```

3. On the DSM, in the Host Group, apply a GuardPoint to the Raw Device: <rawDevice1Name>.

4. From **RAC Node 1**, to display the status of the guarded disks, type:

```
# secfsd -status guard
```

5. On both **RAC Node 1 and 2** type:

```
# chown oracle:oinstall /dev/secvm/<rawDevice1Name>
# chmod 660 /dev/secvm/<rawDevice1Name>
```

6. From **RAC Node**, on the **ASM**, add the protected disk to the disk group:

```
SQL> ALTER DISKGROUP <diskGroupName> ADD DISK /dev/secvm/<rawDevice1Name> NAME <disk1Name>;
```

The disk is now added to the diskgroup and ready for use.

7. The system is now ready for a reboot and failover test. For details, see ["Surviving the Reboot and Failover Testing" on page 123](#).

Troubleshooting

Occasionally, settings do not persist when the system is rebooted. To ensure they do persist, edit the `/etc/rc.local` file and add the following lines:

```
Echo "Changing Permission for secvm devices"
chown oracle:oinstall /dev/secvm/dev/<rawDevice1Name>
chmod 660 /dev/secvm/dev/<rawDevice1Name>
```

Oracle RAC ASM Multi-Disk Offline Method (Backup/Restore)

Using the Offline Method assumes that there is not enough free space in the diskgroup.

1. Open a terminal session on both RAC Nodes.
2. On RAC Node 1, on the ASM, type the following to remove the disk group.

```
SQL> DROP DISKGROUP <diskGroupName> FORCE INCLUDING CONTENTS;
```

Note: Make sure that the disk is removed before guarding the raw devices.

3. On the DSM, in the Host Group, apply GuardPoints to the three raw devices:

```
<rawDeviceName1>  
<rawDeviceName2>  
<rawDeviceName3>
```

4. On **RAC Node 1**, to display the status of the guarded disks, type:

```
# secfsd -status guard
```

5. On both **RAC Node 1** and 2, type:

```
# chown oracle:oinstall /dev/secvm/<rawDeviceName1>  
# chmod 660 /dev/secvm/<rawDeviceName1>  
# chown oracle:oinstall /dev/secvm/<rawDeviceName2>  
# chmod 660 /dev/secvm/<rawDeviceName2>  
# chown oracle:oinstall /dev/secvm/<rawDeviceName3>  
# chmod 660 /dev/secvm/<rawDeviceName3>
```

6. From **RAC Node 1**, on the **ASM**, add the protected disk to the disk group, type:

```
SQL> ALTER DISKGROUP <diskGroupName> ADD DISK /dev/secvm/<rawDeviceName1> NAME <diskName1>;  
SQL> ALTER DISKGROUP <diskGroupName> ADD DISK /dev/secvm/<rawDeviceName2> NAME <diskName2>;  
SQL> ALTER DISKGROUP <diskGroupName> ADD DISK /dev/secvm/<rawDeviceName3> NAME <diskName3>;
```

The disks are now added to the diskgroup and ready for use.

7. On **RAC Node 1**, restore the database.
8. The system is now ready for a reboot and failover test. Go to the section ["Surviving the Reboot and Failover Testing" on the next page.](#)

Troubleshooting

Occasionally, settings do not persist when the system is rebooted. To ensure they do persist, edit the `/etc/rc.local` file and add the following lines:

```
Echo "Changing Permission for secvm devices"  
# chown oracle:oinstall /dev/secvm/dev/<rawDeviceName1>  
# chmod 660 /dev/secvm/dev/<rawDeviceName1>  
# chown oracle:oinstall /dev/secvm/dev/<rawDeviceName2>  
# chmod 660 /dev/secvm/dev/<rawDeviceName2>  
# chown oracle:oinstall /dev/secvm/dev/<rawDeviceName3>  
# chmod 660 /dev/secvm/dev/<rawDeviceName3>
```

Surviving the Reboot and Failover Testing

Preparing for Failover Testing with ASMLib

When using ASMLib with the `createdisk` command, there is no requirement to make additional changes in `rc.local` or other areas for mapping device names or to use `chmod` or `chown` for SecVM. This is because it is managed for you by the `createdisk` function and you can verify this by running the following command:

```
# ls -l /dev/oracleasm/disks
```

CTE Load Order and Startup Scripts

The last change is to ensure that CTE starts before ASM starts in the startup scripts.

Failover Testing

Confirm that everything is functional:

- Ensure that the GuardPoints are all operational.
- Ensure that you receive valid results when you query the database.
- Verify that the load order ensures that CTE starts before ASM .

Once verified, you can start the failover testing for each RAC Node.

1. Reboot the RAC Node 1 and monitor the startup.
2. Once the restart is clean, reboot RAC Node 2 and monitor the startup.

Issues with Device Mapper and Invalid Guard Path

If CTE is unable to apply a GuardPoint on a raw device, the logs may generate an error similar to the following:

```
[SecFS, 0] EVENT: Failed to guard /dev/mapper/devicename (reason: Invalid Guard Path flags 0x2  
gypped 0x4 status 0x11) - Will retry later
```

If you receive this error, use the `setup` command to check the status of the disks, type:

```
# setup info <deviceName>
```

Before attempting to establish a GuardPoint, look closely at the open count value and ensure that it is 0 on all nodes.

Basic Troubleshooting Techniques

The following are some of the most common configuration issues that prevent the Oracle ASM configuration from working properly.

If you encountering errors similar to:

- ORA-15075: disk(s) are not visible cluster-wide
- ORA-15032: not all alterations performed

This could be the result of improper settings for the I/O layer, meaning that your disks are not properly configured.

Perform the following tasks to verify that the settings are correct:

1. On the DSM Management Console, in the Host Group that was created for the RAC cluster, verify that the host group for this configuration does **NOT** have the Cluster Group option set (this option is only for GPFS, which is not supported with CTE).
2. Ensure that the GuardPoints for the block devices are set at the Host Group level. This ensures that each node receives identical GuardPoints.
3. Verify that the GuardPoints are active on all nodes. When the GuardPoints are set, go to each node and verify that they are set and guarded, using the WebUI or the `secfsd -status guard` command. If they do not guard correctly:
 - Verify that the udev rules are set correctly, as described in ["Modify the UDEV Rules" on page 117](#)
 - Make sure the device names are the same across all nodes.
4. From ASM, make sure that the `asm_diskstring` parameter is modified to include the CTE devices and that the proper pathname is used, see ["Altering ASM_DISKSTRING on ASM" on page 117](#).

Verifying Database Encryption

Option 1

The best way to verify the state of the data, without impacting anything in the existing environment, is to use the Oracle `kfed` command. You can run this command against the native path of the existing GuardPoints and make sure it returns with valid header information. If it returns valid information with the GuardPoint in place, then this confirms that the data is properly encrypted. If it returns with invalid header information, then that indicates that the data is either clear, double encrypted, or not in the expected encrypted state. The syntax for running this command would look similar to the following but will vary based on your environment.

```
# /app/oracle/grid/product/11.2.0/grid/bin/kfed read /dev/rdisk/<diskName>
```

If the location is properly encrypted, following is an example of the viewable output:

```
# /app/oracle/grid/product/11.2.0/grid/bin/kfed read /dev/rdisk/<diskName>
```

System Response:

```
kfbh.endian:          1 ; 0x000: 0x01
kfbh.hard:            242 ; 0x001: 0xf2
kfbh.type:           124 ; 0x002: *** Unknown Enum ***
kfbh.datfmt:          66 ; 0x003: 0x42
kfbh.block.blk:       1088904227 ; 0x004: blk=1088904227
kfbh.block.obj:       1558192170 ; 0x008: file=8234

KFED-00322: Invalid content encountered during block traversal: [kfbtTraverseBlock][Invalid
OSM block type][ ][124]
```

Option 2

The second option to verify the state of the data is to use the `dd` command. This requires you to specify some blocks and write it out to a file. After this completes, read the file using the `strings` command. You can do this while the device is in use. In the example below some sectors are skipped and it only dumps 10000 counts.

For example:

```
# dd if=/dev/mapper/asm_data2p1 of=/tmp/dd2.out skip=1047 count=10000
```

Option 3

The third option to verify the state of the data without impacting the existing environment is to use the `strings` command.

Note

The `strings` command cannot read a busy or large device.

You can run this command against the native path (`/dev/<deviceName>`) of the existing GuardPoints (`/dev/secvm/dev/<deviceName>`). The new path to SecVM would be similar to `/dev/secvm/dev/<deviceName>`. By executing the `strings` command against the native path `strings /dev/devicename | more`, this does not go through the SecVM device and therefore is not be decrypted. If it is encrypted the output should contain illegible text.

Chapter 10: Configuring Support for SAP HANA

This chapter describes SAP HANA, which provides automatic host-failover support. It contains the following sections:

Overview	126
Customizing CTE for SAP HANA in HA Mode	126
Using SAP HANA with LDT	128
Setting Memory Allocation	128

Overview

SAP HANA provides automatic host-failover support. CTE works with HANA fibre storage systems to enable and disable GuardPoints when a protected host starts, stops, or fails over to standby host.

CipherTrust Transparent Encryption - SAP HANA (CTE-SAP HANA) supports non-shared storage where each HANA node has its own separate storage volumes. CTE-SAP HANA provides customized scripts to support startups, shutdowns, and fail overs.

HANA attaches logical unit number (LUNs) or logical volume management (LVMs) using a Fibre Storage Connector (fcClient) providers. Thales provides hooks that are called by the HANA fcClient providers that manage guarding or unguarding of storage locations.

Note

Thales recommends using host groups to manage configuring in a clustered host environment.

Customizing CTE for SAP HANA in HA Mode

CAUTION

The following procedure only applies if multiple HANA nodes are configured in a high availability (HA) environment. If you are installing CTE on a single HANA node, do not change the default HANA or CTE settings.

1. Go to the installation directory:

```
# cd /opt/vormetric/DataSecurityExpert/agent/secfs/saphana
```
2. If required, edit the appropriate CTE `fcClient` refined script:

Script file	Use
<code>fcClientRefinedVTE.py</code>	fcClient provider for LUN
<code>fcClientLVMRefinedVTE.py</code>	fcClientLVM provider for LVMs

3. Copy the appropriate script file to a shared location that is accessible to all nodes. In a HANA cluster environment, all nodes require access to the CTE scripts.
4. Edit the storage section of the `global.ini` file to indicate the corresponding CTE `fcClient` as the High Availability (HA) provider and to point to the location of the CTE script.

LUN Example

```
[storage]
  ha_provider = fcClientRefinedVTE
  ha_provider_path = /hana/shared/myFcClient
```

If necessary, enable debug tracing:

```
[trace]
  ha_provider = debug
  ha_fcclient = debug
  ha_fcclientrefinedvte = debug
```

LVM Example

```
[storage]
  ha_provider = fcClientLVMRefinedVTE
  ha_provider_path = /hana/shared/myFcClient
```

If necessary, enable debug tracing:

```
[trace]
  ha_provider = debug
  ha_fcclientlvm = debug
  ha_fcclientlvmrefinedvte = debug
```

5. Use the same CTE agent with all hosts, including standby hosts.

6. Ensure that `/etc/sudoers` includes the following:

```
<sid>adm ALL=NOPASSWD: /usr/bin/secfsd
```

7. Enable the guard paths at the mount-point level.

For example, individual guards were placed on `/hana/data/HAN/mnt00001`, `/hana/data/HAN/mnt00002`, and so forth.

- Use a similar naming practice for log partitions, such as `/hana/log/HAN/mnt00001`, and so forth.
- Place the guard at the mount-point level. The guarded paths must match the corresponding data and log mount paths.

8. From the DSM, configure GuardPoints as type `manual`. You must enable and disable the guardpoints immediately after the device is attached, or just prior to detachment.

The reason for manual GuardPoints is that it invokes guarding and unguarding from within the HANA during the startup, shutdown, or failover process. The process resembles that of mounting and unmounting guarded auto-mount points.

9. Configure all GuardPoints so that they are available in the standby host, so that any data and log partitions that fail over from any host can be guarded on the standby.

Thales recommends that you configure all GuardPoints on all hosts, because a failed-over active host can then become the new standby, and will require all available GuardPoints.

Example

The following is an example of the data and log volumes for the host that are mounted.

<code>/dev/mapper/VG_HAN_DATA_1-LV_HAN_DATA_1</code>	793971096	3059712	750579916	1%
<code>/hana/data/HAN/mnt00001</code>				
<code>/hana/data/HAN/mnt00001</code>	793971096	3059712	750579916	1%
<code>/hana/data/HAN/mnt00001</code>				
<code>/dev/mapper/VG_HAN_LOG_1-LV_HAN_LOG_1</code>	496233160	2461764	468564152	1%
<code>/hana/log/HAN/mnt00001</code>				
<code>/hana/log/HAN/mnt00001</code>	496233160	2461764	468564152	1%
<code>/hana/log/HAN/mnt00001</code>				

Note that partition `mnt00002` is also configured, although not currently mounted by HANA. The `secfsd` status output should show the GuardPoint configuration as follows:

GuardPoint	Policy	Type	ConfigState	Status	Reason
-----	-----	----	-----	-----	-----
/hana/data/HAN/mnt00001	my-pol	manual	guarded	guarded	N/A
/hana/log/HAN/mnt00001	my-pol	manual	guarded	guarded	N/A
/hana/data/HAN/mnt00002	my-pol	manual	unguarded	not guarded	Inactive
/hana/log/HAN/mnt00002	my-pol	manual	unguarded	not guarded	Inactive

For more information, see the *SAP HANA Fiber Channel Storage Connector Admin Guide* at <http://www.sap.com/documents/2016/06/84ea994f-767c-0010-82c7-eda71af511fa.html>

Using SAP HANA with LDT

SAP HANA is compatible with LDT. You must add additional CTE commands to the HANA administrator entry.

- Using a text editor, edit `/etc/sudoers` and add entries for `/usr/bin/voradmin` and `/usr/bin/vmsec`:

```
# hanadm ALL=NOPASSWD:  
/usr/bin/secfsd, /usr/bin/voradmin, /usr/bin/vmsec, /sbin/multipath, /sbin/multipathd, /etc/init  
.d/multipathd, /usr/bin/sq_  
persist, /bin/mount, /bin/umount, /bin/kill, /usr/bin/lsof, /sbin/vgchange, /sbin/vgscan
```

If you are using an ext3 file system, you must mount it with extended attributes.

- Using a text editor, edit the storage section of the `global.ini` file, type:

```
partition_*_data__mountOptions = -o user_xattr  
partition_*_log__mountOptions = -o user_xattr
```

Setting Memory Allocation

There is a limitation in memory allocations for SAP HANA with asynchronous direct I/O. When you use CTE in conjunction with applications like SAP HANA that can process large numbers of direct I/O writes through the Linux AIO interface, CTE can allocate more memory than is desirable.

To limit the amount of memory that CTE consumes for AIO buffers, use the following configuration to limit the amount of memory CTE consumed for AIO buffers:

```
# max_aio_memory_limit <MB>
```

The MB value specifies how much memory to allocate to temporary DIO buffers.

Note

If you do not specify a value, the default is 0, which has no memory bounding effect.

Set the option by echoing a value into the `/opt/vormetric/DataSecurityExpert/agent//secfs/.sec/conf/` configuration file. For example:

```
echo 1024 > /opt/vormetric/DataSecurityExpert/agent/ secfs/.sec/conf/max_aio_memory_limit
```

This limits the memory consumed by AIO buffers to 1GB.

Note

You **must restart** CTE after changing any values in the configuration directory to make the changes effective.

Chapter 11: Container Security

This chapter describes securing data in container environments, Docker or RedHat OpenShift, using CTE. It contains the following sections:

Installing Docker Automatically	129
Container Security Overview	129
RedHat OpenShift Containers with CTE	141
Creating an OCP Project in CLI with API Commands	143

Note

Currently, this feature is only supported on the DSM. Support for this feature will be added to CipherTrust Manager in a future release.

Installing Docker Automatically

A new option allows for automatically registering the host for Docker during registration. This allows for easily enabling Docker for a large number of hosts.

During the installation phase, the agent indicates to the DSM that it wants DOCKER. Only registration is performed at this time. After registration, the DSM will validate the Docker host to ensure that the agent and the DSM use compatible versions, and that LDT is not enabled for the host.

Note

LDT and Docker are not compatible.

During the installation phase, the agent indicates to the DSM that it wants DOCKER. Only registration is performed at this time.

Container Security Overview

CTE provides data security for container environments. You can set up data protection policies for container images. In addition to data encryption, CTE also provides container-level access control and audit logging. DSM Administrators can create GuardPoints in container images through the DSM Management Console. Users can use either of the following container options:

- **Docker Container:** CLI tool for creating containers.
- **Red Hat OpenShift with Customized Docker Container:** GUI tool for creating containers and persistent storage that mounts like NFS.

Container Terminology

• Containers

The basic unit of OpenShift/Docker Application are called containers. A container runs one or more processes inside of a portable Linux environment. Containers are started from an Image and are usually isolated from other containers on the same machine.

• Image

A layered Linux file system that contains application code, dependencies, and any supporting operating system libraries. An image is identified by a name that can be local to the current cluster or point to a remote Docker registry.

- **Pods (OpenShift only)**

A POD is a set of one or more containers that reside on a host/node and share a unique IP address and volume, (persistent storage). OpenShift leverages the Kubernetes concept of a pod.

- **Project and Users (OpenShift only)**

A namespace that provides a mechanism to scope resources in a cluster. Users interact with OpenShift. It grants permission to access applications.

Docker Containers with CTE

Docker allows for containerizing an environment for application deployment. Docker is an infrastructure built on top of Linux containers and various namespace components. Typically, an application deployment is bundled with all of the dependent packages in a single image called a Docker image. Docker images are ready to run applications in containers. A user can instantiate any number of Docker containers using from one or more Docker images. This makes it easy for users to move applications around on their servers. The containerization removes the pain of setting up an environment for applications and provides isolation for applications.

A Docker container can run any application, for example, a Postgres database server. Docker containers are used widely to run micro-services, which are stateless in nature. But a micro-service, when it is running, might generate a log trail inside the Docker container. This log trail might contain sensitive information. This warrants encrypting directories inside a Docker container. If a Docker container runs a database-server type of service, it will need data protection including encryption of data, granular access control and the ability to audit the log that accesses the data.

CTE: Virtual Machine versus Docker

CTE installs on the Docker container host and orchestrates security from the Docker host. It does not leave a footprint inside the Docker image or containers. You setup the GuardPoints inside individual containers at runtime. The diagram below depicts the difference between CTE deployment on a virtual machine and a Docker container host.

Figure 11-1: CTE in Docker container environment versus virtual machine environment

Using the CTE Agent

In order to use the CTE Agent to protect Docker images and containers, you must obtain a CTE Agent license for Docker. Contact Thales Support for information on obtaining a license.

There is no change to the CTE installation, however CTE agent must be installed on the Docker host system.

Docker containers in custom paths won't start after CTE agent is installed

This problem occurs if you have installed one or more Docker containers on a host in a directory path other than the Docker default of `/var/lib/docker`. After installing the CTE agent on such a host, any Docker containers installed on that host will no longer start if the CTE `secfs` service is running. This problem occurs even to docker containers not configured to work with the CTE agent.

The following error message appears when you attempt to start a Docker container:

```
exec user process caused "permission denied"
```

To work around this issue, create a symbolic link from the current installation path of the docker container to the default Docker path of `/var/lib/docker`:

```
ln -s /custom/path /var/lib/docker
```

After creating this symbolic link, affected Docker containers will start up normally even if `secfs` is running.

Set the Docker Storage Driver

On RHEL 7.x operating systems, the Docker engine default storage driver has changed from `devicemapper` to `overlayfs` for v1.13.1 and later. Currently, CTE only supports `devicemapper`. If your Docker engine uses `overlayfs` or any other storage driver, then you must change it to `devicemapper` before using CTE to protect your data.

Before you change your storage driver, verify your Docker version:

1. Login to your Docker agent CLI.
2. Check your Docker version, type:

```
# docker version
```

System Response:

Client:

```
Version:      17.04.0-ce
API version:  1.28
Go version:   go1.7.5
Git commit:   4845c56
Built:        Mon Apr  3 18:01:50 2017
OS/Arch:      linux/amd64
```

Server:

```
Version:      17.04.0-ce
API version:  1.28 (minimum version 1.12)
Go version:   go1.7.5
Git commit:   4845c56
Built:        Mon Apr  3 18:01:50 2017
OS/Arch:      linux/amd64
Experimental: false
```

3. Check to what option the storage driver is set, type:

```
# docker Info
```

System Response:

