If you wish to schedule the destruction of *all* key versions of a key (for example, all 50 key versions of a key) in Google Cloud KMS at once, CCKM also supports this capability. This capability allows you to bypass having to schedule the destruction of each of the key versions of a key saving you time.

Note that you can cancel the destruction of a key version or all key versions in CCKM before the 24 hours has elapsed to restore the key material for the given key version. Google Cloud KMS does not perform the destruction after this cancellation is made in CCKM. After the cancellation, the key version state changes from DESTROY_SCHEDULED to DISABLED. In this version state, you can enable the key. And from the ENABLED version state, the key version is available for use for cryptographic operations once again.

Note

The Audit logs within the **Logs** page of the CCKM user portal provides the status for the actions of schedule destruction of a key version or all key versions and cancel destruction of a key version or all key versions. In the event that any one of these actions fail, the event name of **Schedule_Destruction_GCP_Key_Material** or **Cancel_Destruction_GCP_Key_Material** displays under the **Event Name** column along with the severity level under the **Severity** column for each impacted version. The actual event name that displays depends on which action failed. If the failed action relates to schedule destruction of all key versions, then an additional log message is provided to summarize the total number of key versions that were successfully scheduled for destruction. For those key versions that were not successfully scheduled for destruction, an additional log message is provided listing each of the version numbers that were not scheduled for destruction. If the failed action relates to cancel schedule destruction of all key versions, then an additional log message is provided to summarize the total number of key versions that were restored and the total number that were not restored.

Note

If you schedule the destruction of a key version, be sure to synchronize your keys with the Google Cloud KMS from the CCKM **Google Cloud Keys** page after the 24 hours has elapsed. Otherwise, your CCKM keys will be out of sync with Google Cloud KMS keys, and the option to cancel the destruction of a key version will still display as being available in CCKM. If you attempt to cancel the key version destruction after the 24 hours has elapsed, the operation will fail because the key material of the key version has already been destroyed within Google Cloud KMS.

For more information, see the following sections:

- [Schedule Destroy Key Version](#)
- [Cancel Schedule Destroy Key Version](#)
- ["Schedule Destruction of All Key Versions" below](#)
- ["Cancel Schedule Destruction of All Key Versions" on the facing page](#)

Schedule Destruction of Key Version

To schedule the destruction of a key version for a given key:

1. In the CCKM portal, in the left navigation bar, select **Keys**.
2. On the **Google Cloud Keys** page, find the name of the key whose key version you wish to schedule for destruction and then expand the row to show the key versions underneath the key name.
3. To see all key versions underneath the key name, click **View all versions**. The **Key Versions** dialog box displays. Scroll through the list to find the key version you wish to schedule for destruction.
4. Select **Schedule Destruction** from the **Actions** drop-down menu for the selected key version. The **Schedule Destruction of Key Material** dialog box is displayed. A warning displays indicating that this action will schedule key material destruction for "<path to key version>" from your Google Cloud key ring. The message also indicates to type the confirmation phrase (I wish to destroy the key material, and I understand it cannot be restored.) in the text box if you wish proceed with scheduled destruction of the key version for the given key.
5. Enter or copy/paste the confirmation phrase in the text box.
6. Click **Destroy**.

Schedule Destruction of All Key Versions

To schedule the destruction of all key versions for a given key:

1. In the CCKM portal, in the left navigation bar, select **Keys**.
2. On the **Google Cloud Keys** page, find the name of the key whose key versions you wish to schedule for destruction.
3. Select **Schedule Destruction All Versions** from the **Actions** drop-down menu for the selected key. The **Schedule Destruction of All Key Version Materials** dialog box is displayed. A warning displays indicating that this action will schedule all key version material destruction for "<path to key>" from your Google Cloud key ring. The message also indicates to type the confirmation phrase (I wish to destroy the key material for all the versions, and I understand they cannot be restored.) in the text box if you wish to proceed with scheduled destruction of all key versions for the given key.
4. Enter or copy/paste the confirmation phrase in the text box.
5. Click **Destroy**.

Cancel Schedule Destruction of Key Version

To cancel the scheduled destruction of a key version for a given key and restore it:

1. In the CCKM portal, in the left navigation bar, select **Keys**.
2. On the **Google Cloud Keys** page, find the name of the key whose key version you wish to cancel the scheduled destruction and then expand the row to show the key versions underneath the key name.
3. Find the key version for which you wish to cancel the scheduled destruction.
4. Select **Cancel Destruction** from the **Actions** drop-down menu. The **Cancel Scheduled Destruction of Key Material** dialog box is displayed. A warning displays indicating that this action will cancel the scheduled destruction of key version "<path to key version>" in your Google Cloud key ring.
5. Click **Restore**.

Cancel Schedule Destruction of All Key Versions

To cancel the scheduled destruction of all key versions of a given key and restore these versions:

1. In the CCKM portal, in the left navigation bar, select **Keys**.
2. On the **Google Cloud Keys** page, find the name of the key whose key versions you wish to cancel the scheduled destruction.
3. Select **Cancel Destruction All Versions** from the **Actions** drop-down menu. The **Cancel Scheduled Destruction of All Key Material** dialog box is displayed. A warning displays indicating that this action will cancel the scheduled destruction of all key versions for "<path to key>" in your Google Cloud key ring.
4. Click **Restore**.

Download Public Key (Asymmetric Key Only)

Before you can begin using a new key version of an asymmetric key after key rotation, you are required to take additional steps. Part of these additional steps include distributing the public key of the new key version. CCKM provides support for downloading a CCKM public key of the new key version.

To download the CCKM public key of a new asymmetric key version:

1. In the CCKM portal, in the left navigation bar, select **Keys**.
2. On the **Google Cloud Keys** page, find the name of the key whose key version you wish to download the public key and then expand the row to show the key versions underneath the key name.
3. Find the key version for which to download the public key.
4. Select **Download** from the **Actions** drop-down menu. The public key file is downloaded to your laptop or desktop. When prompted as to whether to keep or discard the file type, select **Keep**.

Export Keys

Export Keys allows you to export the contents of the **Google Cloud Keys** page into a report in a CSV format.

1. In the CCKM portal, in the left navigation bar, select **Keys**.
2. On the **Google Cloud Keys** page, click **Export Keys**. The report file is downloaded to your laptop or desktop.

Reports

CCKM includes the following reports:

- **Combined Key Activity Reconciliation Report**

Provides the history of a key for a selected period using the following information (in column headings):

- Key name
- Organization
- Project
- Key Ring
- Key Activity
- Cloud Key Manager Key Activity
- Timestamp
- Cloud Key Manager Timestamp

- **Google Cloud Key Activity Report**

Illustrates the activity type performed by a specific user and at the stated time. Information provided in the column headings of this report is the following:

- Key name
- Organization
- Project
- Key Ring
- Key Activity
- Region
- Origin
- Modified By
- Modified Time

- **Google Cloud Key Aging Report**

Provides information about key expiration using the following information (in column headings):

- Key Name
- Organization
- Project
- Key Ring
- Region
- Key Rotation
- Schedule Key Deletion Date

- **Cloud Key Manager User Action Report**

Lists the users and their actions including creating, uploading, rotating, and deleting keys in the CCKM portal. Information provided in the column headings of this report is the following:

- User Name
- Delete Key
- Upload Key
- Schedule Delete Key Material
- Cancel Delete
- Rotate Key

Generate a Report

1. In the CCKM portal, in the left navigation bar, select **Reports**.
2. Under **Report Name**, select the report you wish to run.
3. From **Date Range**, click **Last day** to run the report for the activities from the previous day or **Specific** to run the report using a date range. If you choose to run by a date range, enter the start and end dates in the format MM/DD/YY or select the dates from the calendar button at the right of the box.

If you are running the **Google Cloud Key Aging Report**, click **Next week** to run the report for the activities for the next week or **Specific** to run the report using a date range.

4. Click **Run Report**. A link to the report is made available under the **Last Run** column. To view the report, click on the link and the report displays.
5. To download the report, click **Download** at the top right of the page and select the report format (PDF or CSV) to download.

Delete a Report

1. From the **All Reports** page, select the specific report you wish to delete. The report displays.
2. From the **Actions** column, click **Delete**. The **Delete Current Report** dialog box with a warning that you are about to delete a current report run on a specified date and time.
3. Click **Delete**. The report is deleted from CCKM.

Schedules

The **Schedules** page allows Cloud administrators to view and schedule the following job types:

- Key Rotation
- Key Synchronization

CCKM provides support for multiple schedules for each of the job types.

At the top right of the **Schedules** page, the **Add Schedule** button is available from which to add a scheduled job type.

Schedule Key Rotation

CCKM provides support for multiple schedules of the rotation (autorotation) of symmetric keys within Google cloud. During a scheduled key rotation, new key material is added to the key and the new version of the key is set as the primary key.

When you rotate a symmetric key, the following applies:

- Any data that was encrypted with previous versions of the key is not automatically re-encrypted.
- Existing key versions are not automatically disabled or destroyed.

Google Cloud KMS does *not* support automatic rotation of asymmetric keys. However, CCKM does support automatic rotation of these keys by adding new key material to the key to create a new version. To begin using the new key version for either signing or encryption, you are required to take additional steps. For information about these additional steps, refer to [Considerations for Asymmetric Keys](#).

Scheduled key rotation (for both symmetric and asymmetric keys) requires that this feature be configured in the **Schedules** page prior to enabling the feature from the **Keys** page. For more information about enabling scheduled key rotation of symmetric and asymmetric keys, refer to ["Rotate a Key" on page 163](#).

You can pause or delete a scheduled key rotation in the **Schedules** page.

Set up a Key Rotation Schedule

To set up a key rotation schedule:

Note

The access permissions of an Admin role (roles/cloudkms.admin) within Google Cloud KMS are required to set up a key rotation schedule.

1. In the CCKM portal, in the left navigation bar, select **Schedules**. The **Schedules** page displays.
2. On the **Schedules** page, select the **Add Schedule** button. The **Add Schedule** dialog box displays. Your username associated with your Google Cloud account is automatically populated in the **Username** box.
3. From the **Job Type** drop-down menu, select **KEY_ROTATION**.
4. From **Name** box, enter the name of the schedule. Ensure this name is unique for this job type.
5. (Optional) Enter a description of the schedule in the **Description** box.
6. For **Pause**, select **No**.
7. For **Schedule**, set a schedule for the rotation by selecting **Basic** (to enter a date and interval for the schedule) or **Advanced** (to enter a Cron Expression for the schedule).

If you selected **Basic**, select a start date and time from a date and time selector by clicking the calendar button to the right of the box. The time is based on a 12-hour clock and the A.M./P.M. modifiers. Set the repeat interval of the key rotation by entering a number in **Repeat Interval** and then selecting Day, Week, or Month from the drop-down menu. The supported ranges are 1 through 30 days, 1 through 4 weeks, and 1 through 12 months. You can increase or decrease the number you enter.

If you selected **Advanced**, enter the cron expression in the **Cron Expression** box.
8. Click **Save**.

Pause a Key Rotation Schedule

To pause a key rotation schedule, select **Yes** for **Pause** within the **Add Schedule** dialog box and then click **Save**. The setting is saved. To resume the rotation schedule after pausing it, select **No** for **Pause** and then click **Save**. The setting is saved.

Delete a Key Rotation Schedule

To delete a key rotation schedule, select **Delete** from the **Actions** drop-down menu from the **Schedules** page.

Schedule Key Synchronization

CCKM allows for multiple schedules of the synchronization of Google Cloud keys. Synchronizing downloads the key metadata of any keys that were created in Google Cloud KMS, outside of the CCKM portal, into your CCKM. Scheduled key synchronization requires that this feature be configured in the **Schedules** page. You can also pause or delete a scheduled key synchronization in the **Schedules** page.

Set up a Key Synchronization Schedule

1. In the CCKM portal, in the left navigation bar, select **Schedules**. The **Schedules** page displays.
2. On the **Schedules** page, select the **Add Schedule** button. The **Add Schedule** dialog box displays. Your username associated with your Google Cloud account is automatically populated in the **Username** box.
3. From the **Job Type** drop-down menu, select **KEY_SYNCHRONIZATION**.
4. In the **Name** box, enter the name of the schedule. Ensure this name is unique for this job type.
5. (Optional) Enter a description of the schedule in the **Description** box.
6. For **Pause**, select **No**.
7. For **Schedule**, set a schedule for the key synchronization by selecting **Basic** (to enter a date and interval for the schedule) or **Advanced** (to enter a Cron Expression for the schedule).

If you selected **Basic**, select a start date and time from a date and time selector by clicking the calendar button to the right of the box. The time is based on a 12-hour clock and the A.M./P.M. modifiers. Set the repeat interval of the key synchronization by entering a number in **Repeat Interval** and then selecting Day, Week, or Month from the drop-down menu. The supported ranges are 1 through 30 days, 1 through 4 weeks, and 1 through 12 months. You can increase or decrease the number you enter.

If you selected **Advanced**, enter the cron expression in the **Cron Expression** box.
8. Click **Save**.

Logs

CCKM maintains logs for events, such as login, key generation, synchronizing of keys, and deletion of keys, and displays these logs in the **All Logs** list of the **Logs** page. For each logged event listed on the **Logs** page, the following information is displayed:

- Event name
- Severity level
- Date and time of the event
- Event message
- User (name) associated with the event

You can search for a specific logged event from the **Logs** page using the **Search** box. Allowable filters on the search are event name, severity level, event message, and user (name).

Key Sources

The **Key Sources** page displays **all** of the keys that were generated from the key source you are using. If you are logged into multiple clouds within CCKM, this page displays all of the keys from these clouds.

Three tabs are available at the top of the **Key Sources** page:

- **CipherTrust Manager Key:** Use this tab to use CipherTrust Manager as your key source. The keys are generated and stored within CipherTrust Manager.
- **DSM Key:** Use this tab to use DSM as your key source. The keys are generated and stored within DSM.
- **nShield Key:** This tab is currently unavailable for use as CCKM does not currently support nShield Connect as a key source for Google Cloud.

Note

CCKM does not support the concurrent use of CipherTrust Manager and DSM as key sources.

Keys listed on the **Key Sources** page are listed by name, cloud ID, key type (the cloud in which this key is used), the algorithm of the key, the creation date of the key, key description and actions you can take regarding that key.

A **Search** box is available at the top left of the **Keys Sources** page allowing for a search of a specific key by entering any one of the following parameters:

- Name (key name)
- Cloud ID
- Key Type
- Algorithm
- Description
- Created By (a key created by a specific user)

Add (Generate) a Key

From the **Key Sources** page, you can add (or generate) keys in CCKM using CipherTrust Manager or DSM as a key source for *all* of the clouds into which you are currently logged.

Note

The key algorithms currently supported for a Google Cloud key in CCKM are AES and RSA.

Add (Generate) a CipherTrust Manager Key

1. In the CCKM portal, in the left navigation bar, select **Key Sources**.
2. Select the **CipherTrust Manager Key** tab.
3. Select **Add Key > GoogleCloud Key**.
4. In the **Add CipherTrust Manager Key** dialog box, select the name of the user of the key from the **User** drop-down menu. Service is fixed to **GoogleCloud**.
5. In the **Name** box, enter the name of the new key.
6. Enter a description of the key in the **Description** box.

7. From the **Algorithm** box, select the algorithm (**AES256**, **RSA2048**, **RSA3072**, **RSA4096**, **ECP256**, or **ECP384**) to apply to the key.
8. Click **Save** to save the new key to CCKM. The new key is added to the keys list. (Reset clears the screen before it has been saved.)

Add (Generate) a DSM Key

1. In the CCKM portal, in the left navigation bar, select **Key Sources**.
2. Select the **DSM Key** tab.
3. Select **Add Key > GoogleCloud Key**.
4. In the **Add DSM Key** dialog box, select the name of the user of the key from the **User** drop-down menu.
5. In the **Source Key Tier**, select one of the following as a key source of the key:
 - **DSM**—Generate a key from DSM and import it into a Google cloud.
6. In the **Name** box, enter the name of the new key.
7. Enter a description of the key in the **Description** box.
8. From the **Algorithm** box, select the algorithm (**AES256**, **RSA2048**, **RSA3072**, or **RSA4096**) to apply to the key.
9. Click **Save** to save the new key to CCKM. The new key is added to the keys list. (Reset clears the screen before it has been saved.)

Add (Generate) an nShield Key

The **nShield Key** tab is currently unavailable for use as CCKM does not currently support nShield Connect as a key source for Google cloud.

Delete a Key

Deleting a key from the **Key Sources** page deletes the key from CCKM. When deleting a key from CCKM, the key is deleted from the key source you used to generate the key.

1. In the CCKM portal, in the left navigation bar, select **Key Sources**.
2. Select the **CipherTrust Manager** or **DSM Key** tab depending on the key source you used to generate this key initially.
3. Click **Delete** next to the target key.
4. The **Delete Key** dialog box with a Warning display asking you to confirm the key deletion by entering the supplied phrase.
5. Enter or copy/paste the confirmation phrase.
6. Click **Delete**.

Manage Keys in Key Sources List Page

In addition to adding and deleting keys, the **Key Sources** page allows you to sort the existing keys by Name, Cloud ID, Key Type, Algorithm, and Created Date.

Settings

To access the **Settings** page in CCKM, select **Settings** from the left-hand navigation bar. From the **Settings** page, you can:

- Enter the email addresses of the recipients who are to receive the email notifications.
- Enable email notifications to be sent out from CCKM when specific types of key actions are performed. For example, when a key is uploaded to the cloud service. You can also enable CCKM to send reminder notifications for when to rotate a key.
- Configure remote syslog servers to which to send syslog messages.
- Configure Service account to use for authentication to CCKM API.
- View information about the software release number of the CCKM you are running including the build and version number.

Adding Recipients' Email Addresses (for Notifications)

Use the **General** tab from the **Settings** page to enter the email addresses of the recipients who are to receive email notifications from CCKM. Enter the recipients' email addresses separated by a comma in the **Notification Recipient** box and then click **Save** to save setting.

Enabling Notifications

Using the **Keys Notification** tab from the **Settings** page, you can configure CCKM to send an email notification when a key is deleted from Google Cloud or restored or uploaded to Google Cloud. You can also use this tab to configure CCKM to send a reminder notification for when to manually rotate a key along with the frequency (in days) at which a notification is sent. Add the email address(es) of the recipients in the **General** tab from the **Settings** page. By default, no notifications are sent.

To enable email notifications:

1. In the **Settings** page, select the **Keys Notification** tab.
2. Under **Notifications**, select **On** for each of the notifications you wish to enable:
 - Rotate Google Cloud Key (reminder notification)
 - Delete Google Cloud Key
 - Restore Google Cloud Key
 - Upload Google Cloud Key
3. If you selected to enable **Rotate Google Cloud Key**, in the **Days** box, enter the number of days for the frequency a reminder notification is sent.
4. Click **Save**.

Configuring Syslog Server

Note

In this document, the terms "syslog server" and "log server" are synonymous.

The **Syslog** tab from the **Settings** page allows you to configure the remote syslog or log server to which to send CCKM log data using TCP, TLS, or UDP protocol as the transport protocol. If you use the TLS protocol, then you are required to upload the syslog server certificate to CCKM for the TLS connection.

The **Syslog** tab also allows you to delete your syslog server configuration so that log data are no longer sent to the server.

Prior to configuring the setting for a remote syslog server, ensure that you have installed and configured the syslog server including configuring the setting for the port number the transport protocol will use to connect to CCKM. This port number configuration must match the port configuration you set in the **Syslog** tab of the **Settings** page.

Note

Support for both Syslog and Splunk as a remote syslog server is provided in CCKM. However, the use of a Splunk cloud server as a remote syslog server is currently not supported in CCKM.

Configure Remote Syslog Server

To configure a remote syslog server to which to send CCKM log data:

Note

The facility name of "LOCAL1" for the syslog server displays in the **Facility** box. This default value is not available for modification.

1. In the **Settings** page, select the **Syslog** tab. The **Syslog** dialog box displays.
2. In the **Hostname** box, enter the hostname or IP address of the syslog server.
3. In the **Port** box, enter the port number the transport protocol uses to connect to the syslog server. Enter a value between 1 and 65535. The default value is 514.
4. In the **Protocol** drop-down menu, select **TCP**, **TLS**, or **UDP** for the transport protocol to use when sending the log data to the syslog server. The default value is **UDP**. If you select **TCP**, proceed to Step 6. If you select **TLS**, proceed to the next step. Otherwise, proceed to Step 7.
5. In the **Certificate** box, select **Choose File** and then select the syslog server certificate to upload to CCKM.
6. Click **Test Connection** to test the connection between CCKM and the remote syslog server. This button is only available for use when either **TCP** or **TLS** is the selected transport protocol.
7. In the **Log Format** drop-down menu, select **CEF** (Common Event Format), **Plain Text**, or **RFC5424** for the format of the log message to use when sending the log data. The default value is **RFC5424**.
8. (Optional) In the **Description** box, enter a description of the remote syslog server.
9. Click **Save**.

Delete Remote Syslog Server Configuration

To delete the configuration of a remote syslog server:

1. In the **Settings** page, select the **Syslog** tab. The **Syslog** dialog box displays.
2. Click **Delete**. The **Delete Syslog** dialog box displays.
A warning message displays indicating that this action will delete the syslog settings from CCKM. The message also indicates to type the confirmation phrase (I wish to delete the syslog settings) in the text box if you still wish to delete the syslog settings.
3. Enter or copy/paste the confirmation phrase in the text box.
4. Click **Delete**.

Adding Google Cloud Service Account to CCKM

Use the **Service Account** tab from the **Settings** page to add your Google Cloud service account to CCKM and create a password for it. Your service account must already be created in your Google Cloud Platform console before you proceed with adding your service account to CCKM.

After submitting the request to add your Google service account to CCKM in the **Add Service Account** dialog box, CCKM will call the Google Cloud API to add a key pair to the service account. After the key pair is added, CCKM downloads the private key and saves it in the database as an encrypted key. CCKM also saves your password hash in the database.

Later, you can use the service account email and password to authenticate to CCKM REST API.

The following columns display on the **Service Account** tab:

- Service Account Email
- Key ID
- Key Creation Date
- Key Expiration Date
- Actions

Add Service Account

To add a Google service account to CCKM:

1. In the **Settings** page, select the **Service Account** tab. The **Service Account** dialog box displays.
2. Click **Add Service Account**. The **Add Service Account** dialog box displays.
3. In the **Email** box, enter the email of your Google service account.
4. In the **Password** box, enter your password for the service account. The password must be at least 8 characters long and contain one upper case letter, one lower case letter, one digit, and one special character from a limited set of special characters "!@#\$\$%^&*".
5. In the **Confirm Password** box, enter your password for the service account again to confirm the password.
6. Click **Submit**.

Update Service Account

You have the option to change the service account password and change the key pair for service account from the **Service Account** tab. To change the key pair, select to rotate the key. When Google Cloud rotates the key pair, the current key pair will be deleted, and a new key pair will be created. CCKM then encrypts the new private key and your password hash and saves this data in the CCKM database.

To update the information for Google Cloud service account:

1. In the **Settings** page, select the **Service Account** tab. The **Service Account** dialog box displays.
2. Click **Add Service Account**. The **Add Service Account** dialog box displays.
3. In the **Email** box, enter the email of your Google Cloudservice account.
4. In the **Password** box, enter your password for the service account. The password must be at least 8 characters long and contain one upper case letter, one lower case letter, one digit, and one special character from a limited set of special characters "!@#\$%^&*".
5. In the **Confirm Password** box, enter your password for the service account again to confirm the password.
6. Click **Submit**.

Delete Service Account

To delete a Google Cloud service account:

1. In the **Settings** page, select the **Service Account** tab. The **Service Account** dialog box displays.
2. Select **Delete** from the **Actions** drop-down menu. The **Confirm Deletion of Service Account** dialog box is displayed.
3. Click **Confirm**.

About

Use the **About** tab to view the build number, version number, patch number (if applicable), and build number of the CCKM you are running.

Chapter 16: CCKM for IBM Key Management

Overview	182
Types of Encryption Keys Supported within IBM HPCS and Key Protect	182
IBM Cloud Identity and Access Management	183
Action Permissions Mapping for CCKM and IBM HPCS/Key Protect	184
CCKM's Interaction with IBM HPCS and Key Protect	185
Prerequisites on IBM HPCS and Key Protect	185
Creating an IBM Credentials File in a JSON Format	190
Access CCKM for IBM	190
IBM CCKM User Portal	190
Home	191
Keys	191
Reports	205
Schedules	207
Logs	210
Key Sources	210
Settings	212

Overview

CCKM provides support for the following IBM Cloud key management services:

- IBM Cloud Hyper Protect Crypto Services (IBM HPCS)
- IBM Key Protect

Note: This documentation assumes that you are familiar with using IBM HPCS, IBM Key Protect, and IBM Cloud Identity and Access Management (IAM). For details about these IBM technologies, refer to the IBM Cloud documentation at <https://cloud.ibm.com/docs>.

Types of Encryption Keys Supported within IBM HPCS and Key Protect

The following encryption keys are employed and managed within IBM HPCS and Key Protect that you can also manage from CCKM:

- Standard key—This is a symmetric key used to directly encrypt and decrypt secrets, such as passwords or encryption keys.
- Root key—This is a symmetric key-wrapping key used to protect other cryptographic keys that use envelope encryption.

Both an IBM native key and a BYOK (non-native) key can either be a standard or a root key.

IBM Cloud Identity and Access Management

The IBM Cloud key management services of IBM HPCS and Key Protect for IBM Cloud provide a centralized access control system using IBM IAM to assist you in managing users, service IDs, and access for your encryption keys within your organization. Both of these key management services employ IAM roles in the management of your keys. These roles have different access permissions for the key management service. For detailed information about IBM Cloud IAM, refer to topics covering “IBM Cloud Identity and Access Management” within the IBM Cloud documentation.

As an account administrator in IBM Cloud, the actions you can perform include the following:

- assign and manage access for users
- create resource groups
- create access groups
- create service instances

To provide access for users or access groups, or users and access groups, or service IDs in IBM HPCS and Key Protect, you can create policies that define the resource(s) the users or access groups, or users and access groups, or service IDs are permitted to access and a role or roles that define the type of access permissions (actions allowed) on the given resources.

The following are the two types of roles supported within IBM IAM:

- Platform management role—used to grant permissions at the account level, such as creating or deleting instances in your IBM Cloud account. To access your instances for HPCS or Key Protect through CCKM, ensure to set the platform management role of Viewer (at the least). The supported roles are Administrator, Operator, Editor, and Viewer.
- Service access role—used to define the actions a user or service can perform on an IBM HPCS or Key Protect instance, such as performing API calls. The following table provides the supported service access roles along with the IBM HPCS or Key Protect access permissions allowed for each:

Service Access Role	Access Permissions (Allowed Actions) in IBM Cloud	Notes
Reader	• View keys • Wrap keys • Unwrap keys	CCKM does not support wrap and unwrap keys.
Writer	• Create keys • List keys • Retrieve keys • Rotate keys • Wrap keys • Unwrap keys • Set keys for deletion • Unset keys for deletion • Create import tokens • Retrieve import tokens	CCKM does not support the following: • Wrap keys • Unwrap keys

Service Access Role	Access Permissions (Allowed Actions) in IBM Cloud	Notes
Manager	- All actions that a reader or a writer is allowed to perform - Update keys - Enable keys - Disable keys - Delete keys - Restore keys	

For detailed information about these roles, refer to the topics covering “Managing user access” and “Roles and Permissions” within IBM Cloud documentation.

Action Permissions Mapping for CCKM and IBM HPCS/Key Protect

A mapping of each of the supported CCKM actions (you can perform in the IBM Cloud) to an IBM HPCS or Key Protect action along with the required Service access role(s) to perform the action is provided in the following table:

CCKM Action	IBM HPCS or Key Protect Actions Required	Required Service Access Role
Synchronize	List keys Retrieve keys	Reader/Writer/Manager
View keys	List keys Retrieve keys	Reader/Writer/Manager
Create native key	Create keys Retrieve keys	Writer/Manager
Upload standard key	Create keys Retrieve keys	Writer/Manager
Upload root key	Create keys Retrieve keys Create import tokens Retrieve import tokens	Writer/Manager
Update key	Retrieve keys Set key policies List key policies	Manager
Enable key	Enable key	Manager
Disable key	Disable key	Manager
Schedule Delete key	Set keys for deletion	Writer/Manager
Delete key	Retrieve keys Delete keys	Writer/Manager
Cancel Delete key	Unset Keys for deletion	Writer/Manager

CCKM Action	IBM HPCS or Key Protect Actions Required	Required Service Access Role
Restore key	Retrieve keys Restore keys	Writer/Manager
Rotate key	Rotate keys Retrieve keys	Writer/Manager
Export Keys	There is no equivalent action within IBM HPCS or Key Protect for this CCKM action.	N/A

CCKM's Interaction with IBM HPCS and Key Protect

CCKM uses IBM Cloud credentials to work with the IBM Cloud APIs. To log into the IBM key management service of CCKM, you are required to have an IBM username and IBM Cloud API key or IBM service ID and IBM service ID API Key. To obtain an IBM Cloud API key or service ID API key, generate it in the IBM portal. For information about generating an IBM Cloud API key or IBM service ID API key, see section ["Prerequisites on IBM HPCS and Key Protect" below](#). You can create a IBM credentials file in a JSON format to use when logging into the IBM key management service of CCKM. For more information, see section ["Creating an IBM Credentials File in a JSON Format " on page 190](#).

You can access IBM HPCS or Key Protect instances (depending on which IBM Cloud key management service you are using) by setting access policies on a user or an access group with permissions to the given key management service.

The following access policies are allowed for using CCKM:

- setting a service access policy for a single IBM key
- setting a service access policy for a key management service (HPCS or Key Protect) instance
- setting a service access policy for a resource group containing key management service (HPCS or Key Protect) instances

In order to manage IBM keys in CCKM, a user or service ID must have **Viewer** platform management permission on every key management service (HPCS or Key Protect) instance that contains the keys.

For each IBM key management service (HPCS or Key Protect) instance, CCKM retrieves the following:

- Platform management role the user has on the instance (Administrator, Operator, Editor, or Viewer). Note that the Administrator role should only be assigned to the administrator.
- Service access role the user has on the instance (Reader, Writer, or Manager)

Prerequisites on IBM HPCS and Key Protect

In this section, it is assumed you will use access groups and resource groups when configuring the IBM key management service of IBM HPCS or Key Protect in CCKM.

Note

In this section, it is assumed you are familiar with creating a user and service ID in the IBM portal. Refer to the IBM Cloud documentation for information on how to add a user and a service ID in the IBM portal.

Note

If you plan to configure the IBM key management services of IBM HPCS or Key Protect using user(s) or service ID (without adding them first to an access group), you are required to perform steps 1, 2 (if you are using HPCS), and 3 in this section. However, the remaining steps in this section do not apply. Instead, for step 4, create a user or service ID. Then for step 5, assign an access policy to the user or service ID. The actual step you take in steps 4 and 5 depends on whether you are using a user or service ID. For more information about assigning an access policy to a user or service ID, refer to the IBM Cloud documentation.

Prior to configuring and accessing the IBM key management service of IBM HPCS or Key Protect in CCKM, do the following:

Note

Refer to the sections below for more information about each of these steps.

1. Create an instance of IBM HPCS or Key Protect (depending on which service you are using) in the IBM Cloud by using the IBM Cloud console or the IBM Cloud CLI. For more information, see ["Create an Instance of IBM HPCS or Key Protect in IBM Portal" below](#).
2. (**Applicable to HPCS only**) Initialize your HPCS service instance in the IBM Cloud. For more information, see ["Initialize your HPCS Service Instance" below](#).
3. Generate an API key for a user or service ID in the IBM portal. To generate an API key for a user in the IBM portal, see ["Generate a User API Key in IBM Portal" on the next page](#). To generate an API key for a service ID in the IBM portal, see ["Generate Service ID API Key in IBM Portal" on the next page](#).
4. Create an access group. For more information, see ["Create Access Group" on the next page](#).
5. Add users or service ID to your access group. To add user to your access group, see ["Add User\(s\) to Access Group" on page 188](#). To add a service ID to your access group, see ["Add Service ID\(s\) to Access Group" on page 188](#).
6. Assign an access policy to the access group. For more information, see ["Assign Access to your Access Groups \(for Users and Service IDs\)" on page 188](#).
7. Assign additional access for the service ID. For more information, see ["Assign Additional Access Policy to Service ID" on page 189](#).

Create an Instance of IBM HPCS or Key Protect in IBM Portal

For information on how to create an instance in IBM HPCS or Key Protect, refer to topics related to “provisioning service instance” as it relates to these services in the IBM Cloud documentation.

Initialize your HPCS Service Instance

(**Applicable to HPCS only**) For information on how to initialize your HPCS service instance in the IBM Cloud, refer to the topic of “Initializing your service instance” for HPCS in the IBM Cloud documentation.

Generate a User API Key in IBM Portal

To generate an API key for the user in the IBM portal:

Note

Be sure to save the generated API key to a file as you will not be able to view or retrieve it later from the IBM portal.

1. From the menu bar, click **Manage > Access (IAM)**.
2. Select **IBM Cloud API Keys**.
3. Click **Create API key**.
4. Enter a name and description for the API key.
5. Click **Create**.
6. Click **Copy** to copy the API key or click **Download** to download it.
7. Save the API key.

Generate Service ID API Key in IBM Portal

To generate an API key for the service ID in the IBM portal:

Note

Be sure to save the generated API key to a file as you will not be able to view or retrieve it later from the IBM portal.

1. From the menu bar, click **Manage > Access (IAM)**.
2. Select **Service IDs**.
3. Click on the name of the service ID for which you want to generate the API Key.
4. Select **API keys**.
5. Click **Create**.
6. Enter a name and description for the API key.
7. Click **Create**.
8. Click **Copy** to copy the API key or click **Download** to download it.
9. Save the API key.

Create Access Group

To create an access group, you need to first set up the group and then add users or service IDs (or users and service IDs) to your access group.

To create an access group:

1. From the menu bar, click **Manage > Access (IAM)**, and select **Access Groups**.
2. Click **Create**.
3. Enter a name and description (optional) for your group
4. Click **Create**.

Add User(s) to Access Group

To add users to your access group:

1. Select the name of the access group to which to add users.
2. Click **Add users**.
3. Select the user to add from the list, and then click **Add to group**.

Add Service ID(s) to Access Group

To add a service ID to your access group:

1. Select the name of the access group to which to add service ID.
2. Select **Service IDs**.
3. Click **Add Service ID**.
4. Select the service ID to add from the list, and then click **Add to group**.

Assign Access to your Access Groups (for Users and Service IDs)

After you create your access group and add users or service IDs to it (or add users and service IDs to it), you can assign an access policy to the group. Note that any policy that you set for the access group is applicable to all entities within the group.

Be sure to review the sections in ["IBM Cloud Identity and Access Management" on page 183](#) and ["Action Permissions Mapping for CCKM and IBM HPCS/Key Protect" on page 184](#) before assigning an access policy to your access group(s).

To assign an access policy to your access group:

1. From the menu bar, click **Manage > Access (IAM)**, and select **Access Groups**.
2. From the row for the group that you want to assign access, select the **Actions List** of actions icon menu, and click **Assign access**.
3. Select the name of the access group that you want to assign access.
4. Select the **Access policies** tab, and then click **Assign access**.
5. From **Assign access group additional access**, select **IAM services**.
6. From **Which services do you want to assign access to?**, select **Hyper Protect Crypto Services** or **Key Protect** (depending on which service you will use).
7. Under **How do you want to scope the access?**, select **All resources**.
8. Under **Platform access**, select one or more of the following options depending on the permissions you are granting to this access group:
 - **Administrator**
 - **Editor**
 - **Operator**
 - **Viewer**

9. Under **Service access**, select one or more of the following options depending on the permissions you are granting to this access group:
 - **Manager**
 - **Reader**
 - **Writer**
10. Click **Add > Assign**.

Assign Additional Access Policy to Service ID

To assign additional access policy to your service ID:

1. From the menu bar, click **Manage > Access (IAM)**, and select **Service IDs**.
2. From the row for the Service ID that you want to assign access, select the **Actions List** from the actions icon menu, and click **Assign access**.
3. From **Assign service ID additional access**, select the **Account Management** tab.
4. From **Which services do you want to assign access to**, select **IAM Identity Service**.
5. From **How do you want to scope the access**, select **All resources**.
6. From **Platform access**, select one or more of the following options depending on the permissions you are granting to the service ID:
 - **Operator**
 - **Editor**
 - **Administrator**
7. Click **Add**.
8. From **Which services do you want to assign access to**, select **user management**.
9. From **How do you want to scope the access**, select **All resources**.
10. From **Platform access**, select one or more of the following options depending on the permissions you are granting to the service ID:
 - **Viewer**
 - **Editor**
 - **Administrator**
11. Click **Add**.
12. From **Which services do you want to assign access to**, select **IAM Access Groups Service**.
13. From **How do you want to scope the access**, select **All resources**.
14. From **Platform access**, select one or more of the following options depending on the permissions you are granting to the service ID:
 - **Viewer**
 - **Operator**
 - **Editor**
 - **Administrator**
15. Click **Add > Assign**.

Creating an IBM Credentials File in a JSON Format

When prompted for your IBM login credentials on the IBM login page within CCKM, you can either enter your IBM Username and API Key or IBM service ID and API Key. You can also upload an IBM credentials file. The IBM credentials file should be in a .json format (can be written in Notepad and saved for upload).

The following is sample .json file for username and API key (add your username and API key to the file):

```
{
  "ibm_username": "ibmusernamehere",
  "ibm_apikey": "XQq81eP78EHSG9EZbXwgAYJUfRMpC8wNiNkqiFudkZeT"
}
```

The following is sample json file for service ID and API key (add your service ID and API key to the file):

```
{
  "ibm_serviceid": "ServiceId-number-here",
  "ibm_apikey": "Zr65BVx4yueysm2uxpA8osoNpqSh4GNkj_nOphT29cyX"
}
```

Access CCKM for IBM

For details about accessing CCKM as a CCKM user for the CCKM service for IBM Key Management, see [Chapter 3: "About CCKM Admin and User Portals" on page 27](#). This chapter includes information on the ways in which to access the CCKM service for Key Management.

IBM CCKM User Portal

The CCKM User Portal for IBM contains the following menu options in the left-hand navigation bar:

- **Home:** **Home** page displays key operation and count metrics.
- **Keys:** **Keys** page displays key management overview and provides the upload, create, and synchronize functionality, and the manual rotation, auto-rotation, delete, restore, and update key operations available in CCKM.
- **Reports:** **All Reports** overview page links to detailed individual reports.
- **Schedule:** In **Schedule**, you can schedule automatic key rotation and key synchronization.
- **Logs:** **Logs** page lists individual logs that can be searched, sorted, and viewed.
- **Key Sources:** In **Key Sources**, you can generate keys in CCKM to upload to IBM. CCKM provides support for the use of CipherTrust Manager and DSM as key sources to generate, store, and retrieve the encryption keys that CCKM uses and manages.

Note: CCKM does not support the concurrent use of CipherTrust Manager and DSM as key sources.

- **Settings:** The **Settings** page allows you to add the email addresses of the recipients who are to receive email notifications and configure the settings for email notifications and syslog servers. From this page, you can also enable CCKM reporting for IBM keys using IBM Cloud Activity Tracker and LogDNA and view the release number of the CCKM running.

To display the context of which Key Management service you are currently logged into within CCKM, the icon associated with the Key Management service displays at the top of the left-hand navigation bar.

The arrow button at the bottom of the navigation bar allows you to expand the bar to view the names of the menu options and collapse it to view only the icons associated with the menu options. Click the arrow button to either expand or collapse the navigation bar.

On the top-right side of the CCKM portal for IBM Cloud, the following options are available:

- **Azure Cloud Service Context Switcher:** This context switcher allows you to login into another Azure cloud service different from the current Azure cloud service into which you are currently logged. If you select the Azure cloud in which you are currently logged, the Multi-account Login/Logout window for the Azure account(s) displays. For more information about the Multi-account Login/Logout window, refer to ["Support for Multiple accounts or Multiple Users per Cloud Service in CCKM UI" on page 32.](#)
- **AWS Login:** If you are not already logged into AWS, clicking on the AWS Login icon brings you to the AWS Password Login page where you can enter your AWS credentials to access the CCKM AWS cloud service (from the current cloud service in which you are currently logged). If you are already logged into AWS, clicking on the AWS Login icon brings you to the Multi-account Login/Logout window for the AWS account(s). For more information about the Multi-account Login/Logout window, refer to ["Support for Multiple accounts or Multiple Users per Cloud Service in CCKM UI" on page 32.](#)
- **Google Cloud Service Context Switcher:** This context switcher allows you to login into another Google Cloud organization different from the current Google Cloud organization into which you are currently logged. If you select the Google Cloud in which you are currently logged, the **Multi-account Login/Logout** window for the Google account(s) displays. For more information about the **Multi-account Login/Logout** window, see ["Support for Multiple accounts or Multiple Users per Cloud Service in CCKM UI" on page 32.](#)
- **Salesforce Cloud Service Context Switcher:** This context switcher allows you to login into another Salesforce cloud service different from the current Salesforce cloud service into which you are currently logged. This is Salesforce, Salesforce Government, or Salesforce Sandbox. If you select the Salesforce cloud in which you are currently logged, the Multi-account Login/Logout window for the Salesforce account(s) displays. For more information about the Multi-account Login/Logout window, refer to ["Support for Multiple accounts or Multiple Users per Cloud Service in CCKM UI" on page 32.](#)
- **Logout:** Logout from CCKM.

Home

The **Home** page provides a dashboard to display key operation and count metrics.

Keys

The **IBM Cloud Keys** page allows IBM Cloud administrators to view all of the keys and manage them within the boundary of granted permissions. Only the keys to which you have permissions to access display in **Keys** page.

At the top right of the **Keys** page, the following buttons are available:

- **Export Keys:** Allows you to export the contents of the Keys list into a report in a CSV format.
- **New Key:** Allows you to upload an external key (BYOK) or create a native key. For information on how to upload an external key or create a native key, see section ["Create a Key" on page 194.](#)
- **Synchronize:** Allows you to download any keys that were created in IBM HPCS or Key Protect, outside of the CCKM portal, into CCKM. For information on how to synchronize your keys, see ["Synchronize Keys" on page 204.](#)

In this section, create, delete, update, rotate, synchronize, exports keys are described.

A **Search** box is available at the top the **IBM Cloud Keys** page allowing for a search of a specific key by entering any one of the following parameters:

- Name: The name of the key.
- Key ID: The globally unique identifier for the key.
- Region: The IBM Region to which the key is uploaded.
- Key Protect/HPCS Name: The name of the HPCS or Key Protect instance.
- Creation Date: Indicates the date on which the key was created.
- Type: Indicates whether the key of a Standard or Root Key type.
- Key State: The state of the key. Valid values are:
 - Pre-activation
 - Enabled
 - Disabled
 - Deactivated
 - Destroyed

Note: The key states of Pre-activation and Destroyed transition to other states. For this reason, you may not see keys with these states displayed in the CCKM UI.

- Key Material Origin: Specifies the origin of the key material.
- Rotation Status: Available options are AUTO ON and AUTO OFF.

The **Advanced** tab allows you to filter your search on each of the columns displayed on the IBM Cloud Keys page with the exception of the **Actions** column:

- Name
- Key ID
- Region
- Service Name
- Service ID
- Creation Date.
- Type
- Key State
- Dual Auth Delete State
- Key Expiration Date
- Key Material
- Rotation Status

- Service

Each of these columns are described in more detail below in this section.

To select to filter based on a specific column from the **IBM Cloud Keys** page, click **Advanced**. The **Filters** section displays. From the column filter drop-down menu, select the name of the column on which to filter your search. For example, select **Region**. In the **Search** box, enter the value on which to search (for example, Key Protect Name) and click **Add**. For the **Region**, **Type**, **Key State**, **Dual Auth Delete State**, **Rotation Status**, and **Service** columns, a drop-down menu is available from which to select a value for the search. Click the down arrow, select a value from the available options, and then click **Add**. For the **Creation Date** and **Key Expiration Date**, select a start and end date for the search and then click **Add**. The specified search filter is then added to **Active Filters**. The results of the search displays in the **IBM Cloud Keys** table. You can narrow your search by selecting more columns to add to the filter. To clear the filtered results, from **Active Filters**, click on the “X” (or the **Delete** button) for each of the named filters.

The following columns display on the **IBM Cloud Keys** page:

- Name: The name of the key.
- Region: The IBM Region to which the key is uploaded.
- Service Name: The ID of the HPCS or Key Protect instance in which the key stored.
- Service: HPCS or Key Protect service.
- Creation Date: Indicates the date on which the key was created.
- Type: Indicates whether the key is a Root or a Standard key.
- Key State: The state of the key. The valid values are:
 - Pre-activation
 - Enabled
 - Disabled
 - Deactivated
 - Destroyed

- **Dual Auth Delete State:** The state of the dual authorization. The valid values are:
 - Disabled
 - Enabled
 - Scheduled
 - Expired
 - Canceled
 - Deleted
- **Key Material Origin:**
 - If the key was uploaded from CCKM as a BYOK key, then the value is INTERNAL(<source_key_name>).
 - If the key was not uploaded from CCKM as a BYOK key, then the value is EXTERNAL.
 - If the key material was created within IBM HPCS, then the value is HPCS.
 - If the key material was created within IBM Key Protect, then the value is Key Protect.
- **Rotation Status:** Indicates whether the key is in an active rotation schedule or if it has been rotated in the past.
 - Auto—if the autorotation is currently enabled.
 - blank—if the autorotation is disabled.
- **Version Count:** Reflects the number of versions the key currently has. To view information about all of the key versions, click on the number of the version count. The **Key Versions** dialog box displays. In this dialog box, the key name, version ID, and date on which the key version was created (Created On) displays. For more information, see ["View All Key Versions" on page 205](#).

Note

If you have the manager role, you have the permissions of writer and viewer.

- **Actions:** Allows you to select any of the following actions on a given key:
 - Enable (Manager permission required)
 - Disable (Manager permission required)
 - Rotate (Writer permission required)
 - Schedule Delete (Writer or Manager permission required)
 - Delete (Manager permission required)
 - Cancel Delete (Manager permission required)
 - Restore (Writer/Manager permissions required)
 - Update (Manager permission required)

Note

Writer has permissions of writer and viewer.

Create a Key

You have two options to create a new key in an IBM HPCS or Key Protect instance:

- Create a native key
- Upload a BYOK

Create a Native Key

You can create a native key in either IBM HPCS or Key Protect using CCKM. In the process of creating a native key in either of these supported IBM key management services, key material from IBM HPCS or Key Protect (depending on which key management service you are using) along with key metadata from CCKM are used. Once created, the key displays as either an HPCS or Key Protect key (depending on which key management service you are using) under the Key Material Origin column within the Keys > All Keys list page in CCKM.

Note

The access permission of a Writer or a Manager role is required for creating native keys.

For more information, see the following sections:

- ["Create a Native Key \(IBM HPCS\)" below](#)
- ["Create a Native Key \(IBM Key Protect\)" below](#)

Create a Native Key (IBM HPCS)

Note

The access permission of a Writer or a Manager role is required for creating native keys.

To create a native key in an IBM HPCS instance:

1. In the CCKM portal, in the left navigation bar, select **Keys**.
2. On the **All Keys** list page, select the **New Key** button and then **Create**. The **Create Native Key** dialog box displays.
3. In the **Key Name** box, enter the name of the IBM native key to create.
4. From **IBM Service**, select **HPCS**.
5. From the **Key Protect/HPCS** box, select the IBM HPCS instance to which you will add the new key.
6. For **Key Type**, select whether this key is a **Standard Key** or a **Root Key**.
7. (Optional) Enter the expiration date of the key material in the **Key Expiration Date** box in the format MM/DD/YY or select a day from the calendar button at the right of the box.
8. (Optional) In the **Description** box, enter a description for the key you are uploading.
9. (Optional) In the **Tags** box, enter the tag name and then click the **+** button.
10. Click **Create**.
(Reset clears the page before it is created, if necessary.)
The new key is displayed in the list.

Create a Native Key (IBM Key Protect)

Note

The access permission of a Writer or a Manager role is required for creating native keys.

To create a native key in an IBM Key Protect instance:

1. In the CCKM portal, in the left navigation bar, select **Keys**.
2. On the **All Keys** list page, select the **New Key** button and then **Create**. The **Create Native Key** dialog box displays.

3. In the **Key Name** box, enter the name of the IBM native key to create.
4. From **IBM Service**, select **Key Protect**.
5. From the **Key Protect/HPCS** box, select the IBM Key Protect instance to which you will add the new key.
6. For **Key Type**, select whether this key is a **Standard Key** or a **Root Key**.
7. (Optional) Enter the expiration date of the key material in the **Key Expiration Date** box in the format MM/DD/YY or select a day from the calendar button at the right of the box.
8. (Optional) In the **Description** box, enter a description for the key you are uploading.
9. (Optional) In the **Tags** box, enter the tag name and then click the **+** button.
10. Click **Create**.
(Reset clears the page before it is created, if necessary.)
The new key is displayed in the list.

Upload your Own Key (BYOK)

Upload the AES 256 keys created from the **Key Sources** page of CCKM to an IBM key management service instance (HPCS or IBM Key Protect instance) you are using. These "BYOK" keys are the keys you generated from the key source you are using (CipherTrust Manager or DSM).

For more information, see the following sections:

- ["Upload Your Own Key \(BYOK\) \(IBM HPCS\)" below](#)
- ["Upload Your Own Key \(BYOK\) \(IBM Key Protect\)" on the next page](#)

Upload Your Own Key (BYOK) (IBM HPCS)

Note

The access permission of a Writer or Manager role is required for uploading a BYOK key.

To upload a BYOK key from CCKM to an IBM HPCS instance:

1. In the CCKM portal, in the left navigation bar, select **Keys**.
2. On the **All Keys** list page, select the **New** button and then **Upload**. The **Upload a Key** dialog box displays.
3. In the **Key Name** box, enter the name of the IBM key to upload.
4. From **IBM Service**, select **HPCS**.
5. From the **Key Protect/HPCS** box, select the HPCS instance to which you will upload the new key.
6. For **Key Type**, select whether this key is a **Standard Key** or a **Root Key**.
7. From **Key Provider** box, select **CipherTrust Manager** or **DSM** depending on the key source you are using for the key.
8. From **Source Key** box, select the source key to use for the BYOK key. The keys available in the drop-down menu are the keys generated from CipherTrust Manager or DSM depending on the key source you are using.
9. (Optional) Enter the expiration date of the key material in the **Key Expiration Date** box in the format MM/DD/YY or select a day from the calendar button at the right of the box.
10. (Optional) In the **Description** box, enter a description for the key you are uploading.

11. (Optional) In the **Tags** box, enter the tag name and then click the **+** button.
12. Click **Upload to IBM**.
The uploaded key is displayed in the list.

Upload Your Own Key (BYOK) (IBM Key Protect)

Note

The access permission of a Writer or Manager role is required for uploading a BYOK key.

To upload a BYOK key from CCKM to an IBM Key Protect instance:

1. In the CCKM portal, in the left navigation bar, select **Keys**.
2. On the **All Keys** list page, select the **New** button and then **Upload**. The **Upload a Key** dialog box displays.
3. In the **Key Name** box, enter the name of the IBM key to upload.
4. From **IBM Service**, select **Key Protect**.
5. From the **Key Protect/HPCS** box, select the Key Protect instance to which you will upload the new key.
6. For **Key Type**, select whether this key is a **Standard Key** or a **Root Key**.
7. From **Key Provider** box, select **CipherTrust Manager** or **DSM** depending on the key source you are using for the key.
8. From **Source Key** box, select the source key to use for the BYOK key. The keys available in the drop-down menu are the keys generated from CipherTrust Manager or DSM depending on the key source you are using.
9. (Optional) Enter the expiration date of the key material in the **Key Expiration Date** box in the format MM/DD/YY or select a day from the calendar button at the right of the box.
10. (Optional) In the **Description** box, enter a description for the key you are uploading.
11. (Optional) In the **Tags** box, enter the tag name and then click the **+** button.
12. Click **Upload to IBM**.
The uploaded key is displayed in the list.

Delete a Key

You have the following options to delete a key from IBM HPCS or Key Protect using CCKM:

- ["Delete a Key" below](#)
- ["Delete a Key Using Dual Authorization" on page 199](#)

Delete a Key

From the CCKM **Keys** page, you can delete a key from either IBM HPCS or Key Protect. After deletion, the action of **Restore** is available within the **Actions** column for certain keys. For more information, see ["Restore a Key" on page 201](#).

Note

The access permission of a Manager role is required for deleting a key.

To delete a key:

1. In the CCKM portal, in the left navigation bar, select **Keys**. The **Keys** page displays.
2. Find the row that holds the key you wish to delete and click **Delete** from the **Actions** column. The **Delete Key** dialog box displays.
A warning message displays indicating that this action will delete the named key from the named instance. The dialog box also indicates to type the supplied confirmation phrase in the text box if you still wish to delete the key and provides other pertinent information.
3. Enter or copy/paste the confirmation phrase in the text box.
4. Click **Delete**.

Deleting Keys Using Dual Authorization

To prevent accidental or malicious deletion of root or standard keys in IBM HPCS or Key Protect, IBM provides the ability to use a dual authorization process to delete these keys using a policy. CCKM provides support for the key deletions using dual authorization. When the dual authorization delete policy is enabled, thereafter a key covered under this policy requires authorization from two users to delete it. One user provides the authorization to delete the key by scheduling to delete the key. In CCKM, this user uses the **Schedule Delete** button under the **Actions** column available on the **Keys** page to schedule the key deletion. The schedule is valid for 7 days. During this period, the other authorized user can delete the key using the **Delete** button from the **Actions** column. After the key is deleted, it is placed in the **Destroyed** state as displayed in the **Dual Auth Delete State** column on the **Keys** page. If the key is *not* scheduled for deletion after 7 days, it is placed in the **Expired** state. To schedule to delete a key after the key is in this state, you must schedule to delete a key once again.