```
Containers: 2
  Running: 1
  Paused: 0
  Stopped: 1
Images: 2
Server Version: 17.04.0-ce
Storage Driver: overlay
```

Change the Storage Driver

To change the storage driver:

1. Login to your Docker agent CLI.
2. Stop the Docker daemon, type:

```
# systemctl stop docker.service
```
3. Open another CLI session of agent so you can monitor Docker.
4. In `/etc/docker/` directory, create a file called `daemon.json` if the file does not yet exist.
5. Add a storage driver to the file, type:

```
{  
  "storage-driver": "devicemapper"  
}
```
6. Save the file.
7. Restart the Docker daemon, type:

```
# systemctl start docker.service
```
8. Verify that the storage driver is set to device mapper, type:

```
# docker Info  
Containers: 2  
Running: 1  
Paused: 0  
Stopped: 1  
Images: 2  
Server Version: 17.04.0-ce  
Storage Driver: devicemapper
```
9. Verify that the docker containers are active, type:

```
# docker ps  
CONTAINER ID | IMAGE | COMMAND | CREATED | STATUS | PORTS | NAMES  
bb953565e866 | abc/rh:v1 | "bash" | 4 weeks ago | Up 4 weeks | | jdoe
```

Administering the Docker Host

To protect data inside Docker images or containers, you need to create GuardPoints in the DSM, inside a Docker image or container, to which a CTE Agent policy is applied.

This section describes the administrative tasks related to Docker hosts; creating policies, creating GuardPoints, configuring audit logs, and generating reports.

Creating Policies

Policy creation for Docker hosts is largely the same as CTE's existing policy creation procedure with a few differences described below.

The basic procedure to create a policy is as follows:

1. Log on to your DSM as an administrator of type Security, Domain and Security, or All.
2. Navigate to **Policies > Manage Policies**.
3. Click **Add** to open the *Add Online Policy* page
4. From the **Policy Type** drop down list, select **Standard**.

5. Type in a name for the policy in the **Name** field.
6. Add a description for the policy (optional).

Refer to “Configuring Policies” in the *DSM Administrators Guide* for details about creating a policy. Once you have created a policy, you must add rules to the policy to encrypt data and control access to files and directories.

Adding Security Rules

This section describes how to create security rules in the context of Docker images and containers.

Create Resource Set

A *Resource Set* specifies the hosts, files, and directories to which a user or process will be permitted or denied access.

1. After creating the policy in the previous section, click **Add** in the **Security Rules** panel to open the *Add Security Rule* page.
2. Click **Select** next to the **Resource** field to open the *Select Resource Set* page. The page displays resource sets if any currently exist.
3. Select an existing resource set that meets your requirements, otherwise click **Add** to open the *Add Resource Set* page.
4. Enter a name for the resource you want to create.
5. Click **Add** again to open the *Add Resource* page to add a resource to the resource set you want to create.
6. Click **Select** next to the **Host** field to select a Docker host from which to choose resources. Select the radio button next to the host and click **Select**.
7. Since this is a Docker host, another field displays: **Docker Image**. Click **Browse** to open the **Remote Docker Browser** to select a Docker image or container, from which to select a resource.
8. Click **Browse** next to the **Directory** field to open the **Remote File Browser**.
9. Browse the directories and files on the image or resource that you want to add to the resource set. (Select **Directory Only** or **Directory and File** to browse only directories or files and directories.)
10. Select the resources to add and click **Ok**.
11. Click **Ok** to add the resource set. The *Select Resource Set* page opens.
12. Select the resource you just created and click **Select Resource Set**.
13. Check the **Exclude** box, to the right of the **Resource** field.

This excludes the resources in the resource set and includes all other host resources. Uncheck the box to include just the resources in the resource set.

Create User Set

A *User Set* specifies users that are permitted or denied access to files and directories in a GuardPoint.

1. After creating the policy in the previous section, click **Add** in the **Security Rules** panel to open the *Add Security Rule* page.
2. Click **Select** next to the **User** field to open the *Select User Set* page. The page displays user sets if any currently exist.
3. Select an existing user set if it meets your requirements, otherwise click **Add** to open the *Add User Set* page.

4. Enter a name for the user set and click **Add** to open the *Add User* page.
5. Enter information for the **uname**, **uid**, **gname**, **gid**, and **osDomains** fields. Refer to the online help for more details.
6. If you click **Browse Users**, the *Add Users* page opens, you can select users from an LDAP server if configured, or from a selected Host.
7. To select users from docker images or containers, use the default **Agents** selection and select the host name (FQDN) of the Docker host from the list.
Since this a Docker host, another field displays: **Docker Image/Container**.
8. Click **Browse** to open the **Remote Docker Browser** to select a Docker image or container from which to select users.
9. From the **Remote Docker Browser**, expand the file icon to view the Docker image and containers from which to select users to add to the User Set.
10. Once you've made your selections, click **Ok**, a tabulated list of available users is displayed.
11. Select the appropriate users. Click **Ok** to return to the *Add User Set* page.
12. Select users. Click **Ok** to return to the *Select User Set* page.
13. Select the newly created user set and click **Ok**.

Create Process Set

A *Process Set* specifies the executables that are permitted or denied access to GuardPoint data.

1. After creating a policy in the previous section, click **Add** in the **Security Rules** panel to open the *Add Security Rule* page.
2. Click **Select** next to the **Process** field to open the *Select Process Set* page. The page displays process sets if any currently exist.
3. Select an existing process set if it meets your requirements, otherwise click **Add** to open the *Add Process Set* page.
4. Enter a name for the process set you are about to create and click **Add** to open the *Add Process* page.
5. Click **Select** next to the **Signature Set** field, a list of existing signature sets is displayed.
6. Select an existing signature set if it meets your requirements, otherwise click **Add** to open the *Add Signature Set* page.
7. If you selected **Add** then you need to provide a **Name** for the signature set.
8. Enter the name and click **Ok**, the *Signature Reference* page opens.
9. Click the name of your signature set to edit the signature set, the *Edit Signature Set* page opens.
10. Click the **Source** tab, click **Select** next to the Host field, the **Select a host to continue** page opens, select the Docker host and click **Select** to go back to the **Source** tab.
11. Click **Browse** next to the **Docker Image/Container** field, select a Docker image or container from the **Remote Docker Browser**.
12. Select a binary from the Docker image and sign it similar to a binary on a protected host.
13. Click **Back**, the *Signature Reference* page opens.
14. Select the signature set you just created and click **Select Signature Reference**, the *Add Process* page opens.

15. Select a host. Once you select a Docker host, the **Docker Image/Container** field displays.
16. Select a Docker image or container.
17. Click **Browse** and select a directory from the **Remote File Browser**, fill in the file name field as required. Click **Ok** to return to the *Add Process Set* page.
18. Choose the appropriate (newly created) process set and click **Ok**. This returns you to *Select Process Set* page.
19. Select the process set and click **Select Process Set**. This returns you to the *Add Security Rule* page.
20. Click **Ok** to add the process set to the security rule.

Enable Docker through Host Settings

You must enable Docker in the Agent.

1. At the DSM Management Console, click **Hosts > Hosts**.
2. Click **Add Host**, or click on an existing Host name to edit the host.
3. In the General tab, select **Docker Enabled**.
4. Click **Apply**.
5. Click **Host Settings** tab.
6. Add the Docker Daemon to the host settings:
For Docker v1.12 and above, type:
`|authenticator|/usr/bin/dockerd`
For Docker v1.12 and below, type:
`|authenticator|/usr/bin/docker`
7. Click **Apply**.

CTE Docker GuardPoints

Docker typically provides two types of containers:

- **Transient:** Run micro services which are stateless applications.
- **Long running:** Host stateful applications similar to a database application.

The CTE Docker security feature protects data in both type of containers. You can use CTE to protect either type of containers. You select the container type while configuring the GuardPoint.

CTE provides two types of GuardPoints:

- Image-based
- Container-based

Image-based GuardPoints

You can set up a data protection policy on a Docker image. After an image-based GuardPoint is created, all of the instances running from the protected Docker image inherit the policy and its settings. Any change to the policy is reflected across Docker containers that are started from protected Docker images. You can also refer to Image-based protection as templated protection. The GuardPoints set up on a Docker image serves as a template for protection of all the Docker containers created as CTE protected Docker images.

Users can browse a Docker image to select the path for protection and configure security rules using information from a Docker image. This process is described in the *DSM Administration Guide*.

Container-based GuardPoints

You can set up a GuardPoint for a specific Docker container. You can browse a Docker image to select the path for protection, and to configure security rules using information from a Docker image.

GuardPoints for Docker Containers

Before creating GuardPoints on Docker images and containers, the following must be taken into consideration:

- You must add the Docker engine process to the Host Settings.
- When applying GuardPoint policies to Docker containers, users must ensure that the root user has at least 'permit' effect on the GuardPoint. Otherwise, the GuardPoint is inaccessible to all users, even for users with 'apply_key', and 'permit' effects.

Creating GuardPoints

1. Log on to your DSM as an administrator of type Security, Domain and Security, or All.
2. Navigate to **Hosts**.
3. On the *Hosts* page, click the name of the host in the **Host Name** column, the *Edit Host* page opens.
4. Click the **Guard Docker** tab.
5. Click **Guard** to open the *Guard File System* page.
6. Select a policy to apply to the GuardPoint you are about to create.
7. Click **Browse** next to the **Docker Image/Container** field to browse the Docker host for an image or container to which to apply the policy.
8. Select the type of directory to guard.
9. Click **Browse** next to the **Path** text box to browse the image or container for a file path to add the GuardPoint.
10. Click **Ok**, the *Edit Host* page opens with the newly created GuardPoint listed in the table.

Note: Automount is not supported in a Docker environment.

Viewing GuardPoints

You can view GuardPoints from the Management Console GUI and from the Docker host using the CTE Agent `secfsd` utility. To view GuardPoints using the `secfsd` utility:

1. Log on to your Docker Host as root.
2. At the prompt, type:

```
# secfsd -status guard -tree
```

The output is displayed in a tabular format. The table displays the following information:

- GuardPoint location on the image or container
- Name of the policy applied to the GuardPoint
- Type of directory being guarded

- Container ID
- GuardPoint configuration status; whether or not the GuardPoint has been enabled
- GuardPoint status; whether or not the GuardPoint is currently guarded or not
- Reason for the GuardPoint not being guarded

To view information for each GuardPoint;

1. Log on to your Docker Host as root.
2. At the prompt, type the following;

```
# secfsd -status guard -v
```

The output is displayed for each GuardPoint configured on the host. The following information is displayed for each GuardPoint:

- Name of the policy applied to the GuardPoint
- Directory to which the GuardPoint is applied
- Type of directory being guarded
- GuardPoint configuration status; whether or not the GuardPoint has been enabled
- GuardPoint status; whether or not the GuardPoint is currently guarded or not
- Reason for the GuardPoint not being guarded
- Space usage on the GuardPoint location
- Container ID

Data Security for Docker Images and Containers

The CTE Agent supports data security for directories within Docker images and containers. If a new GuardPoint is added to a directory within an image or container, and that GuardPoint contains data, that data must be transformed before CTE can apply an encryption policy. Therefore, before creating a GuardPoint, determine which of the following conditions is applicable to your situation.

Setting up an image based GuardPoint

If you are setting up an image based GuardPoint:

1. Create a container from that image using the `docker run` command. For example;

```
# docker run Ubuntu
```

CTE creates a container `<container_name>`.
1. Export the container to a TAR file in a directory using the `docker export` command. The following example creates a directory and exports the TAR file:

```
# mkdir -p /tmp/export/GP1  
# docker export <container_name> > /tmp/export/GP1/<container_name>.tar
```
2. Extract TAR file using the command `tar -xvf`. The following example creates a directory and extracts the TAR file to that directory;

```
# mkdir -p /tmp/extract/GP1  
# tar -xvf /tmp/export/GP1/<container_name>.tar -C /tmp/extract/GP1/
```

3. Guard extracted folder with a data transform policy, for example guard a folder with sensitive data under `/tmp/extract`.
4. Transform files using CTE.
5. Unguard the transformed folder.
6. Create a TAR file from the extracted files using the command `tar -czf`. The following example creates a directory, a TAR file and places it in that directory;

```
# mkdir -p /tmp/import/GP1
# cd /tmp/extract/GP1
# tar -czf /tmp/import/GP1/<container_name>.tar *
```

7. Import the TAR file back to the image using the Docker command `docker import`. For example,

```
# cat /tmp/import/GP1/<container_name>.tar | docker import - <image>
sha256:d303c8b357084291f02f5e033660f469705f8e2c1744bf14516783b58b0f3bd7
```

The image `<imageName>` is created in this example, and its ID is;

```
sha256:d303c8b357084291f02f5e033660f469705f8e2c1744bf14516783b58b0f3bd7
```

8. You can now guard directories within this image or container with a production policy.

Notes

- This procedure only works with an image's local file system and cannot transform a Docker data volume or NFS mount.
- Data transformation only occurs on the directory that is guarded, and not the entire Docker image.

Setting up a Container-Based GuardPoint

If you are setting up a container based GuardPoint, stop the Docker container before setting up GuardPoints:

1. Export the container to a TAR file in a directory using the `docker export` command. The following example creates a directory and exports the TAR file;
2. Extract TAR file using the command `tar -xvf`. The following example creates a directory and extracts the TAR file to that directory;

```
# mkdir -p /tmp/export/GP1
# docker export <container_name> > /tmp/export/GP1/<container_name>.tar
```

3. Guard extracted folder with a security policy.
4. Transform files using the CTE.
5. Unguard the transformed folder.
6. Create a TAR file from the extracted files using the command `tar -czf`. The following example creates a directory and creates a TAR file and places it in that directory:

```
# mkdir -p /tmp/import/GP1
# cd /tmp/extract/GP1
# tar -czf /tmp/import/GP1/<container_name>.tar *
```

7. Import the TAR file back to the image using the Docker command `docker import`. For example,

```
# cat /tmp/import/GP1/<container_name>.tar | docker import - <image>
```

sha256:d303c8b357084291f02f5e033660f469705f8e2c1744bf14516783b58b0f3bd7
The image, *<image>* is created in this example, and its ID is;
sha256:d303c8b357084291f02f5e033660f469705f8e2c1744bf14516783b58b0f3bd7
8. You can now guard this image or container with a production policy.

Notes

- This procedure only works with an image's local file system and cannot transform a Docker data volume or NFS mount.
- Data transformation only occurs on the directory that is guarded, and not the entire Docker image.

Setting up a GuardPoint for an Exported Docker Volume

If you are setting up a GuardPoint for a Docker volume exported from a Docker host:

1. Guard a folder on a host with a data transform policy.
2. Transform files using the Thales executable `dataxform`.
3. Unguard the folder on the host.
4. You can now guard this image or container with a production policy.

This approach works with Docker data volume and NFS mount, and can not transform the image/container local file system.

Configuring Audit Logging

Configure Log settings for the CTE Agent (FS Agent Log) at the System level on the DSM. These settings are inherited by all the domains on the DSM. However, you can fine tune log settings for a specific host, and those settings will override the system settings. With the introduction of Docker support, you can now configure log settings for Docker images and containers. Docker logs evaluate GuardPoint policies.

Configure Docker Log Settings

1. Log on to your DSM and switch to a domain. Alternately, log on to a DSM as a local domain administrator of type Security with a Host role.
2. Navigate to the **Hosts** page.
3. Click the name of your Docker host in the **Host Name** column, the *Edit Host* page opens.
4. Click **Docker Log**.
5. Enter the following information in the **Configure Docker Log Setting** panel:
 - a. **Docker Image/Container:** Click **Browse** to select an image or container from the Docker host. If you select an image, the **Docker Image ID** field displays the image ID. If you select a container, the **Docker Image ID** field displays the image from which the container was created, and the **Docker Container ID** displays the container ID. You can use these IDs to search for Docker specific logs on the *Logs* page later.
 - b. **Policy Evaluation Level:** Select a log message level. For more information about log levels, refer to the *DSM Administrators Guide*.
 - c. **Policy Evaluation Duplicated:** Select to suppress or allow duplicate messages. The default is

SUPPRESS.

6. Click **Ok**. CTE saves the Policy Evaluation settings in a tabular format under the **Configure Docker Log Setting** panel.

Searching for Docker Log Messages

Docker log messages display on the Logs page. To search for Docker specific log messages:

1. Click **Logs > Logs**.
2. Enter the following information in the **Search** panel:
 - **Log Type**: Select whether you want to display logs from both the DSM and the agents, only the DSM, or only the agents. The default is All, which means from both DSM and agents.
 - **Source**: Enter the hostname of the DSM server, or agent, for which you want to return log files.
 - **Last Refreshed**: Displays the date and time of when the displayed log files were last refreshed. Format is YYYY-MM-DD HH:MM:SS
 - **Message Contains**: Type in the text string that you want to search for in the log messages.
 - **Docker Host**: Click **Browse** to select the Docker Host for which you want to return log files.
 - **Docker Image/Container**: Click **Browse** to select an image or container for which you want to display logs.
 - **Docker Image ID**: Displays the ID for the selected Docker image.
 - **Docker Container ID**: Displays the ID of the selected Docker container.
3. Click **Go**. The relevant logs display in the table under the **Search** panel.

Generating Reports

The following DSM reports have been updated to include Docker information:

System Level Reports

To view system level reports, log on to a DSM as an administrator of type System or All. The system level reports that contain Docker information are:

- **System License Usage Summary**: Includes information about the total number of Docker licenses in use for the entire DSM.
- **License Usage by Domain**: Includes information about the total number of hosts with the Docker license enabled.

Domain Level Reports

To view domain level reports, log on to a DSM as an administrator of type Domain, Domain and Security, or All. Administrators of type Domain and Security and type Security must have AUDIT role privileges to access the reports. The domain level reports that contain Docker information are:

- **License Usage by Domain Summary**: Includes information about the total number of hosts with the Docker licenses enabled.
- **Host with GuardPoint Status**: Includes identification information about Docker Images and Docker containers that have GuardPoints. The columns are **Docker Image ID** and **Docker Container ID**.

You can download and save all reports locally in CSV format by clicking **Download**.

RedHat OpenShift Containers with CTE

Red Hat OpenShift Container Platform (OCP) provides an immutable, container-based platform to deploy and run applications and micro services. It is Red Hat's on-premise private PaaS product. It is built around a core of application containers powered by Docker Container Packages and Kubernetes Container Cluster Management, on a foundation of Red Hat Enterprise Linux.

Using the CTE Agent

In order to use the CTE Agent to protect OCP images and containers, you must obtain a CTE Agent license for Docker. The Docker license covers both Docker and OCP. Contact Thales Support for information on obtaining a license.

There is no change to the CTE installation, however, CTE agent must be installed on the OCP host system.

CTE: Virtual Machine versus OCP

Similarly to Docker, CTE installs on the OCP container host and orchestrates security from the OCP host. It does not leave a footprint inside the OCP image or containers. You setup the GuardPoints inside the individual containers at runtime.

Set the OpenShift Storage Driver

Although needed for Docker, this is not needed for OCP.

Administering the OpenShift Host

To protect data inside OCP containers, you need to create GuardPoints in the DSM, inside an OCP image or container, to which a CTE Agent policy is applied.

The administrative tasks related to OCP hosts are the same as for Docker hosts. See “Administering the Docker Host” for more information.

Enable OpenShift through Host Settings

If you have obtained a Docker license and enabled it through the DSM Host Settings, then OCP is also enabled.

CTE OCP GuardPoints

OCP typically provides two types of containers:

- **Transient:** Run micro services which are stateless applications
- **Long running:** Host stateful applications similar to a database application.

The CTE OCP security feature protects data in both type of containers. You can use CTE to protect either type of containers. You select the container type while configuring the GuardPoint.

Types of GuardPoints

CTE provides two types of GuardPoints:

- Image-based
- Container (POD)-based

Image-based GuardPoints

You can set up a data protection policy on an OCP image. After an image-based GuardPoint is created, all of the instances, running from the protected OCP image, inherit the policy and its settings. Any change to the policy is reflected across OCP containers that are started from protected OCP images. You can also refer to Image-based protection as templated protection. The GuardPoints set up on an OCP image serves as a template for protection of all of the OCP containers created as CTE protected OCP images.

Users can browse an OCP image to select the path for protection and configure security rules using information from an OCP image. This process is described in the *DSM Administration Guide*. It is the same procedure as for a Docker image.

Container/POD-based GuardPoints

You can set up a GuardPoint for a specific OCP container in the same manner that you do for a Docker container. You can browse an OCP image to select the path for protection, and to configure security rules using information from an OCP image.

Creating GuardPoints

Create GuardPoints in the same manner as for Docker.

Viewing GuardPoints

View GuardPoints in the same manner as for Docker.

Data Security for OpenShift Images and Containers

The CTE Agent supports data security for directories within OCP images and PODS/containers. If a new GuardPoint is added to a directory within an image or container, and that GuardPoint contains data, that data must be transformed before CTE can apply an encryption policy. Therefore, before creating a GuardPoint, determine which of the following conditions is applicable to your situation.

Setting up an Image-based GuardPoint

Set up a GuardPoint in the same manner as for Docker.

Setting up a POD-based GuardPoint

Set up a POD GuardPoint in the same manner as for Docker GuardPoints. Select the POD as you would a container.

Setting up a GuardPoint for an exported OCP volume

Set up a GuardPoint in the same manner as for exported Docker volume.

Configuring Audit Logging

Configure Audit logging in the same manner as for Docker.

Generating Reports

Generate Reports in the same manner as for Docker.

Creating an OCP Project in CLI with API Commands

Creating an OCP Project with a Template

You can create an OCP project in the CLI as well as in the GUI.

Note

RedHat OpenShift is OpenSource technology. Therefore, commands, references and documentation are subject to change. Thales is providing CLI commands that are current at this time. Thales cannot guarantee the integrity of these commands. If commands no longer work, consult the OpenShift developer documentation located at:

https://docs.openshift.com/enterprise/3.2/cli_reference/basic_cli_operations.html#cli-reference-basic-cli-operations

1. Login to the OCP server with a user name and password, type:

```
# oc login <ocp-server> -u <username> -p <password>
```

2. Create a new project, type:

```
# oc new-project <project-name>
```

3. Add an instant application template to your project and deploy it, type:

```
# oc process openshift <instant-app-template-path> | oc create -f -
```

For example:

```
# oc process openshift//django-psql-example | oc create -f -
```

Deploying an OCP Project

Run the following commands after deployment completes.

1. Get pod details, type:

```
# oc get -o name pods
```

2. Parse JSON output and get container details, type:

```
# oc get -o json <pod-name>
```

3. Create directory to be guarded in containers

```
# oc exec <pod-name> -c <container-name> -- <command>
```

```
# oc exec postgresql-1-bag25 -c postgresql -- mkdir /var/tmp/gp
```

4. Guard path inside all containers and inside all pods, type:

- Container-based guarding

```
# vmssc host addgp -d <guard-path> -p <policy> -c <container-id> -i <image-id> <hostname>
```

- Image-based guarding

```
# vmssc host addgp -d <guard-path> -p <policy> -i <image-id> <hostname>
```

Note: You can also guard paths in the DSM Management Console.

5. Unguard all guarded paths, type:

- Container-based guarding

```
# vmssc host delgp -d <guard-path> -p <policy> -c <container-id> -i <image-id> <hostname>
```

- Image-based guarding

```
# vmssc host delgp -d <guard-path> -p <policy> -i <image-id> <hostname>
```

Note: You can also unguard paths in the DSM Management Console.

6. Delete project, type:

```
# oc delete project <project-name>
```

Available OpenShift commands

Commands	Function
clusterresourcequota	Create cluster resource quota resource.
configmap	Create a configmap from a local file, directory or literal value
deployment	Create a deployment with the specified name.
deploymentconfig	Create deployment config with default options that uses a given image.
identity	Manually create an identity (only needed if automatic creation is disabled).
imagestream	Create a new empty image stream.
namespace	Create a namespace with the specified name
policybinding	Create a policy binding that references the policy in the targetted namespace.
quota	Create a quota with the specified name.
route	Expose containers externally via secured routes
secret	Create a secret using specified subcommand
service	Create a service using specified subcommand.
serviceaccount	Create a service account with the specified name
user	Manually create a user (only needed if automatic creation is disabled).
useridentitymapping	Manually map an identity to a user.

Available OPC Options

Options	Parameter	Function
-f	--filename	Filename or URL to file to read a template.
-l	-labels	Label that you can set in all resources for this template.
-o	-o, --output='json'	Output format. It is either: describe json yaml name template templatefile.

Options	Parameter	Function
-o	--output-version	Output the formatted object with the given version (default api-version).
-o	--parameters=false	Do not process but only print available parameters.
-o	--raw=false	If true, output the processed template instead of the template's objects. Implied by -o describe.
-t	--template	Template string or path to template file to use when -o=template or -o=templatefile. The template format is go lang templates. [http://golang.org/pkg/text/template/#pkg-overview]
-v	-v, --value=[]	Specify a key-value pair (ex: -v FOO=BAR) to set/override a parameter value in the template.

Container secfsd Utilities

Move to the Container-appropriate name space for the instance.

Use the following commands for more information.

```
# secfsd -[command] [option]
```

Commands	Function
-status guard [-v/-tree]	list all GuardPoints
-status keys	show current encryption key state
-status auth	list authentication settings
-status lockstat	show status of system and agent lock
-status logger	list logging details
-status policy	list configured policies
-status pslist	list protected process
-status devmap	list guarded devices
-guard path [containerID]	manually guard path
-unguard path [containerID]	manually unguard path
-version	show version of kernel module secfs2
cmd -c debug.<level>.[on off]>	set debug logging on/off
-debug <on off>	enable verbose logging
-help	Displays this help message

Chapter 12: NetApp Snapshot Directory

This chapter describes SecFS support for NetApp .snapshot directory over NFS. It contains the following sections:

Overview	146
Accessing snapshots	146
Enabling Snapshots	146
Dataxform Considerations	146

Overview

The NetApp snapshot directory contains ONTAP snapshot data entries for a specific live volume. Each snapshot is a read-only volume that is automatically mounted over NFS.

A snapshot copy is a read-only image of a traditional, or FlexVol volume, or an aggregate, that captures the state of the file system at a specific point in time.

Data ONTAP maintains a configurable snapshot copy schedule that creates and deletes snapshot copies automatically for each volume.

Accessing snapshots

By default, every volume contains a directory named .snapshot through which users can access previous versions of files. Users can gain access to snapshot copies depending on the file-sharing protocol used, NFS or CIFS. You can also prevent access to snapshot copies.

Snapshot files carry the same read permissions as the original file. A user who has permission to read a file in the volume, can also read that file in a snapshot copy. A user without read permission to the volume cannot read that file in a snapshot copy.

Note

Snapshot copies do not have write permissions.

Snapshot directories only display at the mount point, although they actually exists in every directory in the tree. This means that the .snapshot directory is accessible by name in each directory, but is only seen in the output of the `ls` command at the mount point. The snapshots are stamped with the date and time.

Enabling Snapshots

The NetApp storage administrator, or the OnTap device, must configure this feature. No configuration is required through CTE. CTE guards the client directory mounting the OnTap data volume over NFS.

Note

The NetApp documentation is located here: <https://nt-ap.com/2vEnEeJ>

Dataxform Considerations

You cannot transform snapshot directory entries with Dataxform with a new key, because the snapshots are read only. You must keep previous keys and alter the running security policy accordingly to maintain access to the older snapshot entries alongside any new snapshots taken with the new key.

Also, any snapshots that get created during the data transform process (this may take a long time) have to be discarded/deleted as it may contain a mix of data blocks encrypted with both old and new keys.

Best Practices

Maintaining keys for access to older snapshots can be tedious and cumbersome. Therefore, the simplest and safest practice is to delete all old snapshots once the data is transformed with a new key.

This allows for all new snapshots to be readable with the new key while old keys can be discarded, unless used in other security policies.

Chapter 13: Using CTE with Quantum StorNext

This chapter describes how to configure CTE and Quantum StorNext devices to interoperate to allow CTE policies to apply to storage managed by Quantum StorNext. This chapter contains the following sections:

Overview of using CTE with Quantum StorNext	148
CTE and Quantum StorNext Compatibility	148
Setting up CTE and Quantum StorNext Integration	150
Stop secfs Before Upgrading StorNext LAN Clients	152

Overview of using CTE with Quantum StorNext

Quantum StorNext Fibre Channel-connected devices provide shared file access to third party storage for workstation clients and are optimized for simultaneous access to very large files such as video files. The Quantum StorNext file system is known as SNFS or by its older name, CVFS.

You can encrypt and control access to SNFS files with DSM policies by installing CTE Agents on Linux clients that are configured for access to the SNFS file system. Some limitations apply to this integration, such as supported operating systems, supported SNFS features, concurrent read/write access by multiple clients, and GuardPoint settings (see the next section for more information about these limitations).

CTE and Quantum StorNext Compatibility

The following sections list the supported operating systems and CTE settings supported for use with Quantum StorNext file systems. Important unsupported configuration parameters are also listed.

Supported StorNext Server and Client Configurations

The CTE integration with SNFS file systems works only with certain SNFS versions, SNFS storage policies, and client operating systems.

Configuration parameter	Linux
StorNext (SNFS) operating system version	6.x
StorNext metadata controller (MDC) server OS type	Linux MDC supported
StorNext replication policy	Not supported
StorNext deduplication policy	Not supported
StorNext truncation	Supported
StorNext full and partial backup	Supported
StorNext expand filesystem	Supported
StorNext data migration	Supported
StorNext read-ahead cache	Disable for use with CTE
Client operating systems	Red Hat Enterprise Linux (RHEL) 7.x
StorNext LAN client	DLC

Configuration parameter	Linux
StorNext mount method: locally mounted directory	Supported
StorNext mount method: CIFS	Not supported
StorNext mount method: NFS	Not supported

Supported GuardPoint and Key Settings for SNFS File Systems

When configuring CTE GuardPoints and keys for SNFS, keep in the mind the compatibility limitations listed in the following table.

Note

Because AES-CBC-CS1 keys are not supported on Windows, do not create a policy on Linux that uses AES-CBC-CS1 keys if access to the same SNFS GuardPoint is required by both Windows and Linux LAN clients.

Configuration element	Linux
Offline data transformation	Supported
Live Data Transformation (LDT)	Not supported
Key manager compatibility	See the <i>Compatibility Matrix for CTE Agent with Data Security Manager</i> or the <i>Compatibility Matrix for CTE Agent with Data Security Manager</i> for your CTE version
Guard unstructured data	Supported
Guard structured data	Not supported
GuardPoint type: Directory (including entire SNFS volume)	Supported
GuardPoint type: Raw device	Not supported
GuardPoint type: Block device	Not supported
GuardPoint mount option: manual guard	Supported
GuardPoint mount option: auto guard	Supported
GuardPoint mount option: automount	Not supported
AES-CBC key type	Supported
AES-CBC-CS1 key type	Supported

Supported Concurrent Access Read/Write Scenarios

If you want to allow access by multiple clients (users) to CTE-protected SNFS files under the same GuardPoint, just read-only access is supported. StorNext file locking is not implemented in CTE, so there is currently no way to prevent concurrent conflicting writes to the same file. As a result, Thales does not support write access to the same GuardPoint from multiple clients.

To enable read access to the same GuardPoint from multiple clients, ensure that all clients are configured to use the same policy and key.

Configuration parameter	Linux
Read/write access from a single LAN client to a GuardPoint	Supported
Read/write access from two or more LAN clients to the same GuardPoint	Not supported
Read-only access from one, two, or more LAN clients to the same GuardPoint	Supported

Setting up CTE and Quantum StorNext Integration

For the most part, CTE integration with Quantum StorNext is the same as for any standard file system. The next section provides an overview of the steps involved in making CTE work with SNFS. Later sections provide more information about the steps that are new or differ significantly from a typical CTE setup.

Integration Task Overview

The table below provides an overview of the steps involved in setting up SNFS and CTE to work together. As noted in the table, some of these tasks are described in the documentation for your selected key manager. Some of these steps may need to be performed by other staff members at your organization if you have divided the security administration duties as recommended by Thales and you don't have access to the key manager.

Task	Key configuration notes	For more information
Install and configure a Quantum StorNext MDC server for use with CTE	Disable the StorNext read-ahead cache. Only certain StorNext policies, features, and mount types are supported. See "Supported StorNext Server and Client Configurations" on page 148.	See "Installing and Configuring a Quantum StorNext MDC Server for Use with CTE" on the next page.
Install and configure Quantum StorNext clients for use with CTE	Ensure that SNFS starts before <code>secfs</code> . See "Ensuring that the StorNext SNFS File System Starts Before secfs" on the next page. Only certain operating systems are supported. See "Supported StorNext Server and Client Configurations" on page 148.	See "Installing and configuring Quantum StorNext DLC Clients for Use with CTE" on the next page.
Create a domain for one or more SNFS hosts, or add them to an existing domain	No difference from standard CTE agent configuration.	See "Domain Management" in your key manager documentation.
Add the host to the key manager	No difference from standard CTE agent configuration.	See "Configuring Hosts and Host Groups" in your key manager documentation.
Install and register the CTE Agent on the host system	No difference in installation.	See Chapter 2: "Getting Started with CTE for Linux" on page 22
Create encryption keys (optional)	No difference from standard CTE agent configuration.	See "Managing Keys" in your key manager documentation. For information about AES-CBC-CS1 keys, see Chapter 5: "Enhanced Encryption Mode" on page 70.

Task	Key configuration notes	For more information
Configure host groups containing one or more StorNext LAN clients (optional)	No difference from standard CTE agent configuration.	See “Configuring Hosts and Host Groups” in your key manager documentation.
Configure policies (including user, process, and resource sets) to control access or enable encryption	No difference from standard CTE agent configuration.	See “Configuring Policies” in your key manager documentation.
Configure one or more GuardPoints	Some GuardPoint settings are not supported. See "Supported GuardPoint and Key Settings for SNFS File Systems" on page 149 .	See “Managing GuardPoints” in your key manager documentation

Installing and Configuring a Quantum StorNext MDC Server for Use with CTE

Install and configure a Quantum StorNext metadata controller (MDC) server using the [Quantum StorNext documentation](#) as a guide. The CTE integration works with Linux StorNext MDCs. Ensure that you configure the StorNext server to work with the settings supported by CTE as listed in ["Supported StorNext Server and Client Configurations" on page 148](#). For example, you must disable the StorNext read-ahead cache and only certain StorNext policies, features, and mount types are supported.

Installing and configuring Quantum StorNext DLC Clients for Use with CTE

Install and configure Quantum StorNext DLC clients using the [Quantum StorNext documentation](#) as a guide. The CTE integration works with Linux StorNext DLCs.

Ensure that you configure DLC clients to work with the settings supported by CTE as listed in ["Supported StorNext Server and Client Configurations" on page 148](#). For example, only certain operating systems are supported.

Note

Just read-only access is supported if multiple StorNext LAN clients will access files in the same GuardPoint. For more information, see ["Supported Concurrent Access Read/Write Scenarios" on page 149](#).

Ensuring that the StorNext SNFS File System Starts Before secfs

For CTE to function properly for Linux SNFS clients, the SNFS service must start before the CTE `secfs` service. Add an entry for the SNFS file system to `/etc/fstab` on each Linux client that has a CTE agent installed on it. Use the following format:

```
/snfs_share /stornext/snfs1 cvfs defaults,diskproxy=client 0 0
```

In this example, `/snfs_share` should be a share that has been exported from the StorNext Server. It should not be a local disk. You may have completed this configuration step as part of the StorNext LAN client installation. See the [Quantum StorNext documentation](#) for more details.

Installing the CTE Agent on Each StorNext LAN client

Install a CTE Agent on each computer that is set up as a StorNext LAN client and for which you want to set policies. For supported operating systems, see the table in ["Supported StorNext Server and Client Configurations" on page 148](#).

Use any installation method supported for your operating system. For details, see [Chapter 2: "Getting Started with CTE for Linux" on page 22](#).

Stop secfs Before Upgrading StorNext LAN Clients

Before you upgrade StorNext Linux LAN clients, disable or stop the CTE `secfs` service. To stop the `secfs` service, follow these steps:

1. Log in as root on the computer that contains the LAN client that you want to upgrade.
2. Type the following command: `/etc/vormetric/secfs stop`

After you upgrade the StorNext client, start `secfs` again by logging in as root and running the `/etc/vormetric/secfs start` command.

Chapter 14: Using CTE with McAfee Endpoint Security for Linux Threat Prevention

McAfee Endpoint Security for Linux Threat Prevention detects malware such as viruses and handles the malware according to policies that you configure in McAfee ePO. This chapter describes how to configure McAfee and CTE to work together.

This chapter contains the following sections:

Supported McAfee Versions and Linux Operating Systems	153
Ensuring Correct McAfee Service Startup Order	153
Updating McAfee	154
Virus Scanning Behavior Differences for CIFS and NFS GuardPoints	154

Supported McAfee Versions and Linux Operating Systems

In general, Thales has verified that CTE is compatible with McAfee version 10.6.5 and later on Red Hat Enterprise Linux (RHEL) 7 and RHEL 8. See the most recent *Compatibility Matrix for CTE Agent with CipherTrust Manager* or *Compatibility Matrix for CTE Agent with Data Security Manager* for details about the versions of McAfee Endpoint Security for Linux Threat Prevention that have been verified to work with CTE. You can find that document on the Thales Support website: <https://supportportal.thalesgroup.com> (login account required).

Ensuring Correct McAfee Service Startup Order

CTE services and McAfee services must be started and stopped in the correct order to prevent problems with your data that is guarded by CTE. This order is important any time these services need to be started or stopped, such as:

- During normal startup and shutdown of your Linux host.
- Before enabling a scheduled upgrade of CTE.
- Before performing a manual upgrade of CTE.
- As needed for maintenance or troubleshooting.

Ensuring Correct McAfee Service Startup Order in systemd

Configuring the proper startup and shutdown order of CTE and McAfee services in `systemd` ensures that the services start in the right order during system startup and shutdown. This is also important if you configure a scheduled upgrade of CTE.

The following McAfee services must be configured to start after CTE services:

- `isecesp.service`
- `isectpd.service`

To configure this behavior, add these services to the `Before=` line in the `secfs-fs-barrier.service` file on your system. The order of these services on the `Before=` line in the `secfs-fs-barrier.service` file does not matter. See "[Location of Application Unit Configuration Files](#)" on page 79 for the location of the `secfs-fs-barrier.service` file on your system. See "[Adding Applications to the secfs-fs-barrier.service File](#)" on page 79 for information about how to add services to the `secfs-fs-barrier.service` file.

Ensuring Correct McAfee Service Startup Order Manually

Perform the following commands in this order if you need to stop McAfee and CTE services manually:

1. Stop McAfee services:

```
# systemctl stop isecesp.service isectpd.service
```

2. Stop CTE:

Linux distributions that support systemd	/etc/vormetric/secfs stop
Linux distributions that do not support systemd	service secfs stop

Perform the following commands in this order if you need to start McAfee and CTE services manually:

1. Start CTE:

Linux distributions that support systemd	/etc/vormetric/secfs start
Linux distributions that do not support systemd	service secfs start

2. Start McAfee services:

```
# systemctl start isecesp.service isectpd.service
```

Updating McAfee

It is not necessary to shut down CTE services when you update McAfee Endpoint Security to a new version. Follow the update procedure described by McAfee. Before updating, ensure that the new version of McAfee is compatible with CTE as described in ["Supported McAfee Versions and Linux Operating Systems" on the previous page](#).

Virus Scanning Behavior Differences for CIFS and NFS GuardPoints

By default on McAfee Endpoint Security, on-access virus scanning for remotely mounted file systems such as CIFS and NFS is disabled. However, for GuardPoints configured on CIFS and NFS volumes, this default is ignored. So on-access virus scanning is always on for GuardPoints configured on CIFS and NFS volumes. This means that if a process attempts to save an infected file to a GuardPoint configured on a CIFS or NFS volume, the infected file will be discovered immediately if it matches the McAfee malware detection algorithm and handled according to the appropriate malware policy in McAfee ePO.

Chapter 15: Using CTE with Trend Micro Deep Security Software

Trend Micro's Deep Security software provides comprehensive security in a single solution that is purpose-built for virtual, cloud, and container environments. Thales has verified certain versions of this Trend Deep product for compatibility with CTE on Red Hat Enterprise Linux (RHEL) 7 and RHEL 8.

This chapter contains the following sections:

Supported Deep Security Versions and Linux Operating Systems	155
Ensuring Correct Deep Security Service Startup Order	155
Updating Deep Security	156

Supported Deep Security Versions and Linux Operating Systems

CTE and Deep Security can be used with RHEL 7 and RHEL 8. See the most recent *Compatibility Matrix for CTE Agent with CipherTrust Manager* or *Compatibility Matrix for CTE Agent with Data Security Manager* for the current versions of Trend Micro Deep Security that have been verified to work with CTE. You can find that document on the Thales support website <https://supportportal.thalesgroup.com> (login account required).

Ensuring Correct Deep Security Service Startup Order

CTE services and Deep Security services must be started and stopped in the correct order to prevent problems with your data that is guarded by CTE. This order is important any time these services need to be started or stopped, such as:

- During normal startup and shutdown of your Linux host.
- Before enabling a scheduled upgrade of CTE.
- Before performing a manual upgrade of CTE.
- As needed for maintenance or troubleshooting.

Ensuring Correct Deep Security Service Startup Order in systemd

Configuring the proper startup and shutdown order of CTE and Trend Micro's Deep Security services in `systemd` ensures that the services start in the right order during system startup and shutdown. This is also important if you configure a scheduled upgrade of CTE.

The following Deep Security service must be configured to start after CTE services:

```
ds_agent.service
```

To configure this behavior, add this service to the `Before=` line in the `secfs-fs-barrier.service` file on your system. The order of these services on the `Before=` line in the `secfs-fs-barrier.service` file does not matter. See "[Location of Application Unit Configuration Files](#)" on page 79 for the location of the `secfs-fs-barrier.service` file on your system. See "[Adding Applications to the secfs-fs-barrier.service File](#)" on page 79 for information about how to add services to the `secfs-fs-barrier.service` file.

Ensuring Correct Deep Security Service Startup Order Manually

Perform the following commands in this order if you need to stop Deep Security and CTE services manually:

1. Stop Deep Security services:

```
# systemctl stop ds_agent.service
```

2. Stop CTE:

Linux distributions that support systemd	/etc/vormetric/secfs stop
Linux distributions that do not support systemd	service secfs stop

Perform the following commands in this order if you need to start Deep Security and CTE services manually:

1. Start CTE:

Linux distributions that support systemd	/etc/vormetric/secfs start
Linux distributions that do not support systemd	service secfs start

2. Start Deep Security services:

```
# systemctl start ds_agent.service
```

Updating Deep Security

It is not necessary to shut down CTE services when you update Trend Micro Deep Security to a new version. Follow the update procedure described by Trend Micro. Before updating, ensure that the new version of Deep Security is compatible with CTE as described in ["Supported Deep Security Versions and Linux Operating Systems" on the previous page](#).

Chapter 16: CTE COS for Amazon S3

This chapter discusses how to configure CTE COS for Amazon S3 buckets. It contains the following sections:

Overview	157
System and Software Requirements	159
Client Software Requirements	159
CTE COS S3 Installation Overview	159
Install Required Linux Packages	160
Install CTE	160
Configure the AWS CLI to use the COS Root CA Certificate	161
Configure the AWS CLI Network Proxy	161
Configure CTE COS S3	162
Optionally Configure a CTE COS S3 Role for Guarded Buckets	163
Guard an AWS Bucket	167
Additional COS Proxy Root CA Certificate Information	170
Protecting Python Programs with CTE	172

Overview

CipherTrust Transparent Encryption for Cloud Object Storage (CTE COS) is an object storage service that you can use to store and protect any amount of data for a range of use cases, such as websites, mobile applications, backup and restore, archive, enterprise applications, IoT devices, and big data analytics. CTE COS provides management features so you can organize your data and configure finely-tuned access controls to meet your specific business, organizational, and compliance requirements.

CTE COS for Amazon Simple Storage Service (CTE COS S3) is an extension to CTE for inline encryption and local host access controls involving applications performing REST-API-based operations to S3 object stores.

CTE COS S3 is not a replacement for AWS IAM access controls which are enforced independently at the AWS server end.

The following diagram shows the high-level CTE COS S3 architecture:

Supported operations

- CTE COS S3 will process only AWS S3 REST https calls issued by applications. The interception is done by a bundled TLS proxy with additional CTE services.
- CTE's traditional access controls and inline encryption are transparently applied during the following operations:
 - Create a bucket
 - Write an object
 - Read an object
 - Delete an object
 - List objects

Limitations

- CTE COS S3 is supported only on RHEL 7.
- Only REST API based S3 protocol-aware applications are supported.
- Only locally generated self-signed COS Proxy CA Certificates are supported.
- AWS S3 URL path validations are not currently implemented. CTE COS S3 requires that the user must specify the correct URLs for bucket paths.
- CTE COS S3 permits only AES CBC-CS1 encryption. Encrypted files in protected buckets therefore will prepend the 4K embedded header used in CTE's AES CBC-CS1 encryption. The DSM will enforce usage of AES CBC-CS1 keys within S3 bucket policies.

Multi-part Upload Restrictions

- All upload operations for a multi-part upload must be conducted from the same host.
- Maximum file size upload is 5TB.
- Part sizes during uploads must be identical. The part numbering must be in sequence starting with 1, e.g. 1,2,3,4,... Not 10, 20, 30, etc.
- The part size specified in CTE S3's AWS credential file must match the part size specified within the application.
- Thales recommends that the Content-MD5 header be included in the request message.

System and Software Requirements

- The RHEL 7 Linux host must meet the standard CTE requirements.
- You must have an AWS account
- We recommend that you guard the bucket by restricting it with a CTE COS S3 Role to prevent accidental data corruption from connections outside the control of CTE COS S3. For details, see ["Optionally Configure a CTE COS S3 Role for Guarded Buckets" on page 163](#).
- You must download and install the pre-requisite rpm packages before you install CTE COS S3. For details, see ["Install Required Linux Packages" on the next page](#).
- The CTE Agent must be installed in the default directory on the host. You cannot change the default path if you also enable CTE COS S3.

Client Software Requirements

- Clients must exist on the same host as CTE COS S3. External Client connections will be rejected by the COS Proxy.
- Clients must be AWS S3 protocol aware, and can directly connect to a S3 bucket without the use of an intermediary service, such as the AWS S3 Management Console website.
- Clients must be configured to divert outgoing network connection to a COS proxy (default is localhost:3128 or 127.0.0.1:3128). For more information, see ["Configure the AWS CLI Network Proxy" on page 161](#).
- Clients must use the TLS 1.2 / TLS 1.3 network encryption protocol over TCP/IP to establish connections to the COS proxy.
- Clients must be configured to use the COS CA Root Certificate of the COS proxy to verify and authenticate TLS connections. For more information, see ["Configure the AWS CLI to use the COS Root CA Certificate" on page 161](#).

CTE COS S3 Installation Overview

In order to configure CTE COS S3, you must complete the following tasks.

Note

The AWS CLI is used as a sample application to explain the detailed installation procedure.

1. Install the required packages for CTE COS S3. For details, see ["Install Required Linux Packages" on the next page](#).
2. Install CTE and generate the local COS Proxy CA Certificate. For details, see ["Install CTE" on the next page](#).

3. Configure the client to use the COS Proxy CA Certificate. For details, see ["Configure the AWS CLI to use the COS Root CA Certificate" on the facing page](#).
4. Configure the client to use the COS proxy port. For details, see ["Configure the AWS CLI Network Proxy" on the facing page](#).
5. Configure CTE COS S3 with AWS Credentials. For details, see ["Configure CTE COS S3" on page 162](#).
6. Optionally configure Role & IAM policies for CTE COS S3 for guarded buckets. For details, see ["Optionally Configure a CTE COS S3 Role for Guarded Buckets" on page 163](#).
7. Configure the guarded buckets. For details, see ["Guard an AWS Bucket" on page 167](#).

Install Required Linux Packages

CTE COS S3 requires the following pre-requisite packages:

- `boost-regex`.
- `boost-system`.
- `boost-thread`.
- `lib-curl`.
- `libtool-ltdl`.
- `libxml2`.
- `epel-release`.
- `cryptopp`. This package must be installed *after* `epel-release`.
- `log4cpp`. This package must be installed *after* `epel-release`.

For example:

```
$ sudo yum install boost-regex boost-system boost-thread libcurl libtool-ltdl libxml2 epel-release
$ sudo yum install cryptopp log4cpp
```

CTE COS S3 supports both Python2 and Python3. If both versions of Python are available, CTE COS S3 will use Python3. For either Python package, you also need to install the Python modules `"boto3"` and `"future"` after you install the main python package.

- Example for Python2:

```
$ sudo yum install python-pip
$ sudo pip install boto3 future
```

- Example for Python3:

```
$ sudo yum install python3 python3-pip
$ sudo pip3 install boto3 future
```

Install CTE

When you install CTE COS S3 for use with S3, use the instructions in the *CTE Agent for Linux Quick Start Guide*. In addition to those instructions, answer the following prompts as described in this section.

1. If you are using Fingerprint registration, make sure you know the fingerprint for this agent on the host. This Fingerprint can be seen in the Host Information shown in the DSM Management Console.
2. When the installer asks about Cloud Object Storage, type **Y** and follow the prompts as shown.

Do not change the default CTE installation directory. CTE must be installed in the default location if you enable Cloud Object Storage.

Do you want this host to have Cloud support enabled on the server? (Y/N) [N]: **Y**

CTE COS CA Cert is located in /opt/vormetric/DataSecurityExpert/agent/squid/etc/cosCA.crt
Clients must be updated to use the new CA Certificate

Generating certificate signing request for the kernel component...done.
Signing certificate...done.
Generating EC certificate signing request for the vmd...done. Signing certificate...done.
Generating EC certificate signing request for the vmd...done.
Signing certificate...done.

The following is the fingerprint of the EC CA certificate. Please verify that it matches the fingerprint shown on the Dashboard page of the Management Console.
If they do not match, it can indicate an unsuccessful setup or an attack.
B0:93:C7:67:07:C9:CB:09:E2:21:F1:5C:8A:C8:79:8F:03:86:21:F2
Do the fingerprints match? (Y/N) [N]: **Y**

Successfully registered the CipherTrust Encryption Expert File System Agent with the primary CipherTrust Data Security Server on security.manager.example.com.
Starting CTE Cloud Service
Installation success.

Configure the AWS CLI to use the COS Root CA Certificate

You must configure the AWS CLI to use the COS root CA certificate. To do so, edit `~/.aws/config` and add the following line to the AWS cli configuration file:

```
ca_bundle = /opt/vormetric/DataSecurityExpert/agent/squid/etc/cosCA.crt
```

For example:

```
$ cat ~/.aws/config
[default]
output = json
Region = us-west-1
ca_bundle = /opt/vormetric/DataSecurityExpert/agent/squid/etc/cosCA.crt
```

Configure the AWS CLI Network Proxy

All communications between client applications and the AWS server must be done through the COS proxy and the environment variable `HTTPS_PROXY` or `https_proxy` should be set. If both variables are defined, then the AWS CLI will use `https_proxy`.

For example:

```
Export HTTPS_PROXY=localhost:3128
```

Configure CTE COS S3

In order for CTE COS S3 to do transparent encryption and decryption, all requests sent to the AWS S3 server must be generated and signed using valid AWS credentials. In order to retrieve these credentials for CTE COS S3, you can use any of the following methods:

- **The User Supplies the Credentials for the User's AWS Account**

The application can send the long-term credentials from the user's AWS account to CTE COS S3. These credentials do not expire.

For the AWS CLI, the credentials are in the credential file `~/.aws/credential`. The user credentials consists of an Access Key ID and a Secret Access Key. For details about accessing the user's credentials, see your AWS documentation.

To add the AWS credentials to CTE COS S3, use the `voradmin cos s3 cred add` command:

```
voradmin cos s3 cred add [<aws_key_id> <aws_secret_key>] where:
```

- `<aws_key_id>` is the AWS secret key ID from the `.aws/credentials` file.
- `<aws_secret_key>` is the AWS secret key from the same file.

For example:

```
voradmin cos s3 cred add AKIA****P KQSm****D
```

- **The User Supplies Temporary Security Credentials**

You can use temporary security credentials, which expire after a short period of time. Usually temporary security credential are obtained through IAM roles and other features of the AWS Security Token Service.

Use the `voradmin cos s3 cred add` command, described above, to add the temporary credential to CTE COS S3.

- **CTE COS S3 Captures Temporary Credentials**

CTE COS S3 can capture a temporary, newly generated, security credential and automatically add it to CTE COS S3 if the application generates the temporary security credential using the AWS Security Token Service with one of the following 3 actions *and* `HTTPS_PROXY` is set to `localhost:3128`.

- `AssumeRole`
- `AssumeRoleWithSAML`
- `AssumeRoleWithWebIdentity`

No other action is required from the application or user.

- **CTE COS S3 Retrieves Credentials from EC2 Instance Metadata Service**

When CTE COS S3 is installed on AWS EC2 instance with an attached role, CTE COS S3 automatically retrieves the credential from Instance Metadata Service and uses it. However, if CTE COS S3 already has a valid credential given by the user or admin using the `voradmin` command, then that credential will be used instead. For information about setting up an IAM Role, see your AWS EC2 documentation.

No action is required from application or user.

Setting the Default Chunk Size

Note

If a chunk size is configured in the AWS CLI configuration, you must configure the same chunk size for CTE COS S3.

The default chunk size for multi-part uploads is 8 MB. To change the chunk size, use the following command:

```
voradmin cos s3 chunk [<aws_key_id> <aws_secret_key>] [<chunk_size>] where:
```

- <aws_key_id> is the AWS secret key ID from the `.aws/credentials` file.
- <aws_secret_key> is the AWS secret key from the same file.
- <chunk_size> is the number of MB per chunk that you want to use for multi-part uploads. Enter an integer between 5 and 5120.

The `voradmin` command prompts for any of the optional parameters that you do not specify on the command.

For example, to set a chunk size of 250MB, you would enter:

```
voradmin cos s3 chunk AKIA****P KQSm****D 250
```

Optionally Configure a CTE COS S3 Role for Guarded Buckets

AWS provides the IAM Role feature that contains certain specific permissions. A user can assume the IAM Role and therefore take on those permissions. CTE COS S3 provides a special feature using this IAM Role to prevent access to one or more buckets outside the CTE COS S3 protection as shown in the following diagram:

Only hosts that are configured with the CTE COS S3 Role can access the protected buckets. All other access attempts from any hosts where the CTE COS S3 Role is not configured, including attempts made through the AWS S3 Console, are blocked for the protected buckets.

This is a one-time configuration process. After the CTE COS S3 Role is configured on a host by the system or security administrator, all authorized users in the host can access the protected buckets.

Prerequisites

To set up a CTE COS S3 Role, you need a delegated IAM user, role, and policy. The delegated IAM user should be created by the AWS Administrator without any specific privileges. The role and policy must be created by a user who has at least the following privileges:

- `iam:ListPolicies`
- `iam:CreatePolicy`
- `iam:GetPolicyVersion`
- `iam:ListRoles`
- `iam:ListRolePolicies`
- `iam:ListAttachedRolePolicies`
- `iam:AttachRolePolicy`
- `iam:UpdateAssumeRolePolicy`
- `iam:CreateRole`
- `iam:GetRole`

Procedure

1. In the IAM Management Console, create a policy that allows access to specific S3 resources. You can leave the policy open to include all S3 resources in the account or include only those buckets that require CTE protection. Make sure you name the policy something that you will remember.

Tip: You can also create the policy as an inline policy after you create the CTE COS S3 Role later in this procedure.

For example, you can create a policy called `VTE_S3_Role_Policy` that allows access to the single S3 bucket `vte-cos-s3-rtb`. To verify that the policy restricts access to that bucket, you can look at the Resource allocation in the Policy summary.

The full JSON for the `VTE_S3_Role_Policy` is:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Sid": "VisualEditor1",
      "Effect": "Allow",
      "Action": "s3:*",
      "Resource": [
        "arn:aws:s3::vte-cos-s3-rtb",
        "arn:aws:s3::vte-cos-s3-rtb/*"
      ]
    }
  ]
}
```

2. Create a new role that you can use for the CTE COS S3 Role. For example, you could call the role `VTE_S3_Role`.

3. Assign the CTE COS S3 policy you created to the role, or click **Add inline policy** to create a new policy. For example:

4. Create a delegated IAM user for the CTE COS S3 Role. The user does not require any privileges because its only job is to assume the CTE COS S3 Role. The delegated IAM user can either be in the same account as the role or it can be in a different trusted account. For example, you could create a user called VTE_S3_User with no privileges.
5. Set "Trusted Entities" to the delegated IAM user on the **Trust relationships** tab. For example:

6. Configure the CTE COS S3 Role with the credentials of the delegated IAM user you created earlier by entering the following command in the command line on the host system:

```
voradmin cos s3 role config [<aws_key_id> <aws_secret_key> <user_arn> <role_arn>] where:
```

- <aws_key_id> is the AWS secret key ID for the delegated IAM user that you created.
- <aws_secret_key> is the AWS secret key or the delegated IAM user that you created.
- <user_arn> is the Amazon Resource Name for the delegated IAM user that you created.
- <role_arn> is the Amazon Resource Name for the delegated IAM Role that you created.

If you omit any of the optional parameters, the `voradmin` command prompts you for that information.

For example, if the AWS account number for the delegated IAM user is 1XXXXXXXXXXXX, the user name is VTE_S3_User, and the CTE COS S3 Role is VTE_S3_Role, you would enter:

```
voradmin cos s3 role config AKIA****P KQSm****D arn:aws:iam::1XXXXXXXXXXXX:user/VTE_S3_User  
arn:aws:iam::1XXXXXXXXXXXX:role/VTE_S3_Role
```

After you configure the user and assign the CTE COS S3 Role, CTE will access the S3 bucket through the delegated IAM user account using temporary credentials that CTE regenerates periodically. These credentials are maintained entirely by CTE and are never exposed to end users.

Secure an S3 Bucket with the CTE COS S3 Role

When you enable the CTE COS S3 Role for a bucket, the associated bucket policy prevents unauthorized users from accessing the contents of the bucket. To enable the CTE COS S3 Role for a bucket, use the following command:

```
voradmin cos s3 role secure-bucket <key_id> <secret key> <bucket_name> where:
```

- <aws_key_id> is the AWS secret key ID for the delegated IAM user that you created.
- <aws_secret_key> is the AWS secret key for the delegated IAM user that you created.
- <bucket_name> is the name of the S3 bucket on which you want to enable the CTE COS S3 Role.

For example, if the bucket name is `vte-cos-s3-rtb`, you would enter:

```
voradmin cos s3 role secure-bucket AKIA****P KQSm****D vte-cos-s3-rtb
```

Disable the CTE COS S3 Role for an S3 Bucket

To remove the CTE COS S3 Role restrictions associated with a bucket, use the following command:

```
voradmin cos s3 role release-bucket <key_id> <secret key> <bucket_name> where:
```

- <aws_key_id> is the AWS secret key ID for the delegated IAM user that you created.
- <aws_secret_key> is the AWS secret key for the delegated IAM user that you created.
- <bucket_name> is the name of the S3 bucket on which you want to disable the CTE COS S3 Role.

For example, if the bucket name is `vte-cos-s3-rtb`, you would enter:

```
voradmin cos s3 role release-bucket AKIA****P KQSm****D vte-cos-s3-rtb
```

Guard an AWS Bucket

To Guard an AWS bucket, you must:

1. Create a CBC_CS1 key.
 - For DSM, see ["Create a CBC_CS1 Key in DSM" below](#)
 - For CM, see "Creating a New Key" in the CTE Administrator Guide
2. Create a Cloud Object Storage (COS) policy.
 - For DSM, see ["Create the Cloud Object Storage \(COS\) policy in DSM" on the next page](#)
 - For CM, see "Creating Policies" in the CTE Administrator Guide
3. Apply the policy to the host.
 - For DSM, see ["Creating GuardPoints in a Host" on page 169](#)
 - For CM, see "Managing GuardPoints" in the CTE Administrator Guide

Create a CBC_CS1 Key in DSM

1. Log on to the Management Console as an administrator of type: All or Security Administrator with Key role permissions.
2. In the menu bar select **Keys > Agent Keys > Keys**.
The Agent Keys page displays.
3. Click **Add**. The Add Agent Key window opens.
4. Select the Symmetric tab.

5. Complete the fields in this window by using the following information.

Name: Provide a name for the key.

Algorithm: Select **AES256**.

Encryption Mode for CTE agents only: DSM allows only CBC-CS1 encryption mode for COS policy type.

Key Type: Cached on Host

Key Creation Method: Generate

For example:

6. Click OK.

Create the Cloud Object Storage (COS) policy in DSM

Creating a COS policy differs from creating standard policies. Some notes about COS policies:

- Allow Browsing is not supported for Cloud Object Storage policies.
- Policies for Cloud Object Storage do not contain a resource set. The resource set is automatically the cloud object storage.
- Policies for Cloud Object Storage do not contain a When/Time set.
- Key Rules for Cloud Object Storage policies only contain one Key.
- Policies for Cloud Object Storage do not support Exclusion rules.