The policy for dual authorization deletion can be enabled at a key level or at an instance level. From the CCKM, you can enable the policy at a key level using the **Enable Dual Authorization Delete** toggle within the **Update Key** dialog box available on the **Keys** page. And once this policy is enabled at the key level, you cannot disable it. However, to enable dual authorization deletion at the instance level, you must do so from the IBM Cloud portal. *After* the policy is enabled at the instance level, the policy applies only to the new keys that are created on the instance.

The state of **Enabled** displays in the **Dual Auth Delete State** column on the **Keys** page for keys that have the policy of dual authorization deletion enabled.

For more information about enabling the dual authorization for IBM HPCS or Key Protect in general and at the instance level, refer to the appropriate online IBM Cloud documentation. For more information about enabling dual authorization at a key level from CCKM, see ["Update Key for Dual Authorization of Key Deletion" on page 202](#).

In IBM, you also have the option to cancel the scheduled key deletion. In CCKM, you can cancel the scheduled key deletion using the **Cancel Delete** button from the **Actions** column. To delete a key after this cancellation, you must again go through the dual authorization process starting with schedule delete.

For more information, see the following sections:

- ["Schedule to Delete a Key Using Dual Authorization" on the next page](#)
- ["Delete a Key Using Dual Authorization" on the next page](#)
- ["Cancel Schedule Delete Using Dual Authorization " on page 200](#)

Schedule to Delete a Key Using Dual Authorization

From the **Keys** page, you can schedule to delete a key from IBM HPCS or Key Protect using dual authorization. *Prior* to scheduling to delete a key, you must enable the policy for dual authorization deletion at the key level or instance level. Once enabled, the state of **Enabled** displays in the **Dual Auth Delete State** column and the action of **Schedule Delete Key** is available for selection within the **Actions** column on the **Keys** page.

After the key is scheduled for deletion, the state of **Scheduled** displays in the **Dual Auth Delete State** column and the actions of **Delete** and **Cancel Delete** are available within the **Actions** column for the key.

The schedule is valid for 7 days. During this period, the other authorized user can delete the key using the **Delete** button.

Note

The access permission of a Writer or a Manager role is required for scheduling to delete a key using dual authorization.

To schedule to delete a key using dual authorization:

1. In the CCKM portal, in the left navigation bar, select **Keys**. The **Keys** page displays.
2. Find the row that holds the key you wish to schedule to delete and click **Schedule Delete** from the **Actions** column. The **Schedule Delete Key** dialog box displays.
A warning message displays indicating that this action will schedule delete the named key from the named instance. The dialog box also indicates to type the supplied confirmation phrase in the text box if you still wish to schedule delete the key and provides other pertinent information.
3. Enter or copy/paste the confirmation phrase in the text box.
4. Click **Schedule Delete** to confirm.

Delete a Key Using Dual Authorization

From the **Keys** page, you can delete a key from IBM HPCS or Key Protect using dual authorization. After a key is deleted using dual authorization, the action of **Restore** is available within the **Actions** column for certain keys. For more information, see ["Restore a Key" on page 201](#).

Note

The access permission of a Manager role is required for delete a key using dual authorization.

To delete a key using the dual authorization:

1. In the CCKM portal, in the left navigation bar, select **Keys**. The **Keys** page displays.
2. Find the row that holds the key you wish to delete and click **Delete** from the **Actions** column. The **Delete Key** dialog box displays.
A warning message displays indicating that this action will delete the named key from the named instance. The dialog box also indicates to type the supplied confirmation phrase in the text box if you still wish to delete the key and provides other pertinent information.
3. Enter or copy/paste the confirmation phrase in the text box.
4. Click **Delete**.

Cancel Schedule Delete Using Dual Authorization

From the **Keys** page, you can cancel a scheduled key deletion using dual authorization. *After* the scheduled key deletion is canceled successfully, the state of **Canceled** displays in the **Dual Auth Delete State** column, and the action of **Schedule Delete** is once again available from the **Actions** column for the given key.

Note

The access permission of a Manager role is required to cancel the scheduled deletion of a key using dual authorization.

To cancel the scheduled key deletion using dual authorization:

1. In the CCKM portal, in the left navigation bar, select **Keys**. The **Keys** page displays.
2. Find the row that holds the key you wish to cancel the scheduled key deletion and click **Cancel Delete** from the **Actions** column. The **Cancel Delete Key** dialog box displays.
A warning message displays indicating that this action will cancel the scheduled key deletion for the named key in the named instance. The dialog box also indicates to type the supplied confirmation phrase in the text box if you still wish to cancel the scheduled key deletion and provides other pertinent information.
3. Enter or copy/paste the confirmation phrase in the text box.
4. Click **Cancel Delete** to confirm.

Disable and Enable a Root Key

IBM HPCS and Key Protect key management services provides you the ability to disable a root key that is in an active state to temporarily suspend its key operations (encrypt and decrypt) in cases where there is a potential security risk with the associated data. After determining there is no risk or there is no longer a risk, you can re-enable the disabled key to reactivate it for key operations. CCKM provides support for this feature allowing you to disable and enable a root key in CCKM with the use of the **Disable** and **Enable** options within the **Actions** column on the **Keys** page. A disabled root key displays as **Disabled** within the **Key State** column on the **Keys** page while an enabled root key displays as **Enabled**.

Note

The access permission of a Manager role is required for disabling and enabling a root key.

For more information, see the following sections:

- ["Disable a Root Key" below](#)
- ["Enable a Root Key" on the next page](#)

Disable a Root Key

Note

The access permission of a Manager role is required for disabling a root key.

To disable a root key from an HPCS or Key Protect instance (depending on which key management service you are using):

1. In the CCKM portal, in the left navigation bar, select **Keys**. The **Keys** page displays.
2. Find the row that holds the key you wish to disable and click **Disable** from the **Actions** column. The key is disabled.

Enable a Root Key

Note

The access permission of a Manager role is required for enabling a root key.

To enable a root key on an HPCS or Key Protect instance (depending on which key management service you are using):

1. In the CCKM portal, in the left navigation bar, select **Keys**. The **Keys** page displays.
2. Find the row that holds the key you wish to enable and click **Enable** from the **Actions** column. The key is enabled.

Restore a Key

CCKM allows a key that has been deleted from a given IBM Key Protect instance through CCKM to be restored to the instance. You have the option to delete any key from a given IBM Key Protect instance through CCKM. This key can be an IBM native or BYOK key of either the root or standard key type. After key deletion, its key state changes from **Enabled** to **Destroyed**, which is reflected in the **Key State** column on the **Keys** page. The **Restore** action within the **Actions** column within the **Keys** page is available for a key in a **Destroyed** key state. In the **Destroyed** key state, a key cannot be used for cryptographic operations, such as data encryption or decryption. However, the key metadata is still available to be viewed.

CCKM allows a key that has been deleted from a given IBM HPCS instance through CCKM to be restored to the instance. *However, only* IBM BYOK keys of the root key type can be restored. After an IBM BYOK key of the root key type is deleted, its key state also changes from **Enabled** to **Destroyed**, which is reflected on the **Keys** page. After key deletion, the **Restore** action within the **Actions** column is also available for this key. After key deletion of an IBM native or BYOK key that is of the standard key type, no data is shown in the **Actions** column because there is no longer any action available to be taken for this key.

For the IBM HPCS and Key Protect keys that are eligible for key restoration, you have a period of up to 30 days to restore a key. After a key from an HPCS or Key Protect instance is restored, the key enters the **Enabled** key state once again. For both HPCS and Key Protect keys, the key metadata is accessible between the period of 31 and 90 days (*inclusive*). However, during this period, the key can no longer be restored. **Any** time *after* 90 days, the key is automatically purged, which means the key no longer exists within the given IBM instance.

Note

If a key that is eligible to be restored is deleted successfully using the dual authorization process, and then it is restored successfully, the key's dual authorization delete state as reflected in the **Dual Auth Delete State** column on the **Keys** page is set to **Enabled**.

For more information, see the following sections:

- ["Restore a Key \(IBM HPCS\)" on the facing page](#)
- ["Restore a Key \(IBM Key Protect\)" on the facing page](#)

Restore a Key (IBM HPCS)

To restore an HPCS BYOK key of the root key type in CCKM:

Note

In CCKM, you cannot restore an IBM native or BYOK key that is of the standard key type.

1. In the CCKM portal, in the left navigation bar, select **Keys**.
2. From the **All Keys** list page, select **Restore** from the **Actions** column of the key. The **Restore Key** dialog box displays with a warning indicating that the specified key name will be restored to the specified HPCS instance.
3. Click **Restore**. If successful, a success message is displayed. The key and its metadata are restored to the instance. The key state reflected in the **Key State** column on the **All Keys** list page shows **Enabled**.

Restore a Key (IBM Key Protect)

To restore a Key Protect key in CCKM:

1. In the CCKM portal, in the left navigation bar, select **Keys**.
2. From the **All Keys** list page, select **Restore** from the **Actions** column of the key. The **Restore Key** dialog box displays with a warning indicating that the specified key name will be restored to the specified Key Protect instance.
3. Click **Restore**. If successful, a success message is displayed. The key and its metadata are restored to the instance. The key state reflected in the **Key State** column on the **All Keys** list page shows **Enabled**.

Update Key

You have the following options to update a key in IBM HPCS or Key Protect using CCKM:

- ["Update Key for Dual Authorization of Key Deletion" below](#)
- ["Update Key to Enable Automatic Key Rotation Policy for Root Key" on the next page](#)

Update Key for Dual Authorization of Key Deletion

In CCKM, you can enable dual authorization to delete a key at the key level. After a key is enabled for dual authorization, the state of **Enabled** displays in the **Dual Auth Delete State** column and the action of **Schedule Delete Key** is available for selection within the **Actions** column on the **Keys** page.

Enabling dual authorization at the key level does not affect the other keys in a given instance (HPCS or Key Protect).

Note

After you enable dual authorization on a key, you cannot disable it.

Note

The access permission of a Manager role is required to enable dual authorization for deletion of a key.

To enable dual authorization for key deletion at the key level:

1. In the CCKM portal, in the left navigation bar, select **Keys**. The **Keys** page displays.
2. Find the row that holds the key you wish to update and click **Update** in the **Actions** column. The **Update key** dialog box displays.

3. From the **Update Key** dialog box, click **Enable Dual Authorization Delete** to turn this toggle to turn it to **On**. By default, this toggle is initially set to **Off**.
4. Click **Update**.

Update Key to Enable Automatic Key Rotation Policy for Root Key

In CCKM, you can enable an automatic rotation policy for a root key using the IBM key management service (IBM HPCS or Key Protect) you are employing. These IBM key management services manage and perform the key rotation. After the key rotation takes place in an IBM HPCS or Key Protect instance (depending on which service you are using), you can manually synchronize your IBM keys in CCKM. You can also schedule key synchronization in CCKM to synchronize keys that have been rotated in IBM HPCS or Key Protect. See section ["Synchronize Keys" on the facing page](#) for more information.

Note

The access permission of a Manager role is required to enable an automatic rotation policy for a Root key.

To enable automatic key rotation policy for a root key:

1. In the CCKM portal, in the left navigation bar, select **Keys**. The **Keys** page displays.
2. Find the row that holds the key you wish to update and click **Update** in the **Actions** column. The **Update key** dialog box displays.
3. From the **Update Key** dialog box, click **Enable autorotation in key policy** to turn this toggle to **On**. By default, this toggle is initially set to **Off**.
4. In the **Specify the key rotation time interval in months** box, enter the number of months for the key rotation interval. The minimum is 1, and the maximum is 12.
5. Click **Update**.

Rotate Key

CCKM allows for a manual rotation and a scheduled rotation (autorotation) of IBM Root keys.

Note

IBM does not support the rotation of IBM standard keys.

When you manually rotate a key in CCKM, use the **Rotate Now** tab in the **Rotate IBM Key** dialog box. Upon receiving the CCKM API call to rotate a specific key, IBM rotates the key. During the rotation of a key (manual or autorotation), new key material from the key source is used to replace the existing key material in the key while the key name and key ID remains the same. A new key version is created after the rotation. The supported key sources are CipherTrust Manager, DSM, and Native. If the key source is Native, then the key material originates from either IBM HPCS or Key Protect (depending on which IBM key management service you are using).

Auto rotating a key is simply rotating a key at a scheduled time. Key autorotation requires that you first schedule the autorotation in the **Schedules** page prior to enabling this feature in the **Auto Rotate** tab in the **Rotate IBM Key** dialog box. For information about scheduling autorotation, see ["Schedules" on page 207](#).

Rotate a Key Manually

Note

The access permissions of a Writer or Manager role are required to manually rotate a key.

To rotate a key manually:

1. In the CCKM portal, in the left navigation bar, select **Keys**.
2. From the **All Keys** list, find the row that holds the key you wish to rotate and select **Rotate Key** from the **Actions** column. The **Rotate IBM Key** dialog box is displayed.
3. Select the **Rotate Now** tab.
4. In **Key Provider** box, the key source that is preselected depends on the source (provider) of the key. The supported key sources are **CipherTrust Manager**, **DSM**, and **Native**.
5. Click **Rotate**.

Enable Autorotation of Key

Note

The access permissions of a Writer or Manager role are required to enable autorotation of a key.

To enable autorotation of a key:

1. In the CCKM portal, in the left navigation bar, select **Keys**.
2. From the **All Keys** list, find the row that holds the key you wish to rotate and select **Rotate Key** from the **Actions** column. The **Rotate IBM Key** dialog box is displayed.
3. Select the **Auto Rotate** tab.
4. From **Enable autorotation on this key?**, select **On** to enable the autorotation of this key. By default, this toggle is initially set to **Off**.
5. From the **Schedule** drop-down menu, select a rotation schedule to which to apply to this key. Any key-rotation schedule you set in the **Schedules** page displays as an option for selection in the drop-down menu.
6. From **Key Provider** box, select **CipherTrust Manager**, **DSM**, or **Native** depending on the key source (provider) you are using for the key.
7. Click **Submit**.

Synchronize Keys

After the first login into the CCKM IBM Cloud, all of your keys (Standard and Root) from all instances (IBM HPCS or Key Protect instances) to which you have access are synchronized with CCKM. IBM key metadata will be downloaded to CCKM during synchronization and displayed in the CCKM UI.

Note

If keys are auto-rotated in IBM HPCS or Key Protect, be sure to synchronize your keys in CCKM.

The access permissions of Viewer, Writer or Manager role are required to synchronize keys.

To synchronize your keys:

1. In the CCKM portal, in the left navigation bar, select **Keys**.
2. Click **Synchronize**. The **Synchronize Key** dialog box displays.
3. Click **Synchronize** to proceed with the synchronization.

Export Keys

Export Keys allows you to export the contents of the **Keys** list into a report in a CSV format.

Note

No role access permissions are required to export keys.

To export your **Keys** list:

1. In the left navigation bar, click **Keys**.
2. Click **Export Keys**.
This will download all of the keys in a report in a CSV format.

View All Key Versions

From the **Keys** page, you can view information about all of the key versions of a given key by accessing the **Key Versions** dialog box. A new key version is created after a key rotation (manual or autorotation). The **Key Versions** dialog box displays all the versions of a key including the key name, version ID (**Version**), and date on which it was created (**Created On**). You can display the next 5, 10, 15, 20, 25, 50, or 100 entries using the **Show entries** drop down menu. You can view each available page by scrolling through the pages by clicking the less than "<" or greater than ">" symbols or by clicking on a given page number.

To view all of the key versions of a key:

1. In the CCKM portal, in the left navigation bar, select **Keys**.
2. On the **Keys** page, find the name of the key whose key versions you wish to view.
3. Under the **Version Count** column, click on the number. The **Key Versions** dialog box displays. You can scroll through the list to view all of the key versions.
4. Click the **Close** button to close the **Key Versions** dialog box.

Reports

To run the **Combined Key Activity Reconciliation** and **IBM Key Activity** reports, you are required to provision an instance of IBM Activity Tracker with LogDNA with the IBM HPCS or Key Protect instances (depending on which IBM key management service you are using) that are to be tracked before IBM keys are represented in the CCKM reports. You also must also set these services up in CCKM using the **General** tab in the **Settings** page.

To run an **IBM Cloud Key Service Usage** report successfully, you must *first* create a key registration between the key and the cloud resource that it protects. For information about key registrations and how to create a registration between a key and a resource, refer to IBM Cloud documentation.

Choose **Reports** in the left-hand navigation to access the following reports:

- **Cloud Key Manager User Action Report**

Lists the users and their actions in creating, deleting, updating and rotating keys in the CCKM portal.

- **Combined Key Activity Reconciliation Report**

Click **Run Report** to generate a new list of events connected to a key. Reconciliation before and after key import the cloud service. The following actions can be re conciliated: creation, deletion, rotate, and policy update.

- **IBM Key Activity Report**

Illustrates the activity type performed by a specific user at the stated time.

- **IBM Key Aging Report**

Provides information about key expiration using the following columns:

- Key Name
- Region
- Key expiration: Date and time at which this key expires.

- **IBM Cloud Key Manager User Action Report**

Lists the users and their actions in creating, deleting, updating and rotating keys in the CCKM portal.

- **IBM Cloud Key Service Usage Report**

Provides information about which IBM cloud resources are protected by which IBM HPCS or Key Protect key using the following columns:

- Key ID
- Key Name
- Service ID
- CRN: The Cloud Resource Name (CRN) uniquely identifies cloud resources.
- Last Modified: The date at which the key was last modified.

IBM Cloud Activity Tracker with LogDNA Service

IBM Cloud Activity Tracker in conjunction with LogDNA allows you to do the following:

- Collect and store logs of API calls made to IBM Cloud resources within your IBM Cloud account.
- Monitor all of the API activities within your IBM Cloud account.

CCKM uses these two applications to generate the Combined Key Activity Reconciliation Report and the IBM Key Activity Report. Prior to generating these two reports in CCKM, you must set up and configure IBM Cloud Activity Tracker and LogDNA. For more information about this setup and configuration, refer to section ["Provisioning IBM Cloud Activity Tracker with LogDNA Service" on the next page](#).

You must also configure the settings of the IBM Cloud Activity Tracker and LogDNA in the Settings page of CCKM so that communication between CCKM and IBM Cloud Activity Tracker with LogDNA can take place and enable reporting on the IBM keys. For more information about this configuration, refer to section "Enabling Reporting for IBM Key Activities Using IBM Cloud Activity Tracker and LogDNA" on page 1.

Note

Only the activities associated with the keys that are managed from CCKM are reflected in these reports. To ensure the Combined Key Activity Reconciliation Report and the IBM Key Activity Report, synchronize your keys with IBM Cloud prior to running these reports. Otherwise, any activities that were performed from the IBM Key Protect portal (if any) will not be reflected in these reports. If you are using only CCKM to manage your keys for the IBM Key Protect instances then this note does not apply to you.

Provisioning IBM Cloud Activity Tracker with LogDNA Service

To set up and configure IBM Cloud Activity Tracker and LogDNA, refer to the "Getting Started Tutorial" under the topic of "IBM Cloud Activity Tracker with LogDNA" within *IBM Cloud Docs*.

The prerequisites to setting up and configuring IBM Cloud Activity Tracker and LogDNA are the following:

- Obtain a user ID (or username) that is a member or an owner of an IBM Cloud account.
- To manage access to the service, your user ID needs administrator platform permissions to manage the IBM Cloud Activity Tracker with LogDNA service.

The following are the high-level steps to take to set up and configure IBM Cloud Activity Tracker and LogDNA described in detail within the "Getting Started Tutorial":

1. Provision an instance of the IBM Cloud Activity Tracker with LogDNA service. (Note the name for the LogDNA instance, IBM Cloud region of the LogDNA instance, and LogDNA Service Key for the instance. You will add this information in the Settings page of CCKM.)
2. Manage access to the monitoring service.
3. Generate IBM Cloud Activity Tracker with LogDNA events.
4. Launch the Web UI for the IBM Cloud Activity Tracker with LogDNA.
5. View events in the Web UI.

Schedules

The **Schedules** page allows cloud administrators to view and schedule the following job types:

- Key Rotation
- Key Synchronization

CCKM provides support for multiple schedules for each of the job types.

At the top right of the **Schedules** page, the Add Schedule button is available from which to add a scheduled job type.

Schedule Key Rotation

CCKM provides support for multiple schedules of the rotation (autorotation) of an IBM key. A new version of the key is added to the IBM key during a scheduled rotation. Scheduled rotation requires that this feature be configured in the **Schedules** page prior to enabling the feature in the **Auto Rotate Key** dialog box (from the **Actions** column of the All Keys list). Your IBM key credentials (IBM username and API key) are required as part of the configuration and are saved to the key source you are using (CipherTrust Manager or DSM).

Note

CCKM does not support the concurrent use of CipherTrust Manager and DSM as key sources.

During a scheduled rotation of a key, CCKM uses your associated IBM key credentials to rotate the key. If the IBM API key expired or changed, then a new IBM API key must be reentered. Otherwise, the scheduled rotation will fail.

You can pause or delete a scheduled key rotation in the **Schedules** page. Note that when a key rotation schedule is deleted from CCKM, then the IBM key credentials are also deleted from the key source you are using (CipherTrust Manager or DSM)

Delete a Key Rotation Schedule

Note

No role access permissions are required to delete a key rotation schedule.

To delete a key rotation schedule, select Delete from the Actions drop-down menu from the Schedules page. Note that the IBM username and IBM Cloud API key associated with the given key rotation schedule is also deleted from the key source you are using (CipherTrust Manager or DSM).

Pause a Key Rotation Schedule

Note

No role access permissions are required to pause a key rotation schedule.

To pause a key rotation schedule, select Yes for Pause within the Add Schedule dialog box and then click **Save**. The setting is saved. To resume the rotation schedule after pausing it, select No for Pause and then click **Save**. The setting is saved.

Schedule Key Synchronization

CCKM allows for a scheduled synchronization of IBM keys. Synchronizing downloads any keys that were created in IBM HPCS or Key Protect, outside of the CCKM portal, into your CCKM. Scheduled key synchronization requires that this feature be configured in the **Schedules** page. You can also pause or delete a scheduled key synchronization in the **Schedules** page. Note that when a key synchronization schedule is deleted from CCKM, then the IBM username and IBM Cloud API key associated with the given key scheduled synchronization are also deleted from the key source you are using (CipherTrust Manager or DSM).

Note

CCKM does not support the concurrent use of CipherTrust Manager and DSM as key sources.

Set up a Key Rotation Schedule

To set up a key rotation schedule:

Note

No role access permissions are required to set up a key rotation schedule.

1. In the CCKM portal, in the left navigation bar, select **Schedules**. The **Schedules** page displays.
2. On the **Schedules** page, select the **Add Schedule** button. The **Add Schedule** dialog box displays including your username in the **Username** box.
3. From the **Job Type** drop-down menu, select **KEY_ROTATION**.
4. In the **Name** box, enter the name of the schedule. Ensure this name is unique for this job type.
5. (Optional) Enter a description of the schedule in the **Description** box.
6. For **Pause**, select **No**.
7. For **Schedule**, set a schedule for the rotation by selecting **Basic** (to enter a date and interval for the schedule) or **Advanced** (to enter a Cron Expression for the schedule).
8. If you selected **Basic**, select a start date and time from a date and time selector by clicking the calendar button to the right of the box. The time is based on a 12-hour clock and the A.M./P.M. modifiers.
Set the repeat interval of the key rotation by entering a number in the Repeat Interval and then selecting Day, Week, or Month from the drop-down menu. The supported ranges are 1 through 30 days, 1 through 4 weeks, and 1 through 12 months. You can increase or decrease the number you enter.
9. If you selected **Advanced**, enter the cron expression in the **Cron Expression** box.
10. In the **Username** box, enter your username for the IBM account.
11. In the **IBM API key** box, enter your IBM API key for the IBM account.
12. Click **Save**.

Set up a Key Synchronization Schedule

To set up a key synchronization schedule:

Note

The access permissions of Viewer, Writer or Manager role required to set up a key synchronization schedule. However, it is possible to setup synchronization schedule with none of these permissions on any keys. In this case, synchronization will run on schedule but no key will be downloaded.

1. In the CCKM portal, in the left navigation bar, select **Schedules**. The **Schedules** page displays.
2. On the **Schedules** page, select the **Add Schedule** button. The **Add Schedule** dialog box displays including your username in the **Username** box.
3. From the **Job Type** drop-down menu, select **KEY_SYNCHRONIZATION**.
4. In the **Name** box, enter the name of the schedule. Ensure this name is unique for this job type.
5. (Optional) Enter a description of the schedule in the **Description** box.
6. For **Pause**, select **No**.

7. For **Schedule**, set a schedule for the rotation by selecting **Basic** (to enter a date and interval for the schedule) or **Advanced** (to enter a Cron Expression for the schedule).
8. If you selected **Basic**, select a start date and time from a date and time selector by clicking the calendar button to the right of the box. The time is based on a 12-hour clock and the A.M./P.M. modifiers.
Set the repeat interval of the key rotation by entering a number in the Repeat Interval and then selecting Day, Week, or Month from the drop-down menu. The supported ranges are 1 through 30 days, 1 through 4 weeks, and 1 through 12 months. You can increase or decrease the number you enter.
9. In the **Username** box, enter your username for the IBM account.
10. In the **IBM API key** box, enter your IBM API key for the IBM account.
11. Click **Save**.

Logs

CCKM maintains logs for events, such as login, key generation, synchronizing of keys, and deletion of keys, and displays these logs in the **All Logs** list of the **Logs** page. For each logged event listed on the **Logs** page, the following information is displayed:

- Event name
- Severity level
- Date and time of the event
- Event message
- User (name) associated with the event

You can search for a specific logged event from the **Logs** page using the **Search** box. Allowable filters on the search are event name, severity level, event message, and user (name).

Key Sources

The **Key Sources** page displays **all** of the keys that were generated from the key source you are using. If you are logged into multiple clouds within CCKM, this page displays all of the keys from these clouds.

Three tabs are available at the top of the **Key Sources** page:

- **CipherTrust Manager Key:** Use this tab to use CipherTrust Manager as your key source. The keys are generated and stored within CipherTrust Manager.
- **DSM Key:** Use this tab to use DSM as your key source. The keys are generated and stored within DSM.
- **nShield Key:** This tab is currently unavailable for use as CCKM does not currently support nShield Connect as a key source for IBM.

Note

CCKM does not support the concurrent use of CipherTrust Manager and DSM as key sources.

Keys listed on the **Key Sources** page are listed by name, cloud ID, key type (the cloud in which this key is used), the algorithm of the key, the creation date of the key, key description and actions you can take regarding that key.

A **Search** box is available at the top left of the **Key Sources** page allowing for a search of a specific key by entering any one of the following parameters:

- Name (key name)
- Cloud ID
- Key Type
- Algorithm
- Description
- Created By (a key created by a specific user)

Add (Generate) a Key

From the **Key Sources** page, you can add (or generate) keys in CCKM using CipherTrust Manager or DSM as a key source for *all* of the clouds into which you are currently logged.

Note

The key algorithm currently supported for an IBM key in CCKM is AES256.

Add (Generate) a CipherTrust Manager Key

1. In the CCKM portal, in the left navigation bar, select Key Sources.
2. Select the **CipherTrust Manager Key** tab.
3. Select **Add Key > IBM Key**.
4. In the **Add CipherTrust Manager Key** dialog box, select the name of the user of the key from the **User** drop-down menu. **Service** is fixed to **IBM** and (key) **Algorithm** is fixed to AES256.
5. In the **Name** box, enter the name of the new key.
6. Enter a description of the key in the **Description** box.
7. Click **Save** to save the new key to CCKM. The new key is added to the key list.
(Reset clears the screen before it has been saved.)

Add (Generate) a DSM Key

1. In the CCKM portal, in the left navigation bar, select Key Sources.
2. Select the **DSM Key** tab.
3. Select **Add Key > IBM Key**.
4. In the **Add DSM Key** dialog box, select the name of the user of the key from the **User** drop-down menu. **Service** is fixed to **IBM** and (key) **Algorithm** is fixed to AES256.
5. In the **Name** box, enter the name of the new key.
6. Enter a description of the key in the **Description** box.
7. Click **Save** to save the new key to CCKM. The new key is added to the key list.
(Reset clears the screen before it has been saved.)

Add (Generate) an nShield Key

The **nShield Key** tab is currently unavailable for use as CCKM does not currently support nShield Connect as a key source for Salesforce.

Delete a Key

Deleting a key from the **Key Sources** page deletes the key from CCKM. If you delete a key from **Key Sources** that has already been uploaded to IBM HPCS or Key Protect (depending on which IBM key management service you are using), the key will not be deleted from the given IBM key management service.

1. In the CCKM portal, in the left navigation bar, select **Key Sources**.
2. Select the **DSM Key** or **CipherTrust Manager** tab depending on the key source you used to generate this key.
3. Click **Delete** next to the target key.
4. The **Delete Key** dialog box with a Warning displays asking you to confirm the key deletion by entering the supplied phrase.
5. Enter or Copy/paste the confirmation phrase.
6. Click **Delete**.

Manage keys in Key Sources List Page

In addition to adding and deleting keys, the **Key Sources** page allows you to sort the existing keys by Name, Key Type, Algorithm and Created Date.

Settings

To access the **Settings** page in CCKM, select **Settings** from the left-hand navigation bar. From the **Settings** page, you can:

- Enter the email addresses of the recipients who are to receive the email notifications.
- Enable email notifications to be sent out from CCKM when specific types of key actions are performed. For example, when a key is uploaded to the cloud service. You can also enable CCKM to send reminder notifications for when to rotate a key.
- Enable reporting for IBM keys using IBM Cloud Activity Tracker in conjunction with LogDNA
- Configure a remote syslog server to which to send syslog messages.
- View information about the software release number of the CCKM you are running including the build and version number.

Adding Recipients' Email Addresses (for Notifications)

Use the **General** tab from the **Settings** page to enter the email addresses of the recipients who are to receive email notifications from CCKM. Enter the recipients' email addresses separated by a comma in the **Notification Recipient** box and then click **Save** to save setting.

Enabling Notifications

Using the **Keys Notification** tab from the **Settings** page, you can configure CCKM to send an email notification when a key is deleted from or uploaded to IBM HPCS or Key Protect (depending on which IBM key management service you are using). You can also use this tab to configure CCKM to send a reminder notification for when to manually rotate a key along with the frequency (in days) at which a notification is sent. Add the email address(es) of the recipients in the **General** tab from the **Settings** page. By default, no notifications are sent.

To enable email notifications:

1. In the **Settings** page, select the **Keys Notification** tab.
2. Under **Notifications**, select **On** for each of the notifications you wish to enable:
 - Rotate IBM Cloud Key (reminder notification)
 - Delete IBM Cloud Key
 - Upload IBM Cloud Key
3. If you selected to enable **Rotate IBM Cloud Key**, in the **Days** box, enter the number of days for the frequency a reminder notification is sent.
4. Click **Save**.

Configuring Syslog Server

Note

In this document, the terms "syslog server" and "log server" are synonymous.

The **Syslog** tab from the **Settings** page allows you to configure the remote syslog or log server to which to send CCKM log data using TCP, TLS, or UDP protocol as the transport protocol. If you use the TLS protocol, then you are required to upload the syslog server certificate to CCKM for the TLS connection.

The **Syslog** tab also allows you to delete your syslog server configuration so that log data are no longer sent to the server.

Prior to configuring the setting for a remote syslog server, ensure that you have installed and configured the syslog server including configuring the setting for the port number the transport protocol will use to connect to CCKM. This port number configuration must match the port configuration you set in the **Syslog** tab of the **Settings** page.

Note

Support for both Syslog and Splunk as a remote syslog server is provided in CCKM. However, the use of a Splunk cloud server as a remote syslog server is currently not supported in CCKM.

Configure Remote Syslog Server

To configure a remote syslog server to which to send CCKM log data:

Note

The facility name of "LOCAL1" for the syslog server displays in the **Facility** box. This default value is not available for modification.

1. In the **Settings** page, select the **Syslog** tab. The **Syslog** dialog box displays.
2. In the **Hostname** box, enter the hostname or IP address of the syslog server.
3. In the **Port** box, enter the port number the transport protocol uses to connect to the syslog server. Enter a value between 1 and 65535. The default value is 514.
4. In the **Protocol** drop-down menu, select **TCP**, **TLS**, or **UDP** for the transport protocol to use when sending the log data to the syslog server. The default value is **UDP**. If you select **TCP**, proceed to Step 6. If you select **TLS**, proceed to the next step. Otherwise, proceed to Step 7.
5. In the **Certificate** box, select **Choose File** and then select the syslog server certificate to upload to CCKM.
6. Click **Test Connection** to test the connection between CCKM and the remote syslog server. This button is only available for use when either **TCP** or **TLS** is the selected transport protocol.

7. In the **Log Format** drop-down menu, select **CEF** (Common Event Format), **Plain Text**, or **RFC5424** for the format of the log message to use when sending the log data. The default value is **RFC5424**.
8. (Optional) In the **Description** box, enter a description of the remote syslog server.
9. Click **Save**.

Delete Remote Syslog Server Configuration

To delete the configuration of a remote syslog server:

1. In the **Settings** page, select the **Syslog** tab. The **Syslog** dialog box displays.
2. Click **Delete**. The **Delete Syslog** dialog box displays.
A warning message displays indicating that this action will delete the syslog settings from CCKM. The message also indicates to type the confirmation phrase (I wish to delete the syslog settings) in the text box if you still wish to delete the syslog settings.
3. Enter or copy/paste the confirmation phrase in the text box.
4. Click **Delete**.

Enabling Reporting for IBM Keys

Use the **General** tab within the Settings page to enable CCKM reporting for IBM keys using IBM Cloud Activity Tracker and LogDNA. However, you are required to provision an instance of IBM Activity Tracker with LogDNA with the IBM key management service instances you are using (IBM HPCS or Key Protect) that are to be tracked before IBM keys will be represented in the CCKM reports. Enabling reporting for IBM keys allows you to generate the Combined Key Activity Reconciliation and IBM Key Activity reports. See section "[Provisioning IBM Cloud Activity Tracker with LogDNA Service](#)" on page 207 for more information about provisioning an instance of IBM Activity Tracker with LogDNA.

Enabling Reporting for IBM Key Activities Using IBM Cloud Activity Tracker and LogDNA

To enable CCKM reporting for IBM key activities using IBM Cloud Activity Tracker and LogDNA:

1. In the **Settings** page, select the **General** tab. The **General** page displays.
2. From the **LogDNA Name** box, provide a name for the LogDNA instance.
3. From the **Select LogDNA Region** drop-down menu, select the IBM Cloud region of the LogDNA instance (that you previously created) for which to enable the reporting.
4. From the **LogDNA Service Key** box, enter the LogDNA service key that is used to authenticate to the LogDNA instance.
5. Click **Add LogDNA Instance**. The **LogDNA Instances** table displays the name and region of the selected LogDNA instance along with the available action of **Remove** under the **Actions** column. This table is dynamic and displays only if you enter information in steps 2 through 4. A message also displays prompting you to click **Save** to save the settings based on the new changes to the LogDNA instance.
6. Click **Save**.

About

Use the About tab to view the build number, version number, patch number (if applicable), and build number of the CCKM you are running.

Chapter 17: CCKM for Salesforce Key Management

Overview	216
Prerequisites on Salesforce	216
Enable and Assign System Permissions for CCKM Login	217
Salesforce Cache-only Keys	218
Access CCKM for Salesforce	220
Salesforce CCKM User Portal	220
Home	222
Tenant Secrets	222
Certificates	231
Reports	232
Schedules	232
Logs	235
Key Sources	235
Settings	237

Overview

CCKM provides support for Salesforce, Salesforce Government, and Salesforce Sandbox. The Salesforce Sandbox is a copy of your production Salesforce environment used primarily for testing, development, or training purposes. Note that in this chapter, the information regarding Salesforce is applicable to Salesforce, Salesforce Government, and Salesforce Sandbox unless otherwise noted. The CCKM UI for Salesforce, Salesforce Government, and Salesforce Sandbox is identical with the exception of the display of the names of the clouds. Your login credentials for Salesforce, Salesforce Government, and Salesforce Sandbox are **unique** to each cloud.

Note

Salesforce provides the following profile interfaces: original profile user interface and enhanced user interface. The procedures provided in this chapter reflect the enhanced user interface. For more information about the Salesforce profile interfaces, refer to the appropriate Salesforce online documentation.

Note

In this document, Salesforce Government Cloud Plus is also referred to as Salesforce Government and Salesforce Government Cloud.

Prerequisites on Salesforce

To use CCKM for Salesforce, you must:

- Have Salesforce's Shield Platform Encryption Service enabled
- Have at least one valid certificate in Salesforce with the following settings:
 - Key Size: 4096
 - "Use Platform Encryption" selected
 - "Exportable Private Key" deselected

- **Be familiar with different types of tenant secrets, Salesforce 'Bring Your Own Key' options, and certificates** in Salesforce.
- **Have access to a Salesforce account with the system permissions of Manage Encryption Keys and View Setup and Configuration enabled**, in order to handle tenant secrets. If you wish to disable Salesforce's key derivation process, and use your uploaded key material as the final data encryption key, then enable the **Allow BYOK to Opt Out of Key Derivation** option within the **Security > Platform Encryption > Advanced Settings** page in Salesforce. If you are using Salesforce cache-only keys, ensure your account also has **Customize Application** system permission enabled. Also ensure the **Allow Cache-Only Keys with BYOK** option within the **Security > Platform Encryption > Advanced Settings** page in Salesforce is also enabled. If you wish to enable the Replay Detection for cache-only keys, ensure the **Enable Replay Detection for Cache-Only Keys** option within the **Security > Platform Encryption > Advanced Settings** page in Salesforce is also enabled.

Enable and Assign System Permissions for CCKM Login

You must have the system permissions of **Manage Encryption Keys** and **View Setup and Configuration** enabled in Salesforce to allow CCKM users to log into CCKM. If you are using Salesforce cache-only keys, then you must also have the **Customize Application** system permission enabled in Salesforce to perform operations related to cache-only keys. After enabling these system permissions, assign these to the user account(s), which should these permission assignments.

For more information about managing permissions on encryption keys in Salesforce, see the “Permission Sets” documentation within the Salesforce online documentation.

To enable system permissions and assign these to user accounts:

1. Log in with the administrator privileges to your Salesforce account.
2. Click **Setup**.
3. In the left navigation bar, expand **Manage Users**.
4. Click **Permission Sets**.
Be sure that **Session Activation Required** is not selected.
5. Click **New**, and then select **New Permission Set**.
6. Click **System Permissions**, then click **Edit**.
7. Select the **Manage Encryption Keys** check box.
8. Select the **View Setup and Configuration** check box.
9. If you are using Salesforce cache-only keys, select the **Customize Application** check box.
10. Click **Save**.
11. Click **Manage Assignments** and then **Add Assignments**.
12. Select the user account(s), which should have these permission assignments.
13. Click **Assign**.
14. Click **Done**.

Salesforce Cache-only Keys

CCKM provides support for Salesforce's cache-only key service as part of its extended BYOK capability. With the use of a cache-only key, Salesforce calls the CCKM REST APIs to fetch a tenant secret (or cache-only key) from CCKM. This tenant secret is used for encrypt and decrypt operations in Salesforce. With the initial versions of Salesforce BYOK capability, the upload of the tenant secret and other key operations in Salesforce are initiated from CCKM using the available Salesforce Rest APIs.

In the API call from Salesforce to CCKM to fetch a tenant secret for the use of Salesforce's cache-only key service, a named credential is employed. The named credential is a combination of a URL of a CCKM callout endpoint along with the configured authentication parameters (CCKM username and password) associated with the URL. When CCKM receives the API call and successfully authenticates it, CCKM passes the tenant secret to Salesforce through a secure and authenticated connection. For more information about Salesforce cache-only keys, refer to the Salesforce online documentation.

CCKM also provides support for Replay Detection for cache-only keys. With this feature enabled, Salesforce inserts a unique marker called a RequestIdentifier (or request ID) in each callout to get the cache-only key from CCKM. The request ID serves as a random, one-time identifier for each valid callout request. Once this feature is enabled from the Salesforce portal, CCKM will accept and return the request IDs. No configuration is required on CCKM. Any request without Request ID or mismatched Request ID is aborted.

Notes

- CCKM currently supports CipherTrust Manager and DSM as the key sources for use with Salesforce's cache-only key service.
- In this document and in the context of support for Salesforce's cache-only key service, the term "tenant secret" is used interchangeably with "cache-only key".
- The CCKM cache-only feature is **not** tested on Salesforce Government Cloud Plus.

Configuring Cache-only Keys

The following is a summary of the steps to take to configure the use of cache-only keys within CCKM *and* Salesforce:

1. Configure CCKM with a SSL certificate that is signed by a Salesforce root Certificate Authority (CA) certificate. For more information, see ["Configure CCKM with SSL Certificate Signed by Salesforce Root CA Certificate" on the next page](#).
2. From the CCKM **Settings** page, configure the username and password to associate with the URL of the CCKM Rest API endpoint (or callout endpoint). For more information, see ["Configure Cache-only Key Endpoint" on page 239](#).
3. Set up a named credential in Salesforce for use with the cache-only keys. For more information, see ["Set up Named Credential in Salesforce" on the next page](#).
4. Generate a key in CipherTrust Manager or DSM for use with the cache-only keys. For more information, see ["Add \(Generate\) a Key" on page 236](#).
5. Configure a cache-only key in CCKM. For more information, see ["Create a Tenant Secret/Key" on page 225](#).
6. Verify that Salesforce can fetch the key from CCKM using the call-out connection. For more information, see ["Verify Call-Out Connection for Cache-only Key " on page 227](#).

Configure CCKM with SSL Certificate Signed by Salesforce Root CA Certificate

As part of cache-only key fetch process, Salesforce calls CCKM API over the HTTPS protocol, which requires CCKM to be configured with a valid SSL certificate. Salesforce cache-only key feature does not support self-signed certificates. CCKM must be configured with a SSL certificate that is signed by a Salesforce root Certificate Authority (CA) certificate. You can find the Salesforce root CA certificate list at <https://INSTANCE.salesforce.com/cacerts.jsp> where 'INSTANCE' is any upgraded instance. For example, <https://cs32.salesforce.com/cacerts.jsp>. You can use any one of these certificates from the list to sign the CCKM SSL certificate.

Note

To upload a valid SSL certificate to CCKM, run the following `system` command from the CCKM CLI:

```
system> security --setservercert.
```

For more information about the `system` category commands, see [Appendix A: "CCKM CLI Commands" on page 244](#). This appendix provides a high-level overview of each of the command categories that are available in the CCKM.

Set up Named Credential in Salesforce

Before setting up a named credential in Salesforce, ensure you have a CCKM deployed on a publicly accessible URL. In addition, ensure you have configured the username and password to be associated with the URL of the CCKM Rest API endpoint (or callout endpoint) in the **Endpoint for Cache-only Key** tab from the CCKM **Settings** page. (See ["Configure Cache-only Key Endpoint" on page 239](#) for information about the configuration of the callout endpoint.) The username and password are used to set up the named credential in Salesforce, which in turn provides Salesforce a method for fetching the cache-only key from CCKM through a secure and authenticated connection.

For detailed information about how to set up a named credential in Salesforce, see the Salesforce online documentation.

To set up a named credential in Salesforce:

1. Login into Salesforce.
2. Go to the **Setup** page.
3. In **Quick find** box, enter "Named Credentials" to search on this topic and then select **Named Credentials** in the results. The **Named Credentials Setup** page displays.
4. Select **New Named Credentials**.
5. In the **Label** box, enter the name of the named credential to use for CCKM. It is recommended you include "CCKM" in the name to reflect CCKM-associated information in the labels within Salesforce list views and reports. The name you provide in the **Label** box is automatically populated in the **Name** box.
6. In the **URL** box, enter the URL of the CCKM Rest API endpoint. To obtain the information to enter in this box, go to the **Endpoint for Cache-only Key** tab of the CCKM **Settings** page, and copy the URL from the **Call out URL** box and paste it into this box. Verify the hostname and port number are correct. For example, if CCKM URL is <https://thalescckm.com:8443/kmaas/> and the org ID is 00DB00007731234MAK, then the callout URL will be: <https://thalescckm.com:8443/kmaas/00DB00007731234MAK/>

7. Under **Authentication**, do the following:
 - a. Leave the **Certificate** box blank.
 - b. In the **Identity Type** drop-down menu, select **Named Principal**.

Note: Named Principal is currently the only option supported for the Salesforce identify type within CCKM.

- c. In the **Authentication protocol** drop-down menu, select **Password Authentication**.

Note: Password Authentication is currently the only option supported for authentication protocol within CCKM.

- d. In the **Username** box, enter the username to associate with the URL of the CCKM Rest API endpoint. This username must match the username configured in the **Endpoint for Cache-only Key** tab of the CCKM **Settings** page.
 - e. In the **Password** box, enter the password to associate with the URL of the CCKM Rest API endpoint. This password must match the password configured in the **Endpoint for Cache-only Key** tab of the CCKM **Settings** page.
 - f. Under the **Callout Options**, ensure the **Generate Authorization Header** check box is selected. This check box is selected by default.
 - g. Click **Save**.

Access CCKM for Salesforce

For details about accessing CCKM as a CCKM user for the CCKM service for Salesforce Key Management, see [Chapter 3: "About CCKM Admin and User Portals" on page 27](#) on page 1. This chapter includes information on the ways in which to access the CCKM service for Key Management.

Salesforce CCKM User Portal

The CCKM User Portal for Salesforce contains the following menu options in the left-hand navigation bar:

- **Home:** Home page displays key operation and count metrics
- **Tenant Secrets:** Salesforce terminology for “keys”. The **All Tenant Secrets** page displays key management overview and provides the Upload and Synchronize functionality, and the Create, Destroy, Import, Delete Backup key operations available in CCKM.
- **Certificates:** The **All Certificates** page displays certificate management overview, plus Synchronize functionality.
- **Reports:** **All Reports** overview page links to detailed individual reports.
- **Schedule:** In **Schedule**, you can schedule automatic key rotation and key synchronization.
- **Logs:** **Logs** page lists individual logs that can be searched, sorted, and viewed.
- **Key Sources:** In **Key Sources**, you can create tenant secrets in CCKM to upload to Salesforce. CCKM provides support for the use of either CipherTrust Manager or DSM as a key source to generate, store, and retrieve the encryption keys that CCKM uses and manages.

Note: CCKM does not support the concurrent use of CipherTrust Manager and DSM as key sources.

- **Settings:** The **Settings** page allows you to add the email addresses of the recipients who are to receive email notifications and configure the settings for email notifications, syslog servers, and proxy servers. You can also view the release number of the CCKM running from this page.

To display the context of which Key Management service you are currently logged into within CCKM, the icon associated with the Key Management service displays at the top of the left-hand navigation bar.

The arrow button at the bottom of the navigation bar allows you to expand the bar to view the names of the menu options and collapse it to view only the icons associated with the menu options. Click the arrow button to either expand or collapse the navigation bar.

On the top-right side of the CCKM portal for , the following options are available:

- **Azure Cloud Service Context Switcher:** This context switcher allows you to login into another Azure cloud service different from the current Azure cloud service into which you are currently logged. If you select the Azure cloud in which you are currently logged, the Multi-account Login/Logout window for the Azure account(s) displays. For more information about the Multi-account Login/Logout window, refer to ["Support for Multiple accounts or Multiple Users per Cloud Service in CCKM UI" on page 32](#).
- **AWS Login:** If you are not already logged into AWS, clicking on the AWS Login icon brings you to the AWS Password Login page where you can enter your AWS credentials to access the CCKM AWS cloud service (from the current cloud service in which you are currently logged). If you are already logged into AWS, clicking on the AWS Login icon brings you to the Multi-account Login/Logout window for the AWS account(s). For more information about the Multi-account Login/Logout window, refer to ["Support for Multiple accounts or Multiple Users per Cloud Service in CCKM UI" on page 32](#).
- **Google Cloud Service Context Switcher:** This context switcher allows you to login into another Google Cloud organization different from the current Google Cloud organization into which you are currently logged. If you select the Google Cloud in which you are currently logged, the **Multi-account Login/Logout** window for the Google account(s) displays. For more information about the **Multi-account Login/Logout** window, see ["Support for Multiple accounts or Multiple Users per Cloud Service in CCKM UI" on page 32](#).

- **Salesforce Cloud Service Context Switcher:** This context switcher allows you to login into another Salesforce cloud service different from the current Salesforce cloud service into which you are currently logged. This is Salesforce, Salesforce Government, or Salesforce Sandbox. If you select the Salesforce cloud in which you are currently logged, the Multi-account Login/Logout window for the Salesforce account(s) displays. For more information about the Multi-account Login/Logout window, refer to ["Support for Multiple accounts or Multiple Users per Cloud Service in CCKM UI" on page 32](#).
- **Logout:** Logout from CCKM.

Home

The **Home** page provides a dashboard to display key operation and count metrics.

Tenant Secrets

The **Tenant Secrets** page allows Cloud administrators to view all the keys and manage them within the boundary of granted permissions. Those keys that do not have List permission for the respective Cloud administrator will not be listed.

Within the **Tenant Secrets** page, the following types of Salesforce tenant secrets are available to specify the kind of data to encrypt using a tenant secret:

- Data in Salesforce: Encrypts data using the probabilistic encryption scheme.
- Data in Salesforce (Deterministic): Encrypts data using the deterministic encryption scheme.
- Search Index: Encrypts search index files.
- Analytics: Encrypts Einstein Analytics data.
- Event Bus (Developer Preview): Encrypts data changes and the associated change event.

You specify the key type on the **Tenant Secrets** page when creating a new key using the **Create Tenant Secret** dialog box or uploading an existing key using the **Upload a Tenant Secret** dialog box. The existing key is one you previously created from the **Key Sources** page. For more information about the types of tenant secrets, see the appropriate Salesforce online documentation.

The option to opt out of using the Salesforce key derivation mode when uploading tenant secrets from the **Tenants Secret** page is available in support of this Salesforce feature. The key derivation mode in CCKM allows you to derive a data encryption key based on the tenant secret you create or upload to Salesforce from the **Tenants Secret** page. Opting out of this mode means the tenant secret that you create or upload will be the key used to encrypt and decrypt your data.

From the **Tenant Secrets** page, a **Filter by** box is also available allowing you to filter on the types of tenant secrets to display in the list of tenant secrets.

A **Search** box is available at the top left of the **Tenant Secrets** page allowing for a search of a specific key by entering any one of the following parameters:

- Key Name
- Key ID
- Version
- Status
- Generated by
- Key Material Origin

The **Advanced** tab allows you to filter your search on each of the columns displayed on the **Tenant Secrets** page with the exception of the **Action** column:

- Key Name
- Key ID
- Version—Min and Max
- Status—Available options from the drop-down menu are ACTIVE, ARCHIVED, and DESTROYED.
- Generated By
- Generated On—Enter START DATE and END DATE.
- Key Derivation
- Backup—Available options from the drop-down menu are Backed Up and Not Backed UP.
- Uploaded—Available options from the drop-down menu are Uploaded and Not Uploaded
- Key Material Origin

In addition, you can also search on **Key ID**. A **Key ID** for a given key is only available in the **Tenant Secret** box. To view the **Key ID** of a key, from the **Tenant Secrets** page, select the name of the key listed under the **Name** column. The **Tenant Secret** box displays and includes the name of the key, the Salesforce Key ID, key version, description of the key, and other properties.

Each of these columns are described in more detail below in this section.

To select to filter based on a specific column or Key ID from the **Tenant Secrets** page, click **Advanced**. The **Filters** section displays. From the filter drop-down menu, select the name of the column on which to filter your search or Key ID. For example, select **Key Name**. For the **Status**, **Backup**, and **Uploaded** columns, a drop-down menu is available from which to select a value for the search. Click the down arrow, select a value from the available options, and then click **Add**. For the **Version** column, enter a minimum and maximum version number for the search and then click **Add**. For the **Generated On** column, enter a start and end date for the search and then click **Add**. The specified search filter is then added to **Active Filters**. In the example, **Key Name: MK-createkey** is added to **Active Filters**. The results of the search displays in the **Tenant Secrets** table. You can narrow your search by selecting more columns to add to the filter. To clear the filtered results, from **Active Filters**, click on the “X” (or the **Delete** button) for each of the named filters.

At the top right of the **Tenant Secrets** page, the following buttons are available:

- **Export Secrets:** Allows you to export the contents of the Tenants Secrets list into a report in a CSV format. For information on how to export your tenant secrets, see ["Export Tenant Secrets" on page 230](#).
- **New Key:** Allows you to upload an external key (BYOK) or create a native key. For information on how to upload an external key or create a native key, see ["Create a Tenant Secret/Key" on the next page](#).
- **Synchronize:** Allows you to download any keys that were created in Salesforce, outside of the CCKM portal, into CCKM. For information on how to synchronize your keys, see ["Synchronize Tenant Secrets" on page 230](#).

The following columns display in the **Tenant Secrets** page:

- **Name:** The name of the key.
- **Version:** The version number of the key.
- **Status:**
 - **ACTIVE**
 - **DESTROYED**
 - **ARCHIVED**
- **Generated By:** The username associated with generating the key.
- **Generated On:** The date on which the key was generated.
- **Key Derivation:** Indicates whether the tenant secret is in key derivation mode. A green check icon indicates that it is in this mode.
- **Backup:** Indicates whether a backup of the key exists in CCKM. The status can be one of the following:
 - A green check icon indicates the backup exists in CCKM.
 - A red exclamation icon indicates the backup key does not exist in CCKM.
- **Uploaded:** Indicates whether the key is uploaded to Salesforce. A green check icon indicates that it is uploaded. Cache-only keys that are uploaded to Salesforce also display with the green check icon.
- **Key Material Origin:**
 - If the key was uploaded from CCKM, then the value is **Internal(<source_key_name>)**. For a cache-only key, the value is **FETCHED(<source_key_name>)**.
 - If the key was not uploaded from CCKM as a BYOK key, then the value is **EXTERNAL**.
- **Actions:** Allows you to select any of the following actions on a given key:
 - **Destroy**
Note: For a cache-only key, **Destroy** is the only action available within the **Actions** column. After the key is destroyed, the **Actions** column displays **Edit Key**.
 - **Edit key**

Note: This action is only applicable to a cache-only key.
 - **Import**
 - **Delete Backup**

In this section, create, upload, destroy, import, synchronize, and manage tenant secrets, as well as delete a backup key are described.