To create the policy:

1. Click **Policies > Manage Policies** to list the policies available to this domain.
2. Click **Add**. The **Add Policy** page appears.
3. For **Policy Type**, select **Cloud Object Storage**.
4. In the **Name** field, enter a name for the policy. For example
5. In the **Key Selection Rules** section, click **Add**. The Add Key Rule page appears.

- Click **Select** and choose the CBC_CS1 key you created in ["Create a CBC_CS1 Key in DSM"](#) on page 167.

- Click **Select Key**, then click **OK** to confirm that you want to use the CBC_CS1 key.
- Click **OK** to save the Policy with the CBC_CS1 key rule.

Creating GuardPoints in a Host

Security/All administrators can create new GuardPoints or edit existing host GuardPoints.

Note

DSM allows **exactly one** COS GuardPoint per S3 bucket.

The following features are NOT supported in COS GuardPoints:

- Existing data transformation, either offline or with Live Data Transformation (LDT). If you want to encrypt existing data, you must move it out of the S3 bucket, guard the bucket, then move the existing data back into the guarded bucket. When the data is moved back into the S3 bucket, it will be encrypted by CTE before it becomes accessible to users.
- Secure Start
- Host to Browse

- Auto Mount
- Efficient Storage
- Buckets inside a container or Docker
- Browsing to a bucket to be guarded

Note

In the Edit Host window, you will see that the **GuardPoints** tab has been renamed to **GuardPoints**.

To create a COS GuardPoint:

1. In the Hosts window, click on the host for which you want to set GuardPoints.
2. In the Edit Host window, click **GuardPoints**.
3. In the GuardPoints tab, click **Guard**.
4. In the Policy dropdown menu, select an appropriate policy.
5. For type, click Cloud Object Storage (Auto Guard or Manual Guard).
6. In the Path field, enter the path for the GuardPoint.
7. Click **OK**. COS GuardPoints display on the GuardPoints tab of the Host Detail page.

Additional COS Proxy Root CA Certificate Information

The CTE COS CA Certificate, not to be confused with the Kernel and VMD Kernel Certificates, is used with the COS internal Proxy Certificate Authority and must be used by Clients to validate Certificates received during their TLS connection handshake. The default COS CA Self-Signed root CA is automatically created using a locally generated Public/Private Key with the following parameters:

- `CERT_FIELD_PARAM="/C=OZ/ST=Munchkin-land/L=Emerald City/O=ACME Inc/OU=ACME Deliveries/CN=localhost"`
- `SUBJECT_ALT_NAME_PARAM="DNS.1:localhost,IP.1:127.0.0.1"`

To view the currently installed Certificate for the COS Proxy CA, use the `voradmin cos ca_cert display` command.

In the context of the internal COS Proxy CA, the FQDN of 'localhost' would be the correct value, as well as the loop-back IP address of 127.0.0.1 This results in the following locally generated Root CA Certificate.

```
Certificate:
Data:
Version: 3 (0x2)
Serial Number:

d7:74:83:87
```

If you want to change the defaults, you can use the silent install option with the `CERT_FIELD_PARAM` and `SUBJECT_ALT_NAME_PARAM` set to the desired values, or you can replace the default Certificate using the `voradmin cos ca_cert` command. For more details, see the `voradmin` manpage.

Protecting Python Programs with CTE

CTE uses SHA-256 to generate binary signatures that can be used to allow certain trust levels for a customer application. Capturing the signature of a binary allows CTE to determine if the application's binary has changed in any way, because those changes might mean the security of the binary has been compromised.

While this mechanism works well for executable binaries to verify an application's validity at run time, this mechanism does *not* work for applications implemented with interpreter languages because CTE can only access the interpreter's signature to validate the file. The program itself is something that is executed by the interpreter and thus CTE cannot hook into this process. Scripting languages like Python are particularly difficult because many Python programs include other Python files, which means there is no single program signature that defines the execution path.

While CTE cannot use signature sets to protect traditional Python programs, tools like PyInstaller allow for the creation of a self-contained Python executable that CTE can sign and protect.

Benefits of Using PyInstaller with CTE

Using PyInstaller allows the creation of self-contained Python binary packages. These packages contain the Python interpreter, the Python program, and all required modules and libraries. Because each package includes all of the files it needs, it is immune to changes to the Python modules or libraries on the system. This not only allows CTE to sign the binary but it also adds extra protection against an attacker trying to gain access through modifications of the underlying libraries.

Another benefit is that it provides security administrators with a stable process that reasonably immune to system updates done by a system administrator. Once the application binary has been created and signed, the behavior of the program will not change because of updates made through the OS packaging system or Python's PIP package manager.

Getting PyInstaller

PyInstaller is an OpenSource project. The instruction for installing PyInstaller as well as the documentation are available through the project page at:

<https://PyInstaller.readthedocs.io>

Example Usage

The exact usage of PyInstaller arguments varies based on the details of the Python program being packaged into an executable. This example show what is needed to generate a self-contained AWS CLI binary with PyInstaller. It uses the `--onefile` flag to generate a single, self-contained binary. It assumes that the `pip3` Python package manager is already installed on the system.

Installing PyInstaller

The following command installs PyInstaller in `${HOME}/.local/bin/PyInstaller`:

```
# pip3 install --user PyInstaller
```

Installing the Amazon AWS Command Line Utility

The following command installs the AWS utility in `${HOME}/.local/bin/aws`:

```
# pip3 install --user awscli
```

Creating a Runtime Hook

The following command creates a runtime hook that changes the Python `botocore` root directory within the packaged binary. This is necessary to make sure that we use the `botocore` packaged by PyInstaller. The hook is save to a file named `change-botocore-root.py`. For more information on runtime hooks, see the PyInstaller documentation.

```
# cat <<EOF > ${HOME}/change-botocore-root.py
import sys
import botocore

if getattr(sys, 'frozen', False):
    botocore.BOTOCORE_ROOT = sys._MEIPASS
EOF
```

In order to get the AWS CLI utility working with PyInstaller, we need to specify some hidden imports as well as add some folders from the `awscli` and `botocore` packages into the executable. For more information about hidden imports and adding files to the executable, see the PyInstaller documentation.

```
# ${HOME}/.local/bin/PyInstaller --onefile \
  --hiddenimport=awscli.handlers \
  --hiddenimport=pipes \
  --add-data=${HOME}/.local/lib/python3.6/site-packages/awscli/data:data \
  --add-data=${HOME}/.local/lib/python3.6/site-packages/botocore/data:data \
  --runtime-hook=${HOME}/change-botocore-root.py \
  ${HOME}/.local/bin/aws
```

The resulting binary will be saved in the current working directory as `dist/aws`.

Chapter 17: CTE-Efficient Storage for Linux

Storage arrays offer features such as compression and deduplication for storage efficiency. They also provide simplistic encryption that fails to deliver the requisite levels of security. CipherTrust Transparent Encryption (CTE) offers a much higher level of security. However, in deployments where storage arrays receive encrypted data streams from hosts protected by a CTE instance (protected hosts), the encrypted data streams make the efficiency of storage array systems ineffective. This is because every block written by CTE is different resulting in zero deduplication and compression on these blocks.

CTE offers CTE-Efficient Storage as the solution to the storage efficiency challenge in storage arrays on Linux.

Note

Currently, this feature is only supported on the DSM. Support for this feature will be added to CipherTrust Manager in a future release.

This chapter contains the following sections:

Introduction to CTE-Efficient Storage	174
Guarding an Efficient Storage Device on Linux	180
Guarding a CTE-Efficient Storage Device with Multiple IO Paths on Linux	189
Linux System and ES GuardPoint Administration	189
Changing the Encryption Key on Linux ESG Devices	192
Resizing Guarded Efficient Storage Devices	194
Use Cases involving Efficient Storage GuardPoints	196
Alerts and Errors on Linux	205

Introduction to CTE-Efficient Storage

CTE-Efficient Storage for Linux is a licensed feature available with CTE 7.0.0 or later. In addition, all CTE Agents must be registered with a Vormetric Data Security Manager (DSM) version 6.3 or later.

Note

All references to 'storage array' in this document assume storage array systems capable of supporting CTE-Efficient Storage functionality.

With CTE-Efficient Storage, CTE offers the same degree of security for the data stored on the arrays while offering a new type of encryption key and GuardPoint. The new type of key enables storage array systems to achieve storage efficiencies with encrypted data streams. The coordination between the storage array and CTE is essential for achieving storage efficiency with encrypted data.

In the context of this solution, a LUN exported from a storage array system to a CTE-managed host, is referred to as an *ES GuardPoint*. An ES GuardPoint is a guarded device configured with the CTE-Efficient Storage capability.

Requirements and Considerations

- CTE-Efficient Storage requires XTS-AES mode of the AES algorithm for encryption.
- CTE only supports CTE-Efficient Storage on servers with microprocessors integrated with Advanced Encryption Standard instruction set (AES-NI).

- CTE-Efficient Storage requires that the encryption keys be stored in the KMIP server on the DSM. Therefore, all hosts on which you want to create ES GuardPoints must be registered with a KMIP-enabled domain in the DSM.

Note: Starting with CTE version 6.3 and DSM version 6.4.2, you can also use CipherTrust InPlace Data Transformation to protect storage arrays without needing to store the encryption keys in the KMIP server. For details, see [Chapter 18: "CipherTrust InPlace Data Transformation for Linux" on page 209](#).

CTE-Efficient Storage Enhanced Storage Arrays

CTE shares the encryption key associated with the LUN with a storage system that exports the LUN to a protected host. In this solution, the LUN is a device configured for CTE-Efficient Storage that can be guarded as an ES GuardPoint. When the device is guarded, the storage system and protected hosts coordinate operations for sharing the encryption key applied to the ES GuardPoint.

By sharing the key, the storage system decrypts the encrypted data streams that the protected host writes to the LUN, and then performs the data reduction process on the clear data before encrypting and storing the final encrypted data in the storage array system. The storage system does the reverse operations when the protected host reads data from Efficient Storage devices.

Storage Arrays Compatible with CTE-Efficient Storage

Currently, FlashArray from Pure Storage is the only storage system compatible with CTE-Efficient Storage ES GuardPoints.

FlashArray from Pure Storage is enhanced with CTE-Efficient Storage capabilities and inter-operates with CTE to provide CTE-Efficient Storage on Linux. The Pure Storage system is a client of the Vormetric Data Security Manager (DSM) and shares the encryption keys protecting the LUNs exported from the storage system to the protected hosts registered with the same DSM.

Note

See the EncryptReduce Installation Guide from Pure Storage for information on setting up interoperability with CTE.

Sharing Encryption Keys

CTE shares the encryption key for a LUN with the storage system using the KMIP protocol. In this solution, the DSM is the KMIP server, and the storage system is a KMIP client registered with the DSM. Any host accessing and protecting the LUNs from the storage system is a CTE managed host registered with the same DSM. The protected hosts register with the DSM using the `register_host` script executed on the protected hosts.

With the host and the storage system registered with the same DSM, the protected host continues enforcing policy and security rules on device and directory GuardPoints. The protected host stores an Efficient Storage Device Header, (ES Header) on each LUN configured as ES GuardPoint. The ES Header includes the UUID of the encryption key applied to the LUN and identifies the LUN as an ES GuardPoint to the storage array exporting the LUN. The storage array recognizes the ES Header on the LUN when the protected host writes the header, and then uses the UUID of the key from the header to retrieve the key attributes and material from the DSM (KMIP Server). This process enables the storage array and the protected host to share and apply the same key for encryption and decryption of data streams exchanged between them.

Note

The hosts accessing a shared LUN must be protected hosts registered with the same DSM as the storage array.

When the LUN is permanently de-configured as an ES GuardPoint, the ES Header must be removed. The storage array also detects the removal of the ES Header from the LUN and de-configures the LUN as an CTE-Efficient Storage device. Both the protected host and the storage array stop encryption and decryption of data streams exchanged between hosts and the storage array.

Storage Array Registration

The storage array administrator creates a certificate for the storage array and communicates the certificate to the DSM Administrator. The DSM Administrator produces a corresponding certificate specific to the array which is given to the storage array administrator. The DSM and the storage array system register both certificates and uses them each time they establish a secured session.

Note

See the EncryptReduce Installation Guide from Pure Storage for detailed instructions on registering the FlashArray as KMIP client with the with the DSM's KMIP server.

Efficient Storage Device Header and CTE Private Region

The key sharing aspect of an ES GuardPoint requires a small amount of disk space in the storage device reserved for CTE private use. The reserved space is where CTE shares information with the storage array that is exporting the device to the protected host. The reserved space starts the beginning of the device.

The protected host writes the ES Header to the device when the device is guarded for the first time. The storage array recognizes the header written to the LUN and begins the key sharing process and encrypting/decrypting data streams transferred between the protected host and the storage array on the LUN.

CTE allocates a small amount of storage space on each device configured as CTE-Efficient Storage. This region is reserved for exclusive use by CTE and is referred to as the CTE Private Region. The CTE Private Region is 63 megabytes.

CTE stores the ES Header and other metadata information to allow CTE and the storage array to exchange information. The ES Header occupies the first sector on the device. The method that CTE uses to claim the CTE Private Region on a device depends on whether the device is new (holds no data) or has existing data that you want to preserve. CTE writes the ES Header when guarding the device for the first time. The storage array recognizes the header written to the device and begins the key sharing process for exchange of encrypted data streams between the protected host and the storage array on the device.

Device Size

After you create the ES GuardPoint on the device, the device size reported to applications is the size of the device minus the space reserved for the CTE Private Region. This can lead to a discrepancy between the disk size reported by some applications versus the size reported by system utilities such as `fdisk`.

WARNING

Do not shrink ES GuardPoints. Due to relocation of user data from CTE Private Region, if you shrink the device, you may corrupt data on the device.

The ES Header contains both the available device size and the size of the CTE Private Region. To view the ES Header, use the `voradmin esg status <device-name>` command. The **Exported Disk Size** field shows the disk size available for use by other applications. The **Private Region Size** field shows the disk size reserved for CTE. For example:

```
# voradmin esg status /dev/sdh
ESG Header on /dev/secvm/dev/sdh
    Version: 1
    Change: 0
    Notifications: None
    Storage Status: None
    Private Region Size: 129024 sectors
    Exported Device Size: 20842496 sectors
    Key UUID: 2c3ee4af-010c-3593-898e-f2f62d29222d
    Mount Path: None
```

The `voradmin esg status` command also reports the UUID of the XTS-AES 256 key applied to the device. The reported UUID matches the UUID of the key as shown on the DSM key property and KMIP key object.

DSM Domain Enabled for KMIP

The KMIP protocol is the interface between the DSM and the storage arrays registered with the DSM. The Domain in the DSM for serving security requirements of storage arrays and protected hosts must be KMIP enabled. For deployment of CTE-Efficient Storage, you must create a new domain with the **Enable KMIP** option checked or modify an existing domain so that the **Enable KMIP** box is checked. This allows the DSM to make the keys for guarding CTE-Efficient Storage devices within the domain available to KMIP clients (storage arrays). Existing keys in a domain before checking **KMIP Enable** checkbox will not be accessible through KMIP.

A DSM domain can serve any number of FlashArrays as a KMIP client, but a FlashArray registered with a DSM domain *cannot* register with other domains in the DSM or with another DSM. This restriction forces the FlashArrays registered with a DSM domain to serve LUNs *only* to the CTE hosts registered with that specific DSM domain in that specific DSM.

Note

See the EncryptReduce Installation Guide from Pure Storage for detailed instructions on registering the FlashArray as KMIP client with the DSM's KMIP server.

ES GuardPoint Encryption Keys

ES GuardPoints must be encrypted using XTS-AES 256 keys. An XTS-AES 256 type key is a 512-bit key composed of two components:

- The first 256 bits of the key is the AES 256 encryption key component
- The second 256 bits is the tweak component

You create XTS keys on the DSM using the “Add Key” function, similar to non-XTS keys.

Note

You *must* check the **KMIP Accessible** check box on the “Add Agent Key” page to make the key available to KMIP clients through KMIP. If you do not check the **KMIP Accessible** option, storage arrays cannot get keys for CTE-Efficient Storage devices from the DSM (KMIP server) for sharing those keys with protected hosts.

The DSM also generates a UUID for a newly added key. The DSM provides the key and its attributes to the protected hosts for guarding the CTE-Efficient Storage device. The protected host for the device writes the ES Header to the device, including the UUID of the key, before the initial attempt to enable an ES GuardPoint. The storage array recognizes the ES Header written to the device, retrieves the UUID from the ES Header, and retrieves information and attributes of the AES 256 component of the XTS-AES 256 key from the DSM using KMIP.

Key Attributes - Example

The following figure illustrates the parameters you should specify to add a new XTS-AES 256 key named ESG_DEMO_KEY_1. Note the key algorithm and encryption mode specified for the key and the checked “KMIP Accessible” option.

The following figure illustrates the general properties of ESG_DEMO_KEY_1 after adding the key. Note the UUID of the key.

The following figure illustrates the attributes of ESG_DEMO_KEY_1 after adding the key. Note that this tab displays both the UUID of the key and the UUID of the tweak component.

The attribute “x-deactivation-date” represents the date on which ESG_DEMO_KEY_1 expires. When the expiration date is reached, the key is no longer valid. It is important to choose an expiration date that exceeds any data retention period imposed on the data stored in the protected LUNs where the key is used. Note that any snapshot of a protected LUN inherits the same key protecting the primary LUN, therefore, if the key expires before reaching the end of retention period, the LUN and its snapshots will not be accessible. More importantly, do not delete the key before the data retention period expires on the LUN. The data on the LUN and its snapshots cannot be decrypted if the key is deleted prior to the data retention period.

KMIP Key Object

The following figure shows the attribute of the KMIP object for the specified UUID. The UUID specified in the example is the UUID of ESG_DEMO_KEY_1.

The following figure shows the KMIP attributes of the KMIP objects associated with ESG_DEMO_KEY_1.

The following figure shows the KMIP attributes of the KMIP object associated with the tweak component of ESG_DEMO_KEY_1.

Policy Requirements for ES GuardPoints

Initializing an ES GuardPoint requires a Standard or In-place Data Transformation - Device policy with a KMIP-accessible XTS-AES 256 key as described in ["Initialize Linux Efficient Storage Devices" on page 182](#).

Rekeying an ES GuardPoint requires an In-place Data Transformation - Device policy with a KMIP-accessible XTS-AES 256 key as described in ["Changing the Encryption Key on Linux ESG Devices" on page 192](#).

You may add security rules to restrict certain user/process access to protected devices. For suggestions about what security rules you may want to use, see ["Use Cases Involving Efficient Storage GuardPoints" on page 196](#).

The following figure shows an example of a simple Standard policy that uses ESG_DEMO_KEY_1 key to guard devices.

Guarding an Efficient Storage Device on Linux

The following sections discuss how to guard an efficient storage device on Linux. If you want to guard an efficient storage Windows device, see the *CTE Agent for Windows Advanced Configuration and Integration Guide*.

In order to guard a Linux efficient storage device, you need to:

1. Make sure the devices you intend to guard meet the requirements for ES GuardPoints. For details, see ["Requirements for Efficient Storage GuardPoints on Linux" below](#).
2. Register the protected host with the DSM with CTE-Efficient Storage enabled. For details, see ["Register the Host with DSM" on the next page](#).
3. Initialize the storage device to create a CTE Private Region for the Efficient Storage Device Header. For details, see ["Initialize Linux Efficient Storage Devices" on page 182](#).
4. Log on to the DSM to apply the ES GuardPoint to the storage device. For details, see ["Guard the Linux Device with an ES GuardPoint" on page 184](#).

Requirements for Efficient Storage GuardPoints on Linux

A LUN must meet the following requirements before it can be protected as an ES GuardPoint:

- The LUN is exported from a storage array must be enhanced with the CTE-Efficient Storage capability.
- The storage array exporting the LUN to the protected host must be a KMIP client registered with the same DSM as the protected host.
- The protected host must have direct physical access to the LUN through Fiber Channel Protocol (FCP) or iSCSI.
- The entire LUN must be protected as one and only one ES GuardPoint.
- In an ESXi environment:
 - The LUN added to a virtual machine must be configured for Raw Device Mapping in physical mode or the LUN must be part of a VVol datastore.
 - The LUN *cannot* be a VMDK or a disk in a datastore.
- Devices protected by an ES GuardPoint cannot currently be initialized/added as physical volumes for use by LVM. When LVM support is added, it will be announced in the CTE Release Notes.

- Existing devices divided into one or more logical partitions cannot be guarded as ES GuardPoints. Logical partitions in such devices cannot be accessed or separately guarded after guarding the device.