Create a Tenant Secret/Key

You have three options to create a new tenant secret or key:

- Upload an external key (BYOK) (see ["Upload your Own Tenant Secret" below](#))
- Create a native key (see ["Create a Tenant Secret/Key" on the facing page](#))
- Create cache-only key (see ["Create a Cache-only Key" on the facing page](#))

Upload your Own Tenant Secret

Salesforce supports only one active tenant secret per organization/OrgID. When you upload your own tenant secret, that key becomes active and the previously active key is automatically archived. Use Upload as part of your organization's key rotation policy. You can only upload a tenant secret once every 24 hours, as per Salesforce's policy.

The uploaded key is displayed in the Tenant Secrets list. As part of the upload process, Salesforce generates a corresponding backup key, which CCKM downloads and stores in the key source you are using (CipherTrust Manager or DSM). For more information about the backup key, see ["Backup Key" on page 231](#).

Note

A valid certificate is required, as described in ["Prerequisites on Salesforce" on page 216](#). If no certificate is listed in the certificate drop-down, you must go to Salesforce, create an appropriate certificate, and re-synchronize with CCKM.

To upload your BYOK tenant secret to CCKM:

1. In the CCKM portal, in the left navigation bar, select **Tenant Secrets**. The **Tenant Secrets** list page displays.
2. From the **Tenant Secrets** list page, within the **New Key** box, select **Upload**. The **Upload a Tenant Secret** dialog box displays.
3. From the **Type** box, select the type of tenant secret to upload. The following are the options (in the order of selection):
 - Data in Salesforce
 - Search Index
 - Data in Salesforce (Deterministic)
 - Analytics
 - Event Bus
4. From the **Tenant Secret** drop-down menu, select the tenant secret to upload. Enter the first three characters of the name of the tenant secret to bring it up for selection.
5. Select whether to apply the Salesforce key derivation mode to the tenant secret. If you choose to apply it, ensure that the **Use Salesforce key derivation** check box is selected. By default, the check box is selected. Otherwise, deselect the check box to opt out of applying the key derivation mode to the tenant secret.
6. From the **Certificate** drop-down menu, select a valid certificate (used to wrap the key for secure upload).
7. Click **Upload to Salesforce** to upload the tenant secret to Salesforce.

Create a Tenant Secret/Key

Create a native key in Salesforce using CCKM. After CCKM creates a native key, it displays the key as **EXTERNAL** under the **Key Material Origin** column within the **Tenant Secrets > All Tenant Secrets** list page in CCKM.

As part of creating a native key, Salesforce generates a corresponding backup key, which CCKM downloads and stores in the key source you are using (CipherTrust Manager or DSM).

To create a native tenant secret:

1. From the **Tenant Secrets** list page, within **New Key** box, select **Create**.
2. From the **Type** box of the **Create a Tenant Secret** dialog box, select the type of tenant secret to create.
3. Select whether to apply the Salesforce key derivation mode to the tenant secret. If you choose to apply it, ensure that the **Salesforce key derivation** check box is selected. By default, the check box is selected. Otherwise, deselect the check box to opt out of applying the key derivation mode to the tenant secret.
4. Click **Create** to create the new tenant secret.

Create a Cache-only Key

In CCKM, create a tenant secret or cache-only key for use with Salesforce's cache-only key service. In creating this key, select the key you generated from your key source (CipherTrust Manager or DSM). Also, select a named credential that matches the named credential you previously defined in Salesforce. (For more information, see ["Add \(Generate\) a Key" on page 236](#).) After this key is created, the name of the key is displayed in the **Name** column, a green checkmark icon is displayed in the **Uploaded** column, and a status of **FETCHED(<key_name>)** is displayed in the **Key Material Origin** column of the **Tenant Secrets** page. In addition, a log message in the **Logs** page is recorded and displayed indicating a call-out connection to Salesforce has been created.

In order for Salesforce to use this key for its cache-only key service, Salesforce must be able to reach the endpoint (specified by the named credential) using the call-out connection that is created after you create the cache-only key in CCKM. If Salesforce can reach the endpoint (meaning the call-out connection between CCKM and Salesforce was set up successfully), then the key specified for the Unique Key Identifier is fetched from CCKM and becomes the active key within Salesforce. After performing the steps in this section, verify that Salesforce can reach the endpoint. See ["Verify Call-Out Connection for Cache-only Key " on the next page](#) for more information.

Note

CCKM currently supports CipherTrust Manager and DSM as the key sources for use with Salesforce's cache-only key service.

To create a cache-only key:

1. From the **Tenant Secrets** list page, within **New Key** box, select **Cache Only**. The **Create cache-only key** dialog box displays.
2. From the **Type** box, select the type of cache-only key to create. The following are the options (in the order of selection):
 - Data in Salesforce
 - Search Index
 - Data in Salesforce (Deterministic)
 - Analytics
 - Event Bus
3. From the **Tenant Secret** drop-down menu, select the key you generated using CipherTrust Manager or DSM depending your key source. Enter the first three characters of the name of the key to bring it up for selection.

4. In the **Certificate** box, select a valid certificate (used to wrap the key for secure upload).
5. In the **Named Credentials**, select the named credential to associate with this cache-only key.
6. Click **Create cache-only key** to create the new cache-only key.

Verify Call-Out Connection for Cache-only Key

After creating the cache-only key, verify that Salesforce can fetch the key from CCKM using the call-out connection. When the CCKM receives the API call from Salesforce and successfully authenticates it, CCKM passes the tenant secret to Salesforce through the call-out connection.

To verify that Salesforce can fetch the key from CCKM using the call-out connection:

1. Login to Salesforce.
2. Click **Setup** and from the Search box of the Setup page, enter **Platform Encryption**.
3. Select **Key Management** and the Key Management page displays. You will see a list of keys.
4. From the list of keys, find the row that contains the cache-only key you just created (using the version number to identify it) and then click **Details** button next to it. The **Cache-Only Key: Callout Check** page displays.
5. Click the **Check** button to check the connection for your cache-only key callout. A callout connection starts to test the connection. Details about the results displays on the page.
6. Under the **Callout Collection Details**, verify that the values for **Unique Key identifier**, **Certificate Unique Name**, and **Named Credential** match the values selected during the creation of cache-only key.
7. Verify that the message in the results pane displays the following:
`"The callout was successful".`
8. Login to CCKM User Portal for Salesforce.
9. In the left navigation bar, select **Logs**. The **Logs** page displays.
10. Verify that two events named "Get_Cache_Only_Key" is listed on the page. (The first event indicates a Salesforce cache-only key call was made. The second indicates that the key was successfully read from your key source (CipherTrust Manager or DSM) and returned to Salesforce.

Destroy a Tenant Secret

On the **Tenant Secret** page, destroying a tenant secret permanently deletes it from Salesforce. However, a backup key will remain in the key source you are using (CipherTrust Manager or DSM). After deletion, two new actions are displayed in the Action column: *Import* and *Delete Backup*.

Note

You can destroy only an archived tenant secret. If you want to destroy the currently active tenant secret, first change its status to ARCHIVED by uploading a new tenant secret (see ["Create a Tenant Secret/Key" on page 225](#)).

1. In the CCKM portal, in the left navigation bar, select **Tenant Secrets**.
2. Find the name of the tenant secret and click **Destroy** under the **Actions** column. The **Destroy Tenant Secret** dialog box displays with a warning asking you to confirm the key destruction by entering the supplied phrase.
3. Enter or copy/paste the confirmation phrase.

4. Click **Destroy**.

The **Status** column for this tenant secret shows **DESTROYED**, and *Import* and *Delete Backup* actions are listed under the **Actions** column.

Note: If you simultaneously deleted the backup key using the **check box** option, the **Action** column will be blank.

Destroy a Cache-only Key

On the **Tenant Secret** page, destroying a cache-only key removes it from the Salesforce cache. However, a backup of the key still exists in your key source (CipherTrust Manager or DSM). After the key is destroyed, the action of **Edit Key** is available under the **Action** column for the key. For more information about **Edit Key**, see "[Edit a Cache-only Key](#)" below.

Note

CCKM currently only supports CipherTrust Manager and DSM as the key sources for use with Salesforce's cache-only key service.

1. In the CCKM portal, in the left navigation bar, select **Tenant Secrets**.
2. Find the name of the key and click **Destroy**. The **Destroy Tenant Secret** dialog box displays with a warning asking you to confirm the key destruction by entering the supplied phrase.
3. Enter or copy/paste the confirmation phrase.
4. Click **Destroy**.

The Status column for this key shows **DESTROYED**.

Edit a Cache-only Key

If a certificate configured for use with a cache-only key has expired or you want to use another named credential that is configured with another CCKM hostname in Salesforce other than the one currently in use, edit the cache-only key configuration within the **Tenant Secret** page. You also have the option to edit a cache-only key that has a status of DESTROYED.

1. In the CCKM portal, in the left navigation bar, select **Tenant Secrets**.
2. Find the name of the key and click **Edit Key**. The **Edit <key_name> Cache-only Key** dialog box displays.
3. To update the certificate replacing the current certificate with another one, in the **Certificate** box, select the certificate you wish to use.
4. To update the named credential replacing the current named credential with another one, in the **Named Credentials** box, select the named credential you wish to use.
5. Click **Update cache-only key**.

Import a Tenant Secret

In the event that someone deletes a Salesforce tenant secret directly in Salesforce, it is possible to restore it from the CCKM as follows:

Notes

- The Import action is available for tenant secrets with the status DESTROYED.
- If anyone deletes the backup key from CCKM, it will not be possible to import/restore the key to Salesforce.

1. In the CCKM portal, in the left navigation bar, select **Tenant Secrets**.
2. From the **Tenant Secrets** list, select **Import** in the **Action** column of a Destroyed key. The key and metadata are restored to Salesforce. The Success message is displayed and the key is listed at the top of the **All Tenant Secrets** page with the status **ARCHIVED**.

Rotate a Tenant Secret

CCKM allows for a manual or a scheduled rotation of a Salesforce tenant secret by the tenant secret type. When you rotate a tenant secret, that key becomes active and the previously active key is automatically archived. Scheduling a rotation of a key is adding a new version of the key at a scheduled time. Scheduling the rotation of a tenant secret requires that you first configure this feature from the **Schedules** page prior to enabling it using the **Auto-rotate** button at the top of the **Tenant Secrets** page.

Notes

- If you provide your Salesforce user password when configuring the scheduled rotation of a tenant secret, which is an optional step, the password is saved to the key source you are using (CipherTrust Manager or DSM).
- The **Auto-rotate** button is set to **On** or **Off** depending on the key's autorotation status. If the key is scheduled for autorotation, this button is set to **On**. Otherwise, it is set to **Off** indicating the key is not scheduled for autorotation. The **Auto-rotate Tenant Secret for Type** dialog box displays when you click on the **Auto-rotate** button.

Manually Rotate a Tenant Secret (Add a New Version of a Tenant Secret)

Creating and uploading a tenant secret in CCKM is equivalent to manually rotating a tenant secret in CCKM.

Enable a Scheduled Tenant Secret Rotation

Enabling a scheduled rotation of a tenant secret requires that you first schedule to rotation in the **Schedules** page. Be sure to schedule the rotation of a tenant secret prior to enabling this feature.

During the scheduled date and time for the rotation, the tenant secret is rotated. The new tenant secret becomes active and the previously active tenant secret is automatically archived.

Note

A tenant secret that is a cache-only key remains as a cache-only key after rotation.

To enable a scheduled rotation of a tenant secret:

1. In the CCKM portal, in the left navigation bar, select **Tenant Secrets**. The **Tenant Secrets** list page displays.
2. From the **Tenant Secrets** list page, within the **Filter by** box, select the type of tenant secret to enable for a scheduled rotation. The following are the options:
 - Data in Salesforce
 - Search Index
 - Data in Salesforce (Deterministic)
 - Analytics
 - Event Bus
3. Click the **Auto-rotate** button. The **Auto-rotate Tenant Secret for Type** dialog box displays.
4. For **Enable autorotation on this type?**, select **On** to enable the autorotation of this tenant-secret type. By default, this toggle is initially set to **Off**.
5. From the **Schedule** drop-down menu, select a rotation schedule to which to apply to this key. Any key-rotation schedule you set in the **Schedules** page displays as an option for selection in the drop-down menu.
6. From the **Key Provider** box, select one of the following as the key source to which to add a new version:
 - **DSM**—Key is to be generated from DSM.
 - **CipherTrust Manager**—Key is to be generated from CipherTrust Manager.
7. (Optional) Select whether to apply the Salesforce key derivation mode to the tenant secret. If you choose to apply it, ensure that the **Use Salesforce key derivation** check box is selected. By default, the check box is selected. Otherwise, deselect the check box to opt out of applying the key derivation mode to the tenant secret.
8. From the **Certificate** drop-down menu, select a valid certificate (used to wrap the key for secure upload).
9. Click **Submit**.

Synchronize Tenant Secrets

Synchronization downloads tenant secrets that were directly created in the Salesforce portal (not in CCKM). It does not upload anything from CCKM to Salesforce. Periodically synchronize CCKM with Salesforce to get any newly created tenant secrets from Salesforce.

To synchronize tenant secrets:

1. In the left navigation bar, click **Tenant Secrets**.
2. Click **Synchronize**.

Any new tenant secrets created in Salesforce are retrieved and displayed on the **Tenant Secrets** list.

Export Tenant Secrets

Export Secrets allows you to export the contents of the Tenant Secrets list into a report in a CSV format.

To export your Tenant Secrets list:

1. In the left navigation bar, click **Tenant Secrets**.
2. Click **Export Secrets**.

This will download all of the tenant secrets in a report in a CSV format.

Backup Key

When a tenant secret is uploaded to Salesforce from CCKM, Salesforce creates a backup tenant secret (or key) as an encrypted blob, which contains information about the Salesforce tenant secret. The backup key can be used to restore a tenant secret that has been deleted in Salesforce. After Salesforce creates a backup key, CCKM automatically downloads and stores the tenant secret in the key source you are using (CipherTrust Manager or DSM). In addition, when Salesforce tenant secrets are synchronized, the backup key of any tenant secret that was created directly in the Salesforce portal is also downloaded and stored in the key source you are using.

Delete a Backup Key

Delete a backup key when you definitely do not want the key and have no corresponding data that will ever need decryption. For a tenant secret that has been deleted:

1. In the CCKM portal, in the left navigation bar, select **Tenant Secrets**.
2. From the list, select **Delete Backup** from the **Action** column of a Destroyed tenant secret. The **Destroy Key** warning page is displayed.
3. Enter or copy/paste the confirmation phrase.
4. Click **Delete**.

The key is removed from CCKM.

Certificates

The **All Certificates** list page allows you to view all Salesforce certificates, including Name, Type, Key Size and Expiration Date. Use the **Synchronize** button to download newly created certificates from Salesforce.

Note

See ["Prerequisites on Salesforce" on page 216](#) for the minimum required parameters for creating Salesforce certificates compatible with CCKM.

Synchronize Certificates

Synchronization downloads certificates that were directly created in the Salesforce portal (not in CCKM). Periodically synchronize CCKM with Salesforce to get any newly created tenant certificates from Salesforce.

1. In the left navigation bar, click **Certificates**.
2. Click **Synchronize**.

Any new certificates created in Salesforce are retrieved and appear in the UI.

Reports

Before the Salesforce keys can be represented in the CCKM reports, Event monitoring and Event log files must be activated in Salesforce. In addition, the log files validity must be set to 30 days in Salesforce.

Note

Currently, there is no support for cache-only keys within CCKM reports.

The **All Reports** page displays links to the following detailed individual reports:

- **Key Activity Report**
Displays the key activity type (such as TS (tenant secret) stored or TS generated) performed by a specific user along with the associated key ID, key version number, key name, and time at which the activity took place.
- **Cloud Key Manager User Action Report**
Lists the users and their actions in creating, uploading, importing, destroying, and deleting keys in the CCKM portal.

For each report displayed on the **All Reports** page, the report name, its description, the email address of the user who had run it (Created By), and the date on which it was previously run (Last Run) is displayed. For a specific report you select to view, the date on which it was previously run (Last Run), the start and end dates selected for the report, the email address of the user who had run it (Created By), and the total number of records available in the report (Report Count) is displayed. In addition, an **Actions** column is displayed, which provides the **Delete Report** link to allow for the deletion of the selected report from CCKM.

Delete a Report

1. From **All Reports** page, select the specific report you wish to delete. The report displays.
2. From the **Actions** column, click **Delete Report**. The **Delete Current Report** dialog box with a warning that you are about to delete a current report run on a specified date and time.
3. Click **Delete**. The report is deleted from CCKM.

Generate a Report

1. In the CCKM portal, in the left navigation bar, select **Reports**.
2. Under **Report Name**, select the report you wish to run.
3. From **Date Range**, click **Last day** to run the report for the activities from the previous day or **Specific** to run the report using a date range. If you choose to run by a date range, enter the start and end dates in the format MM/DD/YY or select the dates from the calendar button at the right of the box.
4. Click **Run Report**. The report displays.
5. To download the report, click **Download** at the top right of the page and select the report format (PDF or CSV) to download.

Schedules

The **Schedules** page allows Cloud administrators to view and schedule the following job types:

- Key Rotation
- Key Synchronization

CCKM provides support for multiple schedules for each of the job types.

At the top right of the **Schedules** page, the **Add Schedule** button is available from which to add a scheduled job type.

Note

Currently, there is no support for cache-only keys within CCKM schedules.

Schedule Key Rotation

CCKM provides support for multiple schedules of the rotation (autorotation) of a Salesforce tenant secret. When you rotate a tenant secret, that key becomes active and the previously active key is automatically archived. Scheduled rotation is configured in the **Schedules** page. Note that if you provide your Salesforce user password when configuring a scheduled key rotation, the password is saved to the key source you are using (CipherTrust Manager or DSM).

During a scheduled rotation of a key, CCKM uses the associated username and password to rotate the key. If the password expired or changed, the new password must be reentered. Otherwise, the scheduled rotation will fail.

Also, during a scheduled rotation of a key, CCKM uses the associated wrapping certificate to rotate the key. If this certificate expired, it must be renewed. Otherwise, the scheduled rotation will fail.

Note

If you have added an email address of the recipient who is to receive email notifications from CCKM and set up an SMTP server to send email notifications from CCKM, then a notification is sent to the recipient when the wrapping certificate is detected as expired during autorotation. The notification indicates that the named certificate expired and includes a reminder to renew the certificate. For more information about adding recipients' email addresses for notifications, see ["Adding Recipients' Email Addresses \(for Notifications\)" on page 237](#). For more information about setting up an SMTP server, see ["Set SMTP Settings" on page 83](#).

An error about an expired wrapping certificate is automatically logged on the **Logs** page.

You can pause or delete a scheduled key rotation in the **Schedules** page. Note that when a key rotation schedule is deleted from CCKM, then the Salesforce user password is also deleted from the key source you are using (CipherTrust Manager or DSM).

Note

CCKM does not support the concurrent use of CipherTrust Manager and DSM as key sources.

Set up a Key Rotation Schedule

1. In the CCKM portal, in the left navigation bar, select **Schedules**. The Schedules page displays.
2. On the **Schedules** page, select the **Add Schedule** button. The **Add Schedule** dialog box displays including your username in the **Username** box.
3. From the **Job Type** drop-down menu, select **KEY_ROTATION**.
4. In the **Name** box, enter the name of the schedule. Ensure this name is unique for this job type.
5. (Optional) Enter a description of the schedule in the **Description** box.
6. For **Pause**, select **No**.

7. For **Schedule**, set a schedule for the rotation by selecting **Basic** (to enter a date and interval for the schedule) or **Advanced** (to enter a Cron Expression for the schedule). If you selected **Basic**, select a start date and time from a date and time selector by clicking the calendar button to the right of the box. The time is based on a 12-hour clock and the A.M./P.M. modifiers.

Set the repeat interval of the key rotation by entering a number in **Repeat Interval** and then selecting Day, Week, or Month from the drop-down menu. The supported ranges are 1 through 30 days, 1 through 4 weeks, and 1 through 12 months. You can increase or decrease the number you enter.

If you selected **Advanced**, enter the cron expression in the **Cron Expression** box.

8. (Optional) Enter your Salesforce user password in the **User Password** box.
9. Click **Save**.

Pause a Key Rotation Schedule

To pause a key rotation schedule, select **Yes** for **Pause** within the **Add Schedule** dialog box and then click **Save**. The setting is saved. To resume the rotation schedule after pausing it, select **No** for **Pause** and then click **Save**. The setting is saved.

Delete a Key Rotation Schedule

To delete a key rotation schedule, select **Delete** from the **Actions** drop-down menu from the **Schedules** page. Note that the Salesforce user password associated with the given key rotation schedule is also deleted from the key source you are using (CipherTrust Manager or DSM).

Schedule Key Synchronization

CCKM allows for multiple schedules of the synchronization of Salesforce tenant secrets. Synchronizing downloads any keys that were created in Salesforce, outside of the CCKM portal, into your CCKM. Scheduled key synchronization requires that this feature be configured in the **Schedules** page. You can also pause or delete a scheduled key synchronization in the **Schedules** page. Note that when a key synchronization schedule is deleted from CCKM, then the Salesforce user password is also deleted from the key source you are using (CipherTrust Manager or DSM).

Note

CCKM does not support the concurrent use of CipherTrust Manager and DSM as key sources.

Set up a Key Synchronization Schedule

1. In the CCKM portal, in the left navigation bar, select **Schedules**. The **Schedules** page displays.
2. On the **Schedules** page, select the **Add Schedule** button. The **Add Schedule** dialog box displays including your username in the **Username** box.
3. From the **Job Type** drop-down menu, select **KEY_SYNCHRONIZATION**.
4. In the **Name** box, enter the name of the schedule. Ensure this name is unique for this job type.
5. (Optional) Enter a description of the schedule in the **Description** box.
6. For **Pause**, select **No**.

7. For **Schedule**, set a schedule for the rotation by selecting **Basic** (to enter a date and interval for the schedule) or **Advanced** (to enter a Cron Expression for the schedule). If you selected **Basic**, select a start date and time from a date and time selector by clicking the calendar button to the right of the box. The time is based on a 12-hour clock and the A.M./P.M. modifiers.

Set the repeat interval of the key rotation by entering a number in **Repeat Interval** and then selecting Day, Week, or Month from the drop-down menu. The supported ranges are 1 through 30 days, 1 through 4 weeks, and 1 through 12 months. You can increase or decrease the number you enter.

If you selected **Advanced**, enter the cron expression in the **Cron Expression** box.

7. Enter your Salesforce user password in the **User Password** box.
8. Click **Save**.

Logs

CCKM maintains logs for events, such as login, key generation, synchronizing of keys, calls from Salesforce to CCKM for cache-only keys, and deletion of keys, and displays these logs in the **All Logs** list of the **Logs** page. If Replay Detection for cache-only keys is enabled, then the request ID is included in logged events for cache-only keys. For each logged event listed on the **Logs** page, the following information is displayed:

- Event name
- Severity level
- Date and time of the event
- Event message
- User (name) associated with the event

You can search for a specific logged event from the **Logs** page using the **Search** box. Allowable filters on the search are event name, severity level, event message, and user (name).

Key Sources

The **Key Sources** page displays **all** of the keys that were generated from the key source you are using. If you are logged into multiple clouds within CCKM, this page displays all of the keys from these clouds.

Three tabs are available at the top of the **Key Sources** page:

- **CipherTrust Manager Key:** Use this tab to use CipherTrust Manager as your key source. The keys are generated and stored within CipherTrust Manager.
- **DSM Key:** Use this tab to use DSM as your key source. The keys (including cache-only keys) are generated and stored within DSM.
- **nShield Key:** This tab is currently unavailable for use as CCKM does not currently support nShield Connect as a key source for Salesforce.

Note

CCKM does not support the concurrent use of CipherTrust Manager and DSM as key sources.

Note

CCKM currently only supports CipherTrust Manager and DSM as the key sources for use with Salesforce's cache-only key service.

Note

The Salesforce term “tenant secrets” is used interchangeably with “keys” in CCKM. Manage tenant secrets from two places in the CCKM portal: the **Tenant Secrets** page and the **Key Sources** page.

Keys listed on the **Key Sources** page are listed by name, cloud ID, key type (the cloud in which this key is used), the algorithm of the key, the creation date of the key, key description and actions you can take regarding that key.

A **Search** box is available at the top left of the **Key Sources** page allowing for a search of a specific key by entering any one of the following parameters:

- Name (key name)
- Cloud ID
- Key Type
- Algorithm
- Description
- Created By (a key created by a specific user)

Add (Generate) a Key

From the **Key Sources** page, you can add (or generate) keys in CCKM using CipherTrust Manager or DSM as a key source for *all* of the clouds into which you are currently logged.

Note

The key algorithm currently supported for a Salesforce key in CCKM is AES.

Add (Generate) a CipherTrust Manager Key

1. In the CCKM portal, in the left navigation bar, select **Key Sources**.
2. Select the **CipherTrust Manager Key** tab.
3. Select **Add Key > Salesforce Key**.
4. In the **Add CipherTrust Manager Key** dialog box, select the name of the user of the key from the **User** drop-down menu. **Service** is fixed to **Salesforce Key** and (key) **Algorithm** is fixed to **AES256**.
5. In the **Name** box, enter the name of the new key.
6. Enter a description of the key in the **Description** box.
7. Click **Save** to save the new key to CCKM. The new key is added to the key list.
(Reset clears the screen before it is saved.)

Add (Generate) a DSM Key

1. In the CCKM portal, in the left navigation bar, select **Key Sources**.
2. Select the **DSM Key** tab.
3. Select **Add Key > Salesforce Key**.
4. In the **Add DSM Key** dialog box, select the name of the user of the key from the **User** drop-down menu. **Service** is fixed to **Salesforce Key** and (key) **Algorithm** is fixed to **AES256**.
5. In the **Name** box, enter the name of the new key.

6. Enter a description of the key in the **Description** box.
7. Click **Save** to save the new key to CCKM. The new key is added to the key list.
(Reset clears the screen before it is saved.)

Add (Generate) an nShield Key

The **nShield Key** tab is currently unavailable for use as CCKM does not currently support nShield Connect as a key source for Salesforce.

Delete a Key

Deleting a key from the **Key Sources** page deletes the key from CCKM. If you delete a key from the **Key Sources** page that has already been uploaded to Salesforce, the key will not be deleted from Salesforce.

1. In the CCKM portal, in the left navigation bar, select **Key Sources**.
2. Click **Delete** next to the target key. The **Delete Key** dialog box with a Warning displays asking you to confirm the key deletion by entering the supplied phrase.
3. Enter or copy/paste the confirmation phrase.
4. Click **Delete**.

Manage Keys in Key Sources List Page

In addition to adding and deleting keys, the **Key Sources** page allows you to sort the existing keys by Name, Key Type, Algorithm and Created Date.

Settings

To access the **Settings** page in CCKM, select **Settings** from the left-hand navigation bar. From the **Settings** page, you can:

- Enter the email addresses of the recipients who are to receive the email notifications.
- Enable email notifications to be sent out from CCKM when specific types of key actions are performed from the **Tenant Secrets** page. For example, when a key is uploaded to the cloud service. You can also enable CCKM to send reminder notifications for when to rotate a key.
Configure a remote syslog server to which to send syslog messages.
- Configure the username and password to associate with the CCKM Rest API endpoint (or callout endpoint) for use with cache-only keys.
- View information about the software release number of the CCKM you are running including the build and version number.

Adding Recipients' Email Addresses (for Notifications)

Use the **General** tab from the **Settings** page to enter the email addresses of the recipients who are to receive email notifications from CCKM. Enter the recipients' email addresses separated by a comma in the **Notification Recipient** box and then click **Save** to save setting.

Enabling Notifications

Using the **Keys Notification** tab from the **Settings** page, you can configure CCKM to send an email notification when a tenant secret is destroyed from Salesforce or imported or uploaded to Salesforce. You can also use this tab to configure CCKM to send a reminder notification for when to manually rotate a key along with the frequency (in days) at which a notification is sent. Add the email address(es) of the recipients in the **General** tab from the **Settings** page. By default, no notifications are sent.

To enable email notifications:

1. In the **Settings** page, select the **Keys Notification** tab.
2. Under **Notifications**, select **On** for each of the notifications you wish to enable:
 - Rotate Tenant Secret (reminder notification)
 - Destroy Tenant Secret
 - Import Tenant Secret
 - Upload Tenant Secret
3. If you selected to enable **Rotate Tenant Secret**, in the **Days** box, enter the number of days for the frequency a reminder notification is sent.
4. Click **Save**.

Configuring Syslog Server

Note

In this document, the terms "syslog server" and "log server" are synonymous.

The **Syslog** tab from the **Settings** page allows you to configure the remote syslog or log server to which to send CCKM log data using TCP, TLS, or UDP protocol as the transport protocol. If you use the TLS protocol, then you are required to upload the syslog server certificate to CCKM for the TLS connection.

The **Syslog** tab also allows you to delete your syslog server configuration so that log data are no longer sent to the server.

Prior to configuring the setting for a remote syslog server, ensure that you have installed and configured the syslog server including configuring the setting for the port number the transport protocol will use to connect to CCKM. This port number configuration must match the port configuration you set in the **Syslog** tab of the **Settings** page.

Note

Support for both Syslog and Splunk as a remote syslog server is provided in CCKM. However, the use of a Splunk cloud server as a remote syslog server is currently not supported in CCKM.

Configure a Remote Syslog Server

To configure a remote syslog server to which to send CCKM log data:

Note

The facility name of "LOCAL1" for the syslog server displays in the **Facility** box. This default value is not available for modification.

1. In the **Settings** page, select the **Syslog** tab. The **Syslog** dialog box displays.
2. In the **Hostname** box, enter the hostname or IP address of the syslog server.
3. In the **Port** box, enter the port number the transport protocol uses to connect to the syslog server. Enter a value between 1 and 65535. The default value is 514.
4. In the **Protocol** drop-down menu, select **TCP**, **TLS**, or **UDP** for the transport protocol to use when sending the log data to the syslog server. The default value is **UDP**. If you select **TCP**, proceed to Step 6. If you select **TLS**, proceed to the next step. Otherwise, proceed to Step 7.
5. In the **Certificate** box, select **Choose File** and then select the syslog server certificate to upload to CCKM.
6. Click **Test Connection** to test the connection between CCKM and the remote syslog server. This button is only available for use when either **TCP** or **TLS** is the selected transport protocol.
7. In the **Log Format** drop-down menu, select **CEF** (Common Event Format), **Plain Text**, or **RFC5424** for the format of the log message to use when sending the log data. The default value is **RFC5424**.
8. (Optional) In the **Description** box, enter a description of the remote syslog server.
9. Click **Save**.

Delete Remote Syslog Server Configuration

To delete the configuration of a remote syslog server:

1. In the **Settings** page, select the **Syslog** tab. The **Syslog** dialog box displays.
2. Click **Delete**. The **Delete Syslog** dialog box displays.

A warning message displays indicating that this action will delete the syslog settings from CCKM. The message also indicates to type the confirmation phrase (I wish to delete the syslog settings) in the text box if you still wish to delete the syslog settings.
3. Enter or copy/paste the confirmation phrase in the text box.
4. Click **Delete**.

Configure Cache-only Key Endpoint

Use the **Endpoint for Cache-only Key** tab from the **Settings** page to configure the CCKM username and password to associate with the URL of the CCKM Rest API endpoint (or callout endpoint) for use with cache-only keys.

Note

Note the call-out URL, username, and password when performing the steps in this section. These values are required when you create the Named credential in Salesforce. See ["Set up Named Credential in Salesforce"](#) on page 219 for more information.

To configure the username and password to associate with the URL of the CCKM Rest API endpoint:

1. In the **Settings** page, select the **Endpoint for Cache-only Key** tab. The **Cache-only Key Configuration** page displays.
2. The URL of the CCKM Rest API endpoint automatically displays in the **Call out URL** box.

Note: When defining the named credential for use with cache-only keys within Salesforce's **Named Credentials Setup** page, copy the URL from the **Call out URL** box and paste it into the **URL** box in **Named Credentials Setup** page. Verify that URL points to public facing CCKM instance. Verify hostname and port number is correct. For example, if CCKM URL is `https://thalescckm.com:8443/kmaas/` and the org ID is `00DB00007731234MAK`, then the callout URL will be: `https://thalescckm.com:8443/kmaas/00DB00007731234MAK/`

3. In the **Username** box, enter the username to associate with the URL of the CCKM Rest API endpoint. This username must match the username configured in Salesforce's **Named Credentials Setup** page.
4. In the **Password** box, enter the password to associate with the URL of the CCKM Rest API endpoint. This password must match the password configured in Salesforce's **Named Credentials Setup** page.
5. Click **Save Settings** to save the setting.

About

Use the **About** tab to view the release number of the CCKM you are running.

Chapter 18: Backup and Restore

Backup and Restore Recommendations	241
Backup and Restore for DSM	241
Backup and Restore for CipherTrust Manager	241
Backup and Restore for MongoDB	241

In the event of a software crash or system changes, a backup of the CCKM configuration data stored within the key source you are using (CipherTrust Manager or DSM) and MongoDB can be used to restore CCKM to have your most recent backup of your data. Data stored within your key source and MongoDB include usernames, encryption keys, key attributes, local CAs, external CAs, certificates, signatures, and syslog connections.

Backup and Restore Recommendations

The following are the recommendations for backing up and restoring the CCKM configuration data within the key source you are using and MongoDB:

- CCKM should be inactive when the backups are performed to avoid data corruption.
- Backups of the key source and MongoDB should be performed during the same period (ensuring that the same snapshot of the CCKM configuration is backed up in both).
- Daily backups of your key source and MongoDB are recommended.

Backup and Restore for DSM

See the *Data Security Manager (DSM) Administration Guide* for information on how to backup and restore the CCKM configuration data stored within DSM, in addition to how to configure DSM for high availability.

Backup and Restore for CipherTrust Manager

See the *CipherTrust Manager Administrator Guide* for information on how to backup and restore the CCKM configuration data stored within CipherTrust Manager.

Backup and Restore for MongoDB

For information on how to backup and restore the CCKM configuration data stored within MongoDB or MongoDB Atlas, refer to the appropriate online MongoDB documentation. Likewise, for information on how to backup and restore the CCKM configuration data stored within Percona Server for MongoDB, refer to the appropriate online Percona Server documentation.

Chapter 19: Troubleshooting

Troubleshooting nShield Configurations	242
Troubleshooting Logs Files for Thales Support Team	243
Restrictions	243

Troubleshooting nShield Configurations

This section describes a few of the common issues that may arise during the configuration of the connection from CCKM to nShield Connect HSM(s), and the associated RFS and Security World within the Settings page and the steps to take to attempt to resolve these issues.

For more information on troubleshooting the configuration for nShield Connect, and the associated RFS and Security World, refer to the *nShield Connect User Guide for Unix*.

Table 19-1: Basic Troubleshooting nShield Configurations

Issue	How to Resolve
You entered an incorrect IP address for an nShield Connect during "Configure nShield Connect (for Azure and AWS Clouds)" on page 75 procedure.	Verify the electronic serial number (ESN) of each nShield Connect. To verify this, ensure that the output of the "rfs-sync --setup" command indicates "Configuration successfully written". From the nShield 1 IP Address box of the Key Sources page > nShield tab, enter the correct IP address of the nShield Connect and then click Add to Security World again.
A network connection from CCKM to nShield Connect cannot be detected.	Verify the ESN of each nShield Connect. To verify this, ensure that the output of the "rfs-sync --setup" command indicates "Configuration successfully written". Also, ensure that the output of the "rfs-sync --update" command includes "Updated module ..." or "Finished synchronization".
You entered an incorrect IP address for the RFS computer during the "Configure nShield Connect (for Azure and AWS Clouds)" on page 75 procedure.	The output of the "rfs-sync --update" command does not include "Updated module ...". From the nShield RFS IP Address box of the Key Sources page > nShield tab, enter the correct IP address of the RFS computer and then click Add to Security World again.

Only after you have verified that the output of all commands (displayed on the right side of the nShield Info page) are correct should you proceed to saving the nShield Connect configurations during the Install and Configure nShield Connect as a Key Source procedure. Saving the configuration restarts the hard server (Security World Software server) on which the CCKM is installed and configured.

Troubleshooting Logs Files for Thales Support Team

Thales Support will request for you to download the debug logs from CCKM in order to assist you in troubleshooting your issue(s).

To download the debug logs, click on **Download Debug Logs** on the **Logs** page within the CCKM Admin Portal. You can also download the debug logs through the **upload** command within the CCKM **applog** commands.

Restrictions

The following restrictions apply to the current version of CCKM:

- The Azure key vault name and key name combined cannot exceed 64 characters.
- The DSM domain name prefix must **not** exceed 28 characters.

Appendix A: CCKM CLI Commands

CCKM CLI Navigation	244
Maintenance Commands	245
Network Commands	245
System Commands	246
User Commands	246
Appllog Commands	247

The CCKM Command Line Interface (CLI) enables you to configure the CCKM network and perform other system-level tasks using the CCKM CLI commands.

This appendix provides a high-level overview of each of the command categories that are available in the CCKM. For information about the details of each command and its options, run the command with the “--help” option within the CCKM CLI.

CCKM CLI Navigation

The following are the supported categories of CCKM CLI commands:

- Maintenance
- Network
- System
- User
- Appllog

As a CCKM CLI administrator, log on to the CLI, and then enter a command category by typing the category name at the command line prompt. For example, type `system` to enter the system category. While in the category, you can execute the commands for that category.

Enter the entire category name, command, or argument, or enter just enough characters to identify uniquely the category, command, or argument. You can use the <Tab> key to complete a category, command, or argument. Enter enough characters to uniquely identify a category, command, or argument, and then press the <Tab> key. The CLI will complete it for you.

For example, at the top level, enter `n` and press <Tab>, the CLI expands it to `network`.

Inside the network category, you can enter `d<Tab>` and it expands to `dns`. Type `n<Tab>` and it expands to `netstat`. Note that there are other commands in the network category that start with `n`, such as `nslookup`, and `ntpservice`. To ensure to expand to `netstat` command, enter `ne` to identify it uniquely.

Other supported CLI navigation methods are:

- Enter a question mark (?) to display the next command or argument that is expected. Think of it as a shorthand form of help.
- Enter “up” to return to the top level so that you can enter another category. You can enter another category only from the top level.
- Enter “exit” at any time to end the current CLI session.

Maintenance Commands

The CCKM maintenance commands enable you to upgrade the CCKM and reset the CCKM admin password. [Table A-1: "CCKM Maintenance Commands" below](#) lists the supported CCKM maintenance commands:

Table A-1: CCKM Maintenance Commands

Command	Description
resetwebadmin	Resets the CCKM administrator password to the default value of 'admin123'.
updatedbpassword	Updates the MongoDB password in CCKM configuration. Provide the new password to replace the current password stored in the CCKM conf file.
upgrade	Upgrades the CCKM. As part of the upgrade to CCKM, you have the option to make the upgrade package available for download from a remote host over HTTPS or SCP.
quit q up <ctrl-d>	Quits or returns to the previous menu.
Exit	Exits the application.

Network Commands

The CCKM network commands are used to set, modify, or delete IP addresses on the CCKM, set up DNS servers, and perform other network-related tasks. [Table A-2: "CCKM Network Commands" below](#) lists the supported CCKM network commands:

Table A-2: CCKM Network Commands

Command	Description
checkport	Checks port connection status of a host.
dns	Shows or configures the DNS settings for the CCKM.
ip	Shows the CCKM network interface settings.
netstat	Prints network connections.
nslookup	Queries Internet name servers.
ntpservice	Configures NTP service settings.
ping	Pings an IP address, host name, or FQDN.
route	Sets a static route.
service	Starts, stop, or restart a network service or gets the status of a network service.
set	Configures a network device interface.
setup	Sets up a network configuration.
show	Shows network device configuration.
traceroute	Traces route to an IP address or hostname.
quit q up <ctrl-d>	Quits or returns to the previous menu.
exit	Exits the application.

System Commands

The CCKM system commands enable you to configure the CCKM host settings (such as, date and time or timezone) and security features, reboot or shut down the CCKM, show current CCKM version information, and perform other system administration tasks. [Table A-3: "CCKM System Commands" below](#) lists the supported CCKM system commands:

Table A-3: CCKM System Commands

Command	Description
date	Prints or sets the system date and time.
host	Performs DNS lookups.
hostname	Sets or shows the CCKM hostname.
hosts	Updates the host file.
lastlogin	Shows the last logged-in date for each user on the system.
passwordrecovery	Manages the options for the recovery of the CLI admin user password. When this command is set to enable , you have the option to reset your CCKM CLI admin password (if required) using a password recovery utility. Note: Thales <i>highly recommends</i> that the passwordrecovery is set to enable to ensure you can easily reset your CLI admin password in case you lose or forget it. To reset your admin password, contact Thales Customer Support.
port	Configures the ports of the CCKM Admin Portal and User Portal.
reboot	Reboots the CCKM appliance.
security	Configures the CCKM security features including the certificates.
server	Manages the CCKM server.
shutdown	Stops the CCKM software and powers off the virtual appliance.
sshbanner	Configures, shows, and removes the current ssh banner that displays when you log in to the CCKM CLI. You can also set the current version of the ssh banner to the default version of "Welcome to CipherTrust Cloud Key Manager".
timezone	Sets or shows the system timezone.
uptime	Shows how long the CCKM has been running.
version	Shows the CCKM version information.
who	Shows information about the users who are currently logged into the CCKM appliance using CLI.
quit q up <ctrl-d>	Quits or returns to the previous menu.
exit	Exits the application.

User Commands

The CCKM user commands enable you to add, modify, delete CCKM CLI users, and display information about these users. [Table A-4: "CCKM User Commands" on the next page](#) lists the supported CCKM user commands:

Table A-4: CCKM User Commands

Command	Description
add	Adds a new CLI user.
delete	Deletes a CLI user.
modify	Changes the password of a CLI user.
show	Lists all of the configured CLI users.
quit q up <ctrl-d>	Quits or returns to the previous menu.
Exit	Exits the application.

Applog Commands

The CCKM applog commands enable you to upload debug logs from the CCKM to the remote servers using the secure copy protocol (SCP) to transfer the log files between the two hosts. [Table A-5: "CCKM Applog Commands" below](#) lists the supported CCKM applog commands:

Table A-5: CCKM Applog Commands

Command	Description
upload	Uploads logs to remote server using SCP.
quit q up <ctrl-d>	Quits or returns to the previous menu.
Exit	Exits the application.

Appendix B: How to Export Your DSM Server Certificate from DSM

Exporting your DSM Server Certificate 248

CCKM for a supported cloud performs key operations through REST APIs exposed in the key source (CipherTrust Manager, DSM, or nShield) you are using. If you are using DSM as a key source for CCKM, CCKM requires the DSM server certificate to invoke the APIs. You can download the certificate through the use of a browser pointing to the DSM. Download the file in a Base64 format. When configuring the DSM as your key source in the **Key Sources** page of the CCKM Admin Portal, you are required to upload the DSM certificate to CCKM.

This appendix describes how to export a DSM certificate file from DSM to your laptop or desktop using the Chrome Internet browser. This file is then available to upload to the CCKM. For more information, see ["Configure DSM as Key Source" on page 75](#).

Note

The steps to export a DSM server certificate using the Firefox and IE browsers may differ slightly from the steps for the Chrome browser.

Exporting your DSM Server Certificate

To export your DSM server certificate from DSM using the Chrome browser:

1. Enter "https://<DSM IP address>" in a browser. The DSM user login page is displayed.
2. Log on to the web-based management console of the DSM.
3. In the web URL, click on the **Not Secure** section and click **View Certificate**.
4. Click the **Details** tab of the certificate.
5. Click **Copy to File**. The **Certificate Export Wizard** dialog box displays. This wizard is used to export your certificate in the appropriate format.
6. In the **Export File Format** page, select the **Base-64 encoded X.509 (.CER)** format option.
7. Click **Next**.
8. In the **File to Export** page, enter the directory to which to save the file within your laptop or desktop and specify the file name (for example, "DSM.cer").
9. Click **Finish**.

Appendix C: Configure SSL/TLS Certificate Chain of Trust for CCKM

Create and Configure SSL/TLS Certificate Chain of Trust 249

The chain of trust of an SSL or TLS certificate is an ordered list of certificates. The following certificates are contained within the certificate chain of trust:

- Server Signed Certificate—signed certificate, which would be signed by Intermediate Certificate Authority (CA).
- Intermediate Certificate—Certificate of CA that certifies the server certificate.
- Root Certificate—Certificate of CA that certifies Intermediate CA certificate. This is the root CA.

Note that there can be more than one intermediate CA certificate forming a chain of trust.

The certificate chain of trust enables the receiver of the certificate to verify that the sender and all intermediate certificates are trustworthy and that the certificate is valid.

Using CCKM CLI, you have the ability to generate a Certificate Signing Request (CSR). When you wish to have your CCKM server certificate signed by an external CA, you must first generate a CSR and then send it to a CA. As part of the CSR generation, provide information in the CLI including the following:

- CCKM hostname
- Organizational unit, which is typically a department or group name.
- Organization, which is typically a company name.
- Two-letter country code, which is the abbreviation of the country where the organizational unit is located.

Thereafter, the CA takes this CSR and sends you a digitally signed certificate after it verifies the CSR is a valid.

Using CCKM CLI, you also have the ability to upload a certificate chain of trust for an SSL/TLS certificate, which is sent to the web browser when you open up a browser window to login into the CCKM Admin and User portals.

Create and Configure SSL/TLS Certificate Chain of Trust

To create a chain of trust certificate and then configure a new CCKM server certificate based on the new chain of trust certificate:

1. Log into the CCKM CLI to access CCKM CLI.
2. Generate the Certificate Signing Request using the following command:
3. When prompted, enter the requested information for the CSR ensuring that the information you provide is consistent with the requirements of the external CA you are using:

Please enter the following information for Certificate Signing Request generation.

```
The server hostname[cckm hostname]:
What is the name of your organizational unit? []:
What is the name of your organization? []:
What is the name of your City or Locality? []:
```

```
What is the name of your State or Province? []:  
What is your two-letter country code? [US]:  
What is your email address? []:
```

4. After the CSR is generated, save the contents of the CSR to a file in a directory within your laptop or desktop.
5. Submit the CSR to your external CA to obtain an approved and signed certificate.
6. Obtain the intermediate and root CA certificates from your external CA and save each certificate to your laptop or desktop.
7. Create a certificate chain of trust using the following `cat` command in a Bash shell outside of CCKM CLI. For example:

```
$cat Server.crt IntermediateCA.crt RootCA.crt >> chain_of_trust.crt.
```
8. At CCKM command prompt, enter the following commands to configure a new CCKM server certificate:

```
cckm> system  
system> security --setservercert
```
9. The following message displays:

```
WARNING: Setting a new server certificate operation will implicitly restart the  
application.  
Do you wish to continue? <y/n> [n]:y
```
10. Type `y` to continue.
11. You are prompted to enter the contents of your server certificate and then press **Enter** and **Ctrl+d**. (Copy the contents of the `chain_of_trust.crt` file (from Step 6), paste it into CLI, and then press **Enter** and **Ctrl+d** :

```
Enter server certificate content and press Enter and Ctrl+d:
```
12. After the `chain_of_trust.crt` is uploaded, CCKM restarts the CCKM Admin and User portals. After these portals are back online, open a new browser and login into the CCKM Admin Portal.
13. Verify that the certificate chain of trust for CCKM is valid:

Note

The following steps are based on the use of the Chrome Internet browser. The steps based on the use of the Firefox and IE browsers may differ slightly.

- a. In the web URL, click on the Padlock icon in the address bar, and click **Certificate**.
- b. Click the **General** tab to view that the certificate is valid.

Appendix D: Sample Python Scripts for Authenticate and Call CCKM REST API

cckm-azure.py	252
cckm-aws.py	254
cckm-google.py	255
cckm-salesforce.py	256

This Appendix demonstrates how to authenticate and call CCKM REST API using a Python script. After launching and configuring a CCKM instance, you can access CCKM REST API at <https://<your cckm hostname or ip address>:8443/kmaas/doc>. You can use your preferred tools or scripts to call CCKM REST API. In this appendix, a Python script is used to demonstrate these API calls.

To call CCKM REST API, the script must first authenticate to CCKM using your cloud credentials. The authentication call will differ slightly depending on the following:

- Cloud service you are using
- Whether you are using Azure service principal
- Whether you are using AWS long-term credentials or temporary credentials

After successful authentication, you will get a cookie JSESSIONID and start a new user session. Subsequent calls to CCKM REST API within the user session must include this cookie. In addition, all requests must have a valid "X-XSRF-TOKEN" header to prevent a Cross Site Request Forgery (CSRF) attack. The following is the authentication flow:

1. Call <https://<your cckm>:8443/kmaas>. Get the X-XSRF-TOKEN from the response header, and use it in the request header.
2. Call proper auth API, passing cloud credentials in the Content-Type "application/x-www-form-urlencoded".
3. If auth call succeeds, save the JSESSIONID cookie, and attach it for subsequent calls.
4. Call CCKM REST API, using Content-Type "application/json"
5. Call logout.

The following are the current limitations when using CCKM REST API:

1. If your Azure tenant uses federated authentication, or enable MFA, you cannot use your Azure user credentials in CCKM REST API. You will have to configure CCKM as a service principal and provide admin consent to grant permissions to the CCKM app to access your Azure resources. During the admin consent process, you will choose a tenant password. Thereafter your REST API client or script can use your tenant name and password to authenticate to CCKM REST API.
2. You can use the temporary credentials of the AWS Security Token Service (STS) to authenticate CCKM REST API. However, when you call the add schedule REST API, you have to pass long-term credentials. If you do not have long-term credentials, then create your schedule jobs outside of CCKM instead of using the CCKM schedules.

The sections that follow provide four sample Python scripts used to authenticate and call CCKM REST API. These scripts are used to manage the following:

- Azure keys
- AWS keys
- Google Cloud keys
- Salesforce keys

These scripts use a Python Requests module to handle the session cookie. To see how each script works, enter your cloud credentials and remove commented out calls.

cckm-azure.py

```
import requests
import json
import sys

requests.packages.urllib3.disable_warnings()
session = requests.Session()
session.verify = False
resp = session.get(cckm_url)

# For Azure user login.
# Replace with your host, username and password
cckm_url = "https://host:8443/kmaas/"
username = ""
password = ""

session.headers = {'X-XSRF-TOKEN': resp.headers['X-XSRF-TOKEN']}
data = {'username': username, 'password': password}

Appendix E: Authenticate your REST API Client to CCKM REST APIs for Google Cloud Keys

This appendix shows how to authenticate your API client to the CCKM REST APIs using API calls before making calls to CCKM REST APIs to manage Google Cloud keys.

After submitting a POST call to authenticate to CCKM REST APIs, CCKM will first check your password hash against the password hash in its database. If it matches, CCKM will use the private key of the service account to obtain an access token from Google Cloud. Your REST API client is successfully authenticated to CCKM REST APIs when CCKM receives an access token from Google Cloud. At this point, you will receive a JSESSIONID cookie. Once you have this cookie, you can make calls to CCKM REST APIs to manage Google Cloud keys. You will need to add the JSESSIONID cookie and X-XSRF-TOKEN header to all subsequent REST API calls.

Refer to ["cckm-google.py" on page 255](#) for a sample Python script that demonstrates how to authenticate and call CCKM REST API to manage Google Cloud keys.

To authenticate your API client to the CCKM REST APIs using API calls:

1. Make a GET call:

```
GET https://<cckm hostname>:8443/kmaas
```

2. From the response header, copy the session x-xsrf-token.
3. Make a POST call (paste the session x-xsrf-token in the request header):

```
POST https://<cckm hostname>:8443/kmaas/auth/googleCloud
```

Request body:

```
{
  "email": "you service account email",
  "password": "your service account password",
}
```

Request headers:

```
Content-Type: application/x-www-form-urlencoded
X-XSRF-TOKEN: <your session x-xsrf-token>
```

Appendix F: General Guidelines for CCKM Appliance

This appendix provides the general guidelines for running the CCKM appliance with CipherTrust Manager and DSM.

Note

Each AWS account, Azure subscription, Google project, and IBM and Salesforce organization is considered one cloud unit.

The following are general guidelines for the CCKM Appliance:

- The number of cloud units must **not** exceed the number of CipherTrust Manager or DSM domains:
 - CipherTrust Manager has a limit of 1,000 domains.
 - DSM Enterprise has a limit of 1,000 domains.
 - DSM 25 has a limit of 2 domains.
 - DSM 10 has a limit of 2 domains.
- CipherTrust Manager has a limit of 1,000,000 keys in the CipherTrust Manager k470 and k570 appliance models.
- CipherTrust Manager has a limit of 25,000 keys in the Virtual CipherTrust Manager k470v model.

Note

The use DSM 10 or DSM 25 with CCKM is not supported due to the domain limitations.

Note

The size of your Mongo DB storage may limit the number of keys in CCKM.

 - Integration with CipherTrust Manager 3
 - Verifying Your Integration 16
 - Licensing 16
 - Appendix..... 17

HPE Ezmeral Data Fabric

HPE Ezmeral Data Fabric (EDF) provides a platform that spans core, cloud, and edge environments to ingest any data type or source while handling hundreds of petabytes and thousands of users with ease. It simplifies data management with a single infrastructure that automatically scales as data is ingested without impacting service-level objectives, security, or data resilience. Data on disk (or data-at-rest) on a secure data-fabric cluster can be encrypted, allowing you to protect the data if a disk is compromised.

Encryption of data-at-rest not only prevents unauthorized users from accessing sensitive data, but it also protects against data-theft through sector-level disk access. For encrypted volumes, data-fabric automatically encrypts data-at-rest and manages the keys used to encrypt data seamlessly. You do not need special utilities to encrypt or decrypt the data. Data Fabric uses AES256/XTS to protect data on the disk.

Supported Product Versions

Note

The integration is performed and certified on **LTS release versions** of CipherTrust Manager only. Feature releases support the integration and are covered under technical support but will not be explicitly certified. To know more about CipherTrust Manager release versions, click [here](#).

CipherTrust Manager

- CipherTrust Manager 2.7 and higher

HPE EDF Version

- HPE Ezmeral Data Fabric 7.0 and higher

Integration with CipherTrust Manager

This section lists the steps to integrate HPE EDF with CipherTrust Manager.

-
- Prerequisites
 - Configuration on CipherTrust Manager
 - Configuration on HPE EDF

Prerequisites

This section provides the prerequisites for integration of HPE EDF with CipherTrust Manager.

- Ensure that the CipherTrust Manager is installed and configured. For more details, refer to the [CipherTrust Manager documentation](#).
- HPE EDF communicates with the CipherTrust Manager using the KMIP interface. Ensure that the KMIP interface is configured on the CipherTrust Manager. Refer to [CipherTrust Manager Administration Guide](#) for details.
- **IP address** of the CipherTrust Manager and **port** of the KMIP interface must be accessible from the HPE EDF system.
- CipherTrust Manager recognizes only registered KMIP clients. Ensure that each node of the HPE EDF cluster is registered as a KMIP client on the CipherTrust Manager. Refer to [KMIP Client Registration](#) for more details.

Configuration on CipherTrust Manager

To configure the CipherTrust Manager, you need to perform the following steps:

1. [Creating a Domain \(optional\)](#)
2. [Creating a User](#)
3. [Assigning User to a Group](#)
4. [Creating or Adding a CA \(optional\)](#)
5. [Registering a KMIP Client](#)
6. [Configuring the KMIP Interface](#)

Creating a Domain (Optional)

Perform the following steps to be performed on CipherTrust Manager:

1. Navigate to **Admin Settings > Domains**.
2. Click **Add Domain**. The **Add Domain** page appears.
3. Specify the following information:

- **Name** - Enter the domain name.
- **Admins** - Select the admins (one or more) from the list available in the drop down. For example, admin.
- **Parent CA** - Select parent CA as root CA.
- **Allow Subdomain User Management** - Select this check box if you want to enable the sub-domain user management through this domain.

4. Click **Save**.
5. Switch to the newly created domain by clicking the top right on the current Domain Name.

Creating a User

Root Domain

To create a user, perform the following steps:

1. Log on to the CipherTrust Manager GUI.
2. Open the **Access Management** application.
3. On the left navigation pane, click **Users**. The Users page is displayed.
4. On the Users page, click **Add User**.
5. On the **Add User** page, provide the following details:
 - Select the required **Connection Type**
 - Select the checkbox against the required **Allowed Client Type**.
 - Enter **Full Name**
 - Enter **Username**
 - Enter the desired **Password**. Re-enter the password in the **Password Match** field.
6. Click **Add User**. The newly created user will now appear on the **Users** page.

Sub-Domain

Note

To create a user in sub-domain, you must enable **Allow Subdomain User management**.

To create a user, perform the following steps:

1. Log on to the CipherTrust Manager GUI with the User you created within the sub-domain.
2. Open the **Access Management** application.
3. On the left pane, click **Users**. The Users page is displayed.
4. On the Users page, click **Add User**.
5. On the **Add User** page, provide the following details:
 - Select the required **Connection Type**
 - Select the checkbox against the required **Allowed Client Type**.
 - Enter **Full Name**
 - Enter **Username**
 - Enter **Password**. Re-enter the password in the **Password Match** field.
6. Click **Add User**. The newly created user will now appear on the **Users** page.

Assigning User to a Group

Perform the following steps to add user to a group:

1. Navigate to the **Users** page.
2. Click the ellipsis button (...) corresponding to the user that you created in the previous step.
3. Click **Edit/View**.
4. Click **Group Memberships > Add Group**.
5. In the search bar, enter the desired Group name and select the check box corresponding to it. For example, **Key Admins** or **Key Users**.
6. Click **Add Group**.

Creating or Adding a CA (Optional)

Note

Creating a CA is an optional step in this integration. However, it is recommended to select the CA carefully, as it will be used throughout the process.

Select the **Local CA** tab if you want to create a Local CA **OR** select the **External CA** tab if you wish to add the External CA.

Local CA

To create/add a Self-signed local CA, perform the following steps:

1. Navigate to **CA > Local**. Select **Add Local CA**, the **Add Local CA** page appears.
2. Provide the required information and click **Add Local CA**. The created Local CA will appear under **Pending CAs** section.
3. Click the ellipsis against the Local CA that you created and select the option **Self-sign**.
4. Select a valid duration for the Local CA. Click **Save**.

External CA

To add an external CA, perform the following steps:

1. Navigate to **CA > External**. The **External Certificate Authorities** page appears. Select **Add External CA**, the **Add External Certificate** page appears.
2. Provide the required information.
3. If you want to upload the external CA, select the **File Upload** option and click **Upload Certificate**. Browse and select the required External CA.

OR

Select **Text** and paste the contents of External Certificate.

4. Click **Add External CA**.

Registering a KMIP Client

Root Domain

You can register a KMIP client on the CipherTrust Manager through:

- **Auto Registration**
- **Manual Registration**

Auto-Registration

1. Log on to the CipherTrust Manager.
2. Go to **Products > KMIP**.
3. Create Client Profile using the following steps:
 - a. Navigate to **Client Profile** and click **Add Profile**.

-
- b. Add a **Profile Name**.
 - c. Click **Save**. The new profile is created.
 4. Create Registration Token using the following steps:
 - a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a **Name Prefix**.
 - c. Specify a Token Lifetime value along with the Client Capacity for the token.
 - d. Click **Select CA**.
 - e. Select the CA type as Local/External depending on CA that you created [above](#).
 - f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
 - g. Select the Client Profile from the dropdown which you have created in the above step.
 - h. Click **Create Token**.
 - i. Copy the value of the Token created and click **Done**.

Note

If you are using External CA then you can select the external CA that you created [above](#) and uploaded on the CipherTrust Manager.

5. Turn ON **Auto Registration** using the following steps:
 - a. Go to **Admin Settings > Interfaces**.
 - b. Click the ellipsis button (...) corresponding to the knip interface.
 - c. Click **View/Edit**.
 - d. On the **Interface Detail** window, perform the following:
 - Select the Interface Mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
 - Select **Auto Registration** checkbox.
 - Paste the **Registration Token**.
 - Add the CA (Local or External) to the list of Trusted CAs. The CA will reflect under the dropdown menu of Local/External Trusted CAs depending upon CA that you created [above](#).
-

-
- Click **Update**.

Manual Registration

1. Log on to the CipherTrust Manager.
2. Go to **Products > KMIP**.
3. Create Client Profile using the following steps:
 - a. Go to **Client Profile** and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Select **CN** in **Username Location in Certificate**.
 - d. Click **Certificate Details**.
 - e. You can either paste the content of a generated `client.csr` or you can create one, by filling in the required details.
 - f. Click **Save**.
4. Create Registration Token using the following steps:
 - a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a **Name Prefix**.
 - c. Specify a Token Lifetime value along with the Client Capacity for the token.
 - d. Click **Select CA**.
 - e. Select the CA type as Local/External depending on the CA type that you created [above](#).
 - f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
 - g. Select the Client Profile from the dropdown which you have created in the above step.
 - h. Click **Create Token**.
 - i. Copy the value of the Token created and click **Done**.

Note

If you are using External CA then you can select the external CA that you created [above](#) and uploaded on the CipherTrust Manager.

5. Go to **Registered Clients** and click **Add Client**.

- Specify client name and paste the **Registration Token** that you generated in the above step.

Note

If you are using external CA then you can either upload the client certificate as a file using **Upload Certificate** or paste the signed client certificate in the **Client Certificate** field.

- Click **Save** to save the **client certificate**.

Sub-Domain

You can register a KMIP client on the CipherTrust Manager through:

- **Auto Registration**
- **Manual Registration**

Auto-Registration

1. Log on to the CipherTrust Manager into your domain.
2. Go to **Products > KMIP**.
3. Create **Client Profile** using the following steps:
 - a. Navigate to **Client Profile** and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Click **Save**. The new profile is created.
4. Create Registration Token using the following steps:
 - a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a **Name Prefix**.
 - c. Specify a Token Lifetime value along with the Client Capacity for the token.
 - d. Click **Select CA**.
 - e. Select the CA type as Local/External depending on CA that you created [above](#).
 - f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
 - g. Select the Client Profile from the dropdown which you have created in the above step.

- h. Click **Create Token**.
- i. Copy the value of the Token created and click **Done**.

Note

If you are using External CA then you can select the external CA that you created [above](#) and uploaded on the CipherTrust Manager.

5. Turn ON **Auto Registration** using the following steps:
 - a. Go to **Admin Settings > Interfaces**.
 - b. Click the ellipsis button (...) corresponding to the kmip interface.
 - c. Click **Edit**.
 - d. On the **Interface Detail** window, perform the following:
 - Select the Interface Mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
 - Select **Auto Registration** checkbox.
 - Paste the **Registration Token**.
 - Add the CA (Local or External) to the list of Trusted CAs. The CA will reflect under the dropdown menu of Local/External Trusted CAs depending upon CA that you created [above](#).
 - Click **Update**.

Manual Registration

1. Log on to the CipherTrust Manager into your domain.
2. Go to **Products > KMIP**.
3. Create **Client Profile** using the following steps:
 - a. Go to Client Profile and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Select **CN** in Username Location in Certificate.
 - d. Expand the **Certificate Details** section.

- e. You can either paste the content of a generated `client.csr` or you can create one, by filling in the required details.

For domain, the format to enter the Common Name field of the cert is always:

`domainName | | domainUser`

- f. Click **Save**.

4. Create a Registration Token using the following steps:

- a. Go to **Registration Token** and click **New Registration Token > Begin**.
- b. Add a **Name Prefix**.
- c. Specify a Token Lifetime value along with the Client Capacity for the token.
- d. Click **Select CA**.
- e. Select the CA type as Local/External depending on CA that you created [above](#).
- f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
- g. Select the Client Profile from the dropdown which you have created in the above step.
- h. Click **Create Token**.
- i. Copy the value of the Token created and click **Done**.

5. If you are using External CA then you can select the external CA which you created earlier. Refer to **External CA** under [Creating or Adding a CA](#).

6. Go to Registered Clients and click **Add Client**.

- a. Specify client name and paste the Registration Token generated in the above step.

Note

If you are using external CA then you need to paste the signed client certificate in the Client Certificate field.

- a. Click **Save** to save the client certificate.

Configuring the KMIP Interface

The KMIP interface can be configured through:

Root Domain

1. Go to **Admin Settings > Interfaces**.
2. On the KMIP Interface, click the ellipsis button (...) and then click **View/Edit**.
3. Select the **Auto Registration** checkbox if you auto-registered your KMIP client and paste the value of the registration token that you created.

Note

By default, the **Auto Registration** is disabled.

4. Select the mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
5. Specify selections for **Local CA for Automatic Server Certificate Generation** as desired.

Note

In case of External CA, **Local CA for Automatic Server Certificate Generation** should be set to **Turn off auto generation from Local CA**.

6. Depending upon the CA that you created [above](#), select an option from the following::
 - If you are using **Local CA** then select the CA under **Local Trusted CAs**
 - If you are using **External CA** then select the CA under **External Trusted CAs**, provided you have the external CA that you created and uploaded on the CipherTrust Manager. For more information on creating or uploading CA, refer to [Creating or Adding a CA](#).

Sub-Domain

1. Select the CA according to your preference.

Local CA

- a. Login to your sub-domain. Go to **CA > Local**. Click the ellipsis (...) and copy the contents of your CA Certificate.
- b. Logout of your sub-domain and now login to the root domain.
- c. Go to **CA > External > Add External CA**.
- d. Enter a name for this Domain CA and select the text radio button and paste the certificate contents.

- e. Click **Add External CA**.
- f. Go to **Admin Settings > Interfaces**.
- g. Click the **Add** icon to add the External CA.
- h. Click **Update**.

External CA

Note

If you are using an External CA in the Sub-Domain, you need to add the CA as an External CA in both the root domain as well as the sub-domain and modify the interface accordingly.

- a. Login to your sub-domain. Go to **CA > Local**. Click the ellipsis (...) and copy the contents of your CA Certificate.
 - b. Logout of your sub-domain and now login to the root domain.
 - c. Go to **CA > External > Add External CA**.
 - d. Enter a name for this Domain CA and select the text radio button and paste the certificate contents.
 - e. Click **Add External CA**.
 - f. Go to **Admin Settings > Interfaces**.
 - g. Click the **Add** icon to add the External CA.
 - h. Click **Update**.
 - i. On the **KMIP interface**, click the ellipsis (...) > **Certificate Options > Upload New Certificate > Ok**.
 - j. Select the **Certificate Chain** option and click **Build Certificate Chain**.
 - k. Click on Text and paste the contents of Server Certificate, CA, and Server Key file in the same order. Do not introduce any space, character or symbol between the contents of these files.
 - l. Select certificate Format as **PEM**.
 - m. Click on **Upload Certificate**.
2. On the KMIP Interface, click the ellipsis button (...) and then click **View/Edit**.
 3. Select the **Auto Registration** checkbox if you auto-registered your KMIP client and paste the value of the registration token that you created.

Note

By default, the **Auto Registration** is disabled.

4. Select the mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
5. Specify selections for **Local CA for Automatic Server Certificate Generation** as desired.

Note

In case of External CA, **Local CA for Automatic Server Certificate Generation** should be set to **Turn off auto generation from Local CA**.

Configuration on HPE EDF

Perform the following steps to integrate HPE Ezmeral Data Fabric with the CipherTrust Manager:

1. Create a directory named `tokens` at `/opt/mapr/conf/` to store the key files and change the owner to `mapr`.

```
mkdir /opt/mapr/conf/tokens
chown mapr:mapr /opt/mapr/conf/tokens
```

2. Run the following command to create the KMIP token for the first time and initialize the KMIP configuration:

```
mrhsm init
-sopin <PIN for S0>
-label "CipherTrustManager"
-storetype kmip
```

3. After the Keystore is initialized, configure your KMIP settings using `mrhsm set` to configure the IP, Port, Certificates, KMIP Version, and the SO Pin.

```
mrhsm set
-sopin <PIN for S0>
-ip comma-separated list of KMIP server IP addresses>
-port <KMIP port number. Default is 5696>
-cacert <Path to KMIP server CA certificate in PEM format>
-clientcert <Path to client certificate in PEM format>
```

```
-clientkey <Path to client private key in PEM format>
-kmipversion 1.1
-storetype kmip
```

4. Use the `mrhsm info` command to view the updated HSM configuration information and status.

```
mrhsm info
```

5. Run the following command to enable DARE on the current node:

```
mrhsm enable -dare
```

After the above command is executed, the keys are generated and you can verify the integration by matching the UUID keys.

Verifying Your Integration

Perform the following steps to ensure the integration is successful:

1. Use the `mrhsm rekey` command on a CLDB node to rekey the common or core KEK, and use the core KEK to re-encrypt the CLDB and DARE keys. Run the following command with the appropriate parameters:

```
mrhsm rekey
-keytype core|common  Specifies the key type, which is either core or common
-sopin <so-pin>       PIN for SO (Security Officer)
```

Rekeying the Core KEK also involves decrypting the CLDB and DARE keys using the existing Core KEK before generating a new Core KEK, and then re-encrypting the CLDB and DARE keys using the new Core KEK. This command only updates the KMIP configuration on the CLDB node on which this command was invoked.

After the successful re-keying operation, a new key is generated on the CipherTrust Manager with its version upgraded by one.

Licensing

This section provides the licensing requirements for KMIP clients.

Condition	License Requirement
Encryption at cluster Level	x1 KMIP client license for each node in the cluster

Appendix

Troubleshooting

Issue	Error Message	Remediation
KMIP registration is not enabled	The following error message is displayed in CipherTrust Records: <i>"errorMessage": "Unregistered client, please register a new client from CLI or API or UI."</i>	Check whether the Autoregistration option is selected in Admin Settings > System > Interfaces > kmip . If it is not selected, turn on the Autoregistration option. Refer to the steps mentioned in Enable KMIP Client Registration .
User corresponding to username location in the certificate (for example, OU/UID) is not created	The following error messages are displayed in CipherTrust Records: <i>"errorMessage": "username not found: "</i> <i>"errorMessage": "Could not authenticate certificate user, hence the client is not auto registered in mode <code>tls-cert-pw-opt</code>"</i>	Check whether the user corresponding to UID/OU of the node certificates is created in Keys & Access Management > Users . If the user is not created, create a new user with the same name as the OU/UID field of the node certificates. After creating the user, add this user to the Key Admins . Refer to the steps mentioned in Create a New User .
User is not added to the Key Admin group	The following error message is displayed in CipherTrust Records: <i>"errorMessage": "authorization denied: verdict was deny: CreateKey"</i>	Check whether the user corresponding to UID/OU of the node certificates is created under Keys & Access Management > Users . If the user is not added, add the user to the Key Admins group.
The username location in the Certificate is set incorrectly	The following error messages are displayed in CipherTrust Records: <i>"errorMessage": "username not found: "</i> <i>"errorMessage": "Could not authenticate certificate user, hence the client is not auto registered in mode <code>tls-cert-pw-opt</code>"</i>	Check whether the username location in the Certificate option is set correctly to OU/UID in Admin Settings > System > Interfaces > kmip . If it is not set correctly, set the correct value for the username location in the Certificate.

CipherTrust Integrations

4 February 2026

Contents

- HPE Nimble Storage 3
 - Integration with CipherTrust Manager 3
 - Verifying Your Integration 16
 - Appendix. 17

HPE Nimble Storage

HPE Nimble Storage arrays are engineered for high performance using flash, low cost using dense, capacity-optimized disks, and easy installation and administration. Data written to the array is compressed and then stored in the disk-drive layer. HPE Nimble Storage arrays take advantage of multi-core processors to provide high-speed in-line variable-block compression without introducing noticeable latency. Nimble Storage arrays provide, accelerated performance for higher throughput or I/Os per second and sub-millisecond latencies, higher storage efficiency, non-disruptive scaling to fit changing application needs, maximized data, and storage availability with integrated data protection and disaster recovery.

Security in an HPE Nimble Storage group of arrays includes several features, including role-based access control for user accounts, encryption of data at rest, secure socket layer (SSL) certificates, and secure SMTP. You can enable encryption at the group level or volume level as required for each group of Nimble Storage arrays in your environment. Before you can create encrypted volumes, you must perform an initialization step that creates the master key. The master key protects the keys that are used to encrypt volume data. The encryption state of a volume is established when the volume is created, and cannot be changed afterward. Cloned volumes inherit the encryption state of their parent. The group configuration contains a default encryption setting, where you can enable or disable AES-256-XTS encryption.

Supported Product Versions

Note

The integration is performed and certified on **LTS release versions** of CipherTrust Manager only. Feature releases support the integration and are covered under technical support but will not be explicitly certified. To know more about CipherTrust Manager release versions, click [here](#).

CipherTrust Manager

- CipherTrust Manager 2.8

HPE Nimble Storage Version

- HPE Nimble Storage 6.0.0.400-991061-opt

Integration with CipherTrust Manager

This section lists the steps to integrate Nimble Storage with CipherTrust Manager.

-
- Prerequisites
 - Configuration on CipherTrust Manager
 - Configuration on HPE Nimble Storage

Prerequisites

This section provides the prerequisites for integration of Nimble Storage with CipherTrust Manager.

- Ensure that the CipherTrust Manager is installed and configured. For more details, refer to the [CipherTrust Manager documentation](#).
- Nimble Storage communicates with the CipherTrust Manager using the KMIP interface. Ensure that the KMIP interface is configured on the CipherTrust Manager. Refer to [CipherTrust Manager Administration Guide](#) for details.
- **IP address** of the CipherTrust Manager and **port** of the KMIP interface must be accessible from the Nimble Storage system.
- CipherTrust Manager recognizes only registered KMIP clients. Ensure that each node of the Nimble Storage cluster is registered as a KMIP client on the CipherTrust Manager. Refer to [KMIP Client Registration](#) for more details.

Configuration on CipherTrust Manager

To configure the CipherTrust Manager, you need to perform the following steps:

1. [Creating a Domain \(optional\)](#)
2. [Creating a User](#)
3. [Assigning User to a Group](#)
4. [Creating or Adding a CA \(optional\)](#)
5. [Registering a KMIP Client](#)
6. [Configuring the KMIP Interface](#)

Creating a Domain (Optional)

Perform the following steps to be performed on CipherTrust Manager:

1. Navigate to **Admin Settings > Domains**.
2. Click **Add Domain**. The **Add Domain** page appears.
3. Specify the following information:

-
- **Name** - Enter the domain name.
 - **Admins** - Select the admins (one or more) from the list available in the drop down. For example, admin.
 - **Parent CA** - Select parent CA as root CA.
 - **Allow Subdomain User Management** - Select this check box if you want to enable the sub-domain user management through this domain.

4. Click **Save**.

5. Switch to the newly created domain by clicking the top right on the current Domain Name.

Creating a User

Root Domain

To create a user, perform the following steps:

1. Log on to the CipherTrust Manager GUI.
2. Open the **Access Management** application.
3. On the left navigation pane, click **Users**. The Users page is displayed.
4. On the Users page, click **Add User**.
5. On the **Add User** page, provide the following details:
 - Select the required **Connection Type**
 - Select the checkbox against the required **Allowed Client Type**.
 - Enter **Full Name**
 - Enter **Username**
 - Enter the desired **Password**. Re-enter the password in the **Password Match** field.
6. Click **Add User**. The newly created user will now appear on the **Users** page.

Sub-Domain

Note

To create a user in sub-domain, you must enable **Allow Subdomain User management**.

To create a user, perform the following steps:

1. Log on to the CipherTrust Manager GUI with the User you created within the sub-domain.
2. Open the **Access Management** application.
3. On the left pane, click **Users**. The Users page is displayed.
4. On the Users page, click **Add User**.
5. On the **Add User** page, provide the following details:
 - Select the required **Connection Type**
 - Select the checkbox against the required **Allowed Client Type**.
 - Enter **Full Name**
 - Enter **Username**
 - Enter **Password**. Re-enter the password in the **Password Match** field.
6. Click **Add User**. The newly created user will now appear on the **Users** page.

Assigning User to a Group

Perform the following steps to add user to a group:

1. Navigate to the **Users** page.
2. Click the ellipsis button (...) corresponding to the user that you created in the previous step.
3. Click **Edit/View**.
4. Click **Group Memberships > Add Group**.
5. In the search bar, enter the desired Group name and select the check box corresponding to it. For example, **Key Admins** or **Key Users**.
6. Click **Add Group**.

Creating or Adding a CA (Optional)

Note

Creating a CA is an optional step in this integration. However, it is recommended to select the CA carefully, as it will be used throughout the process.

Select the **Local CA** tab if you want to create a Local CA **OR** select the **External CA** tab if you wish to add the External CA.

Local CA

To create/add a Self-signed local CA, perform the following steps:

1. Navigate to **CA > Local**. Select **Add Local CA**, the **Add Local CA** page appears.
2. Provide the required information and click **Add Local CA**. The created Local CA will appear under **Pending CAs** section.
3. Click the ellipsis against the Local CA that you created and select the option **Self-sign**.
4. Select a valid duration for the Local CA. Click **Save**.

External CA

To add an external CA, perform the following steps:

1. Navigate to **CA > External**. The **External Certificate Authorities** page appears. Select **Add External CA**, the **Add External Certificate** page appears.
2. Provide the required information.
3. If you want to upload the external CA, select the **File Upload** option and click **Upload Certificate**. Browse and select the required External CA.

OR

Select **Text** and paste the contents of External Certificate.

4. Click **Add External CA**.

Registering a KMIP Client

Root Domain

You can register a KMIP client on the CipherTrust Manager through:

- **Auto Registration**
- **Manual Registration**

Auto-Registration

1. Log on to the CipherTrust Manager.
2. Go to **Products > KMIP**.
3. Create Client Profile using the following steps:
 - a. Navigate to **Client Profile** and click **Add Profile**.

-
- b. Add a **Profile Name**.
 - c. Click **Save**. The new profile is created.
 4. Create Registration Token using the following steps:
 - a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a **Name Prefix**.
 - c. Specify a Token Lifetime value along with the Client Capacity for the token.
 - d. Click **Select CA**.
 - e. Select the CA type as Local/External depending on CA that you created [above](#).
 - f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
 - g. Select the Client Profile from the dropdown which you have created in the above step.
 - h. Click **Create Token**.
 - i. Copy the value of the Token created and click **Done**.

Note

If you are using External CA then you can select the external CA that you created [above](#) and uploaded on the CipherTrust Manager.

5. Turn ON **Auto Registration** using the following steps:
 - a. Go to **Admin Settings > Interfaces**.
 - b. Click the ellipsis button (...) corresponding to the knip interface.
 - c. Click **View/Edit**.
 - d. On the **Interface Detail** window, perform the following:
 - Select the Interface Mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
 - Select **Auto Registration** checkbox.
 - Paste the **Registration Token**.
 - Add the CA (Local or External) to the list of Trusted CAs. The CA will reflect under the dropdown menu of Local/External Trusted CAs depending upon CA that you created [above](#).
-

-
- Click **Update**.

Manual Registration

1. Log on to the CipherTrust Manager.
2. Go to **Products > KMIP**.
3. Create Client Profile using the following steps:
 - a. Go to **Client Profile** and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Select **CN** in **Username Location in Certificate**.
 - d. Click **Certificate Details**.
 - e. You can either paste the content of a generated `client.csr` or you can create one, by filling in the required details.
 - f. Click **Save**.
4. Create Registration Token using the following steps:
 - a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a **Name Prefix**.
 - c. Specify a Token Lifetime value along with the Client Capacity for the token.
 - d. Click **Select CA**.
 - e. Select the CA type as Local/External depending on the CA type that you created [above](#).
 - f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
 - g. Select the Client Profile from the dropdown which you have created in the above step.
 - h. Click **Create Token**.
 - i. Copy the value of the Token created and click **Done**.

Note

If you are using External CA then you can select the external CA that you created [above](#) and uploaded on the CipherTrust Manager.

5. Go to **Registered Clients** and click **Add Client**.

- Specify client name and paste the **Registration Token** that you generated in the above step.

Note

If you are using external CA then you can either upload the client certificate as a file using **Upload Certificate** or paste the signed client certificate in the **Client Certificate** field.

- Click **Save** to save the **client certificate**.

Sub-Domain

You can register a KMIP client on the CipherTrust Manager through:

- **Auto Registration**
- **Manual Registration**

Auto-Registration

1. Log on to the CipherTrust Manager into your domain.
2. Go to **Products > KMIP**.
3. Create **Client Profile** using the following steps:
 - a. Navigate to **Client Profile** and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Click **Save**. The new profile is created.
4. Create Registration Token using the following steps:
 - a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a **Name Prefix**.
 - c. Specify a Token Lifetime value along with the Client Capacity for the token.
 - d. Click **Select CA**.
 - e. Select the CA type as Local/External depending on CA that you created [above](#).
 - f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
 - g. Select the Client Profile from the dropdown which you have created in the above step.

-
- h. Click **Create Token**.
 - i. Copy the value of the Token created and click **Done**.

Note

If you are using External CA then you can select the external CA that you created [above](#) and uploaded on the CipherTrust Manager.

5. Turn ON **Auto Registration** using the following steps:
 - a. Go to **Admin Settings > Interfaces**.
 - b. Click the ellipsis button (...) corresponding to the kmip interface.
 - c. Click **Edit**.
 - d. On the **Interface Detail** window, perform the following:
 - Select the Interface Mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
 - Select **Auto Registration** checkbox.
 - Paste the **Registration Token**.
 - Add the CA (Local or External) to the list of Trusted CAs. The CA will reflect under the dropdown menu of Local/External Trusted CAs depending upon CA that you created [above](#).
 - Click **Update**.

Manual Registration

1. Log on to the CipherTrust Manager into your domain.
2. Go to **Products > KMIP**.
3. Create **Client Profile** using the following steps:
 - a. Go to Client Profile and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Select **CN** in Username Location in Certificate.
 - d. Expand the **Certificate Details** section.

-
- e. You can either paste the content of a generated `client.csr` or you can create one, by filling in the required details.

For domain, the format to enter the Common Name field of the cert is always:

`domainName | | domainUser`

- f. Click **Save**.

4. Create a Registration Token using the following steps:

- a. Go to **Registration Token** and click **New Registration Token > Begin**.
- b. Add a **Name Prefix**.
- c. Specify a Token Lifetime value along with the Client Capacity for the token.
- d. Click **Select CA**.
- e. Select the CA type as Local/External depending on CA that you created [above](#).
- f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
- g. Select the Client Profile from the dropdown which you have created in the above step.
- h. Click **Create Token**.
- i. Copy the value of the Token created and click **Done**.

5. If you are using External CA then you can select the external CA which you created earlier. Refer to **External CA** under [Creating or Adding a CA](#).

6. Go to Registered Clients and click **Add Client**.

- a. Specify client name and paste the Registration Token generated in the above step.

Note

If you are using external CA then you need to paste the signed client certificate in the Client Certificate field.

- a. Click **Save** to save the client certificate.

Configuring the KMIP Interface

The KMIP interface can be configured through:

Root Domain

1. Go to **Admin Settings > Interfaces**.
2. On the KMIP Interface, click the ellipsis button (...) and then click **View/Edit**.
3. Select the **Auto Registration** checkbox if you auto-registered your KMIP client and paste the value of the registration token that you created.

Note

By default, the **Auto Registration** is disabled.

4. Select the mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
5. Specify selections for **Local CA for Automatic Server Certificate Generation** as desired.

Note

In case of External CA, **Local CA for Automatic Server Certificate Generation** should be set to **Turn off auto generation from Local CA**.

6. Depending upon the CA that you created [above](#), select an option from the following::
 - If you are using **Local CA** then select the CA under **Local Trusted CAs**
 - If you are using **External CA** then select the CA under **External Trusted CAs**, provided you have the external CA that you created and uploaded on the CipherTrust Manager. For more information on creating or uploading CA, refer to [Creating or Adding a CA](#).

Sub-Domain

1. Select the CA according to your preference.

Local CA

- a. Login to your sub-domain. Go to **CA > Local**. Click the ellipsis (...) and copy the contents of your CA Certificate.
- b. Logout of your sub-domain and now login to the root domain.
- c. Go to **CA > External > Add External CA**.
- d. Enter a name for this Domain CA and select the text radio button and paste the certificate contents.

- e. Click **Add External CA**.
- f. Go to **Admin Settings > Interfaces**.
- g. Click the **Add** icon to add the External CA.
- h. Click **Update**.

External CA

Note

If you are using an External CA in the Sub-Domain, you need to add the CA as an External CA in both the root domain as well as the sub-domain and modify the interface accordingly.

- a. Login to your sub-domain. Go to **CA > Local**. Click the ellipsis (...) and copy the contents of your CA Certificate.
 - b. Logout of your sub-domain and now login to the root domain.
 - c. Go to **CA > External > Add External CA**.
 - d. Enter a name for this Domain CA and select the text radio button and paste the certificate contents.
 - e. Click **Add External CA**.
 - f. Go to **Admin Settings > Interfaces**.
 - g. Click the **Add** icon to add the External CA.
 - h. Click **Update**.
 - i. On the **KMIP interface**, click the ellipsis (...) > **Certificate Options > Upload New Certificate > Ok**.
 - j. Select the **Certificate Chain** option and click **Build Certificate Chain**.
 - k. Click on Text and paste the contents of Server Certificate, CA, and Server Key file in the same order. Do not introduce any space, character or symbol between the contents of these files.
 - l. Select certificate Format as **PEM**.
 - m. Click on **Upload Certificate**.
2. On the KMIP Interface, click the ellipsis button (...) and then click **View/Edit**.
 3. Select the **Auto Registration** checkbox if you auto-registered your KMIP client and paste the value of the registration token that you created.

Note

By default, the **Auto Registration** is disabled.

4. Select the mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
5. Specify selections for **Local CA for Automatic Server Certificate Generation** as desired.

Note

In case of External CA, **Local CA for Automatic Server Certificate Generation** should be set to **Turn off auto generation from Local CA**.

Configuration on HPE Nimble Storage

Perform the following steps to integrate HPE Nimble Storage with the CipherTrust Manager:

1. Log in to the **Nimble Storage** using the credentials.
2. Navigate to **Administration >> Security >> SSL Certificate**. Add the CA (in case of domains, add the domain CA followed by the Root CA) and the Client Cert.
3. Navigate to **Administration >> Security >> Encryption**. Click on **External Key Manager** followed by **Add Key Manager**.
4. Enter the information for the following fields to set up your key management server:

Create Key Manager

Name *

CipherTrustManager

Description

Hostname or IP address *

Port *

Protocol *

Username

admin

Password

Show typing

Save Cancel

- Once the connection is successful, you can see the status as connected on Nimble Storage. You can also verify the key creation by logging on to CipherTrust Manager.

Verifying Your Integration

Perform the following steps to ensure the integration is successful:

- Restart the instance of Nimble Storage after the EKM has been set and configured.
- Navigate to **Manage > Data Storage**.
- Create a new volume and confirm if the status is online and encrypted.

Total Used: 0B		Settings		IOPS		IOPS	
Volumes		Folders					
				Summary		Status	
				Performance		General	
				Protection

Test 01-01-2024	Online	0 B	10 GB	0	0	1	0

Appendix

Troubleshooting

Issue	Error Message	Remediation
KMIP registration is not enabled	The following error message is displayed in CipherTrust Records: <i>"errorMessage": "Unregistered client, please register a new client from CLI or API or UI."</i>	Check whether the Autoregistration option is selected in Admin Settings > System > Interfaces > kmip . If it is not selected, turn on the Autoregistration option. Refer to the steps mentioned in Enable KMIP Client Registration .
User corresponding to username location in the certificate (for example, OU/UID) is not created	The following error messages are displayed in CipherTrust Records: <i>"errorMessage": "username not found: "</i> <i>"errorMessage": "Could not authenticate certificate user, hence the client is not auto registered in mode <code>tls-cert-pw-opt</code>"</i>	Check whether the user corresponding to UID/OU of the node certificates is created in Keys & Access Management > Users . If the user is not created, create a new user with the same name as the OU/UID field of the node certificates. After creating the user, add this user to the Key Admins . Refer to the steps mentioned in Create a New User .
User is not added to the Key Admin group	The following error message is displayed in CipherTrust Records: <i>"errorMessage": "authorization denied: verdict was deny: CreateKey"</i>	Check whether the user corresponding to UID/OU of the node certificates is created under Keys & Access Management > Users . If the user is not added, add the user to the Key Admins group.
The username location in the Certificate is set incorrectly	The following error messages are displayed in CipherTrust Records: <i>"errorMessage": "username not found: "</i> <i>"errorMessage": "Could not authenticate certificate user, hence the client is not auto registered in mode <code>tls-cert-pw-opt</code>"</i>	Check whether the username location in the Certificate option is set correctly to OU/UID in Admin Settings > System > Interfaces > kmip . If it is not set correctly, set the correct value for the username location in the Certificate.

CipherTrust Integrations

Contents

HPE StoreEver. 3

 Integration with CipherTrust Manager 4

 Verifying Your Integration 17

 Appendix. 18

HPE StoreEver

HPE StoreEver is a tape automation product that helps SMB customers to meet long-term data retention requirements, as well as provides air-gapped data protection from the growing threat of ransomware. The HPE StoreEver tape library offers broad capacity options including LTO-9, LTO-8, LTO-7, or LTO-6 Ultrium drives. HPE CVTL makes the HPE StoreEver tape library easy to manage from any location, mitigating the need for remote office IT staff. You can simply manage tape media in and out of the library with the standard bar code reader, configurable mail slots, and removable magazines.

Using the Key Management Interoperability Protocol (KMIP) Wizard, you can set up KMIP key management servers with the MSL3040 and MSL6480 libraries. The wizard is accessible through the Encryption menu on the RMI, but only for the security user and requires a KMIP license.

If a tape is lost or stolen, you can protect important business data from unauthorized access with data encryption.

Supported Product Versions

Note

The integration is performed and certified on **LTS release versions** of CipherTrust Manager only. Feature releases support the integration and are covered under technical support but will not be explicitly certified. To know more about CipherTrust Manager release versions, click [here](#).

CipherTrust Manager

- CipherTrust Manager 2.7 and higher

HPE StoreEver Version

- MSL3040
- MSL6480
- HPE 1/8 G3

-
- MSL2024 G4

** Key Management Interoperability Protocol (KMIP)**

- Upto KMIP 1.4

Integration with CipherTrust Manager

This section lists the steps to integrate HPE StoreEver with CipherTrust Manager.

- Prerequisites
- Configuration on CipherTrust Manager
- Configuration on HPE StoreEver

Prerequisites

This section provides the prerequisites for integration of HPE StoreEver with CipherTrust Manager.

- Ensure that the CipherTrust Manager is installed and configured. For more details, refer to the [CipherTrust Manager documentation](#).
- HPE StoreEver communicates with the CipherTrust Manager using the KMIP interface. Ensure that the KMIP interface is configured on the CipherTrust Manager. Refer to [CipherTrust Manager Administration Guide](#) for details.
- **IP address** of the CipherTrust Manager and **port** of the KMIP interface must be accessible from the HPE StoreEver system.
- CipherTrust Manager recognizes only registered KMIP clients. Ensure that each node of the HPE StoreEver cluster is registered as a KMIP client on the CipherTrust Manager. Refer to [KMIP Client Registration](#) for more details.

Configuration on CipherTrust Manager

To configure the CipherTrust Manager, you need to perform the following steps:

1. [Creating a Domain \(optional\)](#)
 2. [Creating a User](#)
 3. [Assigning User to a Group](#)
 4. [Creating or Adding a CA \(optional\)](#)
 5. [Registering a KMIP Client](#)
 6. [Configuring the KMIP Interface](#)
-

Creating a Domain (Optional)

Perform the following steps to be performed on CipherTrust Manager:

1. Navigate to **Admin Settings > Domains**.
2. Click **Add Domain**. The **Add Domain** page appears.
3. Specify the following information:
 - **Name** - Enter the domain name.
 - **Admins** - Select the admins (one or more) from the list available in the drop down. For example, admin.
 - **Parent CA** - Select parent CA as root CA.
 - **Allow Subdomain User Management** - Select this check box if you want to enable the sub-domain user management through this domain.
4. Click **Save**.
5. Switch to the newly created domain by clicking the top right on the current Domain Name.

Creating a User

Root Domain

To create a user, perform the following steps:

1. Log on to the CipherTrust Manager GUI.
2. Open the **Access Management** application.
3. On the left navigation pane, click **Users**. The Users page is displayed.
4. On the Users page, click **Add User**.
5. On the **Add User** page, provide the following details:
 - Select the required **Connection Type**
 - Select the checkbox against the required **Allowed Client Type**.
 - Enter **Full Name**
 - Enter **Username**
 - Enter the desired **Password**. Re-enter the password in the **Password Match** field.
6. Click **Add User**. The newly created user will now appear on the **Users** page.

Sub-Domain

Note

To create a user in sub-domain, you must enable **Allow Subdomain User management**.

To create a user, perform the following steps:

1. Log on to the CipherTrust Manager GUI with the User you created within the sub-domain.
2. Open the **Access Management** application.
3. On the left pane, click **Users**. The Users page is displayed.
4. On the Users page, click **Add User**.
5. On the **Add User** page, provide the following details:
 - Select the required **Connection Type**
 - Select the checkbox against the required **Allowed Client Type**.
 - Enter **Full Name**
 - Enter **Username**
 - Enter **Password**. Re-enter the password in the **Password Match** field.
6. Click **Add User**. The newly created user will now appear on the **Users** page.

Assigning User to a Group

Perform the following steps to add user to a group:

1. Navigate to the **Users** page.
2. Click the ellipsis button (...) corresponding to the user that you created in the previous step.
3. Click **Edit/View**.
4. Click **Group Memberships > Add Group**.
5. In the search bar, enter the desired Group name and select the check box corresponding to it. For example, **Key Admins** or **Key Users**.
6. Click **Add Group**.

Creating or Adding a CA (Optional)

Note

Creating a CA is an optional step in this integration. However, it is recommended to select the CA carefully, as it will be used throughout the process.

Select the **Local CA** tab if you want to create a Local CA **OR** select the **External CA** tab if you wish to add the External CA.

Local CA

To create/add a Self-signed local CA, perform the following steps:

1. Navigate to **CA > Local**. Select **Add Local CA**, the **Add Local CA** page appears.
2. Provide the required information and click **Add Local CA**. The created Local CA will appear under **Pending CAs** section.
3. Click the ellipsis against the Local CA that you created and select the option **Self-sign**.
4. Select a valid duration for the Local CA. Click **Save**.

External CA

To add an external CA, perform the following steps:

1. Navigate to **CA > External**. The **External Certificate Authorities** page appears. Select **Add External CA**, the **Add External Certificate** page appears.
2. Provide the required information.
3. If you want to upload the external CA, select the **File Upload** option and click **Upload Certificate**. Browse and select the required External CA.

OR

Select **Text** and paste the contents of External Certificate.

4. Click **Add External CA**.

Registering a KMIP Client

Root Domain

You can register a KMIP client on the CipherTrust Manager through:

- **Auto Registration**

- **Manual Registration**

Auto-Registration

1. Log on to the CipherTrust Manager.
2. Go to **Products > KMIP**.
3. Create Client Profile using the following steps:
 - a. Navigate to **Client Profile** and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Click **Save**. The new profile is created.
4. Create Registration Token using the following steps:
 - a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a **Name Prefix**.
 - c. Specify a Token Lifetime value along with the Client Capacity for the token.
 - d. Click **Select CA**.
 - e. Select the CA type as Local/External depending on CA that you created [above](#).
 - f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
 - g. Select the Client Profile from the dropdown which you have created in the above step.
 - h. Click **Create Token**.
 - i. Copy the value of the Token created and click **Done**.

Note

If you are using External CA then you can select the external CA that you created [above](#) and uploaded on the CipherTrust Manager.

5. Turn ON **Auto Registration** using the following steps:
 - a. Go to **Admin Settings > Interfaces**.
 - b. Click the ellipsis button (...) corresponding to the kmip interface.
 - c. Click **View/Edit**.
-

-
- d. On the **Interface Detail** window, perform the following:
 - Select the Interface Mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
 - Select **Auto Registration** checkbox.
 - Paste the **Registration Token**.
 - Add the CA (Local or External) to the list of Trusted CAs. The CA will reflect under the dropdown menu of Local/External Trusted CAs depending upon CA that you created [above](#).
 - Click **Update**.

Manual Registration

1. Log on to the CipherTrust Manager.
2. Go to **Products > KMIP**.
3. Create Client Profile using the following steps:
 - a. Go to **Client Profile** and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Select **CN** in **Username Location in Certificate**.
 - d. Click **Certificate Details**.
 - e. You can either paste the content of a generated `client.csr` or you can create one, by filling in the required details.
 - f. Click **Save**.
4. Create Registration Token using the following steps:
 - a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a **Name Prefix**.
 - c. Specify a Token Lifetime value along with the Client Capacity for the token.
 - d. Click **Select CA**.
 - e. Select the CA type as Local/External depending on the CA type that you created [above](#).
 - f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
 - g. Select the Client Profile from the dropdown which you have created in the above step.

-
- h. Click **Create Token**.
 - i. Copy the value of the Token created and click **Done**.

Note

If you are using External CA then you can select the external CA that you created [above](#) and uploaded on the CipherTrust Manager.

5. Go to **Registered Clients** and click **Add Client**.

- Specify client name and paste the **Registration Token** that you generated in the above step.

Note

If you are using external CA then you can either upload the client certificate as a file using **Upload Certificate** or paste the signed client certificate in the **Client Certificate** field.

- Click **Save** to save the **client certificate**.

Sub-Domain

You can register a KMIP client on the CipherTrust Manager through:

- **Auto Registration**
- **Manual Registration**

Auto-Registration

1. Log on to the CipherTrust Manager into your domain.
2. Go to **Products > KMIP**.
3. Create **Client Profile** using the following steps:
 - a. Navigate to **Client Profile** and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Click **Save**. The new profile is created.
4. Create Registration Token using the following steps:

-
- a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a **Name Prefix**.
 - c. Specify a Token Lifetime value along with the Client Capacity for the token.
 - d. Click **Select CA**.
 - e. Select the CA type as Local/External depending on CA that you created [above](#).
 - f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
 - g. Select the Client Profile from the dropdown which you have created in the above step.
 - h. Click **Create Token**.
 - i. Copy the value of the Token created and click **Done**.

Note

If you are using External CA then you can select the external CA that you created [above](#) and uploaded on the CipherTrust Manager.

5. Turn ON **Auto Registration** using the following steps:
 - a. Go to **Admin Settings > Interfaces**.
 - b. Click the ellipsis button (...) corresponding to the kmip interface.
 - c. Click **Edit**.
 - d. On the **Interface Detail** window, perform the following:
 - Select the Interface Mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
 - Select **Auto Registration** checkbox.
 - Paste the **Registration Token**.
 - Add the CA (Local or External) to the list of Trusted CAs. The CA will reflect under the dropdown menu of Local/External Trusted CAs depending upon CA that you created [above](#).
 - Click **Update**.

Manual Registration

1. Log on to the CipherTrust Manager into your domain.
2. Go to **Products > KMIP**.
3. Create **Client Profile** using the following steps:
 - a. Go to Client Profile and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Select **CN** in Username Location in Certificate.
 - d. Expand the **Certificate Details** section.
 - e. You can either paste the content of a generated `client.csr` or you can create one, by filling in the required details.

For domain, the format to enter the Common Name field of the cert is always:
`domainName | | domainUser`

- f. Click **Save**.
4. Create a Registration Token using the following steps:
 - a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a **Name Prefix**.
 - c. Specify a Token Lifetime value along with the Client Capacity for the token.
 - d. Click **Select CA**.
 - e. Select the CA type as Local/External depending on CA that you created [above](#).
 - f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
 - g. Select the Client Profile from the dropdown which you have created in the above step.
 - h. Click **Create Token**.
 - i. Copy the value of the Token created and click **Done**.
5. If you are using External CA then you can select the external CA which you created earlier. Refer to **External CA** under [Creating or Adding a CA](#).
6. Go to Registered Clients and click **Add Client**.
 - a. Specify client name and paste the Registration Token generated in the above step.

Note

If you are using external CA then you need to paste the signed client certificate in the Client Certificate field.

- a. Click **Save** to save the client certificate.

Configuring the KMIP Interface

The KMIP interface can be configured through:

Root Domain

1. Go to **Admin Settings > Interfaces**.
2. On the KMIP Interface, click the ellipsis button (...) and then click **View/Edit**.
3. Select the **Auto Registration** checkbox if you auto-registered your KMIP client and paste the value of the registration token that you created.

Note

By default, the **Auto Registration** is disabled.

4. Select the mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
5. Specify selections for **Local CA for Automatic Server Certificate Generation** as desired.

Note

In case of External CA, **Local CA for Automatic Server Certificate Generation** should be set to **Turn off auto generation from Local CA**.

6. Depending upon the CA that you created [above](#), select an option from the following::
 - If you are using **Local CA** then select the CA under **Local Trusted CAs**
 - If you are using **External CA** then select the CA under **External Trusted CAs**, provided you have the external CA that you created and uploaded on the CipherTrust Manager. For more information on creating or uploading CA, refer to [Creating or Adding a CA](#).

Sub-Domain

1. Select the CA according to your preference.

Local CA

- a. Login to your sub-domain. Go to **CA > Local**. Click the ellipsis (...) and copy the contents of your CA Certificate.
- b. Logout of your sub-domain and now login to the root domain.
- c. Go to **CA > External > Add External CA**.
- d. Enter a name for this Domain CA and select the text radio button and paste the certificate contents.
- e. Click **Add External CA**.
- f. Go to **Admin Settings > Interfaces**.
- g. Click the **Add** icon to add the External CA.
- h. Click **Update**.

External CA

Note

If you are using an External CA in the Sub-Domain, you need to add the CA as an External CA in both the root domain as well as the sub-domain and modify the interface accordingly.

- a. Login to your sub-domain. Go to **CA > Local**. Click the ellipsis (...) and copy the contents of your CA Certificate.
- b. Logout of your sub-domain and now login to the root domain.
- c. Go to **CA > External > Add External CA**.
- d. Enter a name for this Domain CA and select the text radio button and paste the certificate contents.
- e. Click **Add External CA**.
- f. Go to **Admin Settings > Interfaces**.
- g. Click the **Add** icon to add the External CA.
- h. Click **Update**.
- i. On the **KMIP interface**, click the ellipsis (...) > **Certificate Options > Upload New Certificate > Ok**.

-
- j. Select the **Certificate Chain** option and click **Build Certificate Chain**.
 - k. Click on Text and paste the contents of Server Certificate, CA, and Server Key file in the same order. Do not introduce any space, character or symbol between the contents of these files.
 - l. Select certificate Format as **PEM**.
 - m. Click on **Upload Certificate**.
2. On the KMIP Interface, click the ellipsis button (...) and then click **View/Edit**.
 3. Select the **Auto Registration** checkbox if you auto-registered your KMIP client and paste the value of the registration token that you created.

Note

By default, the **Auto Registration** is disabled.

4. Select the mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
5. Specify selections for **Local CA for Automatic Server Certificate Generation** as desired.

Note

In case of External CA, **Local CA for Automatic Server Certificate Generation** should be set to **Turn off auto generation from Local CA**.

Configuration on HPE StoreEver

For the visual representation of the configuration steps on HPE StoreEver, refer to the GIF displayed below.

Key Management Interoperability Protocol (KMIP) Wizard

► **Wizard Information**

- Certificate Authority Information
- Certificate Authority Certificate Entry
- Library Certificate Information
- KMIP Client Configuration
- Certificate Generation
- Sign Library Certificate
- KMIP Server Configuration
- Setup Summary

Wizard Information

With the KMIP Wizard you can configure the library for use with the KMIP key management server. Before starting the wizard, ensure that the library configuration is complete, including defining all library partitions. Also, ensure that the KMIP server has been put on the network and configured for use with this library.

For questions on the KMIP server setup, see the applicable KMIP server user guide.

To continue the wizard, click **Next**.

To clear the wizard settings when no longer using this encryption method or reset the wizard configuration to its default state, click **Clear All Wizard Settings**.

Clear All Wizard Settings

Back Next Finish Cancel

Perform the following steps to integrate HPE StoreEver with the CipherTrust Manager:

1. Log in to the **StoreEver** console as a security user.
2. Navigate to **Configuration > Encryption > KMIP Wizard**.
3. Click **Next**. The **Certificate Authority Information** screen displays prerequisites for using the KMIP certificate. When the prerequisites are met, click **Next**.
4. The **Certificate Authority Certificate Entry** screen displays instructions for obtaining the certificate for the KMIP server. Follow the instructions to copy the certificate from the management console. Paste the certificate into the wizard and then click **Next**.
5. The **Library Certificate Information** screen displays information about the next wizard steps. Click **Next**.
6. The **KMIP Client Configuration** screen provides options for two types of server authentication.
 - When the KMIP server uses a client username and password for authentication, enter the username and password that were specified on the KMIP management console for the library.
 - When the KMIP server uses only certificate passing for authentication, select **Enable KMIP Certificate-only authentication**.

Note

Select **Enable KMIP Certificate-only authentication** option only if it is required and a client's username and password is not available.

Click **Next**.

7. The **Certificate Generation** screen displays the current library certificate, if one exists.

To use the current certificate, select **Keep Current Certificate** and then click **Next**.

To generate a new certificate, select **Generate New Certificate**. The wizard will generate and display a new library certificate. Click **Select Certificate** to copy the new certificate text and then click **Next**.

8. When selected **Generate New Certificate**, the **Sign Library Certificate** screen displays the new certificate for the library. Sign the new library certificate with the certificate authority as a client certificate, paste the new KMIP certificate in the box, and then click **Next**.
9. On the **KMIP Server Configuration** page, enter the IP address or fully-qualified hostname and port number for up to ten KMIP servers. To verify access to the KMIP servers, click **Connectivity Check**.
10. The Setup Summary screen displays the settings that were collected by the wizard. Verify that the settings are correct and that there are no errors in the **Done** column. To modify any settings or fix any issues, either click **Back** to reach the applicable screen or cancel out of the wizard to fix the issues and return later. If the settings are correct and there are no errors, click **Finish**.
11. On the **Configuration** page:
 - Under the **Set Default Encryption Mode for new Partitions** section, select **Controlled by Backup Application** from the dropdown menu and Click **Apply to all existing partitions** to configure partitions for use with KMIP
 - Under the **Set Encryption Mode per Partition**, select **KMIP (Licensed)** from the dropdown menu.
12. Click **Next**.

Verifying Your Integration

For the visual representation of the steps to verify the integration, refer to the GIF displayed below.

Perform the following steps to verify the integration of HPE StoreEver with the CipherTrust Manager:

1. Launch **HPE Library and Tape Tools** and select the following options to perform the Hardware Scan:
 - **Scan Mode:** Select Hardware Scan
 - **I/O Mode:** Select Miniport
 - Select **Check for Backup Application and Services** check box and click **Continue**
2. Select the required libraries and then select **Dev Perf** option available at the menu bar.
3. Select the drives and then click **Options** to set the parameters.
4. Use the parameters for the **Drive Performance Test**.
5. Click **OK**, and click **Start** to begin the test.

Appendix

Troubleshooting

Issue	Error Message	Remediation
KMIP registration is not enabled	The following error message is displayed in CipherTrust Records: <i>"errorMessage": "Unregistered client, please register a new client"</i>	Check whether the Autoregistration option is selected in Admin Settings > System > Interfaces > kmip .

Issue	Error Message	Remediation
	<i>from CLI or API or UI."</i>	If it is not selected, turn on the Autoregistration option. Refer to the steps mentioned in Enable KMIP Client Registration .
User corresponding to username location in the certificate (for example, OU/UID) is not created	The following error messages are displayed in CipherTrust Records: "errorMessage": "username not found: " "errorMessage": "Could not authenticate certificate user, hence the client is not auto registered in mode <code>tls-cert-pw-opt</code> "	Check whether the user corresponding to UID/OU of the node certificates is created in Keys & Access Management > Users . If the user is not created, create a new user with the same name as the OU/UID field of the node certificates. After creating the user, add this user to the Key Admins . Refer to the steps mentioned in Create a New User .
User is not added to the Key Admin group	The following error message is displayed in CipherTrust Records: "errorMessage": "authorization denied: verdict was deny: CreateKey"	Check whether the user corresponding to UID/OU of the node certificates is created under Keys & Access Management > Users . If the user is not added, add the user to the Key Admins group.
The username location in the Certificate is set incorrectly	The following error messages are displayed in CipherTrust Records: "errorMessage": "username not found: " "errorMessage": "Could not authenticate certificate user, hence the client is not auto registered in mode <code>tls-cert-pw-opt</code> "	Check whether the username location in the Certificate option is set correctly to OU/UID in Admin Settings > System > Interfaces > kmip . If it is not set correctly, set the correct value for the username location in the Certificate.

HPE StoreOnce 3

 Integration with CipherTrust Manager 3

 Verifying Your Integration 15

 Appendix. 16

HPE StoreOnce

HPE StoreOnce delivers scalable backup and restore for small to midsize data centers, and provides an ideal replication target device for up to 36 remote and branch offices. This scalable 2U appliance offers from 36 to 108TB of usable local capacity using an upgrade kits and up to 324TB with Cloud bank storage, and provides a solution to shrinking backup windows with speeds of up to 18TB/hr using HPE StoreOnce catalyst.

HPE StoreOnce delivers a unified solution for data movement across the enterprise under the control of your data protection application.

Supported Product Versions

Note

The integration is performed and certified on **LTS release versions** of CipherTrust Manager only. Feature releases support the integration and are covered under technical support but will not be explicitly certified. To know more about CipherTrust Manager release versions, click [here](#).

CipherTrust Manager

- CipherTrust Manager 2.8

HPE StoreOnce Version

- HPE StoreOnce 4.3.2-2221.21

Integration with CipherTrust Manager

This section lists the steps to integrate Integration of HPE Primera with CipherTrust Manager.

- [Prerequisites](#)
- [Configuration on CipherTrust Manager](#)
- [Configuration on HPE StoreOnce](#)

Prerequisites

This section provides the prerequisites for integration of HPE StoreOnce with CipherTrust Manager.

- Ensure that the CipherTrust Manager is installed and configured. For more details, refer to the [CipherTrust Manager documentation](#).
- HPE StoreOnce communicates with the CipherTrust Manager using the KMIP interface. Ensure that the KMIP interface is configured on the CipherTrust Manager. Refer to [CipherTrust Manager Administration Guide](#) for details.
- **IP address** of the CipherTrust Manager and **port** of the KMIP interface must be accessible from the HPE StoreOnce system.
- CipherTrust Manager recognizes only registered KMIP clients. Ensure that each node of the HPE StoreOnce cluster is registered as a KMIP client on the CipherTrust Manager. Refer to [KMIP Client Registration](#) for more details.

Configuration on CipherTrust Manager

To configure the CipherTrust Manager, you need to perform the following steps:

1. [Creating a Domain \(optional\)](#)
2. [Creating a User](#)
3. [Assigning User to a Group](#)
4. [Creating or Adding a CA \(optional\)](#)
5. [Registering a KMIP Client](#)
6. [Configuring the KMIP Interface](#)

Creating a Domain (Optional)

Perform the following steps to be performed on CipherTrust Manager:

1. Navigate to **Admin Settings > Domains**.
2. Click **Add Domain**. The **Add Domain** page appears.
3. Specify the following information:
 - **Name** - Enter the domain name.
 - **Admins** - Select the admins (one or more) from the list available in the drop down. For example, admin.
 - **Parent CA** - Select parent CA as root CA.

-
- **Allow Subdomain User Management** - Select this check box if you want to enable the sub-domain user management through this domain.

4. Click **Save**.

5. Switch to the newly created domain by clicking the top right on the current Domain Name.

Creating a User

Root Domain

To create a user, perform the following steps:

1. Log on to the CipherTrust Manager GUI.
2. Open the **Access Management** application.
3. On the left navigation pane, click **Users**. The Users page is displayed.
4. On the Users page, click **Add User**.
5. On the **Add User** page, provide the following details:
 - Select the required **Connection Type**
 - Select the checkbox against the required **Allowed Client Type**.
 - Enter **Full Name**
 - Enter **Username**
 - Enter the desired **Password**. Re-enter the password in the **Password Match** field.
6. Click **Add User**. The newly created user will now appear on the **Users** page.

Sub-Domain

Note

To create a user in sub-domain, you must enable **Allow Subdomain User management**.

To create a user, perform the following steps:

1. Log on to the CipherTrust Manager GUI with the User you created within the sub-domain.
2. Open the **Access Management** application.
3. On the left pane, click **Users**. The Users page is displayed.

-
4. On the **Users** page, click **Add User**.
 5. On the **Add User** page, provide the following details:
 - Select the required **Connection Type**
 - Select the checkbox against the required **Allowed Client Type**.
 - Enter **Full Name**
 - Enter **Username**
 - Enter **Password**. Re-enter the password in the **Password Match** field.
 6. Click **Add User**. The newly created user will now appear on the **Users** page.

Assigning User to a Group

Perform the following steps to add user to a group:

1. Navigate to the **Users** page.
2. Click the ellipsis button (...) corresponding to the user that you created in the previous step.
3. Click **Edit/View**.
4. Click **Group Memberships > Add Group**.
5. In the search bar, enter the desired Group name and select the check box corresponding to it. For example, **Key Admins** or **Key Users**.
6. Click **Add Group**.

Creating or Adding a CA (Optional)

Note

Creating a CA is an optional step in this integration. However, it is recommended to select the CA carefully, as it will be used throughout the process.

Select the **Local CA** tab if you want to create a Local CA **OR** select the **External CA** tab if you wish to add the External CA.

Local CA

To create/add a Self-signed local CA, perform the following steps:

1. Navigate to **CA > Local**. Select **Add Local CA**, the **Add Local CA** page appears.
-

-
2. Provide the required information and click **Add Local CA**. The created Local CA will appear under **Pending CAs** section.
 3. Click the ellipsis against the Local CA that you created and select the option **Self-sign**.
 4. Select a valid duration for the Local CA. Click **Save**.

External CA

To add an external CA, perform the following steps:

1. Navigate to **CA > External**. The **External Certificate Authorities** page appears. Select **Add External CA**, the **Add External Certificate** page appears.
2. Provide the required information.
3. If you want to upload the external CA, select the **File Upload** option and click **Upload Certificate**. Browse and select the required External CA.

OR

Select **Text** and paste the contents of External Certificate.

4. Click **Add External CA**.

Registering a KMIP Client

Root Domain

You can register a KMIP client on the CipherTrust Manager through:

- **Auto Registration**
- **Manual Registration**

Auto-Registration

1. Log on to the CipherTrust Manager.
2. Go to **Products > KMIP**.
3. Create Client Profile using the following steps:
 - a. Navigate to **Client Profile** and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Click **Save**. The new profile is created.
4. Create Registration Token using the following steps:

- a. Go to **Registration Token** and click **New Registration Token > Begin**.
- b. Add a **Name Prefix**.
- c. Specify a Token Lifetime value along with the Client Capacity for the token.
- d. Click **Select CA**.
- e. Select the CA type as Local/External depending on CA that you created [above](#).
- f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
- g. Select the Client Profile from the dropdown which you have created in the above step.
- h. Click **Create Token**.
- i. Copy the value of the Token created and click **Done**.

Note

If you are using External CA then you can select the external CA that you created [above](#) and uploaded on the CipherTrust Manager.

5. Turn ON **Auto Registration** using the following steps:
 - a. Go to **Admin Settings > Interfaces**.
 - b. Click the ellipsis button (...) corresponding to the kmip interface.
 - c. Click **View/Edit**.
 - d. On the **Interface Detail** window, perform the following:
 - Select the Interface Mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
 - Select **Auto Registration** checkbox.
 - Paste the **Registration Token**.
 - Add the CA (Local or External) to the list of Trusted CAs. The CA will reflect under the dropdown menu of Local/External Trusted CAs depending upon CA that you created [above](#).
 - Click **Update**.

Manual Registration

1. Log on to the CipherTrust Manager.
2. Go to **Products > KMIP**.
3. Create Client Profile using the following steps:
 - a. Go to **Client Profile** and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Select **CN** in **Username Location in Certificate**.
 - d. Click **Certificate Details**.
 - e. You can either paste the content of a generated `client.csr` or you can create one, by filling in the required details.
 - f. Click **Save**.
4. Create Registration Token using the following steps:
 - a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a **Name Prefix**.
 - c. Specify a Token Lifetime value along with the Client Capacity for the token.
 - d. Click **Select CA**.
 - e. Select the CA type as Local/External depending on the CA type that you created [above](#).
 - f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
 - g. Select the Client Profile from the dropdown which you have created in the above step.
 - h. Click **Create Token**.
 - i. Copy the value of the Token created and click **Done**.

Note

If you are using External CA then you can select the external CA that you created [above](#) and uploaded on the CipherTrust Manager.

5. Go to **Registered Clients** and click **Add Client**.
-

- Specify client name and paste the **Registration Token** that you generated in the above step.

Note

If you are using external CA then you can either upload the client certificate as a file using **Upload Certificate** or paste the signed client certificate in the **Client Certificate** field.

- Click **Save** to save the **client certificate**.

Sub-Domain

You can register a KMIP client on the CipherTrust Manager through:

- **Auto Registration**
- **Manual Registration**

Auto-Registration

1. Log on to the CipherTrust Manager into your domain.
2. Go to **Products > KMIP**.
3. Create **Client Profile** using the following steps:
 - a. Navigate to **Client Profile** and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Click **Save**. The new profile is created.
4. Create Registration Token using the following steps:
 - a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a **Name Prefix**.
 - c. Specify a Token Lifetime value along with the Client Capacity for the token.
 - d. Click **Select CA**.
 - e. Select the CA type as Local/External depending on CA that you created [above](#).
 - f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
 - g. Select the Client Profile from the dropdown which you have created in the above step.
 - h. Click **Create Token**.

- i. Copy the value of the Token created and click **Done**.

Note

If you are using External CA then you can select the external CA that you created [above](#) and uploaded on the CipherTrust Manager.

5. Turn ON **Auto Registration** using the following steps:
 - a. Go to **Admin Settings > Interfaces**.
 - b. Click the ellipsis button (...) corresponding to the kmip interface.
 - c. Click **Edit**.
 - d. On the **Interface Detail** window, perform the following:
 - Select the Interface Mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
 - Select **Auto Registration** checkbox.
 - Paste the **Registration Token**.
 - Add the CA (Local or External) to the list of Trusted CAs. The CA will reflect under the dropdown menu of Local/External Trusted CAs depending upon CA that you created [above](#).
 - Click **Update**.

Manual Registration

1. Log on to the CipherTrust Manager into your domain.
2. Go to **Products > KMIP**.
3. Create **Client Profile** using the following steps:
 - a. Go to Client Profile and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Select **CN** in Username Location in Certificate.
 - d. Expand the **Certificate Details** section.
 - e. You can either paste the content of a generated `client.csr` or you can create one, by filling in the required details.

For domain, the format to enter the Common Name field of the cert is always:

`domainName | | domainUser`

- f. Click **Save**.
4. Create a Registration Token using the following steps:
 - a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a **Name Prefix**.
 - c. Specify a Token Lifetime value along with the Client Capacity for the token.
 - d. Click **Select CA**.
 - e. Select the CA type as Local/External depending on CA that you created [above](#).
 - f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
 - g. Select the Client Profile from the dropdown which you have created in the above step.
 - h. Click **Create Token**.
 - i. Copy the value of the Token created and click **Done**.
5. If you are using External CA then you can select the external CA which you created earlier. Refer to **External CA** under [Creating or Adding a CA](#).
6. Go to Registered Clients and click **Add Client**.
 - a. Specify client name and paste the Registration Token generated in the above step.

Note

If you are using external CA then you need to paste the signed client certificate in the Client Certificate field.

- a. Click **Save** to save the client certificate.

Configuring the KMIP Interface

The KMIP interface can be configured through:

Root Domain

1. Go to **Admin Settings > Interfaces**.
 2. On the KMIP Interface, click the ellipsis button (...) and then click **View/Edit**.
-

3. Select the **Auto Registration** checkbox if you auto-registered your KMIP client and paste the value of the registration token that you created.

Note

By default, the **Auto Registration** is disabled.

4. Select the mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
5. Specify selections for **Local CA for Automatic Server Certificate Generation** as desired.

Note

In case of External CA, **Local CA for Automatic Server Certificate Generation** should be set to **Turn off auto generation from Local CA**.

6. Depending upon the CA that you created [above](#), select an option from the following::
 - If you are using **Local CA** then select the CA under **Local Trusted CAs**
 - If you are using **External CA** then select the CA under **External Trusted CAs**, provided you have the external CA that you created and uploaded on the CipherTrust Manager. For more information on creating or uploading CA, refer to [Creating or Adding a CA](#).

Sub-Domain

1. Select the CA according to your preference.

Local CA

- a. Login to your sub-domain. Go to **CA > Local**. Click the ellipsis (...) and copy the contents of your CA Certificate.
- b. Logout of your sub-domain and now login to the root domain.
- c. Go to **CA > External > Add External CA**.
- d. Enter a name for this Domain CA and select the text radio button and paste the certificate contents.
- e. Click **Add External CA**.
- f. Go to **Admin Settings > Interfaces**.
- g. Click the **Add** icon to add the External CA.

- h. Click **Update**.

External CA

Note

If you are using an External CA in the Sub-Domain, you need to add the CA as an External CA in both the root domain as well as the sub-domain and modify the interface accordingly.

- a. Login to your sub-domain. Go to **CA > Local**. Click the ellipsis (...) and copy the contents of your CA Certificate.
 - b. Logout of your sub-domain and now login to the root domain.
 - c. Go to **CA > External > Add External CA**.
 - d. Enter a name for this Domain CA and select the text radio button and paste the certificate contents.
 - e. Click **Add External CA**.
 - f. Go to **Admin Settings > Interfaces**.
 - g. Click the **Add** icon to add the External CA.
 - h. Click **Update**.
 - i. On the **KMIP interface**, click the ellipsis (...) > **Certificate Options > Upload New Certificate > Ok**.
 - j. Select the **Certificate Chain** option and click **Build Certificate Chain**.
 - k. Click on Text and paste the contents of Server Certificate, CA, and Server Key file in the same order. Do not introduce any space, character or symbol between the contents of these files.
 - l. Select certificate Format as **PEM**.
 - m. Click on **Upload Certificate**.
2. On the KMIP Interface, click the ellipsis button (...) and then click **View/Edit**.
 3. Select the **Auto Registration** checkbox if you auto-registered your KMIP client and paste the value of the registration token that you created.

Note

By default, the **Auto Registration** is disabled.

4. Select the mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
5. Specify selections for **Local CA for Automatic Server Certificate Generation** as desired.

Note

In case of External CA, **Local CA for Automatic Server Certificate Generation** should be set to **Turn off auto generation from Local CA**.

Configuration on HPE StoreOnce

Perform the following steps to integrate HPE StoreOnce with the CipherTrust Manager (CM):

1. Download the client certificate and corresponding CA from the CM and save them.
2. Go back to **StoreOnce** and click **Enroll**.
3. Click **Backup the key manager configuration**, add a password, and click **Backup**. A backup file gets downloaded.
4. Click **Configure External Key Manager Server** and select **SafeNet**.
5. Enter the IP address of CM with port and password and click **OK**.
6. Click **Import Root Certificate** and paste the CA certificate that you have downloaded from the CM.
7. Click **Import Signed Certificate** and paste the client certificate that you have downloaded from the CM.
8. Click **Enroll** and a connection is created with the CM.
9. On successful integration, two keys will be created on the CM.

Verifying Your Integration

Perform the following steps to ensure the integration is successful:

1. Navigate to **Data Services > NAS Shares**.
2. Click **Create Share**, the **Create Share** Window appears.
3. Add name of the share and under **Security Settings** enable **Share Encryption** and click **Create**.

On successful creation of the NAS share, the status of NAS share will turn green and a key is created on CM.

Settings and more (Alt+F): An update is available.

←	 NAS Shares so3b40				
Name	Status	User Data Stored	Size on Disk	Dedupe Ratio	Replication Rule
myNAS	● Online	0 B	3.3 MB	—	Non-Replicating

Appendix

Troubleshooting

Issue	Error Message	Remediation
KMIP registration is not enabled	The following error message is displayed in CipherTrust Records: <i>"errorMessage": "Unregistered client, please register a new client from CLI or API or UI."</i>	Check whether the Autoregistration option is selected in Admin Settings > System > Interfaces > kmip . If it is not selected, turn on the Autoregistration option. Refer to the steps mentioned in Enable KMIP Client Registration .
User corresponding to username location in the certificate (for example, OU/UID) is not created	The following error messages are displayed in CipherTrust Records: <i>"errorMessage": "username not found: "</i> <i>"errorMessage": "Could not authenticate certificate user, hence the client is not auto registered in mode <code>tls-cert-pw-opt</code>"</i>	Check whether the user corresponding to UID/OU of the node certificates is created in Keys & Access Management > Users . If the user is not created, create a new user with the same name as the OU/UID field of the node certificates. After creating the user, add this user to the Key Admins . Refer to the steps mentioned in Create a New User .
User is not added to the Key Admin group	The following error message is displayed in CipherTrust Records: <i>"errorMessage": "authorization denied: verdict was deny: CreateKey"</i>	Check whether the user corresponding to UID/OU of the node certificates is created under Keys & Access Management > Users . If the user is not added, add the user to the Key Admins group.
The username location in the Certificate is set incorrectly	The following error messages are displayed in CipherTrust Records: <i>"errorMessage": "username not found: "</i> <i>"errorMessage": "Could not authenticate certificate user, hence the client is not auto registered in mode <code>tls-cert-pw-opt</code>"</i>	Check whether the username location in the Certificate option is set correctly to OU/UID in Admin Settings > System > Interfaces > kmip . If it is not set correctly, set the correct value for the username location in the Certificate.

CipherTrust Integrations

- IBM DB2..... 3
 - Integration with CipherTrust Manager 3
 - Verifying Your Integration 20

IBM DB2

IBM Db2 is a family of data management products, including the Db2 relational database. The products feature AI-powered capabilities to help you modernize the management of both structured and unstructured data across on-premises and multicloud environments. By helping to make your data simple and accessible, the Db2 family positions your business to pursue the value of AI.

DB2 integrates with the CipherTrust Manager to maintain the confidentiality of the keys and certificates. The integration provides a trusted system for Data At Rest encryption.

Supported Product Versions

Note

The integration is performed and certified on **LTS release versions** of CipherTrust Manager only. Feature releases support the integration and are covered under technical support but will not be explicitly certified. To know more about CipherTrust Manager release versions, click [here](#).

CipherTrust Manager

- CipherTrust Manager 2.3 and higher

IBM DB2

- DB2 11.5 and higher

This integration is validated on **Red Hat Enterprise Linux 8.2**.

Integration with CipherTrust Manager

This section lists the steps to integrate IBM DB2 with CipherTrust Manager.

- [Prerequisites](#)
- [Configuration on CipherTrust Manager](#)

-
- Adding the CA Cert and Generating the CSR
 - Generating the Client Certificate
 - Configuration on IBM DB2

Prerequisites

This section provides the prerequisites for integration of IBM Db2 with CipherTrust Manager.

- Ensure that the CipherTrust Manager is installed and configured. For more details, refer to the [CipherTrust Manager documentation](#).
- Ensure that Db2 is installed and configured. For more details, refer to the [IBM Documentation](#).
- Db2 communicates with the CipherTrust Manager using the KMIP interface. Ensure that the KMIP interface is configured on CipherTrust Manager. Refer to [CipherTrust Manager Administration Guide](#) for details.
- **IP address** of the CipherTrust Manager and **port** of the KMIP interface must be accessible from the Db2.
- Ensure that the required licenses are activated. For more details, refer to the [CipherTrust Manager documentation](#).

Configuration on CipherTrust Manager

To configure the CipherTrust Manager, you need to perform the following steps:

1. [Creating a Domain \(optional\)](#)
2. [Creating a User](#)
3. [Assigning User to a Group](#)
4. [Creating or Adding a CA \(optional\)](#)
5. [Registering a KMIP Client](#)
6. [Configuring the KMIP Interface](#)

Creating a Domain (Optional)

Perform the following steps to be performed on CipherTrust Manager:

1. Navigate to **Admin Settings > Domains**.
 2. Click **Add Domain**. The **Add Domain** page appears.
 3. Specify the following information:
 - **Name** - Enter the domain name.
-

-
- **Admins** - Select the admins (one or more) from the list available in the drop down. For example, admin.
 - **Parent CA** - Select parent CA as root CA.
 - **Allow Subdomain User Management** - Select this check box if you want to enable the sub-domain user management through this domain.

4. Click **Save**.
5. Switch to the newly created domain by clicking the top right on the current Domain Name.

Creating a User

Root Domain

To create a user, perform the following steps:

1. Log on to the CipherTrust Manager GUI.
2. Open the **Access Management** application.
3. On the left navigation pane, click **Users**. The Users page is displayed.
4. On the Users page, click **Add User**.
5. On the **Add User** page, provide the following details:
 - Select the required **Connection Type**
 - Select the checkbox against the required **Allowed Client Type**.
 - Enter **Full Name**
 - Enter **Username**
 - Enter the desired **Password**. Re-enter the password in the **Password Match** field.
6. Click **Add User**. The newly created user will now appear on the **Users** page.

Sub-Domain

Note

To create a user in sub-domain, you must enable **Allow Subdomain User management**.

To create a user, perform the following steps:

1. Log on to the CipherTrust Manager GUI with the User you created within the sub-domain.

-
2. Open the **Access Management** application.
 3. On the left pane, click **Users**. The Users page is displayed.
 4. On the Users page, click **Add User**.
 5. On the **Add User** page, provide the following details:
 - Select the required **Connection Type**
 - Select the checkbox against the required **Allowed Client Type**.
 - Enter **Full Name**
 - Enter **Username**
 - Enter **Password**. Re-enter the password in the **Password Match** field.
 6. Click **Add User**. The newly created user will now appear on the **Users** page.

Assigning User to a Group

Perform the following steps to add user to a group:

1. Navigate to the **Users** page.
2. Click the ellipsis button (...) corresponding to the user that you created in the previous step.
3. Click **Edit/View**.
4. Click **Group Memberships > Add Group**.
5. In the search bar, enter the desired Group name and select the check box corresponding to it. For example, **Key Admins** or **Key Users**.
6. Click **Add Group**.

Creating or Adding a CA (Optional)

Note

Creating a CA is an optional step in this integration. However, it is recommended to select the CA carefully, as it will be used throughout the process.

Select the **Local CA** tab if you want to create a Local CA **OR** select the **External CA** tab if you wish to add the External CA.

Local CA

To create/add a Self-signed local CA, perform the following steps:

1. Navigate to **CA > Local**. Select **Add Local CA**, the **Add Local CA** page appears.
2. Provide the required information and click **Add Local CA**. The created Local CA will appear under **Pending CAs** section.
3. Click the ellipsis against the Local CA that you created and select the option **Self-sign**.
4. Select a valid duration for the Local CA. Click **Save**.

External CA

To add an external CA, perform the following steps:

1. Navigate to **CA > External**. The **External Certificate Authorities** page appears. Select **Add External CA**, the **Add External Certificate** page appears.
2. Provide the required information.
3. If you want to upload the external CA, select the **File Upload** option and click **Upload Certificate**. Browse and select the required External CA.

OR

Select **Text** and paste the contents of External Certificate.

4. Click **Add External CA**.

Registering a KMIP Client

Root Domain

You can register a KMIP client on the CipherTrust Manager through:

- **Auto Registration**
- **Manual Registration**

Auto-Registration

1. Log on to the CipherTrust Manager.
2. Go to **Products > KMIP**.
3. Create Client Profile using the following steps:
 - a. Navigate to **Client Profile** and click **Add Profile**.

-
- b. Add a **Profile Name**.
 - c. Click **Save**. The new profile is created.
 4. Create Registration Token using the following steps:
 - a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a **Name Prefix**.
 - c. Specify a Token Lifetime value along with the Client Capacity for the token.
 - d. Click **Select CA**.
 - e. Select the CA type as Local/External depending on CA that you created [above](#).
 - f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
 - g. Select the Client Profile from the dropdown which you have created in the above step.
 - h. Click **Create Token**.
 - i. Copy the value of the Token created and click **Done**.

Note

If you are using External CA then you can select the external CA that you created [above](#) and uploaded on the CipherTrust Manager.

5. Turn ON **Auto Registration** using the following steps:
 - a. Go to **Admin Settings > Interfaces**.
 - b. Click the ellipsis button (...) corresponding to the knip interface.
 - c. Click **View/Edit**.
 - d. On the **Interface Detail** window, perform the following:
 - Select the Interface Mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
 - Select **Auto Registration** checkbox.
 - Paste the **Registration Token**.
 - Add the CA (Local or External) to the list of Trusted CAs. The CA will reflect under the dropdown menu of Local/External Trusted CAs depending upon CA that you created [above](#).
-

-
- Click **Update**.

Manual Registration

1. Log on to the CipherTrust Manager.
2. Go to **Products > KMIP**.
3. Create Client Profile using the following steps:
 - a. Go to **Client Profile** and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Select **CN** in **Username Location in Certificate**.
 - d. Click **Certificate Details**.
 - e. You can either paste the content of a generated `client.csr` or you can create one, by filling in the required details.
 - f. Click **Save**.
4. Create Registration Token using the following steps:
 - a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a **Name Prefix**.
 - c. Specify a Token Lifetime value along with the Client Capacity for the token.
 - d. Click **Select CA**.
 - e. Select the CA type as Local/External depending on the CA type that you created [above](#).
 - f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
 - g. Select the Client Profile from the dropdown which you have created in the above step.
 - h. Click **Create Token**.
 - i. Copy the value of the Token created and click **Done**.

Note

If you are using External CA then you can select the external CA that you created [above](#) and uploaded on the CipherTrust Manager.

5. Go to **Registered Clients** and click **Add Client**.

- Specify client name and paste the **Registration Token** that you generated in the above step.

Note

If you are using external CA then you can either upload the client certificate as a file using **Upload Certificate** or paste the signed client certificate in the **Client Certificate** field.

- Click **Save** to save the **client certificate**.

Sub-Domain

You can register a KMIP client on the CipherTrust Manager through:

- **Auto Registration**
- **Manual Registration**

Auto-Registration

1. Log on to the CipherTrust Manager into your domain.
 2. Go to **Products > KMIP**.
 3. Create **Client Profile** using the following steps:
 - a. Navigate to **Client Profile** and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Click **Save**. The new profile is created.
 4. Create Registration Token using the following steps:
 - a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a **Name Prefix**.
 - c. Specify a Token Lifetime value along with the Client Capacity for the token.
 - d. Click **Select CA**.
 - e. Select the CA type as Local/External depending on CA that you created [above](#).
 - f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
 - g. Select the Client Profile from the dropdown which you have created in the above step.
-

-
- h. Click **Create Token**.
 - i. Copy the value of the Token created and click **Done**.

Note

If you are using External CA then you can select the external CA that you created [above](#) and uploaded on the CipherTrust Manager.

5. Turn ON **Auto Registration** using the following steps:
 - a. Go to **Admin Settings > Interfaces**.
 - b. Click the ellipsis button (...) corresponding to the kmip interface.
 - c. Click **Edit**.
 - d. On the **Interface Detail** window, perform the following:
 - Select the Interface Mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
 - Select **Auto Registration** checkbox.
 - Paste the **Registration Token**.
 - Add the CA (Local or External) to the list of Trusted CAs. The CA will reflect under the dropdown menu of Local/External Trusted CAs depending upon CA that you created [above](#).
 - Click **Update**.

Manual Registration

1. Log on to the CipherTrust Manager into your domain.
2. Go to **Products > KMIP**.
3. Create **Client Profile** using the following steps:
 - a. Go to Client Profile and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Select **CN** in Username Location in Certificate.
 - d. Expand the **Certificate Details** section.

-
- e. You can either paste the content of a generated `client.csr` or you can create one, by filling in the required details.

For domain, the format to enter the Common Name field of the cert is always:

`domainName | | domainUser`

- f. Click **Save**.

4. Create a Registration Token using the following steps:

- a. Go to **Registration Token** and click **New Registration Token > Begin**.
- b. Add a **Name Prefix**.
- c. Specify a Token Lifetime value along with the Client Capacity for the token.
- d. Click **Select CA**.
- e. Select the CA type as Local/External depending on CA that you created [above](#).
- f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
- g. Select the Client Profile from the dropdown which you have created in the above step.
- h. Click **Create Token**.
- i. Copy the value of the Token created and click **Done**.

5. If you are using External CA then you can select the external CA which you created earlier. Refer to **External CA** under [Creating or Adding a CA](#).

6. Go to Registered Clients and click **Add Client**.

- a. Specify client name and paste the Registration Token generated in the above step.

Note

If you are using external CA then you need to paste the signed client certificate in the Client Certificate field.

- a. Click **Save** to save the client certificate.

Configuring the KMIP Interface

The KMIP interface can be configured through:

Root Domain

1. Go to **Admin Settings > Interfaces**.
2. On the KMIP Interface, click the ellipsis button (...) and then click **View/Edit**.
3. Select the **Auto Registration** checkbox if you auto-registered your KMIP client and paste the value of the registration token that you created.

Note

By default, the **Auto Registration** is disabled.

4. Select the mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
5. Specify selections for **Local CA for Automatic Server Certificate Generation** as desired.

Note

In case of External CA, **Local CA for Automatic Server Certificate Generation** should be set to **Turn off auto generation from Local CA**.

6. Depending upon the CA that you created [above](#), select an option from the following::
 - If you are using **Local CA** then select the CA under **Local Trusted CAs**
 - If you are using **External CA** then select the CA under **External Trusted CAs**, provided you have the external CA that you created and uploaded on the CipherTrust Manager. For more information on creating or uploading CA, refer to [Creating or Adding a CA](#).

Sub-Domain

1. Select the CA according to your preference.

Local CA

- a. Login to your sub-domain. Go to **CA > Local**. Click the ellipsis (...) and copy the contents of your CA Certificate.
- b. Logout of your sub-domain and now login to the root domain.
- c. Go to **CA > External > Add External CA**.
- d. Enter a name for this Domain CA and select the text radio button and paste the certificate contents.

- e. Click **Add External CA**.
- f. Go to **Admin Settings > Interfaces**.
- g. Click the **Add** icon to add the External CA.
- h. Click **Update**.

External CA

Note

If you are using an External CA in the Sub-Domain, you need to add the CA as an External CA in both the root domain as well as the sub-domain and modify the interface accordingly.

- a. Login to your sub-domain. Go to **CA > Local**. Click the ellipsis (...) and copy the contents of your CA Certificate.
 - b. Logout of your sub-domain and now login to the root domain.
 - c. Go to **CA > External > Add External CA**.
 - d. Enter a name for this Domain CA and select the text radio button and paste the certificate contents.
 - e. Click **Add External CA**.
 - f. Go to **Admin Settings > Interfaces**.
 - g. Click the **Add** icon to add the External CA.
 - h. Click **Update**.
 - i. On the **KMIP interface**, click the ellipsis (...) > **Certificate Options > Upload New Certificate > Ok**.
 - j. Select the **Certificate Chain** option and click **Build Certificate Chain**.
 - k. Click on Text and paste the contents of Server Certificate, CA, and Server Key file in the same order. Do not introduce any space, character or symbol between the contents of these files.
 - l. Select certificate Format as **PEM**.
 - m. Click on **Upload Certificate**.
2. On the KMIP Interface, click the ellipsis button (...) and then click **View/Edit**.
 3. Select the **Auto Registration** checkbox if you auto-registered your KMIP client and paste the value of the registration token that you created.

Note

By default, the **Auto Registration** is disabled.

4. Select the mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
5. Specify selections for **Local CA for Automatic Server Certificate Generation** as desired.

Note

In case of External CA, **Local CA for Automatic Server Certificate Generation** should be set to **Turn off auto generation from Local CA**.

Further, you need to configure the following:

- Adding the CA Cert and Generating the CSR
- Generating the Client Certificate

Adding the CA Cert and Generating the CSR

You can download and add the CA cert in the local keystore for any of the following Certificate Authorities:

Local CA

1. In the CipherTrust Manager, download the Local CA Cert (Certificate.pem).
2. Move the downloaded CA Cert to work folder that you created in DB2 Server.
3. Rename the `Certificate.pem` to `ca.crt`.