For example, the logical partition `/dev/sda1` or `/dev/sda2` inside `/dev/sda` cannot be accessed after guarding `/dev/sda` as an ES GuardPoint. Using `/dev/secvm/dev/sda1` is invalid as `/dev/secvm/dev/sda1` is not a GuardPoint and cannot be guarded, and, as such, would not provide access to clear-text data on `/dev/sda1`.

Note: If you want to use VVol datastores with CTE-Efficient Storage devices, see the available documentation from the Storage Array system vendor.

Register the Host with DSM

If the host is already registered with a DSM, you can initialize the devices you want to protect as ES GuardPoints as described in ["Initialize Linux Efficient Storage Devices" on the facing page](#) as long as:

- The host is part of a domain that has KMIP enabled.
- A license for the Efficient Storage feature has been uploaded to the DSM.

To verify this, have the DSM Administrator check the host settings in the DSM.

If the host is not already registered with a DSM, you need to register it before you can protect the devices on that host. When you register the host with the DSM, you must have AES-NI available on the host, a current license for registering host, and a current license for CTE-Efficient Storage.

- If you are planning to use the fingerprint registration method, make sure the DSM Security Administrator has added the host to the appropriate KMIP-enabled domain.
- If necessary, install CTE on the host. Follow the installation prompts as until you get to the registration portion of the installation. If CTE is already installed, you can start the registration process by running `/opt/vormetric/DataSecurityExpert/agent/vmd/bin/register_host`.
- Follow the prompts to register the host with the DSM. During the registration process, make sure that you enable Efficient Storage support when prompted.

```
Enter a number, or type a different host name or IP address in manually:
What is the name of this machine? [1]:
You selected "vmfsodtl.i.vormetric.com".
```

```
Would you like to register to the Security Server using
a registration shared secret (S) or using fingerprints (F)? (S/F) [S]: F
```

```
It is possible to associate this installation with the hardware of this
machine. If selected, the agent will not contact the DSM or use any
cryptographic keys if any of this machine's hardware is changed. This
can be rectified by running this registration program again.
Do you want to enable this functionality? (Y/N) [Y]: n
```

```
Do you want this host to have docker support enabled on the server? (Y/N) [N]:
```

```
Do you want this host to have LDT support enabled on the server? (Y/N) [N]: y
```

```
Do you want this host to have Efficient Storage support enabled on the server? (Y/N) [N]: y
```

```
Generating certificate signing request for the kernel component...done.
Signing certificate...done.
Generating EC certificate signing request for the vmd...done.
Signing certificate...done.
Generating EC certificate signing request for the vmd...done.
Signing certificate...done.
```

- Complete the registration process as normal.

5. To verify that the host is properly registered with the CTE-Efficient Storage option enabled, have the DSM Administrator verify that **Efficient Storage** is checked for the host as shown below.

6. After the host is registered with the DSM, initialize each device that you want to guard as described in the next section.

Initialize Linux Efficient Storage Devices

When you initialize a Linux efficient storage device, the process creates a private region on the device for CTE to write the Efficient Storage header along with metadata that identifies the ES device as a guarded device. The CTE private region also contains the metadata for the initial transformation of clear-text data on device to cipher-text, and for the subsequent transformation of cipher-text on the device to another encryption key as needed.

How you initialize the device depends on whether it is a new device or an existing device that already has data that needs to be transformed into cipher-text. For details, see:

- ["Initialize a New Linux Device" below](#)
- ["Initialize and Resize an Existing Linux Device" on the next page](#)

Initialize a New Linux Device

Run the `voradmin esg config new` command to initialize a new device. The `new` option specifies that the device does not hold user data, and that CTE can reserve the first 63MB of storage on the device for the CTE private region. The remaining storage space is available for new user data. The device size reported to applications is the actual device size minus CTE private region size.

For a shared device that is accessed from multiple protected hosts, you must initialize the device only once and on only one protected host.

Note

To configure devices with multiple IO paths for Linux, see ["Guarding a CTE-Efficient Storage Device with Multiple IO Paths on Linux" on page 189](#).

1. Log into the device as root.
2. Run the `voradmin esg config new [-c <n>] <device-name>` command, where:
 - `new` (required) indicates that the device contains no data (it is a new disk). CTE will create the CTE private region at the beginning of the disk and the rest of the disk will be available for user data.
 - `-c <n>` (optional). If you use this option on Linux, CTE sets the number of data transformation jobs to run in parallel to the number specified in `<n>`. `<n>` can be an integer between 1 and 60 (default: 8).

Each data transformation job transforms 1MB worth of data and requires CPU resources in addition to three I/O operations as part of data transformation. Each job reads 1MB of data from the device, preserves the data in the CTE private region, rekeys the data to cipher-text, and writes the transformed data to the device. If you increase the number of parallel jobs, the data transformation process will complete faster but there will be an increased performance impact on the system. Only increase the `-c` option if you are certain that the system resources are available to handle the additional load.

The value for the `-c` option you specify here remains in effect for all subsequent data transformations (such as any data rekeys) until you specify a new value.
 - `<device-name>` (required). Specifies the device name. For example, `/dev/sdh`.

For example, if you want to initialize a new Linux disk named `/dev/sdh` using 10 parallel data transformation jobs, you would specify:

```
# voradmin esg config new -c 10 /dev/sdh
```

 3. To verify that the disk has been initialized, run the `voradmin esg status` command.

```
# voradmin esg status /dev/sdh
```

Device /dev/sdh is configured to guard as an Efficient Storage GuardPoint.
 4. At this point the DSM Administrator can protect the device as an ES GuardPoint through the DSM Management Console. For details, see ["Guard the Linux Device with an ES GuardPoint" on the facing page](#).

Note

The initialization process prepares the device to be guarded but does not actually guard it. You need to assign an ES GuardPoint to the device in the DSM before the device is actually protected. In addition, the initialization process is only kept in memory until the device is guarded or rebooted. If the device is rebooted before you guard it, you will need to perform the initialization procedure again.

Initialize and Resize an Existing Linux Device

If the device has existing data, you need to use the `voradmin esg config xform` command to initialize the disk for CTE-Efficient Storage. This command examines the current disk size and computes the size required to hold the existing data plus the CTE Private Region at the beginning of the device. After the CTE initialization is complete, you then need to resize the device before you can guard it with an ES GuardPoint.

The following procedure describes how to initialize the device for CTE. Note that the existing data is not altered in any way until after you perform this procedure and you guard the data with an ES GuardPoint. CTE does *not* begin transforming the data from clear-text to cipher-text until the ES GuardPoint has been applied and the encryption key has been pushed to the device through the GuardPoint Policy.

1. Log into the device as root.
2. Run the `voradmin esg config xform [-c <n>] <device-name>` command, where:
 - `xform` (required) indicates that the device contains existing data. CTE will transform all existing data on the device from clear-text to cipher-text as soon as you guard the device. The device will be inaccessible until the transformation is complete, and the device must remain offline during the entire transformation process. No user access will be permitted until all data has been transformed.

- `-c <n>` (optional). If you use this option on Linux, CTE sets the number of data transformation jobs to run in parallel to the number specified in `<n>`. `<n>` can be an integer between 1 and 60 (default: 8).

Each data transformation job transforms 1MB worth of data and requires CPU resources in addition to three I/O operations as part of data transformation. Each job reads 1MB of data from the device, preserves the data in the CTE private region, rekeys the data to cipher-text, and writes the transformed data to the device. If you increase the number of parallel jobs, the data transformation process will complete faster but there will be an increased performance impact on the system. Only increase the `-c` option if you are certain that the system resources are available to handle the additional load.

The value for the `-c` option you specify here remains in effect for all subsequent data transformations (such as any data rekeys) until you specify a new value.

- `<device-name>` (required). Specifies the device name. For example, `/dev/sdh`.

For example, if you want to initialize an existing Linux disk named `/dev/sdh` using 10 parallel data transformation jobs, you would specify:

```
# voradmin esg config xform -c 10 /dev/sdh
```

Device `/dev/sdh` must be resized to at least 21100544 sectors (20606 MBs) before guarding as Efficient Storage GuardPoint.

In this case you must manually resize the Linux disk by at least 20606 MBs before you can guard it. After you guard the disk, you can expand it again later but you cannot shrink it unless you remove the GuardPoint.

3. To verify that the disk has been initialized, run the `voradmin esg status` command.

```
# voradmin esg status /dev/sdh
```

Device `/dev/sdh` is configured to guard as an Efficient Storage GuardPoint.

4. At this point, you need to resize the device using your standard disk management tools before you can guard it. Make sure you increase the device size by at least the amount shown in the `voradmin esg config xform` message.

You cannot assign an ES GuardPoint to the device until it has been resized. If you do not resize the device, the GuardPoint assignment will fail.

5. After the device has been resized, the DSM Administrator can protect the device as an ES GuardPoint through the DSM Management Console as described in ["Guard the Linux Device with an ES GuardPoint" below](#).

Note

The initialization process prepares the device to be guarded but does not actually guard it. You need to assign an ES GuardPoint to the device in the DSM before the device is actually protected. In addition, the initialization process is only kept in memory until the device is guarded or rebooted. If the device is rebooted before you guard it, you will need to perform the initialization procedure again.

Guard the Linux Device with an ES GuardPoint

Note

For details about how to create a GuardPoint, see the chapter, "Managing GuardPoints", in the *DSM Administration Guide*.

After the device has been initialized, you can guard the device as an ES GuardPoint from the DSM Management Console. For existing devices, as soon as the GuardPoint configuration has been pushed to the host and the status changes to guarded, CTE begins transforming the data on the disk using the encryption key associated with the GuardPoint Policy.

1. Log on to the DSM Management Console as an administrator of type Security with Host role permissions, type Domain and Security, or type All.
2. Make sure that you know what Policy you want to associate with the ES GuardPoint or create a new standard policy if needed. The policy you use for CTE-Efficient Storage must use an XTS-AES 256 key as the key rule. For details, see ["ES GuardPoint Encryption Keys" on page 177](#).
3. Select **Hosts > Hosts** on the menu bar. The *Hosts* window opens.
4. Click the target host in the **Host Name** column. The Edit Host window opens to the General tab for the selected host.
5. Click the **GuardPoints** tab and then click **Guard**. The Guard window opens.
6. In the **Policy** field, select the Policy you identified or created earlier in this procedure. CTE will use the XTS-AES 256 key associated with this policy to encrypt the data on the device.
7. In the **Type** field, select either **Raw or Block Device (Auto Guard)** or **Raw or Block Device (Manual Guard)**.
If you select **Auto Guard**, CTE starts the guard process as soon as the policy is pushed to the host. You enable, disable, guard, and unguard the GuardPoint in the DSM. If you want to have the device automatically guarded and mounted at system start up, add the device to `/etc/fstab`. For details, see ["Auto Mount Options for File System Devices on Linux" on page 190](#).
If you select **Manual Guard**, You guard the GuardPoint on the protected host with the `secfsd -guard <path>` and `secfsd -unguard <path>` commands. At system startup, you must guard the device and then mount it. This gives you more control over when data transformations occur because CTE will not start encrypting or rekeying the device until you manually start the process.
8. In the **Path** field, add the path for the device you want to guard. For example, `/dev/sdh`.
If you specify multiple paths in this field, all specified devices will be guarded and all will be encrypted with the encryption key specified in the associated policy.
9. Make sure the **Efficient Storage** check box is checked. If this option is not selected, the host will *not* enable the device as an ES GuardPoint.

10. Click **OK**.

The DSM pushes the policy and the GuardPoint configuration to the host and the CTE agent on the host writes the ES Header into the CTE private region for the specified devices. If this is a new device, the status changes to guarded and the disk is available for user access immediately.

If there is existing data on the device, CTE begins transforming the data from clear-text to cipher-text as soon as the GuardPoint configuration is available and the device status changes to guarded. The device will remain inaccessible until this data transformation completes. The length of time required to transform the data depends on the amount of existing data and the number of parallel data transformation jobs specified on the `voradmin config` command. For details, see ["Data Relocation on Existing Linux Devices" below](#) and ["Data Transformation on Existing Linux Devices" below](#).

To see the data transformation progress, use the `voradmin esg xform status <device-name>` command, as described in ["Viewing Device Status and the ES Header on Linux" on page 189](#).

After the device is initialized and guarded, the protected device must be accessed through the CTE device pathname. This pathname corresponds to the `secvm` device. For example, the Linux device pathname `/dev/sdh` becomes `/dev/secvm/dev/sdh` as soon as the process is complete.

Notes

- Be sure to use the `secvm` device name when using file system management tools such as `mkfs` and `fsck`.
- Do not use the device mapper names corresponding to ES GuardPoints for GuardPoint administration on protected hosts.

Data Relocation on Existing Linux Devices

When you add an ES GuardPoint to a device that has been initialized with the `xform` option, CTE first relocates existing data in the region of the device designated as CTE Private Region. The data is relocated to the end of the LUN, into the new space allocated. The relocation occurs once when the device is guarded for the first time.

Relocation of data is transparent to applications accessing data through the ES GuardPoint. CTE will map application I/O requests over the CTE Private Region to the relocated region. After guarding the device, you can grow the device size further if necessary. However, you cannot shrink the device size.

Data Transformation on Existing Linux Devices

As the ES Header is written before data transformation begins, the data transformed to cipher-text and written back to the device during data transformation process is subject to data reduction process through the storage array.

Existing devices populated with data are transformed from clear-text to cipher-text using the encryption key applied to each device. Data transformation is also called CipherTrust InPlace Data Transformation (CTE-IDT).

CTE-IDT is not the same as the legacy offline data transformation. CTE-IDT is a block level data transformation with built-in resiliency to recover from system crashes during the data transformation process. CTE-IDT uses the CTE Private Region on the device to manage the entire transformation process. CTE-IDT partitions the data on a device in segments of 1MB in size and transforms one or multiple segments, up to 60 segments, in parallel. The CTE-IDT process preserves existing data in a segment during transformation in the private region of the device, and then transforms the data in-place. CTE-IDT also maintains the segments undergoing transformation in the private region. In the event of system crash, CTE-IDT will recover the segments undergoing transformation at the time of crash and then resume the transformation process.

You can specify the number of segments to transform concurrently using `-c` option of the `voradmin` command when initializing the device. Choose a concurrency level that does not affect performance of your production workload. By default, CTE-IDT transforms 8 segments concurrently, if the concurrency level has not been specified through the `voradmin` command.

Note

When choosing the concurrency level for your system you must consider the number of CPU cores, the total IOPS of your storage system and production workload, the size of the device to transform, and the duration for the data transformation.

Another advantage of CTE-IDT over legacy offline data transformation is that CTE-IDT does not require a separate policy for data transformation. With the same production policy applied to the device, CTE-IDT determines whether the device is in need of data transformation, per specification of `xform` option when device was initialized, and starts the CTE-IDT process when transformation is required. During the CTE-IDT process, access to the device is blocked until the CTE-IDT process completes.

```
# voradmin esg status xform /dev/sdb
Status: In-Progress
Relocation time 2155544 (relocated = 1)
SegSp: 27, Xformation Range: 3217 ... 4799, SegID: 4795 4796 4781 4782 4787 4795 4799

```

Thin-Provisioned Devices

CTE-IDT skips transforming thin-provisioned regions of a device. Data returned to CTE-IDT as sequence of clear-text zeros, in sector size granularity, is indication of possible sparse or un-allocated regions of the device that do not have to be transformed.

CTE-IDT Recovery From Crash

CTE-IDT is fault tolerant in the event of system crashes. CTE-IDT keeps track of the transformation process over the entire device. In the event of a crash, CTE-IDT will automatically resume transformation from the point of failure as soon the GuardPoint is enabled after system startup.

If you find the transformation status set to **In-Progress** when the GuardPoint is not enabled, the **In-Progress** state reflects an earlier system crash after which the GuardPoint has not been enabled to recover from the interruption in the CTE-IDT process.

Example of Creating an ES GuardPoint on an Existing Linux Device

The following figure shows an example of initializing an existing Linux device using `voradmin esg config xform` and guarding it as an ES GuardPoint from the viewpoint of the Linux root user.

```
# voradmin esg status /dev/sdh
Native device /dev/sdh is not labeled as ESG

# fdisk -l /dev/sdh

Disk /dev/sdh: 21.2 GB, 21169700864 bytes, 41347072 sectors
Units = sectors of 1 * 512 = 512 bytes
Sector size (logical/physical): 512 bytes / 512 bytes
I/O size (minimum/optimal): 512 bytes / 4194304 bytes

# mkfs.xfs /dev/sdh
meta-data=/dev/sdh          isize=512    agcount=4, agsize=1288064 blks
                         =   sectsz=512   atime=1, noctime=1
                         =   dir=1        info=0*0, sparse=0
data      =   bsize=4096   blocks=6132256, leap=0-33
                         =   sunit=0      swidth=0 blks
naming     =version 2      bsize=4096   ascii-ci=0 ftype=1
log        =internal log   bsize=4096   blocks=1360, version=2
                         =   sectsz=511   sunit=0 blks, lazy-count=1
realtime   =none          extsz=4096   blocks=0, rtextents=0

# mount -t xfs /dev/sdh /xfs
# cd /bin/* /xfs
# umount /xfs
# voradmin esg config xfs /dev/sdh
Device /dev/sdh must be resized to at least 41347072 sectors (40376 MBs) before guarding as Efficient Storage GuardPoint
```

Now you must resize the device on the storage array to the specified size or larger, and then guard the device on the DSM as ES GuardPoint using Manual Guard. For details about guarding the device on the DSM, see ["Guard the Linux Device with an ES GuardPoint" on page 184](#).

After resizing the device and configuring the GuardPoint in the DSM:

```
# fdisk -l /dev/sdh

Disk /dev/sdh: 21.2 GB, 21169700864 bytes, 41347072 sectors
Units = sectors of 1 * 512 = 512 bytes
Sector size (logical/physical): 512 bytes / 512 bytes
I/O size (minimum/optimal): 512 bytes / 4194304 bytes

# secfsd -guard /dev/sdh
secfsd: Path is guarded
```

At this point CTE begins data relocation and transformation. Data transformation will require some amount of time to complete. You can monitor the transformation process with the `voradmin esg status xform <device-name>` command.

```
# voradmin esg status xform /dev/sdh
Status: In-Progress
Relocation done 11111111 (Relocated = 1)
SegSpr 27, Xformation Range: 128 ... 139, SegID: 139
KeyID: 988905 Key Name: ESG DEMO KEY_1
Old KeyID: 0 Old Key Name: clear_key

Wait for data transformation to complete:

# voradmin esg status xform /dev/sdh
Status: Complete
Relocation done 11111111 (Relocated = 1)
SegSpr 27, Xformation Range: 1281 ... 13189, SegID: none
KeyID: 988905 Key Name: ESG DEMO KEY_1
Old KeyID: 0 Old Key Name: clear_key

# voradmin esg status /dev/sdh
ESG Header on /dev/secure/dev/sdh
Version: 1
Change: 0
Notification: None
Storage Status: None
Private Region Size: 128016 sectors
Exported Device Size: 41315048 sectors
Key UUID: 2c3e6af-010c-3595-359e-e2661d19121d
Mount Path: None

# mount -t xfs /dev/secure/dev/sdh /xfs
# for file in $(ls /xfs); do cmp /bin/$file /xfs/$file done
# umount /xfs
```

Guarding a CTE-Efficient Storage Device with Multiple IO Paths on Linux

Each individual IO path from a server node to a storage controller is treated as a separate device on the host. DM-Multipath on a Linux host provides a management framework to group the individual IO paths to the same LUN into a single multipath device. If you use DM-Multipath to manage devices on the protected host, the individual devices that correspond to each IO path to the LUN cannot be configured for guarding as ES GuardPoints, as those devices are under control of DM-Multipath. To guard such devices, you must guard the device mapper generated by DM-Multipath (multipathd) under the `/dev/mapper` directory.

Note

CTE-Efficient Storage is the only feature of CTE that exclusively supports guarding of device mapper generated devices under DM-Multipath framework.

The following example illustrates the procedure for guarding a device mapper generated device with the alias name `/dev/mapper/mpathA`.

1. Create a standard policy using an XTS key as the key rule.
2. On the host, prepare the device to be configured as ESG using the `voradmin` command with `new` or `xform` option. For example:

```
# voradmin esg config new /dev/mapper/mpathA
```
3. On the DSM, guard `/dev/mapper/mpathA` as Device GuardPoint using the policy created above. Be sure to check the **Efficient Storage** check box.
4. For Manual-Guard configuration, enable the GuardPoint using the `secfsd` command as follows:

```
# secfsd -guard /dev/mapper/mpathA
```
5. For Auto-Guard, wait for the `/dev/mapper/mpathA` device to be guarded on the protected host.
6. Once the device is guarded, provide the pathname of the `secvm` device to applications and/or file system operations. For example, `/dev/secvm/dev/mapper/mpathA`.