```
mv <work_folder_location/Certificate.pem> <work_folder_location/ca.crt
```

For example: `mv /opt/wallet/KMIP/Certificate.pem /opt/wallet/KMIP/ca.crt`

4. Add the CA cert to the local keystore.

```
</home/<DB2 user instance>/sqlllib/gskit/bin/gsk8capicmd_64 -cert -add -db <work_folder_location/local_keystore> -stashed -label <LABEL FOR CA CERTIFICATE> -file <CA CERTIFICATE FILE>
```

For Example: `/home/db2user/sqllib/gskit/bin/gsk8capicmd_64 -cert -add -db "/opt/wallet/KMIP/clientkeydb.p12" -stashed -label "DB2_CA_CERT" -file "/opt/wallet/KMIP/ca.crt"`

External CA

1. Generate the External CA using OpenSSL or any other CA generator.
2. Upload the CA on the CipherTrust Manager, using the following steps:
 - a. Go to **CA > External**.
 - b. On the CA page, click **Add External CA**.
 - c. Paste the contents of the `rootCACert.pem` and click **Save**.
3. Move the downloaded CA Cert to work folder that you created in DB2 Server.
4. Add the CA cert to the local keystore.

```
</home/<DB2 user instance>/sqllib/gskit/bin/gsk8capicmd_64 -cert -add -db <work_folder_location/local_keystore> -stashed -label <LABEL FOR CA CERTIFICATE> -file <CA CERTIFICATE FILE>
```

For Example: `/home/db2user/sqllib/gskit/bin/gsk8capicmd_64 -cert -add -db "/opt/wallet/KMIP/clientkeydb.p12" -stashed -label "DB2_CA_CERT" -file "/opt/wallet/KMIP/ca.crt"`

Generating the CSR for Client Certificate

After adding the CA cert to the local keystore, generate the Client Certificate request using the following steps:

Root

In the DB2 server, generate the Client Certificate Request. Use the newly created user created on CipherTrust Manager (DB2_CLIENT_CERT in this case) as reference while generating the CSR.

```
<DB2_HOME>/sqllib/gskit/bin/gsk8capicmd_64 -certreq -create -db < LOCAL KEYSTORE FILE> -stashed -label <LABEL FOR CLIENT CERTIFICATE> -dn <CLIENT CERTIFICATE DETAILS> -target <CLIENT CSR FILE> -size 2048 -sigalg SHA256
```

For Example: `/home/db2user/sqllib/gskit/bin/gsk8capicmd_64 -certreq -create -db "/opt/wallet/KMIP/clientkeydb.p12" -stashed -label "DB2_CLIENT_CERT" -dn "CN=DB2_CLIENT_CERT, O=Gemalto, OU=PA, L=Noida, ST=UP, C=IN" -target "/opt/wallet/KMIP/client_cert_request.arm" -size 2048 -sigalg SHA256`

Sub-Domain

To generate the CSR for client certificate in a sub-domain, pass the CN as `CN=DB2_CLIENT_CERT| |username`, where **username** is the user created above.

```
<DB2_HOME>/sqllib/gskit/bin/gsk8capicmd_64 -certreq -create -db < LOCAL KEYSTORE
```

```
FILE> -stashed -label <LABEL FOR CLIENT CERTIFICATE> -dn <CLIENT CERTIFICATE DATA>
ILS> -target <CLIENT CSR FILE> -size 2048 -sigalg SHA256
```

For Example: /home/db2user/sql/lib/gskit/bin/gsk8capicmd_64 -certreq -create -db "/opt/wallet/KMIP/clientkeydb.p12" -stashed -label "DB2_CLIENT_CERT" -dn "CN=DB2_CLIENT_CERT|user1, O=Gemalto, OU=PA, L=Noida, ST=UP, C=IN" -target "/opt/wallet/KMIP/client_cert_request.arm" -size 2048 -sigalg SHA256

Generating the CSR for Server Certificate

Note

Server certificate is required only when you are using External CA. You may skip this step if you are using the Local CA.

To create a server certificate, perform the following steps:

1. Create a server key using the following command.

```
openssl genrsa -out server.key 2048
```

2. Create a CSR for the server, using the above generated key.

```
openssl req -key server.key -new -sha256 -out server.csr -subj /O=my-org/OU=my-org/OU=server/CN=server
```

After generating the CSR (`server.csr` in this case), create a server certificate using the following openssl command:

```
openssl x509 -req -days 7300 -in server.csr -CA rootCACert.pem -CAkey rootCAKey.pem -CAcreateserial -out server.cert -sha256
```

This Server key and Server certificate will be used in configuring the KMIP interface.

Generating the Client Certificate

Before generating the client certificate, ensure that you have registered the KMIP client.

Tip

To register the KMIP client, click [here](#).

You can generate the client certificate using any of the following two options:

Manual Registration

1. Generate a registration token using the Local Root CA and the profile [generated in the previous step](#) under Manual Registration.
2. Copy the registration token and go to Registered clients > Add client. Specify the client name and paste the registration token and click **Save**.
3. Download the resultant client certificate.
4. Move the downloaded client certificate in the working folder (/opt/wallet/KMIP) of DB2 server and rename it to **client.crt**.

After moving and renaming the client certificate as mentioned above, add the signed client certificate into local KeyStore. To do so, execute the following command:

```
/home/<db2 instance user>/sqllib/gskit/bin/gsk8capicmd_64 -cert -receive -db <LOCAL KEYSTOREFILE> -stashed -file <CLIENT CERTIFICATE>
```

For Example: /home/db2user/sqllib/gskit/bin/gsk8capicmd_64 -cert -receive -db "/opt/wallet/KMIP/clientkeydb.p12" -stashed -file "client.crt"

Auto Registration

1. Copy the CSR generated [previously](#).
2. On the CipherTrust Manager GUI perform the following steps:
 - a. Go to **CA > Local** , click on the Local CA present there.
 - b. Click on **Upload CSR**.
 - c. Add a specified name in **Display name** and paste the content of CSR in the **CSR** column and select **Certificate Purpose** as **client**.
 - d. Click on **Issue Certificate** and save the certificate.
3. Move the downloaded client certificate in the working folder (/opt/wallet/KMIP) of DB2 server and rename it to **client.crt**.

After moving and renaming the client certificate as mentioned above, add the signed client certificate into local KeyStore. To do so, execute the following command:

```
/home/<db2 instance user>/sqllib/gskit/bin/gsk8capicmd_64 -cert -receive -db <LOCAL KEYSTOREFILE> -stashed -file <CLIENT CERTIFICATE>
```

For Example: /home/db2user/sqllib/gskit/bin/gsk8capicmd_64 -cert -receive -db "/opt/wallet/KMIP/clientkeydb.p12" -stashed -file "client.crt".

Configuration on IBM DB2

Generating Master Encryption Key in the CipherTrust Manager

To generate the Master Encryption Key in the CipherTrust Manager, perform the following steps:

1. Create a centralized KeyStore.
 - a. To store a Master Encryption Key in CipherTrust Manager for a DB2 native encryption, you need to create a configuration file that contains all details about this centralized KeyStore i.e. the CipherTrust Manager.
 - b. In the work folder (/opt/wallet/KMIP) of the DB2 server, create kmip.cfg file with the following details:

```
VERSION=1
PRODUCT_NAME=KEYSECURE
ALLOW_KEY_INSERT_WITHOUT_KEYSTORE_BACKUP=true
SSL_KEYDB=/opt/wallet/KMIP/clientkeydb.p12
SSL_KEYDB_STASH=/opt/wallet/KMIP/clientkeydb.sth
SSL_KMIP_CLIENT_CERTIFICATE_LABEL=DB2_CLIENT_CERT
ALLOW_NONCRITICAL_BASIC_CONSTRAINT=false
MASTER_SERVER_HOST=IP of CM
MASTER_SERVER_KMIP_PORT=<port for KMIP interface>
CLONE_SERVER_HOST=
CLONE_SERVER_KMIP_PORT=
```

where:

- **SSL_KEYDB (Required):** Absolute path and name of the local keystore file that holds the SSL certificates for communication between DB2 server and the CipherTrust Manager.
- **SSL_KEYDB_STASH (Optional):** Absolute path and name of the stash file for the local keystore that hold the certificates for communication between DB2 server and the CipherTrust Manager.
- **SSL_KMIP_CLIENT_CERTIFICATE_LABEL (Required):** The label of the SSL certificate for authenticating the client during communication with the CipherTrust Manager.
- **MASTER_SERVER_HOST** is the CipherTrust Manager IP.
- **MASTER_SERVER_KMIP_PORT** is the KMIP interface Port in the CipherTrust Manager.

2. Configure a DB2 instance to use CipherTrust Manager as centralized keystore.

- a. Enter into DB2 command line using the **db2** command with the DB2@instance user.
- b. Update the keystore to point to our new config file **kmip.cfg**.

```
db2 => update dbm cfg using keystore_location <file path>/kmip.cfg
```

```
db2 => update dbm cfg using keystore_type kmip
```

c. Stop and Start the database.

```
db2 => db2stop  
db2 => db2start
```

Creating an Encrypted Database

To create an encrypted database you need to add the parameter **encrypt** in the create database command.

```
db2 => create db <database_name> encrypt
```

For Example: db2 => create db myencdb encrypt

Note

- In the above example, an encrypted database **myencdb** is created. This database is using the native encryption of DB2.
- After executing the above command, a master encryption key is created in the CipherTrust Manager.

Verifying Your Integration

On successful integration a master encryption key should be generated in the CipherTrust Manager under **Keys**.

To verify your database has been successfully encrypted by DB2 Native encryption, execute the following command:

```
db2 => get db cfg for <database_name>
```

Ensure that the value of the **Encrypted database** configuration parameter is set to **YES**.

CipherTrust Integrations

 - Appendix. 8

IBM FileNet Content Manager

IBM FileNet Content Manager is a flexible, full-featured content management solution that provides the foundation for IBM Cloud Pak® for Business Automation. It uses AI to deliver deep insights from your unstructured content. Use it to create innovative business applications on any cloud and more effectively manage all your content, from any source.

Supported Product Versions

Note

This integration has been validated in the field by a partner or in a customer environment with the following software versions. It is recommended to test the integration in a non-production environment with desired software versions before deploying it to production. Thales will provide best-effort support.

CipherTrust Manager

- CipherTrust Manager 2.4.0

IBM FileNet Content Manager

- IBM FileNet Content Manager 5.5

Integration with CipherTrust Manager

This section lists the steps to integrate FileNet with CipherTrust Manager.

- [Prerequisites](#)
- [Configuration on CipherTrust Manager](#)
- [Configuration on FileNet Content Manager](#)

Prerequisites

This section provides the prerequisites for integration of FileNet Content Manager with CipherTrust Manager.

- Ensure that the CipherTrust Manager is installed and configured. For more details, refer to the [CipherTrust Manager documentation](#).
- FileNet Content Manager communicates with the CipherTrust Manager using the KMIP interface. Ensure that the KMIP interface is configured on the CipherTrust Manager. Refer to [CipherTrust Manager Administration Guide](#) for details.
- **IP address** of the CipherTrust Manager and **port** of the KMIP interface must be accessible from the FileNet

Content Manager system.

- CipherTrust Manager recognizes only registered KMIP clients. Ensure that each node of the FileNet Content Manager cluster is registered as a KMIP client on the CipherTrust Manager. Refer to [KMIP Client Registration](#) for more details.

Configuration on CipherTrust Manager

Creating and Signing Certificates Using KSCTL Utility

Note

KSCTL is used to create CA and CSRs at the CipherTrust Manager. To know about how to install and configure KSCTL refer to the [CipherTrust Manager Documentation](#).

Creating the CA Certificate

The rootCA is by default available at the CipherTrust Manager. If you want to create a Local CA other than rootCA, use the following command:

```
ksctl ca locals create --cn "Test CA" --csr-outfile csrfile
```

To self-sign the CA for a specific duration, use the id returned in the above command:

```
ksctl ca locals self-sign --id <id of CA> -x <duration>
```

For Example:

```
ksctl ca locals self-sign --id 3593c53b-fbeb-4edb-b84d-c85526ae2f83 -x 365
```

Creating the Client Certificate

To create the client certificate, use the following steps:

1. Create CSR and its private key.

```
ksctl ca csr --cn "FileNet Content Manager" --csr-outfile client.csr --key-outfile client.key
```

This command generates a CSR along with its private key.

Note

In this document, common name **CN=FileNet Content Manager** is used, which will be further used as a user name on the CipherTrust Manager.

2. Sign the CSR with CA.

```
ksctl ca locals certs issue --ca-id <id of CA> --csr-infile client.csr -x <duration> -o client
```

For Example:

```
ksctl ca locals certs issue --ca-id c84d66e1-2101-4a46-ad44-3656354b5097 --csr-infile client.csr -x 700 -o client
```

--ca-id is the id which can be obtained from CA details on the Ciphertrust Manager.

Note

--csr-infile is the csr name which is created in the previous step.

Creating the Server Certificate

Note

Server Certificate is needed only in case if you are using external CA instead of Local CA.

To create a server certificate, create CSR and its private key.

```
ksctl ca csr --cn "server" --csr-outfile server.csr --key-outfile server.key
```

This command generates a CSR along with its private key.

You can sign the above created CSR using external CA. The generated certificate will be uploaded to the CipherTrust Manager.

Configuring the CipherTrust Manager

1. Create User on CipherTrust Manager.

- a. In the CipherTrust Manager UI, go to **Access Management > Users** and create a new user.
- b. Click on the newly created user, click on **GROUPS** and select the Key Users and Key Admins Group.

Note

Username must be same as common name mentioned above while creating the client certificate.

2. Register KMIP client.

To perform KMIP client registration, refer to [KMIP Client Registration](#).

3. Configure KMIP Interface.

- a. Go to **Admin Settings > Interfaces**.
- b. On the KMIP Interface, click the action button (...) and then click **Edit**.

Configure KMIP popup opens.

- c. Check **Auto Registration** option if you are going with Auto Registration or uncheck if you are going with the Manual Registration.
- d. Select the mode as **TLS, verify client cert, username taken from client cert, auth request is optional**.
- e. Specify selections for **Local CA for Automatic Server Certificate Generation and Local Trusted CAs** as desired.

Note

Local CA for Automatic Server Certificate Generation should be set to **Turn off auto generation from Local CA** in case of External CA.

- f. Select the CA according to your preference.
 - If you are using External CA then select the CA under **External Trusted CAs**
 - If you are using Local CA then select the CA under **Local Trusted CAs**
- g. This step is required if you are using external CA.

Expand the **Upload Certificate** section:

- In the **Certificate** field, paste the contents of Server Certificate, CA, and Server Key file in the same order. Do not introduce any space or character or symbol between the contents of these files.
- Select certificate **Format** as **PEM**.
- **Password** field is optional and can be skipped.
- Click **Update**.

Configuration on FileNet Content Manager

Connect to the instance using SSH. The FileNet Content Manager shell appears. Perform the following steps on the FileNet Content Manager shell:

1. Import the External CA root certificate to truststore on application server.
2. Import the PFX certificate file for FileNet client to certificate store on application server.
3. On KMIP configuration (Key Management Tab)
 - a. Select **KMIP** for **Key Service type** dropdown box.
 - b. Enter the IP address or hostname on **Primary Host** field.
 - c. Enter the the port for KMIP interface you use on CTM for **Primary port**.
 - d. If you do not have secondary server, enter the same values to secondary IP and port otherwise FileNet will throw an error.
4. Click **Save** button on top left.

This completes the configuration on FileNet Content Manager.

Verifying Integration

Perform the following steps to ensure the successful integration:

After performing the integration steps, you can create keys to verify if the integration is successful.

Execute the following command to create a key from IBM FileNet Content Manager:

```
security key-manager key create
```

In the CipherTrust Manager GUI, navigate to **Keys**. Check if there is an entry for this newly created key. Usually, most recently created keys are listed on the top of the table.

If the key is created, the integration is successful.

Appendix

Troubleshooting

This section describes the how to troubleshoot the issue that you may encounter while integrating CipherTrust Manager with IBM FileNet Content Manager.

Issue	Error Message	Remediation
KMIP registration is not enabled	The following error message is displayed in CipherTrust Records: <i>"errorMessage": "Unregistered client, please register a new client from CLI or API or UI."</i>	Check whether the KMIP registration is completed or not in Admin Settings > System > Interfaces > kmip . If it is not completed, refer to the steps mentioned in KMIP Client Registration .
User corresponding to username location in certificate (example: CN) has not been created CN = Common Name	The following error messages are displayed in CipherTrust Records: *"errorMessage": "username not found: " "errorMessage": "Could not authenticate certificate user, *	Check whether the user corresponding to CN of the client certificates has been created in Keys & Access Management > Users . If the user is not created, create a new user with the same name as the CN field of the client certificates. After creating the user, add this user to the Key Admins and Key Groups . Refer to steps mentioned in
User has not been added to Key Admin group	The following error message is displayed in CipherTrust Records: <i>"errorMessage": "authorization denied: verdict was deny: CreateKey"</i>	Check whether the user corresponding to CN of the client certificates has been created under Keys & Access Management > Users . If the user is not added, add the user to the Key Admins group.
The Username location in Certificate has been set incorrectly	The following error messages are displayed in CipherTrust Records: <i>"errorMessage": "username not found: "</i> <i>"errorMessage": "Could not authenticate certificate user,</i>	Check whether the Username Location in the Certificate option is set correctly to CN in Admin Settings > System > Interfaces > kmip . If it is not set correctly, set the correct value for the Username Location in the Certificate.

CipherTrust Integrations

4 February 2026

Contents

- IBM Spectrum Scale 3
 - Pre-Integration 4
 - Integration with CipherTrust Manager 9
 - Verifying Your Integration 15
 - High Availability 16
- Appendix 19

IBM Spectrum Scale

Enterprises and organizations are creating, analyzing, and keeping more data than ever before. Those that can deliver insights faster while managing rapid infrastructure growth are the leaders in their industry. In delivering those insights, an organization's underlying storage must support new-era big data and artificial intelligence workloads along with traditional applications while ensuring security, reliability, and high performance.

IBM Spectrum Scale™ meets these challenges as a high-performance solution for managing data at scale with the distinctive ability to perform archive and analytics in place.

Supported Product Versions

Note

The integration is performed and certified on **LTS release versions** of CipherTrust Manager only. Feature releases support the integration and are covered under technical support but will not be explicitly certified. To know more about CipherTrust Manager release versions, click [here](#).

This integration is validated on the following software versions:

CipherTrust Manager

- CipherTrust Manager 2.3 and higher

IBM Spectrum Scale

- IBM Spectrum Scale 5.1.1.1 and higher

Prerequisites

- Spectrum Scale communicates with the CipherTrust Manager through KMIP interface. Ensure that the CipherTrust Manager is installed and configured properly. For more details, refer to the [Administrator Guide of CipherTrust Manager](#).
- Ensure that IBM Spectrum Scale is installed and configured. For more information, refer to the [IBM documentation](#).
- Ensure that the required licenses are activated. For more details, refer to the [CipherTrust Manager documentation](#).
- CipherTrust Manager recognizes only registered KMIP clients. Ensure that KMIP client is registered. Refer [KMIP client Registration](#) for more details.

Pre-Integration

This section lists the following procedure that needs to be performed before integration.

1. [Creating Certificates](#)
2. [Creating Client Keystore \(PKCS#12 file\)](#)
3. [Configuring the RKM.conf File](#)

Creating Certificates

You can create and use the certificate using any of the following methods:

- [Using KSCTL Utility](#): Use this method if you want to create and use certificates generated on the CipherTrust Manager using KSCTL utility.
- [Using openssl](#): Use this method if you want to create and use certificates generated using openssl.

Creating Certificates Using KSCTL Utility

Note

KSCTL is used to create CA and CSRs at the CipherTrust Manager. To know about how to install and configure KSCTL refer to the [CipherTrust Manager Documentation](#)

Creating the CA Certificate

The rootCA is by default available at the CipherTrust Manager. If you want to create a Local CA other than rootCA, use the following command:

```
ksctl ca locals create --cn "Test CA" --csr-outfile csrfile
```

To self-sign the CA for a specific duration, use the id returned in the above command:

```
ksctl ca locals self-sign --id <id of CA> -x <duration>
```

For Example:

```
ksctl ca locals self-sign --id 3593c53b-fbeb-4edb-b84d-c85526ae2f83 -x 365
```

Creating Client Certificate

To create the client certificate, use the following steps:

1. Create CSR and its private key.

```
ksctl ca csr --cn "client" --csr-outfile client.csr --key-outfile client.key
```

This command generates a CSR along with its private key.

Note

In this document, common name CN=client is used, which will be further used as a user name on the CipherTrust Manager.

2. Sign the CSR with CA.

```
ksctl ca locals certs issue --ca-id <id of CA> --csr-infile client.csr -x <duration> -o client
```

For Example:

```
ksctl ca locals certs issue --ca-id c84d66e1-2101-4a46-ad44-3656354b5097 --csr-infile client.csr -x 700 -o client
```

--ca-id is the id which can be obtained from CA details on the Ciphertrust Manager.

Note

--csr-infile is the csr name which is created in the previous step.

Creating Server Certificate

Note

This section is applicable if you want to generate certificates at the CipherTrust Manager and sign them using external CA.

To create a server certificate, you need to create the CSR and its Private key, using the following command:

```
ksctl ca csr --cn "server" --csr-outfile server.csr --key-outfile server.key
```

This command generates a CSR along with its private key.

You can sign the above created CSR using external CA. The generated certificate will be uploaded to the CipherTrust Manager. Refer to [Adding User and Configuring Interface](#) for details.

Creating Certificates Using openssl

You can use openssl to create external CA and CSRs outside CipherTrust Manager.

Before creating the CA and CSRs, ensure that the openssl is configured properly.

- To create the external CA, client, and server certificate, you will need:
 - bash (version 4.4.20 or above)
 - openssl (version 1.1.1 or above)
- `openssl.conf` file is at the following location:
 - `/etc/pki/tls` for RHEL
 - `/etc/ssl` for Ubuntu
- Open `openssl.conf` file and go to [`v3_ca`] tab and add `basicConstraints = critical, CA: true`.

Creating the CA Certificate

To create an External CA and upload it on the CipherTrust Manager, follow the below steps:

1. Create a RSA key using the following openssl command:

```
openssl genrsa -out rootCAKey.pem 2048
```

This command will generate `rootCAKey.pem` file.

2. Create a CA certificate using the generated RSA key.

```
openssl req -x509 -sha256 -new -nodes -key rootCAKey.pem -days 3650 -out rootCACert.pem
```

The above command uses `rootCAKey.pem` generated in previous step to generate the CA Certificate, `rootCACert.pem`.

3. Upload the CA on the CipherTrust Manager, using the following steps:
 - a. Go to **CA > External**.
 - b. On the CA page, click **Add External CA**.
 - c. Paste the contents of the `rootCACert.pem` and click **Save**.

Creating Client Certificate

To create a client certificate, perform the following steps:

1. Create a key to be used in the client certificate.

```
openssl genrsa -out client.key 2048
```

This command generates the RSA key `client.key`.

2. Create a client CSR using the key generated above.

```
openssl req -key client.key -new -sha256 -out client.csr -subj /O=my-org/OU=my-org/OU=client/CN=client
```

In this document, common name `CN=client` is used, which will be further used as a user name on the CipherTrust Manager.

This command uses the `client.key` generated in previous step to generate the client CSR `client.csr`.

3. Sign the CSR using the RSA key generated above and the CA.

```
openssl x509 -req -days 360 -in client.csr -CA rootCACert.pem -CAkey rootCAKey.pem -CAcreateserial -out client.cert -sha256
```

Creating Server Certificate

To create a server certificate, perform the following steps:

1. Create a server key using the following command.

```
openssl genrsa -out server.key 2048
```

2. Create a CSR for the server using the above generated key.

```
openssl req -key server.key -new -sha256 -out server.csr -subj /O=my-org/OU=my-org/OU=server/CN=server
```

3. Create a server certificate using the following openssl command.

```
openssl x509 -req -days 7300 -in server.csr -CA rootCACert.pem -CAkey rootCAKey.pem -CAcreateserial -out server.cert -sha256
```

Creating a Client Keystore (PKCS#12 file)

Create a PKCS#12 file by packaging the client key, client certificate, and CA file using the following openssl command.

```
openssl pkcs12 -export -in client.cert -inkey client.key -certfile rootCACert.pem  
-out client.p12 -name client
```

Note

If you are creating certificates using `ksctl`, then you need to download the client certificate, client key, and Local CA(rootCA) from the CipherTrust Manager and use it while creating the PKCS#12 file.

- You will be prompted to set a password for the keystore file. Specify the **client keystore password**, then the `client.p12` file will be created. This password and the keystore path will be used later in the Remote Key Management configuration file `RKM.conf` of the Spectrum Scale. For simplicity, let's assume that the client keystore password specified for this integration is `abcd`.
- In the above command, the name `client` is applied to the collection of files contained within the PKCS#12 package.

Configuring the RKM.conf File

1. Create a directory `/var/mmfs/etc/RKMcerts` on all nodes of the Spectrum Scale cluster and copy the client keystore `client.p12` created in the [previous step](#) to this directory.
2. Create the Remote Key Management (RKM) configuration file (`/var/mmfs/etc/RKM.conf`) and add a stanza that contains the information necessary to communicate with the CipherTrust Manager. The stanza should be in the following format:

```
client {  
  type = KMIP  
  kmipServerUri = tls://10.164.x.xxx:5696  
  keyStore = /var/mmfs/etc/RKMcerts/client.p12  
  passphrase = abcd  
  clientCertLabel = client  
}
```

Stanza contains the following fields:

- **client:** Name of the RKM stanza. It can be set as desired, "client" here is just an example name for the stanza.

- **type:** Must be KMIP.
- **kmipServerUri:** IP addresses or the DNS names of the CipherTrust Managers and their SSL ports.

In the above example, 10.164.x.xxx is the CipherTrust Manager IP and 5696 is the SSL port.

Note

- For high availability (HA), multiple *kmipServerUri* entries can be added.
- In an event when a CipherTrust Manager fails or is inaccessible, then request is sent to the other CipherTrust Managers configured using *kmipServerUri*.

Refer to [High Availability](#) for High Availability.

- **keyStore:** The name and path of the `client.p12` file (for example: `/var/mmfs/etc/RKMcerts/client.p12`).
 - **passphrase:** The password of the client keystore and client certificate. This is the same password which you specified while creating `client.p12` file.
 - **clientCertLabel:** The label of the client certificate in the client keystore. This is the same label which you specified while creating `client.p12` file.
3. Copy the `/var/mmfs/etc/RKM.conf` and the client keystore `/var/mmfs/etc/RKMcerts/client.p12` file to all nodes in the cluster.

Caution

Ensure the user has READ and WRITE permissions (mode '0600') for the files `var/mmfs/etc/RKM.conf` and `var/mmfs/etc/RKMcerts/client.12`.

Integration with CipherTrust Manager

To integrate Spectrum Scale with the CipherTrust Manager, you need to:

- [Configure the CipherTrust Manager](#)
- [Configure Spectrum Scale](#)

Configuring the CipherTrust Manager

To configure the CipherTrust Manager, you need to perform the following steps:

1. Add User
2. Registering a KMIP Client
3. Configure Interface
4. Create Key
5. Update the Key Attributes

Add User

Note

Username should be same as the CN (Common Name) specified while creating the client certificate.

1. In the CipherTrust Manager UI, go to **Access Management -> Users** and create a new user.
2. Select the newly created user and then click **GROUPS**. Further, select the **Key Users** and **Key Admins** Group.

Registering a KMIP Client

You can register a KMIP client on the CipherTrust Manager using:

- Auto Registration
- Manual Registration

Using Auto-Registration

1. Create a registration token using the following steps:
 - a. Log on to the CipherTrust Manager.
 - b. Go to **Access Management > Registration Tokens** in the sidebar.
 - c. Click **Create New Registration Token**.

Copy the **Registration Token** once it is created.

2. Turn ON **Auto Registration** using the following steps:

-
- a. Go to **Admin Settings > Interfaces**.
 - b. Click the ellipsis button corresponding to the kmip interface.
 - c. Click **Edit**.
 - d. Under **Configure KMIP** window, select **Auto Registration**.
 - e. Paste the **Registration Token**.
 - f. Select the mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
 - g. Click **Update**.

Using Manual Registration

1. Log on to the CipherTrust Manager.
 2. Go to **Products > KMIP**.
 3. Create Client Profile using the following steps:
 - a. Go to **Client Profile** and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Select **CN** in **Username Location in Certificate**.
 - d. Click **Certificate Details**.
 - e. Paste the content of **client.csr**.
 - f. Click **Save**.
 4. Create Registration Token using the following steps:
 - a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a Name Prefix.
 - c. Click **Select CA**.
 - d. Select CA type as Local if you are using **Local CA** or select external if you are using **External CA**.
 - e. Select appropriate CA from dropdown menu and click **Select Profile**.
 - f. Select the Client Profile from dropdown which you have created in the above step.
 - g. Click **Create Token**.
 - h. Copy the Token created and click **Done**.
-

Note

If you are using External CA then you can select the external CA which was created using openssl and uploaded on the CipherTrust Manager.

5. Go to **Registered Clients** and click **Add Client**.

- Specify client name and paste the **Registration Token** generated in the above step.

Note

If you are using external CA then you need to paste the signed client certificate in the **Client Certificate** field.

- Click **Save** to save the **client certificate**.

Configure Interface

Configure a KMIP Interface using the following steps:

1. Go to **Admin Settings > Interfaces**.
2. On the KMIP Interface, click the action button (...) and then click **Edit**.

Configure KMIP popup opens.

3. Check **Auto Registration** option if you are going with Auto Registration or uncheck if you are going with the Manual Registration.
4. Select the mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
5. Specify selections for **Local CA for Automatic Server Certificate Generation** as desired.

Note

Local CA for Automatic Server Certificate Generation should be set to **Turn off auto generation from Local CA** in case of External CA.

6. Select the CA according to your preference.

- If you are using External CA then select the CA under **External Trusted CAs**
- If you are using Local CA then select the CA under **Local Trusted CAs**

7. This step is required if you are using external CA.

Expand the **Upload Certificate** section:

- In the **Certificate** field, paste the contents of Server Certificate, CA, and Server Key file in the same order. Do not introduce any space or character or symbol between the contents of these files.
- Select certificate **Format** as **PEM**.
- **Password** field is optional and can be skipped.
- Click **Update**.

Creating Key using API Playground

1. At the top right corner of the main toolbar, click **API** to go to the API playground.
2. Click **Authenticate** on the top right corner. Specify username and password, then click **Post**.

Note

The session will be valid for 300 seconds. You can also authenticate later if you are unable to perform the following steps within this time frame.

3. Go to **Keys** section in the left sidebar. Click **Create - Post**.
4. Specify the following content in the body, and click **POST**. Specify a value equal to or less than 60 characters.

```
{
  "idSize": 60
}
```

Here **idSize:60** will be set to the **ID** of the key, which will be further used while configuring the policy file of the Spectrum Scale.

Caution

Specifying a value greater than 60 leads to integration failure. To view the list of possible errors, go to

the [Troubleshooting](#) section.

Updating the Key Attributes

1. In the CipherTrust Manager UI, go to **Keys** and click the Key you have created using API.
2. Ensure that **Exportable** option is checked.
3. Select the user ([created above](#)) as the **Key Owner**.
4. Click **Update**.

Configuring the Spectrum Scale

1. IBM Spectrum Scale connects with the CipherTrust Manager configured using the `RKM.conf` stanza.

For more details, refer to the [Pre-Integration](#) section.

2. Create a policy file with any desired name, ex `hsm62` in any of the client node. Paste the following content in this policy file.

```
RULE 'p1' SET POOL 'system' /* one placement rule is required at all times */
RULE 'Encrypt all files in file system with rule E1'
SET ENCRYPTION 'E1'
WHERE NAME LIKE '%'
RULE 'rule1' ENCRYPTION 'E1' IS
ALGO 'DEFAULTNISTSP800131A'
KEYS( 'cd1929c52e4b2e5a8047d6e6815cf41df8d4d664bb78b85991ecce5bce56:client' )
```

Note

- `cd1929c52e4b2e5a8047d6e6815cf41df8d4d664bb78b85991ecce5bce56` is the **ID** of the key created on the CipherTrust Manager.
- `client` is the RKM stanza ID in `/var/mmfs/etc/RKM.conf`.
- Ensure that the correct key ID and RKM ID are used in the policy. For details regarding the IBM Spectrum Scale policy rules, click [here](#).

3. Install the encryption policy, using the following command.

```
/usr/lpp/mmfs/bin/mmchpolicy fs0 hsm62
```

Note

fs0 is an IBM Spectrum Scale file system that is created during installation and deployment phase of IBM Spectrum Scale.

Upon successful encryption, following message is displayed:

```
Policy 'hsm62' installed and broadcast to all nodes.
```

If all steps were followed correctly, the integration between CipherTrust Manager and IBM Spectrum Scale will be successful. Both devices can now communicate with each other, and the IBM Spectrum Scale can now encrypt the data present in its nodes using the HSM key.

You can further verify if the integration is successful, using the steps mentioned in [Verifying Your Integration](#).

Verifying Your Integration

Perform the following steps to ensure the integration is successful:

1. Create a test file on any node and then copy it to **/fs0**. Consider that the user created a file **test.txt**, and then copied it to **/fs0**.

```
cp /tmp/test.txt /fs0
```

2. Verify that file is encrypted with the key present in the CipherTrust Manager, using the following commands:

```
[root@ss1 ~]# /usr/lpp/mmfs/bin/mmlsattr -n gpfs.Encryption /fs0/test.txt
```

```
[root@ssl ~]# /usr/lpp/mmfs/bin/mmfsattr -n gpfs.Encryption /fs0/test.txt
file name: /fs0/test.txt
gpfs.Encryption: "EAGC????#???????????????? ????]??,???????????????? ?6(?6?
?B??d?L????l?????????m??f?test.txt aaaaaaaaaacccccccccccccccceerrrrrrff?client?"
EncPar 'AES:256:XTS:FEC:HMF
type: wrapped FEK wrpPar 'AES:KWRAP' CmbPar 'XORHMACSHA512'
aaaaaaaaaaaaaaaaacccccccccccccccceerrrrrrff:client
```

```
[root@ss1 ~]# /usr/lpp/mmfs/bin/mmlsattr -L /fs0/test.txt
```

```
[root@ssl ~]# /usr/lpp/mmfs/bin/mmlsattr -L gpfs.Encryption: /fs0/test.txt
gpfs.Encryption: Stat failed: No such file or directory

file name:                /fs0/test.txt
metadata replication: 1 max 2
data replication:         1 max 2
immutable:                no
appendOnly:               no
flags:
storage pool name:        system
fileset name:              root
snapshot name:
creation time:             Wed May 20 07:03:46 2020
Misc attributes:          ARCHIVE
Encrypted:                 yes
[root@ssl ~]#
```

Since the Encryption flag is true (Encrypted: **yes**), the integration is successful.

High Availability

This section explains the procedure to integrate the CipherTrust Manager present in a cluster with Spectrum Scale.

Note

- The steps mentioned below are to be performed only after performing the steps specified in the [Pre-Integration](#) section.
- To know about cluster creation on the CipherTrust Manager, refer to the [CipherTrust Manager Documentation](#)

Integration Steps

In a high availability setup, primary and backup CipherTrust Manager server(s) can be configured in the `RKM.conf` file.

- The `kmipServerUri` attribute represents the **DNS name** or **IP address** of the CipherTrust Manager and the KMIP SSL port.
- The backup server(s) should be listed in the `kmipServerUri2`, `kmipServerUri3`, etc.

Note

- If you're using External CA, **Local CA for Automatic Server Certificate Generation** should be set to **Turn off auto generation from Local CA**.
- In case of External CA , update the certificate chain (server cert , CA , server key) in the KMIP interface of the backup server, same as of the primary server.
- For high availability (HA), it is recommended to add multiple backup servers, that is, multiple *kmipServerUri* entries. You can have up to five backup key servers.

The following example has the primary key server and a secondary key server.

1. Add the following RKM (Remote Key Managment) stanza to the `RKM.conf` file (created in the [Pre-Integration](#) section). This stanza contains the information required to connect to the CipherTrust Manager server.

```
RKM_Stanza {
type = KMIP
kmipServerUri = tls://10.164.x.xxx:5696
kmipServerUri2 = tls://10.164.x.abc:5696
keyStore = /var/mmfs/etc/RKMcerts/client.p12
passphrase = abcd
clientCertLabel = client
}
```

Brief description of fields contained in the stanza:

- **RKM_Stanza:** Name of the RKM Stanza. It can be set as desired, "RKM_Stanza" here is just an example name for the stanza.
- **type:** Must be KMIP.
- **kmipServerUri:** IP addresses or the DNS names of the CipherTrust Manager and their SSL ports.
 - For high availability (HA), multiple *kmipServerUri* entries may be added.
 - In an event when a CipherTrust Manager fails or is inaccessible, then request is sent to the other nodes specified here.
- **keyStore:** The name and path of the `client.p12` file (for example: `/var/mmfs/etc/RKMcerts/client.p12`).
- **passphrase:** The password of the client keystore and client certificate. This is the same password which you specified while creating `client.p12` file.

- **clientCertLabel:** The label of the client certificate in the client keystore. This is the same label which you specified while creating `client.p12` file.

2. Install the encryption policy on the file system using the following command.

```
/usr/lpp/mmfs/bin/mmchpolicy fs0 hsm62
```

Verifying Integration

To verify the integration performed using High Availability, follow the below steps:

1. Create a *Key Export* call in the primary CipherTrust Manager of the cluster.
2. Shut down the CipherTrust Manager.
3. Clear the key cache on the IBM Spectrum Scale client.

```
/usr/lpp/mmfs/bin/tsctl encKeyCachePurge 'cd1929c52e4b2e5a8047d6e6815cf41df8d4d664bb78b85991ecce5bce56:client'
```

Note

- `cd1929c52e4b2e5a8047d6e6815cf41df8d4d664bb78b85991ecce5bce56` is the ID for the key created in the CipherTrust Manager.
- `client` is the RKM stanza ID.

Both values can be retrieved by running the command: `mmlspolicy fs0 -L`

For example:

```
[root@ss1 etc]# /usr/lpp/mmfs/bin/mmlspolicy fs0 -L
RULE 'p1' SET POOL 'system' /* one placement rule is required at all time
s */
RULE 'Encrypt all files in file system with rule E1'
SET ENCRYPTION 'E1'
WHERE NAME LIKE '%'
RULE 'rule1' ENCRYPTION 'E1' IS
ALGO 'DEFAULTNISTSP800131A'
KEYS('cd1929c52e4b2e5a8047d6e6815cf41df8d4d664bb78b85991ecce5bce56:client')
```

- Access an existing encrypted file or try to create a new encrypted file. The Spectrum Scale daemon log will show a warning message that indicates its inability to retrieve the encryption key from the primary key server:

```
2020-04-07_11:51:19.637-0400: [W] The key server 10.164.x.xxx (port 5696) had a failure and will be quarantined for 1 minute(s).
```

Spectrum Scale will try the second key server in the list, and the I/O operation should be successful if the secondary/backup server is able to serve the encryption key.

- Check CipherTrust Manager activity logs or records for Key Export calls.

Note

If integration is successful, then KMIP encryption operation is processed by secondary server present in the cluster. That means the *Key Export* calls would be created in secondary server activity logs if the primary is down.

- If the *Key Export* calls are created on the secondary CipherTrust Manager present in the cluster, then the integration is successful.

Appendix

Troubleshooting

You may face following errors while performing the integration steps mentioned in previous sections. The document lists errors from both appliances separately:

IBM Spectrum Scale Errors

Error	Troubleshooting
If the IBM Spectrum Scale client is not able to contact the key server when accessing an encrypted file, the following error message can be found in the daemon log: 2020-04-23_13:06:47.564-0400: [E] Key 'cd1929c52e4b2e5a8047d6e6815cf41df8d4d664bb78b85991ecce5bce56:client' could not be fetched. The TCP connection with the RKM could not be established.	Check the connectivity between the client and the key server.
The following error message is printed in the daemon log when a bad certificate is detected: 2020-04-22_18:13:06.623-0400: [E] Key 'cd1929c52e4b2e5a8047d6e6815cf41df8d4d664bb78b85991ecce5bce56:client' could not be fetched. Bad	Check and ensure the client and server certificates are valid.

Error	Troubleshooting
certificate.	
The following error message indicates that the <code>/var/mmfs/etc/RKM.conf</code> file is missing the RKM stanza "RKM3": <pre>2020-04-28_12:00:23.459-0400: [E] Key 'cd1929c52e4b2e5a8047d6e6815cf41df8d4d664bb78b85991ecce5bce56:client' could not be fetched. The specified RKM ID does not exist; check the RKM.conf settings.</pre>	Ensure that <code>/var/mmfs/etc/RKM.conf</code> on all nodes contains the required RKM stanza.
The following error message indicates that the client key store file specified in the <code>/var/mmfs/etc/RKM.conf</code> file is missing: <pre>2020-05-01_17:20:22.972-0400: [E] Error while validating policy 'for file system dsm64': rc=778: While parsing file '/var/mmfs/etc/RKM.conf':[E] Could not open the key store file ('/var/mmfs/etc/RKMcerts/dsm64Client.p12' was specified).</pre>	Check the <code>/var/mmfs/etc/RKM.conf</code> file and ensure that the correct client keystore file is specified in the <code>keyStore</code> attribute. Verify that the client keystore (<code>.p12</code>) file is present on all nodes in the cluster.
The following error message indicates that the permissions on the client keystore file are incorrect. Access to this file should be granted to root only: <pre>2020-05-01_17:25:24.173-0400: [E] Error while validating policy 'for file system dsm64': rc=778: While parsing file '/var/mmfs/etc/RKM.conf':[E] The keyStore permissions are incorrect for /var/mmfs/etc/RKMcerts/dsm64Client.p12. Access should be only granted to root, and no execute permission is allowed for the file</pre>	Check and fix the permissions on the client keystore file.
If <code>RKM.conf</code> file is not copied to all nodes, following error may occur: <pre>[root@ss1 etc]# /usr/lpp/mmfs/bin/mmchpolicy fs0 hsm62 Validated policy 'hsm62': Parsed 3 policy rules. The RKM identifier specified for key 'cd1929c52e4b2e5a8047d6e6815cf41df8d4d664bb78b85991ecce5bce56:client' does not exist; check the RKM.conf file. Make sure the RKM.conf and keystore(s) files are copied to all nodes in the cluster.</pre>	Copy the <code>RKM.conf</code> file on all nodes.
Setting incorrect or insufficient permissions for <code>RKM.conf</code> file may cause the following error: <pre>[root@ss1 etc]# /usr/lpp/mmfs/bin/mmchpolicy fs0 hsm62 [E] Error while validating policy 'hsm62': rc=778:[E] Incorrect permissions for the configuration file /var/mmfs/etc/RKM.conf on node ss2. mmchpolicy: Command failed. Examine previous error messages to determine cause.</pre>	Set correct permissions for <code>RKM.conf</code> file
If keystore file is missing from <code>/var/mmfs/etc/RKMcerts</code> folder, following error may occur: <pre>[root@ss1 etc]# /usr/lpp/mmfs/bin/mmchpolicy fs0 hsm62 [E] Error while validating policy 'hsm62': rc=778: While parsing file '/var/mmfs/etc/RKM.conf':[E] Could not open the key store file ('/var/mmfs/etc/RKMcerts/client.p12' was specified). mmchpolicy: Command failed. Examine previous error messages to determine cause.</pre>	Make sure that keystore file is in <code>/var/mmfs/etc/RKMcerts</code>

CipherTrust Manager Errors

Error	Troubleshooting
If the username specified while creating a key is not same as the CN (Common Name) specified in the client certificate, following error may occur: <pre>[root@ss1 etc]# cp /root/test.txt /fs0 cp: cannot create regular file '/fs0/test.txt': Operation not permitted [root@ss1 etc]# vim /var/adm/ras/mmfs.log.latest 2020-05-20_08:25:47.961-0400: [E] Unable to create encrypted file test.txt (inode 86532, fileset 0, file system fs0). 2020-05-20_08:25:47.962-0400: [E] Key 'cd1929c52e4b2e5a8047d6e6815cf41df8d4d664bb78b85991ecce5bce56:client' could not be fetched (RKM reported error -1256). "/var/adm/ras/mmfs.log.latest" 537L, 49635C</pre>	Specify the Username same as the CN (Common Name) specified while creating the client certificate.
If mode of the KMIP Interface is selected as TLS, Verify client cert, user must supply password, following error may occur. Error <pre>[root@ss1 etc]# cp /root/test2.txt /fs0 cp: cannot create regular file '/fs0/test2.txt': Operation not permitted [root@ss1 etc]# vim /var/adm/ras/mmfs.log.latest 2020-05-20_08:34:13.693-0400: [W] The key server 10.164.10.118 (port 9889) had a failure and will be quarantined for 1 minute(s). 2020-05-20_08:34:13.924-0400: [W] The key server 10.164.10.123 (port 9889) had a failure and will be quarantined for 1 minute(s). 2020-05-20_08:34:13.924-0400: [E] Unable to create encrypted file test2.txt (inode 86541, fileset 0, file system fs0). 2020-05-20_08:34:13.924-0400: [E] Key 'cd1929c52e4b2e5a8047d6e6815cf41df8d4d664bb78b85991ecce5bce56:client' could not be fetched (RKM reported error -115).</pre>	IBM Spectrum Scale does not support this setting. Choose one of the other two options: • Optional • Not Used
If you are using external CA and primary server fails to serve the key	In KMIP interface, Local CA for Automatic Server Certificate Generation should be set to Turn off auto generation from Local CA.

CipherTrust Integrations

Contents

- MySQL..... 3
 - Integration with CipherTrust Manager 3
 - Verifying Your Integration 18
 - Appendix..... 19

MySQL

MySQL supports transparent data encryption, which provides data-at-rest encryption for physical tablespace data files. This feature uses a two-tier encryption key architecture, consisting of a master encryption key and tablespace keys. When a table is encrypted, a tablespace key is encrypted and stored in the tablespace header. When an application user wants to access the encrypted tablespace data, a master encryption key is used to decrypt the tablespace key. When integrated with CipherTrust Manager, the master encryption key resides on CipherTrust Manager.

Supported Product Versions

Note

The integration is performed and certified on **LTS release versions** of CipherTrust Manager only. Feature releases support the integration and are covered under technical support but will not be explicitly certified. To know more about CipherTrust Manager release versions, click [here](#).

CipherTrust Manager

- CipherTrust Manager 2.3 and higher

MySQL Version

- MySQL 8.0.27 and higher

Operating System

- Red Hat Enterprise Linux 7

Integration with CipherTrust Manager

This section lists the steps to integrate MySQL with CipherTrust Manager.

-
- Prerequisites
 - Configuration on CipherTrust Manager
 - Configuration on MySQL

Prerequisites

This section provides the prerequisites for integration of MySQL with CipherTrust Manager.

- Ensure that the CipherTrust Manager is installed and configured. For more details, refer to the [CipherTrust Manager documentation](#).
- MySQL communicates with the CipherTrust Manager using the KMIP interface. Ensure that the KMIP interface is configured on the CipherTrust Manager. Refer to [CipherTrust Manager Administration Guide](#) for details.
- **IP address** of the CipherTrust Manager and **port** of the KMIP interface must be accessible from the MySQL system.
- CipherTrust Manager recognizes only registered KMIP clients. Ensure that each node of the MySQL cluster is registered as a KMIP client on the CipherTrust Manager. Refer to [KMIP Client Registration](#) for more details.

Configuration on CipherTrust Manager

To configure the CipherTrust Manager, you need to perform the following steps:

1. [Creating a Domain \(optional\)](#)
2. [Creating a User](#)
3. [Assigning User to a Group](#)
4. [Creating or Adding a CA \(optional\)](#)
5. [Registering a KMIP Client](#)
6. [Configuring the KMIP Interface](#)

Creating a Domain (Optional)

Perform the following steps to be performed on CipherTrust Manager:

1. Navigate to **Admin Settings > Domains**.
2. Click **Add Domain**. The **Add Domain** page appears.
3. Specify the following information:
 - **Name** - Enter the domain name.

-
- **Admins** - Select the admins (one or more) from the list available in the drop down. For example, admin.
 - **Parent CA** - Select parent CA as root CA.
 - **Allow Subdomain User Management** - Select this check box if you want to enable the sub-domain user management through this domain.

4. Click **Save**.
5. Switch to the newly created domain by clicking the top right on the current Domain Name.

Creating a User

Root Domain

To create a user, perform the following steps:

1. Log on to the CipherTrust Manager GUI.
2. Open the **Access Management** application.
3. On the left navigation pane, click **Users**. The Users page is displayed.
4. On the Users page, click **Add User**.
5. On the **Add User** page, provide the following details:
 - Select the required **Connection Type**
 - Select the checkbox against the required **Allowed Client Type**.
 - Enter **Full Name**
 - Enter **Username**
 - Enter the desired **Password**. Re-enter the password in the **Password Match** field.
6. Click **Add User**. The newly created user will now appear on the **Users** page.

Sub-Domain

Note

To create a user in sub-domain, you must enable **Allow Subdomain User management**.

To create a user, perform the following steps:

1. Log on to the CipherTrust Manager GUI with the User you created within the sub-domain.

-
2. Open the **Access Management** application.
 3. On the left pane, click **Users**. The Users page is displayed.
 4. On the Users page, click **Add User**.
 5. On the **Add User** page, provide the following details:
 - Select the required **Connection Type**
 - Select the checkbox against the required **Allowed Client Type**.
 - Enter **Full Name**
 - Enter **Username**
 - Enter **Password**. Re-enter the password in the **Password Match** field.
 6. Click **Add User**. The newly created user will now appear on the **Users** page.

Assigning User to a Group

Perform the following steps to add user to a group:

1. Navigate to the **Users** page.
2. Click the ellipsis button (...) corresponding to the user that you created in the previous step.
3. Click **Edit/View**.
4. Click **Group Memberships > Add Group**.
5. In the search bar, enter the desired Group name and select the check box corresponding to it. For example, **Key Admins** or **Key Users**.
6. Click **Add Group**.

Creating or Adding a CA (Optional)

Note

Creating a CA is an optional step in this integration. However, it is recommended to select the CA carefully, as it will be used throughout the process.

Select the **Local CA** tab if you want to create a Local CA **OR** select the **External CA** tab if you wish to add the External CA.

Local CA

To create/add a Self-signed local CA, perform the following steps:

1. Navigate to **CA > Local**. Select **Add Local CA**, the **Add Local CA** page appears.
2. Provide the required information and click **Add Local CA**. The created Local CA will appear under **Pending CAs** section.
3. Click the ellipsis against the Local CA that you created and select the option **Self-sign**.
4. Select a valid duration for the Local CA. Click **Save**.

External CA

To add an external CA, perform the following steps:

1. Navigate to **CA > External**. The **External Certificate Authorities** page appears. Select **Add External CA**, the **Add External Certificate** page appears.
2. Provide the required information.
3. If you want to upload the external CA, select the **File Upload** option and click **Upload Certificate**. Browse and select the required External CA.

OR

Select **Text** and paste the contents of External Certificate.

4. Click **Add External CA**.

Registering a KMIP Client

Root Domain

You can register a KMIP client on the CipherTrust Manager through:

- **Auto Registration**
- **Manual Registration**

Auto-Registration

1. Log on to the CipherTrust Manager.
2. Go to **Products > KMIP**.
3. Create Client Profile using the following steps:
 - a. Navigate to **Client Profile** and click **Add Profile**.

-
- b. Add a **Profile Name**.
 - c. Click **Save**. The new profile is created.
 4. Create Registration Token using the following steps:
 - a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a **Name Prefix**.
 - c. Specify a Token Lifetime value along with the Client Capacity for the token.
 - d. Click **Select CA**.
 - e. Select the CA type as Local/External depending on CA that you created [above](#).
 - f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
 - g. Select the Client Profile from the dropdown which you have created in the above step.
 - h. Click **Create Token**.
 - i. Copy the value of the Token created and click **Done**.

Note

If you are using External CA then you can select the external CA that you created [above](#) and uploaded on the CipherTrust Manager.

5. Turn ON **Auto Registration** using the following steps:
 - a. Go to **Admin Settings > Interfaces**.
 - b. Click the ellipsis button (...) corresponding to the knip interface.
 - c. Click **View/Edit**.
 - d. On the **Interface Detail** window, perform the following:
 - Select the Interface Mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
 - Select **Auto Registration** checkbox.
 - Paste the **Registration Token**.
 - Add the CA (Local or External) to the list of Trusted CAs. The CA will reflect under the dropdown menu of Local/External Trusted CAs depending upon CA that you created [above](#).
-

-
- Click **Update**.

Manual Registration

1. Log on to the CipherTrust Manager.
2. Go to **Products > KMIP**.
3. Create Client Profile using the following steps:
 - a. Go to **Client Profile** and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Select **CN** in **Username Location in Certificate**.
 - d. Click **Certificate Details**.
 - e. You can either paste the content of a generated `client.csr` or you can create one, by filling in the required details.
 - f. Click **Save**.
4. Create Registration Token using the following steps:
 - a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a **Name Prefix**.
 - c. Specify a Token Lifetime value along with the Client Capacity for the token.
 - d. Click **Select CA**.
 - e. Select the CA type as Local/External depending on the CA type that you created [above](#).
 - f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
 - g. Select the Client Profile from the dropdown which you have created in the above step.
 - h. Click **Create Token**.
 - i. Copy the value of the Token created and click **Done**.

Note

If you are using External CA then you can select the external CA that you created [above](#) and uploaded on the CipherTrust Manager.

5. Go to **Registered Clients** and click **Add Client**.

- Specify client name and paste the **Registration Token** that you generated in the above step.

Note

If you are using external CA then you can either upload the client certificate as a file using **Upload Certificate** or paste the signed client certificate in the **Client Certificate** field.

- Click **Save** to save the **client certificate**.

Sub-Domain

You can register a KMIP client on the CipherTrust Manager through:

- **Auto Registration**
- **Manual Registration**

Auto-Registration

1. Log on to the CipherTrust Manager into your domain.
2. Go to **Products > KMIP**.
3. Create **Client Profile** using the following steps:
 - a. Navigate to **Client Profile** and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Click **Save**. The new profile is created.
4. Create Registration Token using the following steps:
 - a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a **Name Prefix**.
 - c. Specify a Token Lifetime value along with the Client Capacity for the token.
 - d. Click **Select CA**.
 - e. Select the CA type as Local/External depending on CA that you created [above](#).
 - f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
 - g. Select the Client Profile from the dropdown which you have created in the above step.

-
- h. Click **Create Token**.
 - i. Copy the value of the Token created and click **Done**.

Note

If you are using External CA then you can select the external CA that you created [above](#) and uploaded on the CipherTrust Manager.

5. Turn ON **Auto Registration** using the following steps:
 - a. Go to **Admin Settings > Interfaces**.
 - b. Click the ellipsis button (...) corresponding to the kmip interface.
 - c. Click **Edit**.
 - d. On the **Interface Detail** window, perform the following:
 - Select the Interface Mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
 - Select **Auto Registration** checkbox.
 - Paste the **Registration Token**.
 - Add the CA (Local or External) to the list of Trusted CAs. The CA will reflect under the dropdown menu of Local/External Trusted CAs depending upon CA that you created [above](#).
 - Click **Update**.

Manual Registration

1. Log on to the CipherTrust Manager into your domain.
2. Go to **Products > KMIP**.
3. Create **Client Profile** using the following steps:
 - a. Go to Client Profile and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Select **CN** in Username Location in Certificate.
 - d. Expand the **Certificate Details** section.

-
- e. You can either paste the content of a generated `client.csr` or you can create one, by filling in the required details.

For domain, the format to enter the Common Name field of the cert is always:

`domainName | | domainUser`

- f. Click **Save**.

4. Create a Registration Token using the following steps:

- a. Go to **Registration Token** and click **New Registration Token > Begin**.
- b. Add a **Name Prefix**.
- c. Specify a Token Lifetime value along with the Client Capacity for the token.
- d. Click **Select CA**.
- e. Select the CA type as Local/External depending on CA that you created [above](#).
- f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
- g. Select the Client Profile from the dropdown which you have created in the above step.
- h. Click **Create Token**.
- i. Copy the value of the Token created and click **Done**.

5. If you are using External CA then you can select the external CA which you created earlier. Refer to **External CA** under [Creating or Adding a CA](#).

6. Go to Registered Clients and click **Add Client**.

- a. Specify client name and paste the Registration Token generated in the above step.

Note

If you are using external CA then you need to paste the signed client certificate in the Client Certificate field.

- a. Click **Save** to save the client certificate.

Configuring the KMIP Interface

The KMIP interface can be configured through:

Root Domain

1. Go to **Admin Settings > Interfaces**.
2. On the KMIP Interface, click the ellipsis button (...) and then click **View/Edit**.
3. Select the **Auto Registration** checkbox if you auto-registered your KMIP client and paste the value of the registration token that you created.

Note

By default, the **Auto Registration** is disabled.

4. Select the mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
5. Specify selections for **Local CA for Automatic Server Certificate Generation** as desired.

Note

In case of External CA, **Local CA for Automatic Server Certificate Generation** should be set to **Turn off auto generation from Local CA**.

6. Depending upon the CA that you created [above](#), select an option from the following::
 - If you are using **Local CA** then select the CA under **Local Trusted CAs**
 - If you are using **External CA** then select the CA under **External Trusted CAs**, provided you have the external CA that you created and uploaded on the CipherTrust Manager. For more information on creating or uploading CA, refer to [Creating or Adding a CA](#).

Sub-Domain

1. Select the CA according to your preference.

Local CA

- a. Login to your sub-domain. Go to **CA > Local**. Click the ellipsis (...) and copy the contents of your CA Certificate.
- b. Logout of your sub-domain and now login to the root domain.
- c. Go to **CA > External > Add External CA**.
- d. Enter a name for this Domain CA and select the text radio button and paste the certificate contents.

-
- e. Click **Add External CA**.
 - f. Go to **Admin Settings > Interfaces**.
 - g. Click the **Add** icon to add the External CA.
 - h. Click **Update**.

External CA

Note

If you are using an External CA in the Sub-Domain, you need to add the CA as an External CA in both the root domain as well as the sub-domain and modify the interface accordingly.

- a. Login to your sub-domain. Go to **CA > Local**. Click the ellipsis (...) and copy the contents of your CA Certificate.
 - b. Logout of your sub-domain and now login to the root domain.
 - c. Go to **CA > External > Add External CA**.
 - d. Enter a name for this Domain CA and select the text radio button and paste the certificate contents.
 - e. Click **Add External CA**.
 - f. Go to **Admin Settings > Interfaces**.
 - g. Click the **Add** icon to add the External CA.
 - h. Click **Update**.
 - i. On the **KMIP interface**, click the ellipsis (...) > **Certificate Options > Upload New Certificate > Ok**.
 - j. Select the **Certificate Chain** option and click **Build Certificate Chain**.
 - k. Click on Text and paste the contents of Server Certificate, CA, and Server Key file in the same order. Do not introduce any space, character or symbol between the contents of these files.
 - l. Select certificate Format as **PEM**.
 - m. Click on **Upload Certificate**.
2. On the KMIP Interface, click the ellipsis button (...) and then click **View/Edit**.
 3. Select the **Auto Registration** checkbox if you auto-registered your KMIP client and paste the value of the registration token that you created.
-

Note

By default, the **Auto Registration** is disabled.

4. Select the mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
5. Specify selections for **Local CA for Automatic Server Certificate Generation** as desired.

Note

In case of External CA, **Local CA for Automatic Server Certificate Generation** should be set to **Turn off auto generation from Local CA**.

Configuration on MySQL

To integrate MySQL with the CipherTrust Manager:

- Installing the `keyring_okv` plugin
- Creating a Client Certificate
- Importing the KMIP Certificates to `keyring_okv` plugin
- Verify that `keyring_okv` plugin is working

Installing the `keyring_okv` plugin

1. The configuration directory used by `keyring_okv` to store its support files should have restricted permissions, allowing access only to the account running the MySQL server. For instance, on Linux-based systems, you can create a directory structure like: `/usr/local/mysql/mysql-keyring-okv` and set its ownership and permissions by running the following commands as the root user:

```
cd /usr/local
mkdir -p mysql/mysql-keyring-okv/ssl
chmod -R 750 mysql
chown -R mysql mysql
chgrp -R mysql mysql
```

2. To ensure the `keyring_okv` plugin is available during server startup, it must be loaded using the `--early-plugin-load` option. Additionally, the `keyring_okv_conf_dir` system variable should be set to specify the location of the configuration directory for `keyring_okv`.

To do this, edit the `/etc/my.cnf` file and add the plugin under the `mysqld` section:

```
[mysqld]
early-plugin-load=keyring_okv.so
keyring_okv_conf_dir=/usr/local/mysql/mysql-keyring-okv
```

3. In the configuration directory, create a file named `okvclient.ora` file and add the IPs of both the nodes of CipherTrust Manager to it in the following format:

```
SERVER=<IP of Primary Node>:5696
STANDBY_SERVER=<IP of Secondary Node>:5696
```

4. Configure the permissions for these files as follows:

```
cd /usr/local/mysql/mysql-keyring-okv
cd /usr/local/
chmod -R 750 mysql
chown -R mysql
chgrp -R mysql
```

5. If the firewall is active, allow traffic on port 5696. Run the following commands as the root user on the MySQL server:

```
firewall-cmd --zone=public --add-port=5696/tcp --permanent
firewall-cmd --zone=public --add-port=5696/udp --permanent
firewall-cmd --reload
```

6. Disable SELinux on the next server reboot by setting `SELINUX=disabled` in the `/etc/selinux/config` file.

For immediate disabling in the current shell, use the following command:

```
setenforce 0
```

7. After completing the steps above, restart the MySQL server:

```
sudo systemctl restart mysqld
sudo systemctl status mysqld
```

Creating a Client Certificate

Note

This section is applicable to KMIP clients registered using Auto Registration.

1. Log on to the CipherTrust Manager.
2. Navigate to the **CA > Local CA** and click on the name of the CA certificate you need to issue the certificate from.
3. Click on **Issue Certificate**.
4. Enter the **Display Name**, followed by **Common Name**.

Note

- The common Name of the certificate should be the same as the name of the user you created on CipherTrust Manager. Refer to [Creating a User](#) section.
- For more information on the format of common name of the certificate, refer to [LDAP and Multi-Domain Client Usernames in KMIP Certificates](#).

5. Select the **Algorithm** and **Size**, and click **Issue Certificate**.
6. Save the **Private Key** and the **CSR**.
7. Select the **Certificate Purpose** as client, specify the validity of the certificate in days, and click **Issue Certificate**.
8. Download a copy of this certificate by clicking the ellipsis next to the certificate name.
9. Navigate to the **CA > Local CA** and download a copy of the CA that issued the certificate in the previous steps.

Importing the KMIP Certificates to keyring_okv plugin

Tip

Certificates are necessary to enable KMIP communication between the CipherTrust Manager and MySQL.

1. Navigate to the directory `mysql/mysql-keyring-okv/ssl` and import the downloaded copies of all the certificates (CA, Client Certificate, and Key).

Verify that keyring_okv plugin is working

To confirm the keyring_okv plugin installation with the MySQL server running, log in into your MySQL database and run the following query:

```
SELECT PLUGIN_NAME, PLUGIN_STATUS FROM INFORMATION_SCHEMA.PLUGINS WHERE PLUGIN_NAME LIKE 'keyring%';
```

If you receive the plugin name along with the active status in the query response, your installation is successful. If not, investigate the logs at `/var log/mysqlld.log` to ensure there are no connection issues.

Verifying Your Integration

After all the files have been configured, you can verify your integration using either of the following.

Identifying the Encrypted Tablespaces

```
SELECT TABLE_SCHEMA, TABLE_NAME, CREATE_OPTIONS FROM INFORMATION_SCHEMA.TABLES WHERE CREATE_OPTIONS LIKE '%ENCRYPTION%';
```

Encrypting a table using keyring_okv plugin

1. Create a new user and grant all privileges to the user.

```
CREATE USER 'TestUser'@'localhost' IDENTIFIED BY '*****';  
GRANT ALL PRIVILEGES ON *.* TO 'TestUser'@'localhost';
```

2. Log on to MySQL as “TestUser”, and create a database called `Players` and a table named `BaseballPlayers`.

```
mysql -u TestUser -p  
create database Players;  
use Players;  
CREATE table BaseballPlayers (lastname varchar(16), firstname varchar(12), position varchar(16));
```

3. Insert some sample data into the table `BaseballPlayers`.

```
INSERT INTO BaseballPlayers ( firstname, lastname, position ) values ('John', 'Doe', 'Outfield' );
```

```
INSERT INTO BaseballPlayers ( firstname, lastname, position ) values ('Joe','Smith','Pitcher' );
INSERT INTO BaseballPlayers ( firstname, lastname, position ) values ('Willie','Mays', 'Outfield' );
```

4. Encrypt the table.

```
ALTER TABLE BaseballPlayers ENCRYPTION='Y';
```

This generates your master encryption key on the CipherTrust Manager and completes your integration. Move to the next section to verify your integration.

Rotating Master Key

The master encryption key should be rotated periodically or whenever you suspect that the key has been compromised.

To rotate the master key:

1. Run the following query:

```
ALTER INSTANCE ROTATE INNODB MASTER KEY;
```

2. Check the server records on the CipherTrust Manager to verify the status of the operation.

Appendix

Troubleshooting

Issue	Error Message	Remediation
KMIP auto-registration is not enabled	The following error message is displayed in the CipherTrust Manager Records: "errorMessage": "Unregistered client, please register a new client from CLI or API or UI."	Check whether the auto registration option is selected in Admin Settings > System Interfaces > kmip . If it is not selected, turn on the auto registration option. Refer to Configuration steps for CipherTrust Manager using the GUI or ksctl.
Incorrect KMIP interface mode has been selected	The following error message is displayed in the mongod logs: "initandlisten Unable to retrieve key .system, error: socket exception [CONNECT_ERROR] for The server certificate does not match the host name."	Check whether the mode selected in Admin Settings > System Interfaces > kmip is "TLS, verify client cert, allow anonymous logins". If not, make appropriate changes.

Issue	Error Message	Remediation
Unable to view load the keyring_okv plugin after configuration	<pre> 2021-05-24T16:44:45.524984Z 0 [System] [MY-010116] [Server] /usr/sbin/mysqld (mysqld 8.0.25-commercial) starting as process 2399 2021-05-24T16:44:45.544113Z 0 [ERROR] [MY-011400] [Server] Plugin keyring_okv reported: 'Error setting the key file.' 2021-05-24T16:44:45.544307Z 0 [ERROR] [MY-011386] [Server] Plugin keyring_okv reported: 'Could not initialize ssl layer' 2021-05-24T16:44:45.544351Z 0 [ERROR] [MY-011377] [Server] Plugin keyring_okv reported: 'keyring_okv initialization failure. Please check that the keyring_okv_conf_dir points to a readable directory and that the directory contains Oracle Key Vault configuration file and ssl materials. Also, please check that Oracle Key Vault is up and running.' </pre>	Restrict permission on the complete set of directories as mentioned in the integration steps. Investigate the logs in <code>/var log/ mysqld.log</code> to make sure there are no errors when connecting to CipherTrust Manager.

CipherTrust Integrations

4 February 2026

Contents

- NetApp ONTAP Data Management Software 3
 - Pre-Integration 4
 - Integration with CipherTrust Manager 7
 - Verifying Integration 9
 - Appendix. 10

NetApp ONTAP Data Management Software

This document describes how to configure and integrate the CipherTrust Manager in NetApp ONTAP Data Management Software.

ONTAP is an operating system, which is used to store disk arrays such as NetApp FAS/AFF, ONTAP Select, and Cloud Volumes ONTAP.

Supported Product Versions

Note

The integration is performed and certified on **LTS release versions** of CipherTrust Manager only. Feature releases support the integration and are covered under technical support but will not be explicitly certified. To know more about CipherTrust Manager release versions, click [here](#).

This integration is validated on the following software versions:

CipherTrust Manager

- CipherTrust Manager 2.3 or higher

ONTAP

- ONTAP version 9.6 or higher

KMIP

- Upto KMIP 1.4

Prerequisites

- Ensure that the CipherTrust Manager is installed and configured. For more details, refer to the [CipherTrust Manager documentation](#).
- ONTAP communicates with the CipherTrust Manager using the KMIP interface. Ensure that the KMIP interface is configured on the CipherTrust Manager. Refer to [CipherTrust Manager Administration Guide](#) for details.
- **IP address** of the CipherTrust Manager and **port** of the KMIP interface must be accessible from the Ontap system.
- CipherTrust Manager recognizes only registered KMIP clients. Ensure that each node of the Ontap cluster is registered as a KMIP client on the CipherTrust Manager. Refer to [KMIP Client Registration](#) for more details.

Pre-Integration

This section lists the steps to be performed before integrating Cloud ONTAP with the CipherTrust Manager.

Creating and Signing Certificates Using KSCTL Utility

Note

KSCTL is used to create CA and CSRs at the CipherTrust Manager. To know about how to install and configure KSCTL refer to the [CipherTrust Manager Documentation](#).

Creating the CA Certificate

The rootCA is by default available at the CipherTrust Manager. If you want to create a Local CA other than rootCA, use the following command:

```
ksctl ca locals create --cn "Test CA" --csr-outfile csrfile
```

To self-sign the CA for a specific duration, use the id returned in the above command:

```
ksctl ca locals self-sign --id <id of CA> -x <duration>
```

For Example:

```
ksctl ca locals self-sign --id 3593c53b-fbeb-4edb-b84d-c85526ae2f83 -x 365
```

Creating the Client Certificate

To create the client certificate, use the following steps:

1. Create CSR and its private key.

```
ksctl ca csr --cn "ontap" --csr-outfile client.csr --key-outfile client.key
```

This command generates a CSR along with its private key.

Note

In this document, common name **CN=ontap** is used, which will be further used as a user name on the CipherTrust Manager.

2. Sign the CSR with CA.

```
ksctl ca locals certs issue --ca-id <id of CA> --csr-infile client.csr -x <duration> -o client
```

For Example:

```
ksctl ca locals certs issue --ca-id c84d66e1-2101-4a46-ad44-3656354b5097 --csr-infile client.csr -x 700 -o client
```

--ca-id is the id which can be obtained from CA details on the Ciphertrust Manager.

Note

--csr-infile is the csr name which is created in the previous step.

Creating the Server Certificate

Note

Server Certificate is needed only in case if you are using external CA instead of Local CA.

To create a server certificate, create CSR and its private key.

```
ksctl ca csr --cn "server" --csr-outfile server.csr --key-outfile server.key
```

This command generates a CSR along with its private key.

You can sign the above created CSR using external CA. The generated certificate will be uploaded to the CipherTrust Manager.

Configuring the CipherTrust Manager

1. Create User on CipherTrust Manager.
 - a. In the CipherTrust Manager UI, go to **Access Management > Users** and create a new user.
 - b. Click on the newly created user, click on **GROUPS** and select the Key Users and Key Admins Group.

Note

Username must be same as common name mentioned above while creating the client certificate.

2. Register KMIP client.

To perform KMIP client registration follow the steps mentioned in the [Appendix](#).

3. Configure KMIP Interface.

- a. Go to **Admin Settings > Interfaces**.
- b. On the KMIP Interface, click the action button (...) and then click **Edit**.

Configure KMIP popup opens.

- c. Check **Auto Registration** option if you are going with Auto Registration or uncheck if you are going with the Manual Registration.
- d. Select the mode as **TLS, verify client cert, username taken from client cert, auth request is optional**.

- e. Specify selections for **Local CA for Automatic Server Certificate Generation and Local Trusted CAs** as desired.

Note

Local CA for Automatic Server Certificate Generation should be set to **Turn off auto generation from Local CA** in case of External CA.

- f. Select the CA according to your preference.
- If you are using External CA then select the CA under **External Trusted CAs**
 - If you are using Local CA then select the CA under **Local Trusted CAs**
- g. This step is required if you are using external CA.

Expand the **Upload Certificate** section:

- In the **Certificate** field, paste the contents of Server Certificate, CA, and Server Key file in the same order. Do not introduce any space or character or symbol between the contents of these files.
- Select certificate **Format** as **PEM**.
- **Password** field is optional and can be skipped.
- Click **Update**.

Integration with CipherTrust Manager

This section outlines the steps to integrate Cloud ONTAP with the CipherTrust Manager.

Integrate CipherTrust Manager with ONTAP

Connect to the ONTAP instance using SSH. The ONTAP shell appears. Perform the following steps on the ONTAP shell:

1. Install Client Certificate for KMIP Server.

```
::> security certificate install -type client
Please enter Certificate: Press <Enter> when done
-----BEGIN CERTIFICATE-----
...
...
-----END CERTIFICATE-----
```

```

Please enter Private Key: Press <Enter> when done
-----BEGIN RSA PRIVATE KEY-----
...
...
-----END RSA PRIVATE KEY-----
Please enter certificates of Certification Authorities (CA) which form the cer
tificate chain of the client certificate. This starts with the issuing CA cert
ificate of the client certificate and can range up to the root CA certificate.
Do you want to continue entering root and/or intermediate certificates
{y|n}: n
You should keep a copy of the private key and the CA-signed digital certificat
e for future reference.
The installed certificate's CA and serial number for reference:
CA: CA_Name
Serial: xxx
The certificate's generated name for reference: Client_Common_Name

```

Note

Here, the client certificate and key are the ones that you have generated in [Creating the Client Certificate](#) section.

2. Install the `server-ca` certificate for KMIP server.

```

::> security certificate install -type server-ca
Please enter Certificate: Press <Enter> when done
-----BEGIN CERTIFICATE-----
...
...
-----END CERTIFICATE-----
You should keep a copy of the CA-signed digital certificate for future
reference.
The installed certificate's CA and serial number for reference:
CA: CA_Name
Serial: xxxx
The certificate's generated name for reference: ServerCA_Common_Name

```

Note

Here, the server-ca belongs to the Certificate Authority which is used for signing the certs.

3. Install and enable the external key-management setup.

```
::> security key-manager external enable -key-servers CipherTrust-Manager-private-ip:5696 -client-cert Client_Common_Name -server-ca-certs ServerCA_Common_Name
```

Here,

- **CipherTrust-Manager-private-ip** refers to the IP of CipherTrust Manager.
- **Client_Common_Name** refers to the certificate's generated name received after uploading client certificate and key on ONTAP shell.
- **ServerCA_Common_Name** refers to the certificate's generated name received after uploading CA on ONTAP Shell.

4. Verify that external key-management is configured, and its status is available.