Linux System and ES GuardPoint Administration

voradmin ESG Commands on Linux

The `voradmin` command is a command line utility for management of CTE specific configuration and status reporting. The `voradmin` command also supports configuration management related to ES GuardPoints (ESG).

For details about the Linux `voradmin esg` command options, see the man page for the `voradmin` command.

Viewing Device Status and the ES Header on Linux

After you guard a device, you can view the status of that device using the `voradmin esg [xform] status <device-name>` command, where:

- `xform` (optional). If you specify this option, CTE shows the status of any data transformation processes happening on the device. If you do not specify this option, CTE displays the ES Header for the device.
- `<device-name>` (required). The standard Linux name of the device whose status you want to view. (For example, `/dev/sdh`.)

For example, if you want to view the ES Header for the Linux device `/dev/sdh`, you would enter:

```
# voradmin esg status /dev/sdh
ESG Header on /dev/secvm/dev/sdh
  Version:          1
  Change:           0
  Notifications:    None
  Storage Status:   None
  Private Region Size: 129024 sectors
  Exported Device Size: 20842496 sectors
  Key UUID:         2c3ee4af-010c-3593-898e-f2f62d29222d
  Mount Path:       None
```

If you want to view the data transformation status on `/dev/sdh`, you would enter:

```
# voradmin esg xform status /dev/sdh
  Status:           In-Progress
  Relocation Zone 22939646 (relocated = 1)
  SegSpc 27, Xformation Range: 3217 ... 4799, SegIDs: 4795 4796 4791 4792...
  KeyID:            988905 Key Name: ESG_DEMO_KEY_1
  Old KeyID:        0      Key Name: clear_key
```

The **Status** field displays **In-Progress** if a data transformation process is running, and **Completed** if the process has finished.

File System Mount Points on Linux

You can create and mount a file system on an ES GuardPoint. CTE imposes one restriction on the mount point pathname selected for a device. Once you mount the device on a pathname, you cannot change the mount point to a different pathname. This restriction is enforced to allow the file system mount point to be guarded using a separate policy to enforce access control rules on the mounted file system namespace. For a use case involving a directory GuardPoint guarded over a mounted ES GuardPoint, see ["Use Case 3: Directory-Level GuardPoints" on page 197](#).

The following example shows the mount point of the ES GuardPoint as the `/xfs` directory. The example also shows a failed attempt to mount the file system on a different directory pathname.

```
# voradmin esg status /dev/sdh
ESG Header on /dev/secvm/dev/sdh
  Version:          1
  Change:           0
  Notifications:    None
  Storage Status:   None
  Private Region Size: 129024 sectors
  Exported Device Size: 41218048 sectors
  Key UUID:         b1c045bd-d81e-3e22-b822-5033dd22dd00
  Mount Path:       /xfs
# mount /xfs
# mount /other-xfs
# mount -t xfs /dev/secvm/dev/sdh /other-xfs
mount: permission denied
# mount -t xfs /dev/secvm/dev/sdh /xfs
```

Auto Mount Options for File System Devices on Linux

ES GuardPoints containing file systems can also be added to the `/etc/fstab` configuration file for auto mount at startup or unmount at shutdown. An entry can be for an ES GuardPoint configured for Auto Guard or Manual Guard. For more information about Auto and Manual Guard options, see ["Guard the Linux Device with an ES GuardPoint" on page 184](#).

Use the device path corresponding to an ES GuardPoint device when specifying `fstab` entries, such as `/dev/secvm/dev/sdh`. Do not use the native device pathnames, such as `/dev/sdh`, or device mapper device names. You must also include several settings in the `fstab` entry for each ES GuardPoint, as shown in the following table:

Option	Description
<code>x-systemd.requires=secvm-barrier.service</code>	Ensure that the ES GuardPoint is enabled before the device is mounted at startup and disabled after the device is unmounted at shutdown. The <code>secvm-barrier.service</code> service is a proxy for all the services that make up CTE.
<code>nofail</code>	The system boot will proceed without waiting for the ES GuardPoint device if it can't be mounted successfully.
<code>x-systemd.wanted-by=<es device>.device</code>	Required for Linux distributions running <code>systemd</code> 242 or later. Instructs <code>systemd</code> to add a <code>Wants=</code> dependency on the ES device to ensure that, when the device becomes available, this mount operation is executed. <code><es device>.device</code> is the name of the device specified in <code>fstab</code> with the <code>'/'</code> replaced with <code>'.'</code> . For example, <code>/dev/secvm/dev/sdb</code> becomes <code>dev-secvm-dev-sdb.device</code> .

This is an example of an entry in `/etc/fstab` for an ES GuardPoint with an `xfs` file system that is mounted on `/xfs`:

```
/dev/secvm/dev/sdh /xfs xfs x-systemd.requires=secvm-barrier.service, \
x-systemd.wanted-by=dev-secvm-dev-sdh.device,nofail 0 0
```

For information about configuring `systemd` for CTE, see [Chapter 6: "CTE and systemd" on page 76](#).

Linux System Utilities for Signing

The following table includes recommendations on the system and file system specific utilities for inclusion in the signature set to allow or deny root execution.

EXT Utilities	Deny/Allow	XFS	Deny/Allow	Generic Utilities	Deny/Allow
<code>badblock</code>	Allow	<code>fsck.xfs</code>	Allow	<code>mount</code>	Allow
<code>debugfs</code>	Deny	<code>mkfs.xfs</code>	Allow	<code>umount</code>	Allow
<code>e2freefrag</code>	Allow	<code>xfs_repair</code>	Allow	<code>dmsetup</code>	Allow
<code>e2fsck</code>	Allow	<code>xfs_admin</code>	Allow		
<code>e2image</code>	Allow	<code>xfs_bmap</code>	Allow		
<code>e2label</code>	Allow	<code>xfs_check</code>	Allow		
<code>e2undo</code>	Allow	<code>xfs_copy</code>	Deny		
<code>filefrag</code>	Allow	<code>xfs_db</code>	Deny		
<code>fsck.ext2</code>	Allow	<code>xfs_estimate</code>	Allow		
<code>fsck.ext3</code>	Allow	<code>xfs_freeze</code>	Allow		
<code>fsck.ext4</code>	Allow	<code>xfs_fsr</code>	Allow		
<code>logsave</code>	Allow	<code>xfs_growfs</code>	Allow		
<code>mke2fs</code>	Allow	<code>xfs_info</code>	Allow		
<code>mkfs.ext2</code>	Allow	<code>xfs_logprint</code>	Allow		
<code>mkfs.ext3</code>	Allow	<code>xfs_mdrestore</code>	Allow		
<code>mkfs.ext4</code>	Allow	<code>xfs_metadump</code>	Allow		

EXT Utilities	Deny/Allow	XFS	Deny/Allow	Generic Utilities	Deny/Allow
resize2fs	Allow	xfs_mkfile	Deny		
tune2fs	Allow	xfs_ncheck	Allow		

Changing the Encryption Key on Linux ESG Devices

To meet various compliance requirements, you may want to change the key that CTE has used to encrypt ES GuardPoints. Thales refers to this changing of encryption keys as “Key rotation” or “Rekey”. Unlike the CipherTrust Transparent Encryption - Live Data Transformation product offered by Thales for file systems on traditional storage devices, to change the encryption key on an ES GuardPoint, the device must be taken offline. The data on the device will be inaccessible during the key rotation process.

The key rotation process involves the following:

- Creating a new policy for key rotation
- Preparing the CTE-Efficient Storage device for key rotation
- Applying the new policy to the CTE-Efficient Storage device on the DSM

See the following sections for details of key rotation. If your organization has separated security duties, some of the steps below may need to be completed by different people.

Creating a New DSM Policy for Key Rotation

As part of rekeying the data on a CTE-Efficient Storage device, you must create a new policy with a key rule specifying the new key and include a second key rule that specifies the current key. The screenshot below depicts a policy named ESG_DEMO_POLICY_2 for rekey:

Similar to the policy ESG_DEMO_POLICY_1, the above production policy applies the key specified in the first key rule, ESG_DEMO_KEY_2, on the device guarded with the policy. The second key rule is actually ineffective, because the first key rule is always selected for IO operations to devices guarded with ESG_DEMO_POLICY_2, hence never selecting the second key rule for key operations.

The reason for inclusion of the second key rule is the availability of the key specified in the second key rule (ESG_DEMO_KEY_1) to the protected host. Note that the name and the ID of the key applied to the data on ES GuardPoints are persistently recorded in the CTE private region on the device. However, the recording of the key name and ID in the private region may not be sufficient for availability of ESG_DEMO_KEY_1 to the protected host without the second key rule listed in ESG_DEMO_POLICY_2 policy. If another GuardPoint on the protected host guarded with a

policy that specifies ESG_DEMO_KEY_1 as a key rule, the key ESG_DEMO_KEY_1 is available to the protected host, and the policy ESG_DEMO_POLICY_2 does not have to include the second key rule listing ESG_DEMO_KEY_1. Absence of any GuardPoint not guarded with a policy specifying ESG_DEMO_KEY_1 causes the DSM not to push the key ESG_DEMO_KEY_1 to the protected host.

Notice the resource set empty-Ø listed as the resource set in the second key rule. This is an empty resource set that does not associate any object in a guarded GuardPoint with the key specified in the key rule. An empty resource set is specified in the second key rule because a resource set is required for adding the second or additional key rules to the policy.

Prepare an ES GuardPoint for Rekey

Before you apply the new policy, you must shutdown any applications accessing the ES GuardPoint. This also includes unmounting file system if the ES GuardPoint is a device mounted as a file system. The next step is to unguard the guarded device on the protected host and then on the DSM. Unguarding the device on the DSM deletes the ES GuardPoint on the host.

The following screenshot enumerates the administrative steps for rekeying ES GuardPoints. The following figure shows the transformation from ESG_DEMO_POLICY_1 using ESG_DEMO_KEY_1 to the new policy ESG_DEMO_POLICY_2 using ESG_DEMO_KEY_2.

```
# secfed -status guard | grep adh
/dev/adh          ESG_DEMO_POLICY_1      manualrekeydevice guarded   guarded   N/A
# secfed -unguard /dev/adh
secfed: Path is not guarded
# voradmin esg status xform /dev/adh
Status:          Complete
Relocation Zone  22939040 (relocated = 1)
SegSpd 17, Xformation Range: 0000 --- 0000, SegIter none
KeyID:           000000 Key Name:      ESG_DEMO_KEY_1
Old KeyID:       0      Old Key Name: clear_key
```

Notice the key name and the old key name associated with the device as recorded in the device private region.

Next, unguard the device on the DSM and then run the `voradmin` command to prepare the device for rekey. Be sure the device is unguarded on the DSM before running the `voradmin` command, otherwise the `voradmin` command refuses to prepare the device for rekey. Notice that the ES Header is temporarily deleted from the device in preparation for rekey.

```
# secfed -status guard | grep adh
# voradmin esg rekey /dev/adh
Enter Y/N to prepare device /dev/adh for rekey -> YES
# voradmin esg status /dev/adh
Native device /dev/adh is not labeled as ESG
```

Next, guard the device on the DSM as an Efficient Storage device using the policy ESG_DEMO_POLICY_2. After the DSM pushes the configuration on the ES GuardPoint, proceed with guarding the device on the protected host. The guard operation detects the policy/key change on the device and begins the CTE-IDT process to transform data from ESG_DEMO_KEY_1 to ESG_DEMO_KEY_2. During the CTE-IDT process, user access to the ES GuardPoint is blocked until IDT completes the transformation process.

```
# secfed -status guard | grep adh
/dev/adh          ESG_DEMO_POLICY_2      manualrekeydevice unguarded  not guarded Inactive
# secfed -guard /dev/adh
secfed: Path is guarded
# voradmin esg status xform /dev/adh
Status:          In Progress
Relocation Zone  22939040 (relocated = 1)
SegSpd 17, Xformation Range: 0000 --- 0000, SegIter 3317 3318 3319 3320 3321 3322 3323 3324 3325 3326 3327 3328 3329 3330 3331
KeyID:           000000 Key Name:      ESG_DEMO_KEY_2
Old KeyID:       000000 Old Key Name: ESG_DEMO_KEY_1
```

After CTE-IDT completion you can restart application workloads on the guarded device.

```
# voradbin esg status xform /dev/ada
Status:      Complete
Relocation Done 22939408 (relocated = 1)
SeqNo 27, Information Range: 20159 .. 20159, SeqIDat none
VerID1:      988888 Key Name:   ES0_DSMO_KEY_1
Old KeyID:    688601 Old Key Name: ES0_DSMO_KEY_1
# mount -t xfs /dev/secure/dev/ada /xfs
```

Resizing Guarded Efficient Storage Devices

Devices configured for Efficient Storage can be resized using the system-provided resizing utilities. If you are using a file system on the GuardPoint, you can mount the file system after resizing the device and then grow the file system to the new size using the appropriate utility such as `xfs_growfs` or `resize2fs`.

WARNING

Do not shrink ES GuardPoints. Due to relocation of user data from CTE private region, if you shrink the device, you may corrupt data on the device.

1. Stop applications from accessing the GuardPoint.
 - Unmount the file system if the device is mounted.
 - Disable GuardPoints: auto-guard if is enabled on the DSM, or manual-guard if is enabled on the protected host.
2. Use the native disk management tools to resize the device.
3. After resizing the device, check the size of the device. For Linux, you can use the `fdisk -l` command.
4. If the reported size does not match what you expect, you may need to rescan your storage devices using the command appropriate for the device's connection type.
5. Once the expected size is achieved, enable the GuardPoint and restart your applications.

Example: Resizing a Linux Device

The following example show the administrative steps to grow an XFS file system mounted on an ES GuardPoint. The example shows a device of size 41,347,072 sectors resized to 43,395,072 sectors .

```
# fdisk -l /dev/ada

Disk /dev/ada: 31.3 GB, 3316876800 bytes, 41347072 sectors
Units = sectors of 1 * 512 = 512 bytes
Sector size (logical/physical): 512 bytes / 512 bytes
I/O size (minimum/optimal): 512 bytes / 4194304 bytes

# xfs_info /dev/secvm/dev/ada
meta-data=/dev/secvm/dev/ada      isize=512    bcount=4, agsize=1288064 blks
                                   secbs=512     bsize=4096, firstblock=0, inoctx=25
                                   crc=1          finit=0, rmapnodes=0
                                   bsize=4096     blocks=41347072, maxpct=25
                                   sunit=0        swidth=0 blks
                                   bsize=4096     ascll-ci=0 ftype=1
                                   bsize=4096     blocks=2560, version=2
                                   sector=512     conit=0 blks, lazy-count=1
                                   extsize=4096    blocks=0, rtextents=0

# voradmin esp status /dev/ada
ESG Header on /dev/secvm/dev/ada
  Version: 1
  Change: 0
  Notifications: None
  Storage Status: None
  Private Region Size: 128024 sectors
  Reported Device Size: 41347040 sectors
  Key UUID: 61644444-6164-6164-6164-616461646164
  Mount Path: N/A (GuardPoint not enabled)

# umount /xfs
# secfd -unguard /dev/ada
secfd: Path is not guarded
```

In this example we resize the device on the storage array to 43395072 sectors. Notice that the `voradmin` command reports the old device size until the device is guarded.

```
# fdisk -l /dev/ada

Disk /dev/ada: 31.3 GB, 3316876800 bytes, 43395072 sectors
Units = sectors of 1 * 512 = 512 bytes
Sector size (logical/physical): 512 bytes / 512 bytes
I/O size (minimum/optimal): 512 bytes / 4194304 bytes

# voradmin esp status /dev/ada
ESG Header on /dev/secvm/dev/ada
  Version: 1
  Change: 0
  Notifications: None
  Storage Status: None
  Private Region Size: 128024 sectors
  Reported Device Size: 41347040 sectors
  Key UUID: 61644444-6164-6164-6164-616461646164
  Mount Path: N/A (GuardPoint not enabled)

# secfd -guard /dev/ada
secfd: Path is guarded

# voradmin esp status /dev/ada
ESG Header on /dev/secvm/dev/ada
  Version: 1
  Change: 0
  Notifications: None
  Storage Status: None
  Private Region Size: 128024 sectors
  Reported Device Size: 43395040 sectors
  Key UUID: 61644444-6164-6164-6164-616461646164
  Mount Path: /xfs
```

The final step shown in below is to mount and resize the XFS file system to include the extended space into the file system.

```
# mount -t xfs /dev/sector/0x500 /xfs
# xfs_info /xfs
meta-data=/dev/sector/0x500  isize=512    agcount=4, agsize=131072 bke
=          =          sectsz=512    attr=0, projid32bit=1
=          =          crc=1        finobt=0, inoobt=0
data      =          =          bsize=4096  blocks=512256, logsect=25
=          =          sunit=0      bsize=4096  ascll-ci=0, ftype=1
naming    =version 2   bsize=4096  blocks=2560, version=1
log       =internal    sectsz=512   sunit=0 bke, lazy-count=1
realtime  =none        sectsz=4096  blocks=0, rtextents=0
data blocks changed from 512256 to 540256
# xfs_info /dev/sector/0x500
meta-data=/dev/sector/0x500  isize=512    agcount=5, agsize=131072 bke
=          =          sectsz=512    attr=0, projid32bit=1
=          =          crc=1        finobt=0, inoobt=0
data      =          =          bsize=4096  blocks=540256, logsect=25
=          =          sunit=0      bsize=4096  ascll-ci=0, ftype=1
naming    =version 2   bsize=4096  blocks=2560, version=2
log       =internal    sectsz=512   sunit=0 bke, lazy-count=1
realtime  =none        sectsz=4096  blocks=0, rtextents=0
```

Use Cases involving Efficient Storage GuardPoints

ES GuardPoints support three use cases for managing customer's data in GuardPoints. This section describes those potential use cases.

Use Case 1: Single Encryption Key

Applications, such as an Oracle Database, store structured data in one or multiple LUNs guarded as an ES GuardPoint. In this use case, a LUN may be an independent datastore or a member of a disk group managed by an application, for example an Oracle ASM disk group. In this use case, the policy applied to the GuardPoints specifies one key rule for encryption, and, potentially, a second key rule with an empty resource set for rekey. The policy may include access rules for user or process level access control.

Use Case 2: Device-Level GuardPoints

Protect structured or unstructured data stored in data files. The data files are organized inside one or more directories or folders within a file system namespace, such as ext4 or XFS, without any protection on the folders or the file system namespace. In this use case, the file system resides in the device guarded as Efficient Storage using a policy with a key rule and *no user specified access rule*. Access rules are not applicable in this use case and should not be used. Similar to use case 1, Linux policies supporting this use case can also specify the second key rule with an empty resource set for rekey.

Figure 17-1: File system resides in device guarded as ES GuardPoint

Example

Below is an example of this use case where a Linux file system is created in an ES GuardPoint and then mounted. The policy used for the GuardPoint does not specify user or process-level access rules because I/O operations to the GuardPoint are from the file system module accessing the device on behalf of application I/O operations to the files inside the mounted file system.

```
# secctl -status guard | grep adh
/dev/adh          ESG_POLICY_1          manualrawdevice  unguarded      not guarded  inactive
# voreadmin esg config new /dev/adh
# secctl -guard /dev/adh
secctl: Path is guarded
# voreadmin esg status /dev/adh
ESG Header on /dev/secvm/dev/adh
  Version:          1
  Change:           0
  Notifications:    None
  Storage Status:   None
  Private Region Size: 128024 sectors
  Expected Device Size: 43166040 sectors
  Key UUID:         b16448d4-2d1a-3a8f-b42a-5693d31f9c00
  Mount Path:       None
# mke2fs -t xfs /dev/secvm/dev/adh
mke2fs-data=/dev/secure/adv      inode=612      agcount=4, agsize=1362961 blks
      =          sector=512      attr=2, projid32bit=1
      =          nro=1          finobt=0, sparse=0
data      =          bsize=4096   blocks=540256, imaxpct=21
      =          sunit=0        swidth=0 blks
logging   =version 2          bsize=4096   aextl=0 ftype=1
log       =internal log      bsize=4096   blocks=240, version=2
      =          sectsz=512     sunit=0 blks, lazy-count=1
realtime  =none              bsize=4096   blocks=0, stextents=0
# mount -t xfs /dev/secvm/dev/adh /xfs
# mount | grep xfs
/dev/secvm/dev/adh on /xfs type xfs (rw,relatime,seclabel,attr2,inode64,noquota)
```

Use Case 3: Directory-Level GuardPoints

Protect structured or unstructured data stored in data files. The data files are organized inside one or multiple directories or folders within a file system namespace, such as ext4 or XFS, where the entire file system namespace is guarded with one policy as a Directory GuardPoint. In this use case, the file system resides in a device guarded as ES GuardPoint. Similar to use case 1, Linux policies supporting this use case can also specify the second key rule with an empty resource set for rekey.

Figure 17-2: All Data in file system Device Encrypted through an ES GuardPoint

In this use case, two policies are enforced to protect the data in the device. As stated, one policy protects the entire file system namespace guarded under the Directory GuardPoint, and the guarded directory is the mount point pathname of the mounted file system. The policy on the mount point directory must specify *clear_key* in the key rule. Specifying a key other than *clear_key* must be avoided because all the data in the file system device is encrypted through the ES GuardPoint corresponding to the file system device. The screen shot below represents a sample Linux policy over the file system mount point where the policy blocks root access to read/write files under the subdirectory *dir1* in the mounted file system.

The second policy protecting the device is the same policy as use case 2.

Example

Below is an example of this use case where a file system created in a guarded device and mounted on */xfs* is protected under a policy that denies root access to the files under */xfs/dir1*:

```
# mount | grep xfs
/dev/secure/dev/ssh on /xfs type xfs (rw,relatime,seclabel,attr1,inode64,noquota)
# find /xfs -xsync
/xfs
/xfs/non-secret
/xfs/dir1
/xfs/dir1/secret
cat /xfs/dir1/secret
this file holds highly sensitive data.
cat /xfs/non-secret
this file does not hold sensitive information.
# secfsd -guard /xfs
secfsd: Path is guarded
# secfsd -status guard | grep ssh
/dev/ssh          ESG_DEMO_POLICY_2      manual:secretview guarded   guarded   N/A

# ls /xfs
dir1 non-secret
cat /xfs/dir1/secret
cat: /xfs/dir1/secret: Permission denied
cat /xfs/non-secret
this file does not hold sensitive information.
```

As depicted above, the root user is denied access to read/write the files associated with the resource set representing files under /xfs/dir1 subdirectory.

Challenges with Root Access on Linux

As demonstrated in the example in use case 3, data is protected at two levels using two separate policies and GuardPoints. The data is encrypted at the device level through the policy on the device guarded as Efficient Storage, and user access controls are enforced at the file system level through the policy on the mount point directory. Splitting the full protection through separate GuardPoints poses new challenges with respect to root privilege on Linux.

With the GuardPoint on the file system mount point enabled, the access rule(s) denying root access is enforced. However, when the GuardPoint on the file system mount point is disabled, root gains full access to the files in the file system. As shown below, the file holding secret information and protected against root is exposed as soon as the GuardPoint on file system mount point is disabled.

```
# secfsd -status guard | grep ESG
/dev/ssh          ESG_DEMO_POLICY_2      manual:secretview guarded   guarded   N/A
/xfs              ESG_MOUNTED_FS_POLICY manual          guarded   guarded   N/A
# cat /xfs/dir1/secret
cat: /xfs/dir1/secret: Permission denied
# secfsd -unguard /xfs
secfsd: Path is not guarded
# cat /xfs/dir1/secret
this file holds highly sensitive data.
```

The next two sections describe the challenges with root access and solutions to overcome these challenges.

Challenge 1 - Deny root access to the files in mounted Linux file system

As the above example shows, the policy ESG_MOUNTED_FS_POLICY denies the root user access to the files associated with the resource set dir1. Enforcement of the rule become ineffective as soon as the GuardPoint on the file system mount point is disabled. Since data is in clear-text at the file system level, root would gain access to clear-text in the files associated with the resource set, which includes files with sensitive information.

The solution to this problem is to force the file system to unmount when the GuardPoint on the file system mount point is disabled. Basically, the file system is guarded/enabled immediately when the file system mounts, and the file system is unmounted as soon as the GuardPoint is disabled. To enforce this, the GuardPoint on the file system mount point directory must be guarded with **Auto Mount** option checked on the DSM. With this option, CTE immediately guards the mount point directory as soon as the file system mounts, and similarly, CTE disables the GuardPoint before unmounting the file system. As shown below, the file system mount point is guarded with **Auto Mount** option checked.

This solution imposes one policy protecting the entire file system namespace. Enforcement of a single policy over entire file system namespace may seem restrictive if you wish to impose different sets of access rules to different directories within the file system name. Basically, your option of enforcing one policy with a set of specific access rules for guarding a specific directory within the mounted file system namespace is not possible with this solution. Instead, you have to create a resource set for each directory, which you would have guarded, and specify the desired access rules specific to the directory through association of the rule with the resource set. Let's see the effect of auto-mount on root user attempts to view files that root users are not allowed to read. As shown below, the GuardPoint `/xfs` is automatically mounted as soon as the file system mounts, and the file system unmounts as soon as the GuardPoint is disabled, hence there is no opportunity for root, or any other privileged user, to read the protected files.

```
# mount -t xfs /dev/sectest/dev/ssh /xfs
# secadm -status guard | grep SSG
/dev/ssh          ESB_DEMO_POLICY_1      mandatorydevice  guarded        guarded        N/A
/xfs              ESB_MOUNTED_FS_POLICY  automount        guarded        guarded        N/A

# cat /xfs/dixl/secret
cat: /xfs/dixl/secret: Permission denied

# umount /xfs
# secadm -status guard | grep SSG
/dev/ssh          ESB_DEMO_POLICY_1      mandatorydevice  guarded        guarded        N/A
/xfs              ESB_MOUNTED_FS_POLICY  automount        guarded        not guarded    inactive

# cat /xfs/dixl/secret
cat: /xfs/dixl/secret: No such file or directory
```

As depicted above, the policy `ESG_MOUNTED_FS_POLICY` enforces a single rule to block root access to the files under the `dir1` subdirectory under the mounted file system GuardPoint. We need to add another security rule to the policy to grant root user access to read the files under `dir2` subdirectory under the guarded file system mount point. Note that `dir1` and `dir2` may have been guarded separately under different policies.

Challenge 2 - Deny root access to view sensitive data in protected Linux files

Another challenge with root user privilege is that root can still view sensitive information stored in the ES GuardPoint device. As explained, the policy `ESG_MOUNTED_FS_POLICY` denies root access to the read/writes files under `/xfs/dir1`. Although this policy enforces the rule on the Directory GuardPoint `/xfs`, the rule is not enforced if the root user dumps the content of the ES GuardPoint. As the example below shows, the root user can view sensitive information in the protected files under `/xfs/dir1`.

[illegible]

To block the root user from dumping context of the device, the policy on the ES GuardPoint must enforce a security rule that denies root access to the GuardPoint device. However, denying root access to GuardPoint devices is not feasible because file system utilities require root access for file system administration. Rather than enforcing complete denial of root access, you can impose a restriction that allows only a limited set of system utilities to access ES GuardPoints, such as `mount`, `fsck`, `mkfs`, `dmsetup`, etc., and deny access to other utilities, such as `dd`.

The solution is to restrict root to execute a limited set of utilities, which do not expose content of the file system devices, on Efficient Storage Devices. If the root user attempts to execute other utilities on the device, the root user will be denied access. You can impose this restriction by selecting the administrative utilities that root must execute on ES GuardPoints. See ["Linux System Utilities for Signing" on page 191](#) for the list of utilities that root must be able to execute.

To implement this solution, you can create a signature set on your DSM and add the system utilities that root is permitted to execute on ES GuardPoints. Those utilities can be added to the signature set for signing. After signing the binary files of those system utilities, you can add a security rule to the policy on the ES GuardPoint that grants root the right to execute the system utilities in the signature set to access the ES GuardPoint. In the above example, since `dd` is not in the signature set, the `dd` command is denied access to read the file system device guarded as an ES GuardPoint.

The following screenshot depicts the policy that restricts root access to the ES GuardPoint limited to the system utilities listed in ESG FS ResourceSet.

The resource set `ESG_FS_ResourceSet` consists of the binary files listed in the next screenshot. Let's walk through the steps to add the security rule to limit root access:

1. Select the system utilities that must be granted access to Efficient Storage devices.
2. On the DSM, click on **Signature** in the top menu bar to get to the **Signature Sets** page, and then click **Add** to add a signature set.
3. On the **Add Signature Sets** page, enter the name of the signature set to create and then click on OK. This creates an empty signature set with the name you have selected for the signature set. The name appears on the **Signature Sets** page.
4. On the **Signature Sets** page, click on the name of the signature set to get to the **Edit Signature Set** page to edit your signature set.
5. On the **Edit Signature Set** page, click on the **Source** tab to select the protected host where the file system utilities are located. Click **Select** to select the protected host.
6. Click **Add** to add each system utility from the selected host to the signature set. After adding the system utilities to the set, then click **Sign** to sign the binary files on the selected protected host.

In the example below, the signature set named `ESG_FS_Uutilities` includes sample of file system utilities whose binary files have been signed on the protected host. You may add other system utilities to the set as necessary.

At this point, you have created a signature set consisting of the system utilities that root is allowed to execute on Efficient Storage devices. Next, create a process set from the signature set. The process set will be included in a security rule in the policy protecting the ES GuardPoint. The security rule will allow root or other privileged users to access the device only through the system utilities in the signature set. Continue with the following steps:

1. For Policies in the top menu bar, then click on **Manage Policies**, and then click on **Process Sets** to get to **Process Sets** page.
2. Click **Add** to get to **Add Process Set** page to add a process set.
3. Enter the name of the process set in the **Name** entry and then click **Add** to get to **Add Process** page.
4. Click **Select** next to the **Signature Set** entry to select a signature set. Select the signature set that you just created.

After clicking **Select**, you will be on the **Select Signature Reference** page, and you will see the signature set you just created, for example, the ESG_FS_Utilities signature set. Click on the **Select** button to the left of the signature set and then click on **Select Signature Reference**. You will go back to **Add Process** page with the selected signature set name entered in **Signature Set** box.

- Click **Select** next to the **Host** entry to select the protected host the process set. On the Select a Host to Continue page, select the protected host and then click on **Select**.
- On the **Add Process Set** page, click OK to create the process set associated with the selected signature set and the protected host.
- You have selected the signature set and the protected host. Skip **Directory** and **File** entries, and then click OK to go back to **Add Process Set**.

In the following figure, the process set named ESG_FS_ProcessSet has been created using the ESG_FS_Uutilities signature set which includes system utilities whose binary files have been signed on the protected host.

- Edit the policy protecting ES GuardPoints to add a security rule. In the following figure, the process set that you just created is included in the security rule. The rule allows only the processes listed in the process set to access the ES GuardPoints. This rule prevents any privileged user from reading or dumping the content of an ES GuardPoint.

After adding the security rule, the policy protecting ES GuardPoints will be the same policy as ESG_DEMO_POLICY_2.

After applying the revised policy over the ES GuardPoint, root can no longer dump the contents of the device.

```
# cat /etc/passwd | grep ESTP
/dev/sdb      ESTP DEMO POLICY 2      manualraidwrite    unguarded          not guarded       Inactive
/dev/sdc      ESTP MOUNTED_FS_POLICY   automount          guarded            not guarded       Inactive
# cat /etc/guard /dev/sdb:
cat: /etc/guard /dev/sdb: Not a directory
# cat /etc/guard /dev/sdc:
cat: /etc/guard /dev/sdc: Not a directory
# mount -t xfs /dev/sdc00m /dev/sdb /xfs
mount: /dev/sdb: permission denied
cat: /etc/guard /dev/sdb: Not a directory
cat: /etc/guard /dev/sdc: Not a directory
# dd if=/dev/urandom /dev/sdb bs=1048576 && grep --binary-files=text "file holds highly sensitive data"
dd failed to open '/dev/urandom/dev/sdb': Permission denied
```

Use Case 4: Using CTE-Efficient Storage with LVM

Security rules for access control enforcement on I/O operations are based on the context of real users and/or processes requesting the I/O operations. For ESG devices, security rules are checked and enforced at the CTE `secvm` layer. If the context of the real user or process that requested the I/O operation is not available at the `secvm` layer, then the enforcement of access rules is invalid and may have unpredictable results and potentially cause system failures.

The previous use cases have described environments where CTE can get the context of the real users or processes requesting I/O operations at the `secvm` layer and can properly enforce the access rules in those environments. For example, as described in ["Use Case 3: Directory-Level GuardPoints" on page 197](#), CTE can detect when an ESG device is mounted with a file system and it can apply the access rules in the policy on the ESG device without enforcing the rules on I/O operations from the file system layer.

However, there are other environments where CTE cannot determine how the ESG device is actually used and whether a real user or process context is available at the `secvm` layer. In these environments, CTE cannot properly enforce the access control rules on the ESG device. An example of such an environment is Linux LVM (Logical Volume Manager). A physical device under LVM control is a shared storage resource that can be fully or partially allocated to a logical volume. Adding an ESG device as a physical device to LVM is fully supported for data encryption but not for access control enforcement. In this case, access rules cannot be enforced because when the logical volume with file system is mounted, the mount operation is on the logical volume, not the ESG device. Consequently, CTE cannot determine that the ESG device is part of mounted file system, and therefore, it cannot get the real user or process context for applying access rules.

In order to use CTE in an environment like LVM, the CTE system administrator needs to explicitly tell CTE whether or not it should enforce the access rules for I/O operations on the device when they initialize the device using the `voradmin esg config` command. As described in ["Initialize a New Linux Device" on page 182](#), this initialization must be done *before* the device is guarded as an ES GuardPoint for the first time.

In addition, for LVM specifically, the device must be a new device with no existing data. Existing LVM disks cannot be used with CTE unless CTE can get the proper context at the `secvm` layer.

When you initialize the new device, use the `voradmin esg config -noacc new [-c <n>] <device-name>` command where:

- `-noacc` (required) tells CTE to disable access control rules on this device at the `sevm` layer level.
- `new` (required) indicates that the device contains no data (it is a new disk).
- `<device-name>` (required). Specifies the device name. For example, `/dev/sdh`.

For example, if you want to initialize a new LVM Linux disk named `/dev/sdh`, you would specify:

```
# voradmin esg config -noacc new /dev/sdh
```

CAUTION

When you use `-noacc`, CTE will not perform *any* access checks on read/write operations to the specified device, even if the policy for guarding the device includes security rules enforcing read and/or write access checks. Before you use this option, make sure that your environment requires it. You should always use the options described in the first three use cases if at all possible, so that CTE can apply access controls to all I/O operations and therefore perform all required read/write access checks.

The following example shows the steps for initializing and guarding the device `/dev/sdb`, then adding or using the guarded device under LVM to create a file system.

1. Initialize the device using the `-noacc` option:

```
# voradmin esg config -noacc new /dev/sdb
```

2. Guard the device as described in ["Guard the Linux Device with an ES GuardPoint" on page 184](#).

3. Create and mount the file system.

```
# pvcreate /dev/secvm/dev/sdb
# vgcreate secvm_sdb_vg /dev/secvm/dev/sdb
# lvcreate -y -l 100%FREE -n my_volume
# mkfs.xfs /dev/mapper/my_volume
# mount /dev/mapper/my_volume /mnt
```

Alerts and Errors on Linux

This section lists the alerts and errors that may be encountered during system operations.

Encryption key on device has not been made available

This alert may appear as the reason for a GuardPoint not to have been enabled. The message appears in the output of `secfsd -status guard` command. The status indicates that the encryption key specified in the policy for the GuardPoint has not been made available to the protected host.

Solution: Check the host's connectivity with the DSM.

Specified policy disagrees with metadata set on the Guard Path

This alert may appear as the reason for a GuardPoint not to have been enabled. The message appears in the output of `secfsd -status guard` command. The status indicates that the key specified in the policy for the GuardPoint does not match with the key stored in the ES Header.

Solution: Un-guard the device and check the name and UUID of the key in the ES Header using `voradmin esg status <device-name>` and `voradmin esg status xform <device-name>` and, compare the name and UUID with the key name specified in the policy. Correct the discrepancy and re-guard the device.

Device has not been configured for Efficient Storage

This alert may appear as the reason for a GuardPoint not to have been enabled. The message appears in the output of `secfsd -status guard` command. The status indicates that the device has been properly guarded as ES GuardPoint on the DSM but the device has not been initialized for guarding as Efficient Storage.

Solution: The most probable cause of this error is that you did not initialize the device for guarding as Efficient Storage on protected host. It's also possible that the guarded device has already configured for guarding as ES GuardPoint. If the device needs to be initialized for guarding as Efficient Storage, follow the steps to initialize a device for guarding as Efficient Storage.

Device not resized for guarding as Efficient Storage

This alert may appear as the reason for a GuardPoint not to have been enabled. The message appears in the output of `secfsd -status guard` command. The status indicates that the newly guarded ES GuardPoint, which has been initialized with `xform` option of `voradmin`, has not been resized to accommodate storage space for CTE private region.

Solution: Unguard the GuardPoint from the DSM, resize the LUN and verify that the host sees the expanded size, and then guard the GuardPoint from the DSM.

Data transformation failed

This alert may appear as the reason for a GuardPoint not to have been enabled. The message appears in the output of `secfsd -status guard` command. The status indicates that the protected host encountered an error while transforming the data on the device during IDT.

Solution: Consult with the system and/or storage admin to check on the health of the LUN in the storage array. You may contact Thales Support for troubleshooting and recovery if there has not been a report of any error on the LUN.

Data transformation in progress

This alert may appear as the reason for a GuardPoint not to have been enabled. The message appears in the output of `secfsd -status guard` command. The status indicates that the protected host is transforming the data on the device.

Solution: You must wait for data transformation to complete. Check the status of transformation by running `voradmin esg status xform <device name>`. Access to the device is blocked until transformation completes.

Device <device-name> is configured to guard as Efficient Storage GuardPoint

This error message is reported by the `voradmin` command when initializing a device that has already been initialized for guarding as Efficient Storage.

Solution: The device has already been initialized for guarding as Efficient Storage and is probably waiting to be guarded as an ES GuardPoint. Alternatively, if the device was incorrectly initialized for guarding as Efficient Storage, you can remove the configuration by running `voradmin esg delete <device-name>`.

Device <device-name> is configured as Efficient Storage GuardPoint

This error message is reported by the `voradmin` command when initializing a device that is already being guarded as an Efficient Storage GuardPoint.

Solution: None. The device is already an Efficient Storage device.

GuardPoint for device <device-name> still guarded on DSM

This error message is reported by the `voradmin` command when attempting to initialize a device for rekey or removing the device as Efficient Storage.

Solution: Unguard the GuardPoint from the DSM, wait for the protected host to process the update, and then rerun the `voradmin` command.

Failed to open device <device-name>, error Device or resource busy

This message occurs when `voradmin` detects that the target device is busy.

Solution: The device may already be in use by other application. Rerun the `voradmin` command when the device is no longer in use.

Device <device-name> is not configured as Efficient Storage

This error message is reported by the `voradmin` command when attempting to delete a device as ES GuardPoint.

Solution: This message indicates that the target device has been not initialized for guarding as Efficient Storage. The message may also be reported if the specified device has been initialized for guarding as Efficient Storage but it has not been guarded yet. In this case, it removes the preparation made by `voradmin`. You can remove the Efficient Storage configuration status on the device by running `voradmin esg delete <device-name>`. You may see the same error message again, and if you do, you can ignore it.

Abort! Error: Could not stop secfs, secvm device(s) busy

This error occurs during CTE shutdown when there is a busy CTE protected device.

Solution: Verify that all applications directly accessing `secvm` protected GuardPoints have been shut down. Ensure that all file systems on top of a `secvm` protected devices are under the control of `systemd` and have been unmounted before attempting to shut down the agent.

Abort! Error: Could not unmount file systems

This error occurs during CTE shutdown when a file system under the control of `systemd` fails to unmount.

Solution: Verify that file systems on top of an ES GuardPoint devices are not busy and then rerun the agent shut down command.

A dependency job for `esg.mount` failed. See '`journalctl -xe`' for details

This error occurs during CTE startup when system fails to mount a file system. This error message is typically accompanied by a long timeout during the CTE startup process.

Solution: Check that the underlying device is available and that the ES GuardPoint was successfully applied on the device. Once the device is available, the file system will automatically finish mounting.

ESG-ALERT: IO error on header for [GuardPoint]

This is an alert message to the DSM. It occurs when CTE encounters a general error when attempting to access the private region on an Efficient Storage device.

Solution: An I/O error attempting to read or write to the device may have been caused by errors on the host or storage array. Consult with the system and/or storage admin to check on the health of the LUN in the storage array. You may contact Thales Support for troubleshooting and recovery if there has been no report of errors on the LUN.

ESG-ALERT: Data transformation failure on [GuardPoint]