```
::> security key-manager external show-status
Node Vserver Key Server Status
-----
Node1
Admin_vserver_name
KMS-ip:5696 available
1 entries were displayed.
```

If the status is set to **available** it means that the CipherTrust Manager is now configured as the external KMS for the ONTAP.

Verifying Integration

Perform the following steps to ensure the successful integration:

After performing the integration steps, you can create keys to verify if the integration is successful.

Execute the following command to create a key from ONTAP:

```
security key-manager key create
```

In the CipherTrust Manager GUI, navigate to **Keys**. Check if there is an entry for this newly created key. Usually, most recently created keys are listed on the top of the table.

If the key is created, the integration is successful.

Appendix

Troubleshooting

This section describes the how to troubleshoot the issue that you may encounter while integrating CipherTrust Manager with ONTAP.

Issue	Error Message	Remediation
KMIP registration is not enabled	The following error message is displayed in CipherTrust Records: <i>"errorMessage": "Unregistered client, please register a new client from CLI or API or UI."</i>	Check whether the KMIP registration is completed or not in Admin Settings > System > Interfaces > kmip . If it is not completed, complete it by using the steps mentioned in Appendix .
User corresponding to username location in certificate (example: CN) has not been created CN = Common Name	The following error messages are displayed in CipherTrust Records: <i>"errorMessage": "username not found: "</i> <i>"errorMessage": "Could not authenticate certificate user, *</i>	Check whether the user corresponding to CN of the client certificates has been created in Keys & Access Management > Users . If the user is not created, create a new user with the same name as the CN field of the client certificates. After creating the user, add this user to the Key Admins and Key Groups . Refer to steps mentioned in
User has not been added to Key Admin group	The following error message is displayed in CipherTrust Records: <i>"errorMessage": "authorization denied: verdict was deny: CreateKey"</i>	Check whether the user corresponding to CN of the client certificates has been created under Keys & Access Management > Users . If the user is not added, add the user to the Key Admins group.
The Username location in Certificate has been set incorrectly	The following error messages are displayed in CipherTrust Records: <i>"errorMessage": "username not found: "</i> <i>"errorMessage": "Could not authenticate certificate user,</i>	Check whether the Username Location in the Certificate option is set correctly to CN in Admin Settings > System > Interfaces > kmip . If it is not set correctly, set the correct value for the Username Location in the Certificate.

KMIP client Registration

Registering a KMIP Client

Note

You need to switch the domain before performing this operation.

You can register a KMIP client on the CipherTrust Manager using:

- [Auto Registration](#)
- [Manual Registration](#)

Using Auto-Registration

1. Create a registration token using the following steps:
 - a. Log on to the CipherTrust Manager.
 - b. Go to **Access Management > Registration Tokens** in the sidebar.
 - c. Click **Create New Registration Token**.
2. Copy the **Registration Token** once it is created.
3. Turn ON **Auto Registration** using the following steps:
 - a. Go to **Admin Settings > Interfaces**.
 - b. Click the ellipsis icon corresponding to the KMIP interface.
 - c. Click **Edit**.
 - d. Under the **Configure KMIP** window, select **Auto Registration**.
 - e. Paste the **Registration Token**.
 - f. Select the mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
 - g. Click **Update**.

Using Manual Registration

1. Log on to the CipherTrust Manager.
 2. Go to **Products > KMIP**.
-

3. Create a Client Profile using the following steps:

- a. Go to **Client Profile** and click **Add Profile**.
- b. Add a **Profile Name**.
- c. Select **CN** in **Username Location in Certificate**.

Note

For Domain, the CN will be domain||username.

- d. Click **Certificate Details**.
 - e. Paste the content of the generated `client.csr`.
 - f. Click **Save**.
4. Create a Registration Token using the following steps:
- a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a Name Prefix.
 - c. Click **Select CA**.
 - d. Select the CA type as Local if you are using **Local CA** or select external if you are using **External CA**.
 - e. Select appropriate CA from the dropdown menu and click **Select Profile**.
 - f. Select the Client Profile from the dropdown which you have created.
 - g. Click **Create Token**.
 - h. Copy the Token value and click **Done**.

Note

If you are using an external CA then you can select the external CA which was created using openssl and uploaded on the CipherTrust Manager.

5. Go to **Registered Clients** and click **Add Client**. Specify the client's name and paste the generated **Registration Token**.
-

Note

If you are using an external CA then you need to paste the signed client certificate in the **Client Certificate** field.

6. Click **Save > Save Certificate** to save the Client Certificate.

CipherTrust Integrations

4 February 2026

Contents

- Nutanix Virtual Computing Platform 3
 - Integration with CipherTrust Manager 4
 - Verifying Your Integration 17
 - Licensing 18
 - Appendix. 18

Nutanix Virtual Computing Platform

Nutanix Virtual Computing Platform (VCP) is a converged infrastructure solution that consolidates the Compute (server) tier and the Storage tier into a single, integrated appliance.

Nutanix VCP enables its users to secure their data when it is at rest using software-only encryption and key-based access management (cluster's native or external Key Management Server (KMS) for software-only encryption). Nutanix VCP supports Key Management Interoperability Protocol (KMIP) for interoperability and strong security.

CipherTrust Manager can be integrated with Nutanix VCP to act as an external KMS, as shown in the following diagram.

Supported Product Versions

Note

The integration is performed and certified on **LTS release versions** of CipherTrust Manager only. Feature releases support the integration and are covered under technical support but will not be explicitly certified. To know more about CipherTrust Manager release versions, click [here](#).

CipherTrust Manager

- CipherTrust Manager 1.10 and higher

Nutanix VCP

- AOS version 5.15.x LTS

Key Management Interoperability Protocol (KMIP)

- Upto KMIP 1.4

Integration with CipherTrust Manager

This section lists the steps to integrate Nutanix AHV with CipherTrust Manager.

- Prerequisites
- Configuration on CipherTrust Manager
- Issuing CSR(s) for Each Node of Nutanix AHV
- Getting the CSR(s) signed from CipherTrust Manager
- Configuring CipherTrust Manager as an External KMS on Nutanix AHV
- Enabling encryption on Nutanix AHV

Prerequisites

This section provides the prerequisites for integration of Nutanix AHV with CipherTrust Manager.

- Ensure that CipherTrust Manager is installed and configured. For more details, refer to the [CipherTrust Manager Documentation](#).
- IP address of the CipherTrust Manager and port of the KMIP interface must be accessible from the Nutanix cluster.
- CipherTrust Manager recognizes only registered KMIP clients. Ensure that each node of the Nutanix cluster is registered as a KMIP client on the CipherTrust Manager.

Configuration on CipherTrust Manager

To configure the CipherTrust Manager for the integration, you need to perform the following steps:

1. [Creating a Domain \(optional\)](#)
2. [Creating a User](#)
3. [Assigning User to a Group](#)
4. [Registering a KMIP Client](#)
5. [Configuring the KMIP Interface](#)

Creating a Domain (Optional)

Perform the following steps on CipherTrust Manager:

Note

This step is optional and needs to be performed only if you want to integrate within a domain.

1. Navigate to **Admin Settings > Domains**.
2. Click **Add Domain**. The **Add Domain** page appears.
3. Specify the following information:
 - **Name**: Enter the domain name.
 - **Admins**: Select the admins (one or more) from the list available in the drop down. For example, admin.
 - **Parent CA**: Select parent CA as root CA.
 - **Allow Subdomain User Management**: Select this check box if you want to enable user management in the subdomain through this domain.
4. Click **Save**.
5. Click on the **current domain name** at the top right corner to switch to this newly created domain.

Creating a User

Root Domain

To create a user, perform the following steps:

1. Log on to the CipherTrust Manager UI.
2. Navigate to **Access Management > Users**.
3. On the Users page, click **Create User**.
4. Provide the following details:
 - Username
 - Password
 - Email
5. Click **Add User**. The newly created user is now listed on the Users page.

Sub Domain

To create a user, perform the following steps:

Note

You can only create users in sub domains if you have enabled **Allow Subdomain User Management** while creating a domain.

1. Log on to the CipherTrust Manager UI with the User you created within the Sub Domain.
2. Navigate to **Access Management > Users**.
3. On the Users page, click **Create User**.
4. Provide the following details:
 - Username
 - Password
 - Email
5. Click **Add User**. The newly created user is now listed on the Users page.

Assigning the User to a Group

Perform the following steps to add user to a group:

1. Click on the ellipsis corresponding to the user that you created in the previous step.
2. Click **Edit/View > Groups**.
3. In the search bar, type **Key Admins** or **Key Users** and select **Add**, depending on the level of access you want to grant the user.

Registering a KMIP Client

Root Domain

You can register a KMIP client on the CipherTrust Manager through:

- **Auto Registration**
- **Manual Registration**

Auto-Registration

1. Create a Registration Token using the following steps:
 - a. Log on to the CipherTrust Manager in the root domain.
 - b. Go to **Access Management > Registration Tokens**.
 - c. Click **Add New Registration Token > Begin**.
 - d. Add a **Name Prefix** and specify a **Token Lifetime** value along with the **Client Capacity** for the token.
 - e. Click **Select CA**.
 - f. Select the CA type as Local/External depending on your preference.
 - g. Select the appropriate CA from the dropdown and click **Create Token**.
 - h. Copy the value of the **Registration Token** once it is created.
2. Enable **Auto Registration** using the following steps:
 - a. Go to **Admin Settings > Interfaces**.
 - b. Click on the ellipsis corresponding to the KMIP interface.
 - c. Click **View/Edit**.
 - d. Select the **Auto Registration** checkbox and paste the copied value of the **Registration Token**.
 - e. Select **OU** for the field **Username Location in Certificate**.
 - f. Select the mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
 - g. Scroll down and click **Update** to save your settings.

Manual Registration

1. Log on to the CipherTrust Manager.
2. Go to **Products > KMIP**.
3. Create a **Client Profile** using the following steps:
 - a. Go to **Client Profile** and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Select **OU** for the **Username Location in Certificate** field.
 - d. Expand the Certificate Details section.

-
- e. Paste the contents of the CSRs obtained from Nutanix.
 - f. Click **Save**.
4. Create Registration Token using the following steps:
 - a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a Name Prefix.
 - c. Specify a **Token Lifetime** value along with the **Client Capacity** for the token.
 - d. Click **Select CA**.
 - e. Select the CA type as Local/External depending on what your preference.
 - f. Select the appropriate CA from the dropdown menu and click Select Profile.
 - g. Select the Client Profile from the dropdown which you have created in the above step.
 - h. Click **Create Token**.
 - i. Copy the value of the Token created and click **Done**.

Note

If you are using External CA then you can select the external CA which was created using openssl and uploaded on the CipherTrust Manager. For more details, refer to the [CipherTrust Manager Documentation](#).

5. Go to **Registered Clients** and click **Add Client**.
 - Specify client name and paste the **Registration Token** generated in the above step.

Note

If you are using external CA then you need to paste the signed client certificate in the **Client Certificate** field.

- Click **Save** to save a copy of the **client certificate**.
- Repeat this process for each CSR corresponding to a node on Nutanix AHV.

Sub Domain

You can register a KMIP client on the CipherTrust Manager through:

- **Auto Registration**
- **Manual Registration**

Auto-Registration

1. Create a Registration Token in the sub-domain using the following steps:
 - a. Log on to the CipherTrust Manager in your specified subdomain.
 - b. Go to **Access Management > Registration Tokens**.
 - c. Click **Add Registration Token > Begin**.
 - d. Add a **Name Prefix**.
 - e. Specify a value for the **Token Lifetime** along with the **Client Capacity** for the token.
 - f. Click **Select CA**.
 - g. Select the CA type as **Local/External** depending on your requirements.
 - h. Copy the value of the Registration Token once it is created.

Note

By default, Auto Registration is disabled.

1. Enable **Auto Registration** using the following steps:
 - a. Log on to CipherTrust Manager in the root domain.
 - b. Go to **Admin Settings > Interfaces**.
 - c. Click the ellipsis corresponding to the KMIP interface.
 - d. Click **View/Edit**.
 - e. Select the checkbox corresponding to **Auto Registration**.
 - f. Select **OU** for the field **Username Location in Certificate**.
 - g. Paste the copied value of the **Registration Token**.
 - h. Select the mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.

-
- i. Scroll down and click **Update** to save your interface configuration.

Manual Registration

1. Log on to the CipherTrust Manager into your domain.
2. Go to **Products > KMIP**.
3. Create **Client Profile** using the following steps:
 - a. Go to Client Profile and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Select **OU** in **Username Location in Certificate**.
 - d. Expand the Certificate Details section.
 - e. Paste the content from the CSRs generated by Nutanix.
 - f. Click **Save**.
4. Create a Registration Token using the following steps:
 - a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a **Name Prefix**.
 - c. Specify a **Token Lifetime** value along with the **Client Capacity** for the token.
 - d. Click **Select CA**.
 - e. Select the CA type as **Local/External** depending on your requirements.
 - f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
 - g. Select the Client Profile from the dropdown which you have created in the above step.
 - h. Click **Create Token**.
 - i. Copy the value of the Token and click **Done**.

Note

If you are using External CA then you can select the external CA which was created using openssl and uploaded on the CipherTrust Manager. For more details, refer to the [CipherTrust Manager Documentation](#).

5. Go to Registered Clients and click **Add Client**.
 - a. Specify client name and paste the Registration Token generated in the above step.

Note

If you are using External CA then you need to paste the signed client certificate in the Client Certificate field.

- b. Click **Save** to save the client certificate.

Configuring the KMIP Interface

The KMIP interface can be configured through:

Root Domain

1. Go to **Admin Settings > Interfaces**.
2. On the KMIP Interface, click the ellipsis button (...) and then click **View/Edit**.
3. Select the **Auto Registration** checkbox if you auto-registered your KMIP client and paste the value of the registration token that you created.

Note

By default, Auto Registration is disabled.

4. Select the mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
 5. Specify selections for **Local CA for Automatic Server Certificate Generation** as desired.

Note

Local CA for Automatic Server Certificate Generation should be set to **Turn off auto generation from Local CA** in case of External CA.

6. Select the CA according to your preference:
 - If you are using **External CA** then select the CA under **External Trusted CAs**

- If you are using **Local CA** then select the CA under **Local Trusted CAs**
7. If you are using an External CA, expand the **Upload Certificate** section:
 - In the **Certificate** field, paste the contents of Server Certificate, CA, and Server Key file in the same order.
Do not introduce any space or character or symbol between the contents of these files.
 - Select certificate **Format** as **PEM**.
 - **Password** field is optional and can be skipped.
 - Click **Update**.

Sub Domain

1. Switch to **Root Domain**.
2. Go to **Admin Settings > Interfaces**.
3. On the KMIP Interface, click the ellipsis and then click **View/Edit**.
4. Select the **Auto Registration** checkbox if you auto-registered your KMIP client and paste the value of the registration token that you created.

Note

By default, Auto Registration is disabled.

5. Select the mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
6. Specify selections for **Local CA for Automatic Server Certificate Generation** as desired.

Note

Local CA for Automatic Server Certificate Generation should be set to **Turn off auto generation from Local CA** in case of External CA.

7. Select the CA according to your preference.

Local CA

- a. Login to your sub-domain. Go to **CA > Local**. Click the ellipsis (...) and copy the contents of your CA Certificate.

- b. Logout of your sub-domain and now login to the root domain.
- c. Go to **CA > External > Add External CA**.
- d. Enter a name for this Domain CA and select the text radio button and paste the certificate contents.
- e. Click **Add External CA**.
- f. Go to **Admin Settings > Interfaces**.
- g. Click the **Add** icon to add the External CA.
- h. Click **Update**.

External CA

Note

If you are using an External CA in the root Domain, you need to add the CA as an External CA in both the root domain as well as the sub-domain and modify the interface accordingly.

- a. Go to **Admin Settings > Interfaces**.
- b. Click the **Add** icon to add the External CA.
- c. Click **Update**.
- d. On the **KMIP interface**, click the ellipsis (...) > **Certificate Options > Upload New Certificate > Ok**.
- e. Select the **Certificate Chain** option and click **Build Certificate Chain**.
- f. Click on Text and paste the contents of Server Certificate, CA, and Server Key file in the same order. Do not introduce any space, character or symbol between the contents of these files.
- g. Select certificate Format as **PEM**.
- h. Click on **Upload Certificate**.

Issuing CSR(s) for Each Node of Nutanix AHV

1. Log on to the Nutanix Prism Element, go to **Settings > Data-at-Rest-Encryption**.
2. Click **Edit Configuration**.
3. Under **Select Key Management Server (KMS)**, select **An external KMS** and click **Save KMS Type**.
4. In the **Certificate Signing Request Information** section:

- a. Specify **Email**, **Organization**, **Organizational Unit**, **Country Code**, **City**, and **State**.

Note

The value for the ****OU**** field should be the same as the user you created on CipherTrust Manager in one of the previous steps.

- a. Click **Save CSR Info**.
- b. Click **Download CSRs**.
- c. This will initiate a download of a compressed zip containing all your CSRs. Save this file locally and extract its contents to a folder.

Note

In case of domains, the **Organizational Unit** field for the CSR must be of the format: **domainName||domainUser**.

Certificate Signing Request Information

Enter the following information to generate the Certificate Signing Requests for the cluster.

EMAIL [Input Field]	ORGANIZATION Thales	ORGANIZATIONAL UNIT CiphertrustManager
COUNTRY CODE IN	CITY NO	STATE UP

Save CSR Info Download CSRs

Getting the CSR(s) signed from CipherTrust Manager

Note

In this section, we are using the Local Root CA of CipherTrust Manager to sign the CSRs. However, you

can use any other CA as per your convenience.

Note

This step is applicable only for Auto-Registered KMIP clients.

1. Log on to CipherTrust Manager.
2. Go to **CA > Local**.
3. Click on the ellipsis corresponding to the existing Local CA and click **Download** to save a copy of the CA certificate.
4. Click on the Name of this Local CA and click **Upload CSR**
5. Paste the contents of one of the CSR files, specify a name for the certificate.
6. Select the **Certificate Purpose** as client and click **Issue Certificate**.
7. Repeat the signing process for all the remaining CSRs for each of the nodes.

Configuring CipherTrust Manager as an External KMS on Nutanix AHV

To configure the CipherTrust Manager as an external KMS:

1. On the Nutanix Prism Element UI, go to **Settings > Data at Rest Encryption**.
2. Click **Edit Configuration**.
3. Scroll down to **Key Management Server** and perform the following steps:
 - a. Click **Add New Key Management Server > Add Address**.
 - b. Enter a name for the Key Management Server.
 - c. Enter the IP address and the KMIP port of the CipherTrust Manager.
 - d. Repeat the above steps for each node of CipherTrust Manager if you have a clustered setup.

Add a New Key Management Server

Add Address

Enter a name and at least one address for the Key Management Server.

NAME thales-cm	
ADDRESS 	PORT 5696
ADDRESS 	PORT 5696

◀ Back

Save

4. Scroll down to the **KMS CA Certificates** section and perform the following steps:
 - a. Click **Add New Certificate Authority**.
 - b. Click **Upload CA Certificate**.
 - c. Specify a name for the CA.
 - d. Click **Save**.
5. Scroll down to the **Key Management Server** section and perform the following steps:
 - a. Click **Manage Certificates** for the desired key management server. The **Manage Signed Certificates** screen is displayed.
 - b. Upload the node certificates. Perform either of the following:
 - Click **Upload Files** and upload all the certificates at once.
 - Click the **Upload** link for each node separately.
 - c. Test whether the certificates are correct. Perform either of the following:
 - Click **Test all nodes** to test the certificates for all nodes at once.
 - Click the **Test CS (or Re-Test CS)** link for each node separately.
 - Confirm that the status has changed to **Verified**.

Enabling encryption on Nutanix AHV

- Log on to the Nutanix Prism Element UI.
- Click on the **Settings** icon on the toolbar's right side to open the Settings menu.
- Navigate to **Data-at-rest Encryption** under **Security** in the left pane of the Settings.
- Toggle on the Encryption option.
- In the confirmation pop-up window, type ENCRYPT and then click **Encrypt**.
- This will trigger the encryption of the Nutanix cluster. This step usually takes some time to complete. Once done, the cluster encryption is configured and enabled.

Verifying Your Integration

To verify the successful integration:

1. On the Nutanix VCP UI, go to **Data at Rest Encryption** settings.
2. Select **Enable Encryption**, enter **ENCRYPT** and select **Encrypt**.

Note

This step usually takes a long time, upto few hours. After completion, the key in the settings turns golden and displays the message **Encryption State of Cluster: Software encryption is enabled**.

After the encryption is complete, verify that the keys are created on the Ciphertrust Manager.

3. Test whether the keys are being retrieved from the CipherTrust Manager. To do so:
 - a. Power off the VMs running in the encrypted Nutanix cluster, Nutanix Controller VMs (CVMs), hosts, and CipherTrust Manager VMs.

A Nutanix CVM runs the Nutanix software and serves all the I/O operations for the hypervisor and VMs running on that host.
 - b. Power on the hosts and CVMs.
 - c. Power on the VMs in the encrypted Nutanix cluster.

The power on operation should succeed only when any of the configured CipherTrust Managers are running.

4. Check whether the stored keys are being replaced for the **Rekey** operation. To do so:

- a. In the **Manage Keys** section, select the **Rekey** option.

A message **Encryption State of Cluster: Encryption keys were successfully changed** is displayed.

- b. Test whether the keys can be used for decryption. To do so:
 - a. Power off the VMs running in the encrypted Nutanix cluster, CVMs, hosts, and CipherTrust Manager VMs.
 - b. Power on the hosts and CVMs.
 - c. Power on the VMs in the encrypted Nutanix cluster.
- c. Check the CipherTrust Manager cluster logs to verify whether the keys are exported from the active CipherTrust Manager.

Licensing

This section provides the licensing requirements for KMIP clients and Nutanix clusters.

Condition	License Requirement
Encrypting the Self Encrypting Drives (SEDs)	x1 KMIP client license for each node in a cluster/block
Adding a Node to an existing cluster	x1 KMIP client license for each additional node

Appendix

Troubleshooting

Issue	Error Message	Remediation
KMIP auto-registration is not enabled	The following error message is displayed in the CipherTrust Manager Records: "errorMessage": "Unregistered client, please register a new client from CLI or API or UI."	Check whether the Auto registration option is selected in Admin Settings > System Interfaces > kmip . If it is not selected, turn on the Auto registration option. Refer to Configuration steps for CipherTrust Manager using the GUI or ksctl.
User corresponding to OU/UID has not been created	The following error messages are displayed in the CipherTrust Manager Records: "errorMessage": "username not found: <username> "errorMessage": "Could not authenticate certificate user, hence client is not auto	Check whether the user corresponding to the UID/OU of the node certificates has been created in Keys & Access Management > Users . If the user does not exist, create a new user with the same name as the OU/UID field of the node certificates. Refer to Configuration steps for

Issue	Error Message	Remediation
	registered in mode tls-cert-pw-opt"	CipherTrust Manager using the GUI or ksctl. After creating the user, add it to the Key Users Group.
User has not been added to the Key Users group	The following error message is displayed in the CipherTrust Manager Records: "errorMessage": "authorization denied: verdict was deny: CreateKey"	Check whether the user corresponding to the OU/UID field of node certificates has been added to the Key Users group in the GUI at Keys & Access Management > Users > > Groups . If the user is not added, add it to the Key Users group. Refer to Configuration steps for CipherTrust Manager using the GUI or ksctl.
The Username Location in Certificate has been set incorrectly	The following error messages are displayed in the CipherTrust Manager Records: "errorMessage": "username not found: <username>" "errorMessage": "Could not authenticate certificate user, hence client is not auto registered in mode tls-cert-pw-opt"	Check whether the Username Location in the Certificate option is set correctly to OU/UID in Admin Settings > System > Interfaces > kmip . If it is incorrect, set the correct value for Username Location in the Certificate. Refer to Configuration steps for CipherTrust Manager using the GUI or ksctl.

Rubrik. 3

 Integration with CipherTrust Manager 4

 Appendix. 17

Rubrik

Rubrik software encryption for data at rest works on the application level, meaning all the work and encryption is performed through software. As data is ingested, Rubrik generates a unique one-time-only symmetric Data Encryption Key (DEK). DEKs utilize the AES-256 cipher and are utilized to encrypt both the ingested backup data, along with any associated metadata generated by Rubrik. This process ensures that without the associated DEK the data is essentially unreadable, even by the Rubrik platform. This results in the need to store this associated DEK somewhere alongside the data itself.

Therefore when Rubrik needs to read this data, it must pass through two phases of encryption, first decrypting the DEK with a KEK, then decrypting the data itself. To obtain and manage KEK's, customers can leverage an external Key Management Interoperability Protocol (KMIP) compliant key management server such as the CipherTrust Manager.

Supported Product Versions

Note

This integration has been validated in the field by a partner or in a customer environment with the following software versions. It is recommended to test the integration in a non-production environment with desired software versions before deploying it to production. Thales will provide best-effort support.

CipherTrust Manager

- CipherTrust Manager 2.3

Rubrik

-
- [Rubrik 6.0](#)
 - [Rubrik 7.0](#)

Integration with CipherTrust Manager

This section provides the process of integrating Rubrik with the CipherTrust Manager.

- [Prerequisites](#)
- [Configuration on CipherTrust Manager](#)
- [Configuration on Rubrik](#)

Prerequisites

This section provides the prerequisites for integration of Rubrik with CipherTrust Manager.

- Ensure that the CipherTrust Manager is installed and configured. For more details, refer to the [CipherTrust Manager Documentation](#).
- Rubrik communicates with the CipherTrust Manager using the KMIP interface. Ensure that the KMIP interface is configured on the CipherTrust Manager.
- IP address of the CipherTrust Manager and port of the KMIP interface must be accessible from the Rubrik system.
- CipherTrust Manager recognizes only registered KMIP clients. Ensure that each node of the Rubrik cluster is registered as a KMIP client on the CipherTrust Manager. Refer to [KMIP Client Registration](#) for more details.

Configuration on CipherTrust Manager

To configure the CipherTrust Manager, you need to perform the following steps:

1. [Creating a Domain \(optional\)](#)
2. [Creating a User](#)
3. [Assigning User to a Group](#)
4. [Creating or Adding a CA \(optional\)](#)
5. [Registering a KMIP Client](#)
6. [Configuring the KMIP Interface](#)

Creating a Domain (Optional)

Perform the following steps to be performed on CipherTrust Manager:

-
1. Navigate to **Admin Settings > Domains**.
 2. Click **Add Domain**. The **Add Domain** page appears.
 3. Specify the following information:
 - **Name** - Enter the domain name.
 - **Admins** - Select the admins (one or more) from the list available in the drop down. For example, admin.
 - **Parent CA** - Select parent CA as root CA.
 - **Allow Subdomain User Management** - Select this check box if you want to enable the sub-domain user management through this domain.
 4. Click **Save**.
 5. Switch to the newly created domain by clicking the top right on the current Domain Name.

Creating a User

Root Domain

To create a user, perform the following steps:

1. Log on to the CipherTrust Manager GUI.
2. Open the **Access Management** application.
3. On the left navigation pane, click **Users**. The Users page is displayed.
4. On the Users page, click **Add User**.
5. On the **Add User** page, provide the following details:
 - Select the required **Connection Type**
 - Select the checkbox against the required **Allowed Client Type**.
 - Enter **Full Name**
 - Enter **Username**
 - Enter the desired **Password**. Re-enter the password in the **Password Match** field.
6. Click **Add User**. The newly created user will now appear on the **Users** page.

Sub-Domain

Note

To create a user in sub-domain, you must enable **Allow Subdomain User management**.

To create a user, perform the following steps:

1. Log on to the CipherTrust Manager GUI with the User you created within the sub-domain.
2. Open the **Access Management** application.
3. On the left pane, click **Users**. The Users page is displayed.
4. On the Users page, click **Add User**.
5. On the **Add User** page, provide the following details:
 - Select the required **Connection Type**
 - Select the checkbox against the required **Allowed Client Type**.
 - Enter **Full Name**
 - Enter **Username**
 - Enter **Password**. Re-enter the password in the **Password Match** field.
6. Click **Add User**. The newly created user will now appear on the **Users** page.

Assigning User to a Group

Perform the following steps to add user to a group:

1. Navigate to the **Users** page.
2. Click the ellipsis button (...) corresponding to the user that you created in the previous step.
3. Click **Edit/View**.
4. Click **Group Memberships > Add Group**.
5. In the search bar, enter the desired Group name and select the check box corresponding to it. For example, **Key Admins** or **Key Users**.
6. Click **Add Group**.

Creating or Adding a CA (Optional)

Note

Creating a CA is an optional step in this integration. However, it is recommended to select the CA carefully, as it will be used throughout the process.

Select the **Local CA** tab if you want to create a Local CA **OR** select the **External CA** tab if you wish to add the External CA.

Local CA

To create/add a Self-signed local CA, perform the following steps:

1. Navigate to **CA > Local**. Select **Add Local CA**, the **Add Local CA** page appears.
2. Provide the required information and click **Add Local CA**. The created Local CA will appear under **Pending CAs** section.
3. Click the ellipsis against the Local CA that you created and select the option **Self-sign**.
4. Select a valid duration for the Local CA. Click **Save**.

External CA

To add an external CA, perform the following steps:

1. Navigate to **CA > External**. The **External Certificate Authorities** page appears. Select **Add External CA**, the **Add External Certificate** page appears.
2. Provide the required information.
3. If you want to upload the external CA, select the **File Upload** option and click **Upload Certificate**. Browse and select the required External CA.

OR

Select **Text** and paste the contents of External Certificate.

4. Click **Add External CA**.

Registering a KMIP Client

Root Domain

You can register a KMIP client on the CipherTrust Manager through:

- **Auto Registration**

- **Manual Registration**

Auto-Registration

1. Log on to the CipherTrust Manager.
2. Go to **Products > KMIP**.
3. Create Client Profile using the following steps:
 - a. Navigate to **Client Profile** and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Click **Save**. The new profile is created.
4. Create Registration Token using the following steps:
 - a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a **Name Prefix**.
 - c. Specify a Token Lifetime value along with the Client Capacity for the token.
 - d. Click **Select CA**.
 - e. Select the CA type as Local/External depending on CA that you created [above](#).
 - f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
 - g. Select the Client Profile from the dropdown which you have created in the above step.
 - h. Click **Create Token**.
 - i. Copy the value of the Token created and click **Done**.

Note

If you are using External CA then you can select the external CA that you created [above](#) and uploaded on the CipherTrust Manager.

5. Turn ON **Auto Registration** using the following steps:
 - a. Go to **Admin Settings > Interfaces**.
 - b. Click the ellipsis button (...) corresponding to the kmip interface.
 - c. Click **View/Edit**.
-

-
- d. On the **Interface Detail** window, perform the following:
 - Select the Interface Mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
 - Select **Auto Registration** checkbox.
 - Paste the **Registration Token**.
 - Add the CA (Local or External) to the list of Trusted CAs. The CA will reflect under the dropdown menu of Local/External Trusted CAs depending upon CA that you created [above](#).
 - Click **Update**.

Manual Registration

1. Log on to the CipherTrust Manager.
2. Go to **Products > KMIP**.
3. Create Client Profile using the following steps:
 - a. Go to **Client Profile** and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Select **CN** in **Username Location in Certificate**.
 - d. Click **Certificate Details**.
 - e. You can either paste the content of a generated `client.csr` or you can create one, by filling in the required details.
 - f. Click **Save**.
4. Create Registration Token using the following steps:
 - a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a **Name Prefix**.
 - c. Specify a Token Lifetime value along with the Client Capacity for the token.
 - d. Click **Select CA**.
 - e. Select the CA type as Local/External depending on the CA type that you created [above](#).
 - f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
 - g. Select the Client Profile from the dropdown which you have created in the above step.

-
- h. Click **Create Token**.
 - i. Copy the value of the Token created and click **Done**.

Note

If you are using External CA then you can select the external CA that you created [above](#) and uploaded on the CipherTrust Manager.

5. Go to **Registered Clients** and click **Add Client**.

- Specify client name and paste the **Registration Token** that you generated in the above step.

Note

If you are using external CA then you can either upload the client certificate as a file using **Upload Certificate** or paste the signed client certificate in the **Client Certificate** field.

- Click **Save** to save the **client certificate**.

Sub-Domain

You can register a KMIP client on the CipherTrust Manager through:

- **Auto Registration**
- **Manual Registration**

Auto-Registration

1. Log on to the CipherTrust Manager into your domain.
2. Go to **Products > KMIP**.
3. Create **Client Profile** using the following steps:
 - a. Navigate to **Client Profile** and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Click **Save**. The new profile is created.
4. Create Registration Token using the following steps:

-
- a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a **Name Prefix**.
 - c. Specify a Token Lifetime value along with the Client Capacity for the token.
 - d. Click **Select CA**.
 - e. Select the CA type as Local/External depending on CA that you created [above](#).
 - f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
 - g. Select the Client Profile from the dropdown which you have created in the above step.
 - h. Click **Create Token**.
 - i. Copy the value of the Token created and click **Done**.

Note

If you are using External CA then you can select the external CA that you created [above](#) and uploaded on the CipherTrust Manager.

5. Turn ON **Auto Registration** using the following steps:
 - a. Go to **Admin Settings > Interfaces**.
 - b. Click the ellipsis button (...) corresponding to the kmip interface.
 - c. Click **Edit**.
 - d. On the **Interface Detail** window, perform the following:
 - Select the Interface Mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
 - Select **Auto Registration** checkbox.
 - Paste the **Registration Token**.
 - Add the CA (Local or External) to the list of Trusted CAs. The CA will reflect under the dropdown menu of Local/External Trusted CAs depending upon CA that you created [above](#).
 - Click **Update**.

Manual Registration

1. Log on to the CipherTrust Manager into your domain.
2. Go to **Products > KMIP**.
3. Create **Client Profile** using the following steps:
 - a. Go to Client Profile and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Select **CN** in Username Location in Certificate.
 - d. Expand the **Certificate Details** section.
 - e. You can either paste the content of a generated `client.csr` or you can create one, by filling in the required details.

For domain, the format to enter the Common Name field of the cert is always:
`domainName | | domainUser`

- f. Click **Save**.
4. Create a Registration Token using the following steps:
 - a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a **Name Prefix**.
 - c. Specify a Token Lifetime value along with the Client Capacity for the token.
 - d. Click **Select CA**.
 - e. Select the CA type as Local/External depending on CA that you created [above](#).
 - f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
 - g. Select the Client Profile from the dropdown which you have created in the above step.
 - h. Click **Create Token**.
 - i. Copy the value of the Token created and click **Done**.
5. If you are using External CA then you can select the external CA which you created earlier. Refer to **External CA** under [Creating or Adding a CA](#).
6. Go to Registered Clients and click **Add Client**.
 - a. Specify client name and paste the Registration Token generated in the above step.

Note

If you are using external CA then you need to paste the signed client certificate in the Client Certificate field.

- a. Click **Save** to save the client certificate.

Configuring the KMIP Interface

The KMIP interface can be configured through:

Root Domain

1. Go to **Admin Settings > Interfaces**.
2. On the KMIP Interface, click the ellipsis button (...) and then click **View/Edit**.
3. Select the **Auto Registration** checkbox if you auto-registered your KMIP client and paste the value of the registration token that you created.

Note

By default, the **Auto Registration** is disabled.

4. Select the mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
5. Specify selections for **Local CA for Automatic Server Certificate Generation** as desired.

Note

In case of External CA, **Local CA for Automatic Server Certificate Generation** should be set to **Turn off auto generation from Local CA**.

6. Depending upon the CA that you created [above](#), select an option from the following::
 - If you are using **Local CA** then select the CA under **Local Trusted CAs**
 - If you are using **External CA** then select the CA under **External Trusted CAs**, provided you have the external CA that you created and uploaded on the CipherTrust Manager. For more information on creating or uploading CA, refer to [Creating or Adding a CA](#).

Sub-Domain

1. Select the CA according to your preference.

Local CA

- a. Login to your sub-domain. Go to **CA > Local**. Click the ellipsis (...) and copy the contents of your CA Certificate.
- b. Logout of your sub-domain and now login to the root domain.
- c. Go to **CA > External > Add External CA**.
- d. Enter a name for this Domain CA and select the text radio button and paste the certificate contents.
- e. Click **Add External CA**.
- f. Go to **Admin Settings > Interfaces**.
- g. Click the **Add** icon to add the External CA.
- h. Click **Update**.

External CA

Note

If you are using an External CA in the Sub-Domain, you need to add the CA as an External CA in both the root domain as well as the sub-domain and modify the interface accordingly.

- a. Login to your sub-domain. Go to **CA > Local**. Click the ellipsis (...) and copy the contents of your CA Certificate.
- b. Logout of your sub-domain and now login to the root domain.
- c. Go to **CA > External > Add External CA**.
- d. Enter a name for this Domain CA and select the text radio button and paste the certificate contents.
- e. Click **Add External CA**.
- f. Go to **Admin Settings > Interfaces**.
- g. Click the **Add** icon to add the External CA.
- h. Click **Update**.
- i. On the **KMIP interface**, click the ellipsis (...) > **Certificate Options > Upload New Certificate > Ok**.

-
- j. Select the **Certificate Chain** option and click **Build Certificate Chain**.
 - k. Click on Text and paste the contents of Server Certificate, CA, and Server Key file in the same order. Do not introduce any space, character or symbol between the contents of these files.
 - l. Select certificate Format as **PEM**.
 - m. Click on **Upload Certificate**.
2. On the KMIP Interface, click the ellipsis button (...) and then click **View/Edit**.
 3. Select the **Auto Registration** checkbox if you auto-registered your KMIP client and paste the value of the registration token that you created.

Note

By default, the **Auto Registration** is disabled.

4. Select the mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
5. Specify selections for **Local CA for Automatic Server Certificate Generation** as desired.

Note

In case of External CA, **Local CA for Automatic Server Certificate Generation** should be set to **Turn off auto generation from Local CA**.

Configuration on Rubrik

1. [Uploading CA Certificate to Rubrik](#)
2. [Configuring KMIP Server on Rubrik](#)

Uploading CA Certificate to Rubrik

1. Copy the local **CA certificate** to clipboard.
2. In Rubrik **Certificate Management Console**, add the CA certificate that you generated from CipherTrust Manager by pasting the certificate from the clipboard to the **Certificate** field. Specify the **Display Name**, and click **Add**.

Now you can view both client certificate and CA certificate in the **Certificates** list.

Configuring KMIP Server on Rubrik

1. Select **Manage Encryption** on the System Configuration page.

2. Under the **KMIP Settings** tab, click **Configure Client Settings**.

Configure Client Settings

Client Authentication Mode

☐ Password Only
 ☒ Client Certificate Only
 ☐ Both

Username
rubrik_edge

Select a TLS Certificate. If you have not imported your TLS Certificate, import it from the [Certificate Management page](#).

rubrik_edge X

Select certificate from list or type certificate name

Cancel Update

- On the **Add KMIP Server** page, enter the **KMIP Server Address** and **Port** of the KMIP server. Select a TLS certificate, and click **Add**.

After successful configuration, an AES key is generated that will appear on the list available under **CipherTrust Manager > Keys**.

This completes the integration of Rubrik with the CipherTrust Manager.

Appendix

Troubleshooting

Issue	Error Message	Remediation
KMIP registration is not enabled	The following error message is displayed in CipherTrust Records: <i>"errorMessage": "Unregistered client, please register a new client from CLI or API or UI."</i>	Check whether the Autoregistration option is selected in Admin Settings > System > Interfaces > kmip . If it is not selected, turn on the Autoregistration option. Refer to the steps mentioned in Enable KMIP Client Registration .
User corresponding to username location in the certificate (for example, OU/UID) is not created	The following error messages are displayed in CipherTrust Records: <i>"errorMessage": "username not found: "</i> <i>"errorMessage": "Could not authenticate certificate user, hence the client is not auto registered in</i>	Check whether the user corresponding to UID/OU of the node certificates is created in Keys & Access Management > Users . If the user is not created, create a new user with the same name as the OU/UID field of the node

Issue	Error Message	Remediation
	<code>mode tls-cert-pw-opt"</code>	certificates. After creating the user, add this user to the Key Admins . Refer to the steps mentioned in Create a New User .
User is not added to the Key Admin group	The following error message is displayed in CipherTrust Records: "errorMessage": "authorization denied: verdict was deny: CreateKey"	Check whether the user corresponding to UID/OU of the node certificates is created under Keys & Access Management > Users . If the user is not added, add the user to the Key Admins group.
The username location in the Certificate is set incorrectly	The following error messages are displayed in CipherTrust Records: "errorMessage": "username not found: " "errorMessage": "Could not authenticate certificate user, hence the client is not auto registered in mode tls-cert-pw-opt"	Check whether the username location in the Certificate option is set correctly to OU/UID in Admin Settings > System > Interfaces > kmip . If it is not set correctly, set the correct value for the username location in the Certificate.

CipherTrust Integrations

 - Verifying Integration 22
 - Appendix..... 23

Sangfor HCI

This document describes how to configure and integrate the CipherTrust Manager with Sangfor HCI.

Sangfor Hyper-Converged Infrastructure (HCI) provides an innovative third generation cloud computing architecture that reduces at least 70% of the Total Cost of Ownership (TCO), simplifies operations, and enhances the network security. It converges compute, storage, networking, and security on a single software stack.

- One-stop software-defined data centre solution
- Easy operation and quick installation for business-critical applications
- Integrates with any commodity servers commercially available in the market
- Build your own private cloud, extend to a public cloud or create your own Hybrid Cloud

Supported Product Versions

Note

This integration has been validated in the field by a partner or in a customer environment with the following software versions. It is recommended to test the integration in a non-production environment with desired software versions before deploying it to production. Thales will provide best-effort support.

This integration is validated on the following software versions:

CipherTrust Manager

- CipherTrust Manager 2.3 or higher

Sangfor

- Sangfor version 9.6 or higher

Integration of Sangfor HCI

This section lists the steps to integrate Sangfor HCI with CipherTrust Manager.

- Prerequisites

-
- Configuration on CipherTrust Manager
 - Configuration on Sangfor HCI

Prerequisites

This section provides the prerequisites for integration of Sangfor HCI with CipherTrust Manager.

- Ensure that the CipherTrust Manager is installed and configured. For more details, refer to the [CipherTrust Manager Documentation](#).
- Sangfor HCI communicates with the CipherTrust Manager using the KMIP interface. Ensure that the KMIP interface is configured on the CipherTrust Manager. Refer to [CipherTrust Manager Administration Guide](#) for details.
- **IP address** of the CipherTrust Manager and **port** of the KMIP interface must be accessible from the Sangfor HCI system.
- CipherTrust Manager recognizes only registered KMIP clients. Ensure that each node of the Sangfor HCI cluster is registered as a KMIP client on the CipherTrust Manager. Refer to [KMIP Client Registration](#) for more details.
- Ensure that Sangfor HCI has proper license for data at Rest Encryption. To check the license information in Sangfor HCI, navigate to **Settings > Software and Licenses > License Information**.
- Ensure that the required licenses are activated on CipherTrust Manager. For more details, refer to the [CipherTrust Manager documentation](#).

Configuration on CipherTrust Manager

To configure the CipherTrust Manager, you need to perform the following steps:

1. [Creating a Domain \(optional\)](#)
2. [Creating a User](#)
3. [Assigning User to a Group](#)
4. [Creating or Adding a CA \(optional\)](#)
5. [Registering a KMIP Client](#)
6. [Configuring the KMIP Interface](#)

Creating a Domain (Optional)

Perform the following steps to be performed on CipherTrust Manager:

1. Navigate to **Admin Settings > Domains**.

-
2. Click **Add Domain**. The **Add Domain** page appears.
 3. Specify the following information:
 - **Name** - Enter the domain name.
 - **Admins** - Select the admins (one or more) from the list available in the drop down. For example, admin.
 - **Parent CA** - Select parent CA as root CA.
 - **Allow Subdomain User Management** - Select this check box if you want to enable the sub-domain user management through this domain.
 4. Click **Save**.
 5. Switch to the newly created domain by clicking the top right on the current Domain Name.

Creating a User

Root Domain

To create a user, perform the following steps:

1. Log on to the CipherTrust Manager GUI.
2. Open the **Access Management** application.
3. On the left navigation pane, click **Users**. The Users page is displayed.
4. On the Users page, click **Add User**.
5. On the **Add User** page, provide the following details:
 - Select the required **Connection Type**
 - Select the checkbox against the required **Allowed Client Type**.
 - Enter **Full Name**
 - Enter **Username**
 - Enter the desired **Password**. Re-enter the password in the **Password Match** field.
6. Click **Add User**. The newly created user will now appear on the **Users** page.

Sub-Domain

Note

To create a user in sub-domain, you must enable **Allow Subdomain User management**.

To create a user, perform the following steps:

1. Log on to the CipherTrust Manager GUI with the User you created within the sub-domain.
2. Open the **Access Management** application.
3. On the left pane, click **Users**. The Users page is displayed.
4. On the Users page, click **Add User**.
5. On the **Add User** page, provide the following details:
 - Select the required **Connection Type**
 - Select the checkbox against the required **Allowed Client Type**.
 - Enter **Full Name**
 - Enter **Username**
 - Enter **Password**. Re-enter the password in the **Password Match** field.
6. Click **Add User**. The newly created user will now appear on the **Users** page.

Assigning User to a Group

Perform the following steps to add user to a group:

1. Navigate to the **Users** page.
2. Click the ellipsis button (...) corresponding to the user that you created in the previous step.
3. Click **Edit/View**.
4. Click **Group Memberships > Add Group**.
5. In the search bar, enter the desired Group name and select the check box corresponding to it. For example, **Key Admins** or **Key Users**.
6. Click **Add Group**.

Creating or Adding a CA (Optional)

Note

Creating a CA is an optional step in this integration. However, it is recommended to select the CA carefully, as it will be used throughout the process.

Select the **Local CA** tab if you want to create a Local CA **OR** select the **External CA** tab if you wish to add the External CA.

Local CA

To create/add a Self-signed local CA, perform the following steps:

1. Navigate to **CA > Local**. Select **Add Local CA**, the **Add Local CA** page appears.
2. Provide the required information and click **Add Local CA**. The created Local CA will appear under **Pending CAs** section.
3. Click the ellipsis against the Local CA that you created and select the option **Self-sign**.
4. Select a valid duration for the Local CA. Click **Save**.

External CA

To add an external CA, perform the following steps:

1. Navigate to **CA > External**. The **External Certificate Authorities** page appears. Select **Add External CA**, the **Add External Certificate** page appears.
2. Provide the required information.
3. If you want to upload the external CA, select the **File Upload** option and click **Upload Certificate**. Browse and select the required External CA.

OR

Select **Text** and paste the contents of External Certificate.

4. Click **Add External CA**.

Registering a KMIP Client

Root Domain

You can register a KMIP client on the CipherTrust Manager through:

- **Auto Registration**

- **Manual Registration**

Auto-Registration

1. Log on to the CipherTrust Manager.
2. Go to **Products > KMIP**.
3. Create Client Profile using the following steps:
 - a. Navigate to **Client Profile** and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Click **Save**. The new profile is created.
4. Create Registration Token using the following steps:
 - a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a **Name Prefix**.
 - c. Specify a Token Lifetime value along with the Client Capacity for the token.
 - d. Click **Select CA**.
 - e. Select the CA type as Local/External depending on CA that you created [above](#).
 - f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
 - g. Select the Client Profile from the dropdown which you have created in the above step.
 - h. Click **Create Token**.
 - i. Copy the value of the Token created and click **Done**.

Note

If you are using External CA then you can select the external CA that you created [above](#) and uploaded on the CipherTrust Manager.

5. Turn ON **Auto Registration** using the following steps:
 - a. Go to **Admin Settings > Interfaces**.
 - b. Click the ellipsis button (...) corresponding to the kmip interface.
 - c. Click **View/Edit**.
-

-
- d. On the **Interface Detail** window, perform the following:
- Select the Interface Mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
 - Select **Auto Registration** checkbox.
 - Paste the **Registration Token**.
 - Add the CA (Local or External) to the list of Trusted CAs. The CA will reflect under the dropdown menu of Local/External Trusted CAs depending upon CA that you created [above](#).
 - Click **Update**.

Manual Registration

1. Log on to the CipherTrust Manager.
2. Go to **Products > KMIP**.
3. Create Client Profile using the following steps:
 - a. Go to **Client Profile** and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Select **CN** in **Username Location in Certificate**.
 - d. Click **Certificate Details**.
 - e. You can either paste the content of a generated `client.csr` or you can create one, by filling in the required details.
 - f. Click **Save**.
4. Create Registration Token using the following steps:
 - a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a **Name Prefix**.
 - c. Specify a Token Lifetime value along with the Client Capacity for the token.
 - d. Click **Select CA**.
 - e. Select the CA type as Local/External depending on the CA type that you created [above](#).
 - f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
 - g. Select the Client Profile from the dropdown which you have created in the above step.

-
- h. Click **Create Token**.
 - i. Copy the value of the Token created and click **Done**.

Note

If you are using External CA then you can select the external CA that you created [above](#) and uploaded on the CipherTrust Manager.

5. Go to **Registered Clients** and click **Add Client**.

- Specify client name and paste the **Registration Token** that you generated in the above step.

Note

If you are using external CA then you can either upload the client certificate as a file using **Upload Certificate** or paste the signed client certificate in the **Client Certificate** field.

- Click **Save** to save the **client certificate**.

Sub-Domain

You can register a KMIP client on the CipherTrust Manager through:

- **Auto Registration**
- **Manual Registration**

Auto-Registration

1. Log on to the CipherTrust Manager into your domain.
2. Go to **Products > KMIP**.
3. Create **Client Profile** using the following steps:
 - a. Navigate to **Client Profile** and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Click **Save**. The new profile is created.
4. Create Registration Token using the following steps:

-
- a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a **Name Prefix**.
 - c. Specify a Token Lifetime value along with the Client Capacity for the token.
 - d. Click **Select CA**.
 - e. Select the CA type as Local/External depending on CA that you created [above](#).
 - f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
 - g. Select the Client Profile from the dropdown which you have created in the above step.
 - h. Click **Create Token**.
 - i. Copy the value of the Token created and click **Done**.

Note

If you are using External CA then you can select the external CA that you created [above](#) and uploaded on the CipherTrust Manager.

5. Turn ON **Auto Registration** using the following steps:
 - a. Go to **Admin Settings > Interfaces**.
 - b. Click the ellipsis button (...) corresponding to the kmip interface.
 - c. Click **Edit**.
 - d. On the **Interface Detail** window, perform the following:
 - Select the Interface Mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
 - Select **Auto Registration** checkbox.
 - Paste the **Registration Token**.
 - Add the CA (Local or External) to the list of Trusted CAs. The CA will reflect under the dropdown menu of Local/External Trusted CAs depending upon CA that you created [above](#).
 - Click **Update**.

Manual Registration

1. Log on to the CipherTrust Manager into your domain.
2. Go to **Products > KMIP**.
3. Create **Client Profile** using the following steps:
 - a. Go to Client Profile and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Select **CN** in Username Location in Certificate.
 - d. Expand the **Certificate Details** section.
 - e. You can either paste the content of a generated `client.csr` or you can create one, by filling in the required details.

For domain, the format to enter the Common Name field of the cert is always:
`domainName | | domainUser`

- f. Click **Save**.
4. Create a Registration Token using the following steps:
 - a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a **Name Prefix**.
 - c. Specify a Token Lifetime value along with the Client Capacity for the token.
 - d. Click **Select CA**.
 - e. Select the CA type as Local/External depending on CA that you created [above](#).
 - f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
 - g. Select the Client Profile from the dropdown which you have created in the above step.
 - h. Click **Create Token**.
 - i. Copy the value of the Token created and click **Done**.
5. If you are using External CA then you can select the external CA which you created earlier. Refer to **External CA** under [Creating or Adding a CA](#).
6. Go to Registered Clients and click **Add Client**.
 - a. Specify client name and paste the Registration Token generated in the above step.

Note

If you are using external CA then you need to paste the signed client certificate in the Client Certificate field.

- a. Click **Save** to save the client certificate.

Configuring the KMIP Interface

The KMIP interface can be configured through:

Root Domain

1. Go to **Admin Settings > Interfaces**.
2. On the KMIP Interface, click the ellipsis button (...) and then click **View/Edit**.
3. Select the **Auto Registration** checkbox if you auto-registered your KMIP client and paste the value of the registration token that you created.

Note

By default, the **Auto Registration** is disabled.

4. Select the mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
5. Specify selections for **Local CA for Automatic Server Certificate Generation** as desired.

Note

In case of External CA, **Local CA for Automatic Server Certificate Generation** should be set to **Turn off auto generation from Local CA**.

6. Depending upon the CA that you created [above](#), select an option from the following::
 - If you are using **Local CA** then select the CA under **Local Trusted CAs**
 - If you are using **External CA** then select the CA under **External Trusted CAs**, provided you have the external CA that you created and uploaded on the CipherTrust Manager. For more information on creating or uploading CA, refer to [Creating or Adding a CA](#).

Sub-Domain

1. Select the CA according to your preference.

Local CA

- a. Login to your sub-domain. Go to **CA > Local**. Click the ellipsis (...) and copy the contents of your CA Certificate.
- b. Logout of your sub-domain and now login to the root domain.
- c. Go to **CA > External > Add External CA**.
- d. Enter a name for this Domain CA and select the text radio button and paste the certificate contents.
- e. Click **Add External CA**.
- f. Go to **Admin Settings > Interfaces**.
- g. Click the **Add** icon to add the External CA.
- h. Click **Update**.

External CA

Note

If you are using an External CA in the Sub-Domain, you need to add the CA as an External CA in both the root domain as well as the sub-domain and modify the interface accordingly.

- a. Login to your sub-domain. Go to **CA > Local**. Click the ellipsis (...) and copy the contents of your CA Certificate.
- b. Logout of your sub-domain and now login to the root domain.
- c. Go to **CA > External > Add External CA**.
- d. Enter a name for this Domain CA and select the text radio button and paste the certificate contents.
- e. Click **Add External CA**.
- f. Go to **Admin Settings > Interfaces**.
- g. Click the **Add** icon to add the External CA.
- h. Click **Update**.
- i. On the **KMIP interface**, click the ellipsis (...) > **Certificate Options > Upload New Certificate > Ok**.

-
- j. Select the **Certificate Chain** option and click **Build Certificate Chain**.
 - k. Click on Text and paste the contents of Server Certificate, CA, and Server Key file in the same order. Do not introduce any space, character or symbol between the contents of these files.
 - l. Select certificate Format as **PEM**.
 - m. Click on **Upload Certificate**.
2. On the KMIP Interface, click the ellipsis button (...) and then click **View/Edit**.
 3. Select the **Auto Registration** checkbox if you auto-registered your KMIP client and paste the value of the registration token that you created.

Note

By default, the **Auto Registration** is disabled.

4. Select the mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
5. Specify selections for **Local CA for Automatic Server Certificate Generation** as desired.

Note

In case of External CA, **Local CA for Automatic Server Certificate Generation** should be set to **Turn off auto generation from Local CA**.

Configuration on Sangfor HCI

Add a KMS Server to the Sangfor HCI Server

To add KMS, perform the following steps:

1. Log in to the **Sangfor Cloud Platform** web console.

2. Navigate to the **Security** page and select **Key Management Service**.
3. On the **Key Management Service** page, select **KMS Server**, and click **Add**.

4. Provide the following KMS Server information:

- **KMS Server Authentication**

- KMS Cluster Name: CM_Cluster
- Server IP: 18.167.165.248 (CipherTrust Manager IP address)
- Server Port: 5696 (CipherTrust Manager default KMIP interface)
- Certificate Type: pem
- Auth Certificate: upload "Certificate.pem"

- **KMS User Authentication**

- Alias: sfhci x
- Username: sfhci
- Password: (the one created at CipherTrust Manager for user sfhci)
- Certificate Type: pem
- Auth Certificate: upload "Bundle.pem"

5. Click **OK**

Create an AES encryption key

- On the **Key Management Service** page, select **Encryption Keys**, and click **Create Key**.
- Provide the following KMS Server information:
 - Key Name: CM01 (Any name)

- b. Encryption Server: KMS Server
 - c. Encryption Algorithm: AES_256
 - d. KMS Server: CM_cluster
 - e. KMS User: sfhci
3. Click **OK**.

Encrypt the Virtual Machine

1. Navigate to the **Virtual Machine** page. Ensure the virtual machine is in power off status.

2. Click **More** and select **Enable Disk Encryption**. The **Enable Disk Encryption** window pops up.

3. Select **KMS Server** as **Encryption Server**.
4. Select the key from the drop down menu. Click **OK**.

5. Enter the Sangfor Cloud Platform admin password to proceed with the encryption. Click **OK**.

6. Navigate to **Tasks** list to view the encryption progress.

7. Virtual machine successful encrypted result from Sangfor Cloud Platform.

Verifying Integration

Perform the following steps to ensure the successful integration:

Power On the Encrypted Virtual Machine

After performing the integration steps, **Power ON** the Encrypted Virtual Machine.

1. You can view successful power on result from Sangfor Cloud Platform as shown below:

- Similarly, You can view successful power on result from CipherTrust Manager. Successful power on result from CipherTrust Manager indicates that the integration is successful.

Appendix

Troubleshooting

Issue	Error Message	Remediation
KMIP registration is not enabled	The following error message is displayed in CipherTrust Records: <i>"errorMessage": "Unregistered client, please register a new client from CLI or API or UI."</i>	Check whether the Autoregistration option is selected in Admin Settings > System > Interfaces > kmip . If it is not selected, turn on the Autoregistration option. Refer to the steps mentioned in Enable KMIP Client Registration .
User corresponding to username location in certificate (example: OU/UID) has not been created	The following error messages are displayed in CipherTrust Records: <i>"errorMessage": "username not found: "</i> <i>"errorMessage": "Could not authenticate certificate user, hence client is not auto registered in mode tls-cert-pw-opt"</i>	Check whether the user corresponding to UID/OU of the node certificates has been created in Keys & Access Management > Users . If the user is not created, create a new user with the same name as the OU/UID field of the node certificates. After creating the user, add this user to the Key Admins . Refer to steps mentioned in Create a New User .
User has not been added to Key Admin group	The following error message is displayed in CipherTrust Records:	Check whether the user corresponding to UID/OU of the

Issue	Error Message	Remediation
	<i>"errorMessage": "authorization denied: verdict was deny: CreateKey"</i>	node certificates has been created under Keys & Access Management > Users . If the user is not added, add the user to the Key Admins group.
The Username location in Certificate has been set incorrectly	The following error messages are displayed in CipherTrust Records: <i>"errorMessage": "username not found: "</i> <i>"errorMessage": "Could not authenticate certificate user, hence client is not auto registered in mode tls-cert-pw-opt"</i>	Check whether the Username Location in the Certificate option is set correctly to OU/UID in Admin Settings > System > Interfaces > kmip . If it is not set correctly, set the correct value for the Username Location in the Certificate.

CipherTrust Integrations

Contents

SANtricity 3

 Integration of SANtricity 4

 Verifying Your Integration 16

 Appendix 18

SANtricity

SANtricity optimizes the performance and resource use of E-Series and EF-Series storage systems, ensuring reliable, high-speed data handling for demanding tasks like analytics, video surveillance, and backup operations.

Here are the key features:

- **Boost performance:** Boost performance for applications that need fast response times, high data access speeds, or large data transfers.
- **Maximize uptime:** Experience top-tier reliability with automated tools, online configuration, advanced Dynamic Disk Pools technology, and other smart features.
- **Gain flexibility:** Make storage management easier while gaining the flexibility to fine-tune all E-Series storage systems to meet your specific needs.
- **Manage anytime, from anywhere:** Manage your NetApp E-Series system anytime, from anywhere. The built-in, web-based interface simplifies and streamlines your management tasks.

Supported Product Versions

Note

This integration has been validated in the field by a partner or in a customer environment with the following software versions. It is recommended to test the integration in a non-production environment with desired software versions before deploying it to production. Thales will provide best-effort support.

CipherTrust Manager

-
- [CipherTrust Manager 2.16](#)

SANtricity

- [SANtricity 11.8](#)

Integration of SANtricity

This section lists the steps to integrate SANtricity with CipherTrust Manager.

- [Prerequisites](#)
- [Configuration on CipherTrust Manager](#)
- [Configuration on SANtricity](#)

Prerequisites

This section provides the prerequisites for integration of SANtricity with CipherTrust Manager.

- Ensure that the CipherTrust Manager is installed and configured. For more details, refer to the [CipherTrust Manager Documentation](#).
- SANtricity communicates with the CipherTrust Manager using the KMIP interface. Ensure that the KMIP interface is configured on the CipherTrust Manager. Refer to [CipherTrust Manager Administration Guide](#) for details.
- **IP address** of the CipherTrust Manager and **port** of the KMIP interface must be accessible from the SANtricity system.
- CipherTrust Manager recognizes only registered KMIP clients. Ensure that each node of the SANtricity cluster is registered as a KMIP client on the CipherTrust Manager. Refer to [KMIP Client Registration](#) for more details.
- Ensure that SANtricity has proper license for data at Rest Encryption. To check the license information in SANtricity, navigate to **Settings > Software and Licenses > License Information**.
- Ensure that the required licenses are activated on CipherTrust Manager. For more details, refer to the [CipherTrust Manager documentation](#).

Configuration on CipherTrust Manager

To configure the CipherTrust Manager, you need to perform the following steps:

1. [Creating a User](#)
2. [Assigning User to a Group](#)
3. [Creating or Adding a CA \(optional\)](#)

-
4. Registering a KMIP Client
 5. Configuring the KMIP Interface

Creating a User

To create a user, perform the following steps:

1. Log on to the CipherTrust Manager GUI.
2. Open the **Access Management** application.
3. On the left navigation pane, click **Users**. The Users page is displayed.
4. On the Users page, click **Add User**.
5. On the **Add User** page, provide the following details:
 - Select the required **Connection Type**
 - Select the checkbox against the required **Allowed Client Type**.
 - Enter **Full Name**
 - Enter **Username**
 - Enter the desired **Password**. Re-enter the password in the **Password Match** field.
6. Click **Add User**. The newly created user will now appear on the **Users** page.

Assigning User to a Group

Perform the following steps to add user to a group:

1. Navigate to the **Users** page.
2. Click the ellipsis button (...) corresponding to the user that you created in the previous step.
3. Click **Edit/View**.
4. Click **Group Memberships > Add Group**.
5. In the search bar, enter the desired Group name and select the check box corresponding to it. For example, **Key Admins** or **Key Users**.
6. Click **Add Group**.

Creating or Adding a CA (Optional)

Note

Creating a CA is an optional step in this integration. However, it is recommended to select the CA carefully, as it will be used throughout the process.

Select the **Local CA** tab if you want to create a Local CA **OR** select the **External CA** tab if you wish to add the External CA.

Local CA

To create/add a Self-signed local CA, perform the following steps:

1. Navigate to **CA > Local**. Select **Add Local CA**, the **Add Local CA** page appears.
2. Provide the required information and click **Add Local CA**. The created Local CA will appear under **Pending CAs** section.
3. Click the ellipsis against the Local CA that you created and select the option **Self-sign**.
4. Select a valid duration for the Local CA. Click **Save**.

External CA

To add an external CA, perform the following steps:

1. Navigate to **CA > External**. The **External Certificate Authorities** page appears. Select **Add External CA**, the **Add External Certificate** page appears.
2. Provide the required information.
3. If you want to upload the external CA, select the **File Upload** option and click **Upload Certificate**. Browse and select the required External CA.

OR

Select **Text** and paste the contents of External Certificate.

4. Click **Add External CA**.

Registering a KMIP Client

You can register a KMIP client on the CipherTrust Manager through:

- **Auto Registration**
- **Manual Registration**

Auto-Registration

1. Log on to the CipherTrust Manager.
2. Go to **Products > KMIP**.
3. Create Client Profile using the following steps:
 - a. Navigate to **Client Profile** and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Click **Save**. The new profile is created.
4. Create Registration Token using the following steps:
 - a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a **Name Prefix**.
 - c. Specify a Token Lifetime value along with the Client Capacity for the token.
 - d. Click **Select CA**.
 - e. Select the CA type as Local/External depending on CA that you created [above](#).
 - f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
 - g. Select the Client Profile from the dropdown which you have created in the above step.
 - h. Click **Create Token**.
 - i. Copy the value of the Token created and click **Done**.

Note

If you are using External CA then you can select the external CA that you created [above](#) and uploaded on the CipherTrust Manager.

5. Turn ON **Auto Registration** using the following steps:
 - a. Go to **Admin Settings > Interfaces**.
 - b. Click the ellipsis button (...) corresponding to the knip interface.
 - c. Click **View/Edit**.
 - d. On the **Interface Detail** window, perform the following:

-
- Select the Interface Mode as **TLS**, **verify client cert**, **user name taken from client cert**, **auth request is optional**.
 - Select **Auto Registration** checkbox.
 - Paste the **Registration Token**.
 - Add the CA (Local or External) to the list of Trusted CAs. The CA will reflect under the dropdown menu of Local/External Trusted CAs depending upon CA that you created [above](#).
 - Click **Update**.

Manual Registration

1. Log on to the CipherTrust Manager into your domain.
 2. Go to **Products > KMIP**.
 3. Create **Client Profile** using the following steps:
 - a. Go to Client Profile and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Select **CN** in Username Location in Certificate.
 - d. Expand the **Certificate Details** section.
 - e. You can either paste the content of a generated `client.csr` or you can create one, by filling in the required details.

For domain, the format to enter the Common Name field of the cert is always:
`domainName | | domainUser`
 - f. Click **Save**.
 4. Create a Registration Token using the following steps:
 - a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a **Name Prefix**.
 - c. Specify a Token Lifetime value along with the Client Capacity for the token.
 - d. Click **Select CA**.
 - e. Select the CA type as Local/External depending on CA that you created [above](#).
 - f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
 - g. Select the Client Profile from the dropdown which you have created in the above step.
-

-
- h. Click **Create Token**.
 - i. Copy the value of the Token created and click **Done**.
5. If you are using External CA then you can select the external CA which you created earlier. Refer to **External CA** under [Creating or Adding a CA](#).
 6. Go to Registered Clients and click **Add Client**.
 - a. Specify client name and paste the Registration Token generated in the above step.

Note

If you are using external CA then you need to paste the signed client certificate in the Client Certificate field.

- b. Click **Save** to save the client certificate.

Configuring the KMIP Interface

The KMIP interface can be configured through:

1. Go to **Admin Settings > Interfaces**.
2. On the KMIP Interface, click the ellipsis button (...) and then click **View/Edit**.
3. Select the **Auto Registration** checkbox if you auto-registered your KMIP client and paste the value of the registration token that you created.

Note

By default, the **Auto Registration** is disabled.

4. Select the mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
5. Specify selections for **Local CA for Automatic Server Certificate Generation** as desired.

Note

In case of External CA, **Local CA for Automatic Server Certificate Generation** should be set to **Turn**

off auto generation from Local CA.

6. Depending upon the CA that you created [above](#), select an option from the following::
 - If you are using **Local CA** then select the CA under **Local Trusted CAs**
 - If you are using **External CA** then select the CA under **External Trusted CAs** provided you have the external CA that you created and uploaded on the CipherTrust Manager. For more information on creating or uploading CA, refer to [Creating or Adding a CA](#).

Configuration on SANtricity

1. [Create CSR on SANtricity](#)
2. [Upload the Signed Certificate to SANtricity](#)

Create CSR on SANtricity

1. On SANtricity System Manager, navigate to **Settings > Certificates > Key Management**. Click **Complete CSR. Complete & Download Client Certificate Signing Request** window appears.

2. Enter the required details and click **Download**. A CSR will be downloaded to your local system.

Complete & Download Client Certificate Signing Request ✕

Complete and download a client certificate signing request (CSR) to obtain proper client authentication to access the key management server...

Common name ?

Organization ?

Organizational unit (optional) ?

City/Locality

State/Region (optional) ?

Country ISO code ?

 Generating a new CSR will create a new key pair. This will overwrite any existing key pair, which may cause a loss of access to the key management server.

DownloadCancel

Upload the Signed Certificate to SANtricity

Before uploading the This certificate needs to be signed by the CA and the recieved signed certificate can be uploaded through the following steps:

1. Navigate to **Key Management** and click **Create External Key**.
2. On the **Create External Security Key** window, enter the CipherTrust Manager **IP address** and **Port**.

Create External Security Key

1 Connect to Key Server

2 Create/Backup Key

Connect to the following key management server...

What do I need to know before creating a security key?

Key management server address ?

Key management port number ?

+ Add key server

Select client certificate

Browse...

Select private key file (Optional)

Browse...

Select key server certificate (server, intermediate CA or root CA)

Browse...

Close

Next >

3. Select the SANtricity Certificate and CipherTrust CA certificate. Click **Next**.
4. Enter the **Passphrase**, **Re-enter passphrase** and click **Finish**.

The screenshot shows a window titled "Create External Security Key" with a close button (X) in the top right corner. The window has two steps: "1 Consent to Key Server" and "2 Create Backup Key", with the second step being the active one. Below the steps, the text reads "Create a security key and a backup key (optional) ...". There is a checkbox labeled "Create a backup key" which is checked. Below this, a note states: "Important: When you create a security key, a copy of the key will be saved to your local host. For security purposes, a pass phrase must be provided to encrypt the backup key." This is followed by the instruction "Define a pass phrase" with a help icon. There are two text input fields for the pass phrase, both containing masked characters (dots). At the bottom of the window, there are three buttons: "Back" (disabled), "Close" (disabled), and "Finish" (active).

Create External Security Key

1 Consent to Key Server 2 Create Backup Key

Create a security key and a backup key (optional) ...

☒ Create a backup key

Important: When you create a security key, a copy of the key will be saved to your local host. For security purposes, a pass phrase must be provided to encrypt the backup key.

Define a pass phrase ?

Re-enter the pass phrase

Back Close Finish

5. Click **Back Up Key**. **Back Up Security Key** window appears.

6. Enter the passphrase that you created above and click **Backup**. A backup file will be downloaded to your local system.
7. Click **Validate the backup key**. A pop-up window will appear.
8. Select the **Download backup key**, enter the **passphrase**, and click **Validate**.

9. A security key validated successfully will appear.
10. Under Security Key management, now External should be reflected near certificate key management.

11. Navigate to **CipherTrust Manager > Keys** and verify the keys created on CipherTrust Manager.

Verifying Your Integration

Perform the following steps to ensure the integration is successful:

Encrypt the Volume

1. On SANtricity System Manager, navigate to **Storage > Pools & Volume Group**.

2. Select the volume that needs to be encrypted.
3. Click **More** and select **Enable Security** option.

4. Type **ENABLE** and click **Enable**. The volume gets encrypted and padlock icon appears against the specific volume.

5. Verify the **Records** on CipherTrust Manager where you can locate the **Export Key**.

Appendix

Troubleshooting

Issue	Error Message	Remediation
KMIP registration is not enabled	The following error message is displayed in CipherTrust Records: <i>"errorMessage": "Unregistered client, please register a new client from CLI or API or UI."</i>	Check whether the Autoregistration option is selected in Admin Settings > System > Interfaces > kmip . If it is not selected, turn on the Autoregistration option. Refer to the steps mentioned in Enable KMIP Client Registration .
User corresponding to username location in certificate (example: OU/UID) has not been created	The following error messages are displayed in CipherTrust Records: <i>"errorMessage": "username not found:"</i> <i>"errorMessage": "Could not authenticate certificate user, hence client is not auto registered in mode tls-cert-pw-opt"</i>	Check whether the user corresponding to UID/OU of the node certificates has been created in Keys & Access Management > Users . If the user is not created, create a new user with the same name as the OU/UID field of the node certificates. After creating the user,

Issue	Error Message	Remediation
		add this user to the Key Admins . Refer to steps mentioned in Create a New User .
User has not been added to Key Admin group	The following error message is displayed in CipherTrust Records: <i>"errorMessage": "authorization denied: verdict was deny: CreateKey"</i>	Check whether the user corresponding to UID/OU of the node certificates has been created under Keys & Access Management > Users . If the user is not added, add the user to the Key Admins group.
The Username location in Certificate has been set incorrectly	The following error messages are displayed in CipherTrust Records: <i>"errorMessage": "username not found: "</i> <i>"errorMessage": "Could not authenticate certificate user, hence client is not auto registered in mode tls-cert-pw-opt"</i>	Check whether the Username Location in the Certificate option is set correctly to OU/UID in Admin Settings > System > Interfaces > kmip . If it is not set correctly, set the correct value for the Username Location in the Certificate.

CipherTrust Integrations

4 February 2026

Contents

- VMware 3
 - Integration with CipherTrust Manager 4
 - Licensing 30
 - Appendix..... 30

VMware

Note

This integration is applicable to **vSAN**, **vSphere Trust Authority**, and **vmCrypt**.

vSAN is a VMware storage virtualization software that offers a mechanism to encrypt the virtual machine in place and in transit. The CipherTrust Manager is used to provide a key to the virtual machine and vSAN to enable the encryption.

Supported Product Versions

Note

The integration is performed and certified on **LTS release versions** of CipherTrust Manager only. Feature releases support the integration and are covered under technical support but will not be explicitly certified. To know more about CipherTrust Manager release versions, click [here](#).

This integration is validated on the following software versions:

CipherTrust Manager

- CipherTrust Manager 1.8 and higher

VMware

-
- vSphere 6.5 (u1, u2)
 - vSphere 6.7 (u1, u2, u3)
 - vSphere 7.0 (u1)
 - vSphere 8.0 (u1, u2, u3)

For version compatability, you can also refer [VMware Compatibility Guide](#).

Key Management Interoperability Protocol (KMIP)

- Upto KMIP 1.4

Integration with CipherTrust Manager

This section lists the steps to integrate VMware with CipherTrust Manager.

- [Prerequisites](#)
- [Configuration on CipherTrust Manager](#)
- [Configuration on VMware](#)

Prerequisites

This section provides the prerequisites for integration of VMware with CipherTrust Manager.

- Ensure that the CipherTrust Manager is installed and configured. For more details, refer to the [CipherTrust Manager Documentation](#).
- VMware communicates with the CipherTrust Manager using the KMIP interface. Ensure that the KMIP interface is configured on the CipherTrust Manager.
- IP address of the CipherTrust Manager and port of the KMIP interface must be accessible from the VMware system.
- CipherTrust Manager recognizes only registered KMIP clients. Ensure that each node of the VMware cluster is registered as a KMIP client on the CipherTrust Manager. Refer to [KMIP Client Registration](#) for more details.

Configuration on CipherTrust Manager

To configure the CipherTrust Manager, you need to perform the following steps:

1. [Creating a Domain \(optional\)](#)
2. [Creating a User](#)
3. [Assigning User to a Group](#)

-
4. Creating or Adding a CA (optional)
 5. Registering a KMIP Client
 6. Configuring the KMIP Interface

Creating a Domain (Optional)

Perform the following steps to be performed on CipherTrust Manager:

1. Navigate to **Admin Settings > Domains**.
2. Click **Add Domain**. The **Add Domain** page appears.
3. Specify the following information:
 - **Name** - Enter the domain name.
 - **Admins** - Select the admins (one or more) from the list available in the drop down. For example, admin.
 - **Parent CA** - Select parent CA as root CA.
 - **Allow Subdomain User Management** - Select this check box if you want to enable the sub-domain user management through this domain.
4. Click **Save**.
5. Switch to the newly created domain by clicking the top right on the current Domain Name.

Creating a User

Root Domain

To create a user, perform the following steps:

1. Log on to the CipherTrust Manager GUI.
2. Open the **Access Management** application.
3. On the left navigation pane, click **Users**. The Users page is displayed.
4. On the Users page, click **Add User**.
5. On the **Add User** page, provide the following details:
 - Select the required **Connection Type**
 - Select the checkbox against the required **Allowed Client Type**.
 - Enter **Full Name**

-
- Enter **Username**
 - Enter the desired **Password**. Re-enter the password in the **Password Match** field.

6. Click **Add User**. The newly created user will now appear on the **Users** page.

Sub-Domain

Note

To create a user in sub-domain, you must enable **Allow Subdomain User management**.

To create a user, perform the following steps:

1. Log on to the CipherTrust Manager GUI with the User you created within the sub-domain.
2. Open the **Access Management** application.
3. On the left pane, click **Users**. The Users page is displayed.
4. On the Users page, click **Add User**.
5. On the **Add User** page, provide the following details:
 - Select the required **Connection Type**
 - Select the checkbox against the required **Allowed Client Type**.
 - Enter **Full Name**
 - Enter **Username**
 - Enter **Password**. Re-enter the password in the **Password Match** field.
6. Click **Add User**. The newly created user will now appear on the **Users** page.

Assigning User to a Group

Perform the following steps to add user to a group:

1. Navigate to the **Users** page.
2. Click the ellipsis button (...) corresponding to the user that you created in the previous step.
3. Click **Edit/View**.
4. Click **Group Memberships > Add Group**.
5. In the search bar, enter the desired Group name and select the check box corresponding to it. For example,

Key Admins or Key Users.

6. Click **Add Group**.

Creating or Adding a CA (Optional)

Note

Creating a CA is an optional step in this integration. However, it is recommended to select the CA carefully, as it will be used throughout the process.

Select the **Local CA** tab if you want to create a Local CA **OR** select the **External CA** tab if you wish to add the External CA.

Local CA

To create/add a Self-signed local CA, perform the following steps:

1. Navigate to **CA > Local**. Select **Add Local CA**, the **Add Local CA** page appears.
2. Provide the required information and click **Add Local CA**. The created Local CA will appear under **Pending CAs** section.
3. Click the ellipsis against the Local CA that you created and select the option **Self-sign**.
4. Select a valid duration for the Local CA. Click **Save**.

External CA

To add an external CA, perform the following steps:

1. Navigate to **CA > External**. The **External Certificate Authorities** page appears. Select **Add External CA**, the **Add External Certificate** page appears.
2. Provide the required information.
3. If you want to upload the external CA, select the **File Upload** option and click **Upload Certificate**. Browse and select the required External CA.

OR

Select **Text** and paste the contents of External Certificate.

4. Click **Add External CA**.

Registering a KMIP Client

Root Domain

You can register a KMIP client on the CipherTrust Manager through:

- **Auto Registration**
- **Manual Registration**

Auto-Registration

1. Log on to the CipherTrust Manager.
2. Go to **Products > KMIP**.
3. Create Client Profile using the following steps:
 - a. Navigate to **Client Profile** and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Click **Save**. The new profile is created.
4. Create Registration Token using the following steps:
 - a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a **Name Prefix**.
 - c. Specify a Token Lifetime value along with the Client Capacity for the token.
 - d. Click **Select CA**.
 - e. Select the CA type as Local/External depending on CA that you created [above](#).
 - f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
 - g. Select the Client Profile from the dropdown which you have created in the above step.
 - h. Click **Create Token**.
 - i. Copy the value of the Token created and click **Done**.

Note

If you are using External CA then you can select the external CA that you created [above](#) and uploaded on the CipherTrust Manager.

5. Turn ON **Auto Registration** using the following steps:
-

-
- a. Go to **Admin Settings > Interfaces**.
 - b. Click the ellipsis button (...) corresponding to the kmip interface.
 - c. Click **View/Edit**.
 - d. On the **Interface Detail** window, perform the following:
 - Select the Interface Mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
 - Select **Auto Registration** checkbox.
 - Paste the **Registration Token**.
 - Add the CA (Local or External) to the list of Trusted CAs. The CA will reflect under the dropdown menu of Local/External Trusted CAs depending upon CA that you created [above](#).
 - Click **Update**.

Manual Registration

1. Log on to the CipherTrust Manager.
2. Go to **Products > KMIP**.
3. Create Client Profile using the following steps:
 - a. Go to **Client Profile** and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Select **CN** in **Username Location in Certificate**.
 - d. Click **Certificate Details**.
 - e. You can either paste the content of a generated `client.csr` or you can create one, by filling in the required details.
 - f. Click **Save**.
4. Create Registration Token using the following steps:
 - a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a **Name Prefix**.
 - c. Specify a Token Lifetime value along with the Client Capacity for the token.
 - d. Click **Select CA**.

- e. Select the CA type as Local/External depending on the CA type that you created [above](#).
- f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
- g. Select the Client Profile from the dropdown which you have created in the above step.
- h. Click **Create Token**.
- i. Copy the value of the Token created and click **Done**.

Note

If you are using External CA then you can select the external CA that you created [above](#) and uploaded on the CipherTrust Manager.

5. Go to **Registered Clients** and click **Add Client**.

- Specify client name and paste the **Registration Token** that you generated in the above step.

Note

If you are using external CA then you can either upload the client certificate as a file using **Upload Certificate** or paste the signed client certificate in the **Client Certificate** field.

- Click **Save** to save the **client certificate**.

Sub-Domain

You can register a KMIP client on the CipherTrust Manager through:

- **Auto Registration**
- **Manual Registration**

Auto-Registration

1. Log on to the CipherTrust Manager into your domain.
2. Go to **Products > KMIP**.
3. Create **Client Profile** using the following steps:
 - a. Navigate to **Client Profile** and click **Add Profile**.

-
- b. Add a **Profile Name**.
 - c. Click **Save**. The new profile is created.
 4. Create Registration Token using the following steps:
 - a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a **Name Prefix**.
 - c. Specify a Token Lifetime value along with the Client Capacity for the token.
 - d. Click **Select CA**.
 - e. Select the CA type as Local/External depending on CA that you created [above](#).
 - f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
 - g. Select the Client Profile from the dropdown which you have created in the above step.
 - h. Click **Create Token**.
 - i. Copy the value of the Token created and click **Done**.

Note

If you are using External CA then you can select the external CA that you created [above](#) and uploaded on the CipherTrust Manager.

5. Turn ON **Auto Registration** using the following steps:
 - a. Go to **Admin Settings > Interfaces**.
 - b. Click the ellipsis button (...) corresponding to the knip interface.
 - c. Click **Edit**.
 - d. On the **Interface Detail** window, perform the following:
 - Select the Interface Mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
 - Select **Auto Registration** checkbox.
 - Paste the **Registration Token**.
 - Add the CA (Local or External) to the list of Trusted CAs. The CA will reflect under the dropdown menu of Local/External Trusted CAs depending upon CA that you created [above](#).
-

-
- Click **Update**.

Manual Registration

1. Log on to the CipherTrust Manager into your domain.
2. Go to **Products > KMIP**.
3. Create **Client Profile** using the following steps:
 - a. Go to Client Profile and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Select **CN** in Username Location in Certificate.
 - d. Expand the **Certificate Details** section.
 - e. You can either paste the content of a generated `client.csr` or you can create one, by filling in the required details.

For domain, the format to enter the Common Name field of the cert is always:

`domainName | | domainUser`

- f. Click **Save**.
4. Create a Registration Token using the following steps:
 - a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a **Name Prefix**.
 - c. Specify a Token Lifetime value along with the Client Capacity for the token.
 - d. Click **Select CA**.
 - e. Select the CA type as Local/External depending on CA that you created [above](#).
 - f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
 - g. Select the Client Profile from the dropdown which you have created in the above step.
 - h. Click **Create Token**.
 - i. Copy the value of the Token created and click **Done**.
 5. If you are using External CA then you can select the external CA which you created earlier. Refer to **External CA** under [Creating or Adding a CA](#).
 6. Go to Registered Clients and click **Add Client**.
-

- a. Specify client name and paste the Registration Token generated in the above step.

Note

If you are using external CA then you need to paste the signed client certificate in the Client Certificate field.

- a. Click **Save** to save the client certificate.

Configuring the KMIP Interface

The KMIP interface can be configured through:

Root Domain

1. Go to **Admin Settings > Interfaces**.
2. On the KMIP Interface, click the ellipsis button (...) and then click **View/Edit**.
3. Select the **Auto Registration** checkbox if you auto-registered your KMIP client and paste the value of the registration token that you created.

Note

By default, the **Auto Registration** is disabled.

4. Select the mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
5. Specify selections for **Local CA for Automatic Server Certificate Generation** as desired.

Note

In case of External CA, **Local CA for Automatic Server Certificate Generation** should be set to **Turn off auto generation from Local CA**.

6. Depending upon the CA that you created [above](#), select an option from the following::
 - If you are using **Local CA** then select the CA under **Local Trusted CAs**
 - If you are using **External CA** then select the CA under **External Trusted CAs**, provided you have the external CA that you created and uploaded on the CipherTrust Manager. For more information on creating

or uploading CA, refer to [Creating or Adding a CA](#).

Sub-Domain

1. Select the CA according to your preference.

Local CA

- a. Login to your sub-domain. Go to **CA > Local**. Click the ellipsis (...) and copy the contents of your CA Certificate.
- b. Logout of your sub-domain and now login to the root domain.
- c. Go to **CA > External > Add External CA**.
- d. Enter a name for this Domain CA and select the text radio button and paste the certificate contents.
- e. Click **Add External CA**.
- f. Go to **Admin Settings > Interfaces**.
- g. Click the **Add** icon to add the External CA.
- h. Click **Update**.

External CA

Note

If you are using an External CA in the Sub-Domain, you need to add the CA as an External CA in both the root domain as well as the sub-domain and modify the interface accordingly.

- a. Login to your sub-domain. Go to **CA > Local**. Click the ellipsis (...) and copy the contents of your CA Certificate.
- b. Logout of your sub-domain and now login to the root domain.
- c. Go to **CA > External > Add External CA**.
- d. Enter a name for this Domain CA and select the text radio button and paste the certificate contents.
- e. Click **Add External CA**.
- f. Go to **Admin Settings > Interfaces**.
- g. Click the **Add** icon to add the External CA.
- h. Click **Update**.

- i. On the **KMIP interface**, click the ellipsis (...) > **Certificate Options** > **Upload New Certificate** > **Ok**.
 - j. Select the **Certificate Chain** option and click **Build Certificate Chain**.
 - k. Click on Text and paste the contents of Server Certificate, CA, and Server Key file in the same order. Do not introduce any space, character or symbol between the contents of these files.
 - l. Select certificate Format as **PEM**.
 - m. Click on **Upload Certificate**.
2. On the KMIP Interface, click the ellipsis button (...) and then click **View/Edit**.
 3. Select the **Auto Registration** checkbox if you auto-registered your KMIP client and paste the value of the registration token that you created.

Note

By default, the **Auto Registration** is disabled.

4. Select the mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
5. Specify selections for **Local CA for Automatic Server Certificate Generation** as desired.

Note

In case of External CA, **Local CA for Automatic Server Certificate Generation** should be set to **Turn off auto generation from Local CA**.

Further, You need to perform the following configuration on CipherTrust Manager specific to VMware:

1. [Creating a Client Certificate](#)
2. [Configuring NTP Server \(Optional\)](#)

Creating a Client Certificate

This section is applicable to KMIP clients registered using Auto Registration.

1. Log on to the CipherTrust Manager.
2. Navigate to the **CA > Local CA** and click on the name of the CA certificate you need to issue the certificate from.

3. Click on **Issue Certificate**.

4. Enter the **Display Name**, followed by **Common Name**.

The common Name of the certificate should be the same as the name of the user you created on CipherTrust Manager. Refer to [Creating a User](#) section.

For more information on the format of common name of the certificate, refer to [LDAP and Multi-Domain Client Usernames in KMIP Certificates](#).

5. Select the **Algorithm** and **Size**, and click **Issue Certificate**.

6. Save the **Private Key** and the **CSR**.

7. Select the Certificate Purpose as client, specify the validity of the certificate in days, and click **Issue Certificate**.

8. Download a copy of this certificate by clicking the ellipsis next to the certificate name.

Configuring NTP Server (Optional)

Based on your deployment strategy, you may need to configure an NTP (Network Time Protocol) server. Use either of the following commands to add an NTP server:

Command 1:

```
ksctl ntp servers add --host time.nist.gov
```

Command 2:

```
ksctl ntp servers add --host ntp-b.nist.gov --key secret
```

Configuration on VMware

Add KMS to the vCenter Server

To add KMS, perform the following steps on the vCenter UI.

1. Log in to the **vCenter Server**.
2. Browse the inventory list and select the **vCenter Server** instance.
3. Click **Configure** and under **Security**, click **Key Providers**.
4. Click **Add Standard Key Provider**, enter key provider information, and click **Add Key Provider**. You can click **Add KMS** to add more Key Management Servers.

Add Standard Key Provider

Name key-provider

KMS	Address	Port	
<u>CipherTrust-Node1</u>	<u>192.168.100.145</u>	<u>5696</u>	
<u>CipherTrust-Node2</u>	<u>192.168.100.146</u>	<u>5696</u>	

ADD KMS

> Proxy configuration (optional)

> Password protection (optional)

CANCEL **ADD KEY PROVIDER**

5. Click **Trust**. vCenter Server adds the key provider and displays the status as Connected.

Uploading Client Certificate and Private Key onto vSphere

Perform the following steps to upload Client Certificate and Private Key:

1. Log in to the vSphere Web Client, and select a vCenter Server system.
2. Click **Configure** and select **Key Management Servers**.
3. Select the KMS instance with which you want to establish a trusted connection.
4. Select **Upload a File** and upload copies of the client certificate and private key and click Establish Trust.

Alternatively, you can paste the certificate that you received from the KMS vendor into the top text box or click **Upload File** to upload the certificate file. Paste the key file into the bottom text box or click **Upload File** to upload the key file.

5. Click **OK**.

You can enable the following encryptions:

FCD

First Class Disk (FCD), or Improved Virtual Disk, enables independent lifecycle management of virtual disks separate from VMs. FCDs can be created through FCD APIs or by promoting existing disks.

FCDs are managed via the VSLM API. Newer vSphere versions allow snapshot-based backups of detached FCDs using UUID and datastore ID, unlike earlier versions that required attachment to a dummy VM. Regular I/O still needs attachment. FCDs support encryption via external KMS for enhanced security.

Here are the steps to Configure FCDs:

Steps to Create a New VM Storage Policy with Encryption

1. Go to **Menu > Policies and Profiles > VM Storage Policies**.
2. Click **Create** to create a new storage policy.
3. Enter a name for the policy (for example, **FCD-Encryption-Policy**).
4. Under **Rule Sets**, select **Enable encryption**.
5. Complete the wizard and click **Finish**.

Steps to Create an Encrypted First-Class Disk (FCD)

1. Connect to the vCenter Server using PowerCLI.

```
Connect-VIServer -Server 10.xx.xx.xx -User appuser -Password xxxxxxxx
```

2. Fetch the storage policy and the corresponding datastore.

```
$storagePolicy = Get-SpbmStoragePolicy -Name "TCG-Policy-Thales"
$datastore = Get-Datastore -Name "datastore1"
```

3. Create a new encrypted disk and attach it to your VM.

```
New-HardDisk -CapacityGB 10 -StoragePolicy $storagePolicy -Datastore $datastore  
-Confirm:$false -VM Windows-Test_Machine -KeyProvider $keyprovider
```

VMcrypt

1. Connect to vCenter Server by using the vSphere Client.
2. Right-click the virtual machine that you want to encrypt and select **VM Policies > Edit VM Storage Policies**.
3. Select the storage policy.
4. To encrypt the VM and its hard disks, select an encryption storage policy and click **OK**.
5. To encrypt the VM but not the virtual disks, toggle on **Configure per disk**, select the encryption storage policy for VM Home and other storage policies for the virtual disks, and click **OK**.
6. If you prefer, you can encrypt the virtual machine, or both virtual machine and disks, from the **Edit Settings** menu in the vSphere Client.
7. Right-click the virtual machine and select **Edit Settings**.
8. Select the VM Options tab, and open **Encryption**. Choose an encryption policy. If you deselect all disks, only the VM home is encrypted.
9. Click **OK**.

VSAN

To enable vSAN encryption:

1. Navigate to the KMS cluster created in vCenter.
2. Right-click the cluster and select **Settings**. The Configure tab is displayed.
3. Expand the vSAN section and click **General**.
4. Click **Edit**. Edit vSan Settings window is displayed.
5. Enable Encryption and select the previously created KMS cluster.
6. Click **OK**.

VTA

VMware has added a new feature named vSphere Trust Authority and CipherTrust Manager supports this feature. To configure vSphere Trust Authority, refer to the [VMware documentation](#).

To connect Key Provider Service to KMS, you need to configure the trust setup.

Example:

```
Set-TrustAuthorityKeyProviderClientCertificate -KeyProvider $kp8 -CertificateFile
Path <path/to/certfile.pem> -PrivateKeyFilePath <path/to/privatekey.pem>
```

Configure and Enable Trust Authority State

vSphere Trust Authority is not enabled by default. You must configure your environment for vSphere Trust Authority before you can start using it.

1. Making a vCenter Server cluster into a vSphere Trust Authority Cluster (also called enabling the Trust Authority State) starts the required Trust Authority services on the ESXi hosts in the cluster.
2. Connect as the Trust Authority Administrator user to the vCenter Server of the Trust Authority Cluster.

```
Connect-VIServer -server vsphere-sunnyvale1.gemalto.com -User trustedadmin@vsp
here.local -Password xxxxxxxx
```

3. If you see the following error.

```
Connect-VIServer : 2/14/2022 1:50:42 PM Connect-VIServer Error: Invalid serve
r certificate. Use
Set-PowerCLIConfiguration to set the value for the InvalidCertificateAction op
tion to Prompt if you'd like to connect once or to add a permanent exception f
or this server.
Additional Information: Could not establish trust relationship for the SSL/TLS
secure channel with authority 'xx.xxx.xxx.11'.
```

Run the following command and try again.

```
Set-PowerCLIConfiguration -InvalidCertificateAction Ignore
```

4. Check the current state of the cluster. The output shows either **Disabled** or **Enabled** in the **State** column for each cluster found. **Disabled** means that the Trust Authority services are not running.
5. Enable the Trust Authority Cluster.

```
Set-TrustAuthorityCluster -TrustAuthorityCluster 'Infrastructure' -State Enabl
ed
```

Two services start on the ESXi hosts in the Trust Authority Cluster.

- The Attestation Service
- The Key Provider Service

Collect Information about ESXi Hosts and vCenter Server to be Trusted

To establish trust, the vSphere Trust Authority Cluster requires information about the Trusted Cluster's ESXi hosts and vCenter Server. This information should be exported as files for importing into the Trust Authority Cluster.

Export the ESXi Host Description of Software

1. Disconnect from all connections.

```
Disconnect-VIServer -server * -Confirm:$false
```

2. Connect as the root user to one of the ESXi hosts in the Trusted Cluster.

```
Connect-VIServer -server 10.xxx.xx.xx -User root -Password xxxxxxxxx
Connect-VIServer -server 10.xxx.xx.xx -User root -Password xxxxxxxxx
```

3. Confirm the ESXi host:

```
Get-VMHost
```

4. Assign Get-VMHost to a variable.

```
$vmhost = Get-VMHost
```

5. Export the ESXi host description of software (the ESXi image). By default, this command exports the information to the `image.tgz` file. The `image.tgz` file in the example is named `image-esxi-201.tgz` to indicate what ESXi host this is from. Ensure that the destination directory exists before running this command:

```
Export-VMHostImageDb -VMHost $vmhost -FilePath C:\vta\image-esxi-201.tgz
```

Collect the TPM Endorsement Key

1. Disconnect any current connection.

```
Disconnect-VIServer -server * -Confirm:$false
```

2. Connect as the root user to one of the ESXi hosts in the Trusted Cluster.
-

```
Connect-VIServer -server 10.xxx.xx.xx -User root -Password xxxxxxxx
```

3. Confirm the ESXi host.

```
Get-VMHost
```

4. Assign Get-VMHost to a variable.

```
$vmhost = Get-VMHost
```

5. Export the EK certificate of the ESXi host.

```
Export-Tpm2EndorsementKey -VMHost $vmhost -FilePath -FilePath C:\vta\tpm2ek-201.json
```

The file is created. Repeat the process for the other ESXi hosts you want to trust. Make sure the filename is different for each ESXi host.

Collect Information about the Trusted Cluster's vCenter Server

1. Export the Trusted Cluster's vCenter Server principal information. To do so, first disconnect from the ESXi host.

```
Disconnect-VIServer -server * -Confirm:$false
```

2. Connect to the vCenter Server of the Trusted Cluster using the Trust Authority Administrator user.

```
Connect-VIServer -server 10.xxx.xx.xx -User trustedAdminTC -Password xxxxxxxx
```

3. Export the Trusted Cluster's vCenter Server principal information.

```
Export-TrustedPrincipal -FilePath C:\vta\trustedcluserprincipal-12.json
```

Import the Trusted Host Information to the Trust Authority Cluster

To import a TPM EK certificate into the Trust Authority Cluster, you must change the Trust Authority Cluster's default attestation type to accept EK certificates. The default attestation type accepts TPM Certificate Authority (CA) certificates.

1. Disconnect from the ESXi host.

```
Disconnect-VIServer -server * -Confirm:$false
```

2. Connect as the Trust Authority Administrator user to the vCenter Server of the Trust Authority Cluster.

```
Connect-VIServer -server 10.xxx.xx.xx -User trustedadmin@vsphere.local -Password xxxxxxxx
```

3. Check the current state of the cluster.

```
Get-TrustAuthorityCluster
```

4. Assign the Get-TrustAuthorityCluster cluster information to a variable.

```
$vTA = Get-TrustAuthorityCluster 'infrastructure'
```

5. Assign the Get-TrustAuthorityTpm2AttestationSettings information to a variable.

```
$tpm2Settings = Get-TrustAuthorityTpm2AttestationSettings -TrustAuthorityCluster $vTA
```

6. Run the Set-TrustAuthorityTpm2AttestationSettings cmdlet, specifying RequireEndorsementKey. At the confirmation prompt, press Enter.

```
Set-TrustAuthorityTpm2AttestationSettings -Tpm2AttestationSettings $tpm2Settings -RequireEndorsementKey
```

Output

```
Confirmation
Configure the Tpm2AttestationSettings 'TrustAuthorityTpm2AttestationSettings-domain-c2111'
following parameters:
RequireCertificateValidation: False
RequireEndorsementKey: True
[Y] Yes [A] Yes to All [N] No [L] No to All [S] Suspend [?] Help (default is "Y"):
```

Name	RequireEndorsementKey	RequireCertificateValidation	Health
TrustAuthorityTpm2AttestationSettings...	True	False	Ok

7. Connect to the VI server.

```
Connect-VIServer -server 10.xxx.xx.xx -User trustedadmin@vsphere.local -Password xxxxxxxx
```

Output

```

Name          Port  User
----          -
10.xxx.xx.xx  443   VSPHERE.LOCAL\trustedadmin

```

8. Store the details of **TrustAuthorityCluster** in a variable **vTA**.

```

$vTA = Get-TrustAuthorityCluster 'infrastructure'
$vTA

```

Output

```

Name          State  Id
----          -
Infrastructure Enabled TrustAuthorityCluster-domain-c40

```

9. Fetch the endorsement keys for the trust authority cluster.

```

New-TrustAuthorityTpm2EndorsementKey -TrustAuthorityCluster $vTA -FilePath
C:\vta\tpm2ek-25.json

```

10. Import the ESXi host base image information.

```

New-TrustAuthorityTpm2EndorsementKey -TrustAuthorityCluster $vTA -FilePath
C:\vta\tpm2ek-27.json

```

Output

```

TrustAuthorityClusterId          Name
-----
TrustAuthorityCluster-domain-c40 34323550-3939-4d33-3144-323631314734

```

Health

Ok

11. Import the ESXi host base image information.

```

New-TrustAuthorityVMHostBaseImage -TrustAuthorityCluster $vTA -FilePath C:\vta\image-esxi-25.tgz

```

Output

```

TrustAuthorityClusterId          VMHostVersion          Health

```

```
-----
TrustAuthorityCluster-domain-c40
```

```
-----
ESXi 8.0.3-0.70.24674464
```

```
-----
Ok
```

The Trust Authority Cluster knows which ESXi hosts it can remotely attest, and so, which hosts it can trust.

Create the Key Provider on the Trust Authority Cluster

1. Disconnect from all connections.

```
Disconnect-VIServer -server * -Confirm:$false
```

2. Connect to the vCenter Server of the Trust Authority Cluster.

```
Connect-VIServer -server vsphere-sunnyvale1.gemalto.com -User trustedadmin@vsp
here.local -Password Asdf@1234
```

3. Assign Get-TrustAuthorityCluster information to a variable called \$VTA.

```
$VTA = Get-TrustAuthorityCluster 'Infrastructure'
```

4. Create the trusted key provider using the New-TrustAuthorityKeyProvider cmdlet.

```
New-TrustAuthorityKeyProvider -TrustAuthorityCluster $VTA -PrimaryKeyId db781d
cbdf42481c910117e19631efc0e9d4f39055074eb1b2eec842fd13a23c -Name KeyControl1
-KmipServerAddress 10.xxx.xx.xx -KmipServerPort xxxx
```

5. Use the ID of the keys created earlier and assign a name. For example, KeyControl1.
6. Specify the IP address and the port of the CipherTrust Manager.
7. Each logical key provider must have a unique name across all vCenter Server systems.
8. To add multiple key servers to the key provider, use the Add-TrustAuthorityKeyProviderServer cmdlet.
9. Establish the trusted connection so that the KeyControl server trusts the trusted key provider. Obtain the trusted key providers in the given Trust Authority Cluster.

```
$kp = Get-TrustAuthorityKeyProvider -TrustAuthorityCluster $VTA | Select-Objec
t -First 1
```

10. Upload the certificate and private key using the Set-TrustAuthorityKeyProviderClientCertificate command.

```
Set-TrustAuthorityKeyProviderClientCertificate -KeyProvider $kp -CertificateFilePath C:\Users\Administrator\Downloads\v-cert.pem -PrivateKeyFilePath C:\Users\Administrator\Downloads\v-key.pem
```

As a result, the trusted key provider has established trust with the key server. Finish the trust setup by uploading a key server certificate so that the trusted key provider trusts the key server.

11. Obtain the trusted key providers in the given Trust Authority Cluster.

```
$kp = Get-TrustAuthorityKeyProvider -TrustAuthorityCluster $VTA | Select-Object -First 1
```

12. Get the key server server certificate. Initially, the certificate is not trusted, so the Trusted state is False. If you have more than one key server configured, a list of certificates is returned. Verify and add each certificate using the following instructions. Before trusting the certificate, assign `Get-TrustAuthorityKeyProviderServerCertificate -KeyProviderServer $kp.KeyProviderServers` information to a variable.

```
$cert = Get-TrustAuthorityKeyProviderServerCertificate -KeyProviderServer $kp.KeyProviderServers
```

13. Run this command and verify the output.

```
$cert.Certificate.ToString()
```

Output

```
[Subject]
CN=kmip.ciphertrustmanager.local, O=Thales, L=Austin, S=TX, C=US
[Issuer]
CN=CipherTrust Root CA, O=Thales, L=Austin, S=TX, C=US
[Serial Number]
39986905AFCCD708983A4CE975BC72D9
[Not Before]
6/10/2025 3:37:25 PM
[Not After]
9/14/2027 3:37:25 PM
[Thumbprint]
CC638805FCFAF3E9E3CB1CB4B737E04078BF444D5
```

14. Add the KMIP server certificate to the trusted key provider.

```
Add-TrustAuthorityKeyProviderServerCertificate -ServerCertificate $cert
```

15. Verify the status of the key provider, by refreshing the key provider status.

```
$kp = Get-TrustAuthorityKeyProvider -TrustAuthorityCluster $VTA
```

16. Get the key provider status.

```
$kp.Status
```

Output

KeyProviderId	Health	HealthDetails	ServerStatus
domain-c40-KeyControl4	Ok	{}	{10.xxx.xx.xx}

Export the Trust Authority Cluster Information

After you have imported the vSphere Trust Authority Cluster information to the Trusted Cluster, the Trusted Hosts start the attestation process with the Trust Authority Cluster.

1. To import the Trust Authority Cluster information, Disconnect from all connections.

```
Disconnect-VIServer -server * -Confirm:$false
```

2. Ensure that you are connected as the Trust Authority Administrator to the vCenter Server of the Trusted Cluster.

```
Connect-VIServer -server vsphere-sunnyvale1.gemalto.com -User trustedadmin@vsphere.local -Password xxxxxxxxx
```

3. Export the Trust Authority Cluster's Attestation Service and Key Provider Information, this command exports the service information to the `clsettings.json` file.

```
$VTA = Get-TrustAuthorityCluster 'Infrastructure'
Export-TrustAuthorityServicesInfo -TrustAuthorityCluster $VTA -FilePath C:\vta\clsettings.json
```

Output

Mode	LastWriteTime	Length	Name
----	-----	-----	----
-a----	6/6/2025 9:42 PM	8352	clsettings.json

The file containing the Trust Authority Cluster information is created.

Import the Trust Authority Cluster Information to the Trusted Hosts

To import the Trust Authority Cluster information.

1. Disconnect from all connections:

```
Disconnect-VIServer -server * -Confirm:$false
```

2. Ensure that you are connected as the Trust Authority Administrator to the vCenter Server of the Trusted Cluster (Workload cluster).

```
Connect-VIServer -server TrustedCluster_VC_ip_address -User trust_admin_user  
-Password 'password'
```

3. Verify that the state of the Trusted Cluster is Disabled.

```
Get-TrustedCluster
```

4. Assign the Get-TrustedCluster information to a variable and verify its value.

```
$TC = Get-TrustedCluster -Name 'KMS-Cluster'
```

5. Import the Trust Authority Cluster information to the vCenter Server. Use the `clsettings.json` file previously exported in "Export the Trust Authority Cluster Information".

```
Import-TrustAuthorityServicesInfo -FilePath C:\vta\clsettings.json
```

6. Enable the Trusted Cluster.

```
Set-TrustedCluster -TrustedCluster $TC -State Enabled
```

Output

```
Confirmation  
Setting TrustedCluster 'KMS-Cluster' with new TrustedState 'Enabled'. Do you want to proceed?  
[Y] Yes [A] Yes to All [N] No [L] No to All [S] Suspend [?] Help (default is "Y"):
```

Name	State	Id
----	-----	--
KMS-Cluster	Enabled	TrustedCluster-domain-c9

7. Verify that the Attestation Service and the Key Provider Service are configured in the Trusted Cluster.

```
$TC = Get-TrustedCluster -Name 'KMS-Cluster'
$TC.AttestationServiceInfo
```

Output

ServiceAddress	ServicePort	ServiceGroup
-----	-----	-----
10.xxx.xx.xx	443	host-45:xx7f8085-9ca1-446c-...
10.xxx.xx.xx	443	host-159846:xx7f8085-9ca1-4...

The ESXi Trusted Hosts in the Trusted Cluster begin the attestation process with the Trust Authority Cluster.

Configure the Trusted Key Provider for Trusted Hosts

1. Disconnect from all connections.

```
Disconnect-VIServer -server * -Confirm:$false
```

2. Ensure that you are connected as the Trust Authority Administrator to the vCenter Server of the Trusted Cluster (Workload cluster).

```
Connect-VIServer -server TrustedCluster_VC_ip_address -User trust_admin_user
-Password 'password'
```

3. Obtain the trusted key provider.

```
Get-KeyProvider
```

You can use the `-Name` option to specify a single trusted key provider.

4. Assign the Get-KeyProvider trusted key provider information to a variable.

```
$workload_kp = Get-KeyProvider
```

5. If you have multiple trusted key providers, you can use Select-Object to select one of them: (Optional)

```
$workload_kp = Get-KeyProvider | Select-Object -Index 0
```

6. Register the trusted key provider.

```
Register-KeyProvider -KeyProvider $workload_kp
```

Output

Name	DefaultForSystem	ClientCertificateExpiryDate
----	-----	-----
KeyControl1	False	1/1/0001 12:00:00 AM

Licensing

This section provides the licensing requirements for KMIP client, vSAN, and vCenter.

Condition	License Requirement
Encryption at VM Level	x1 KMIP client license for vCenter
Encryption at vSAN Level	Minimum x2 KMIP client license. x1 for vCenter + x1 per vSAN node

Appendix

Troubleshooting

Issue	Error Message	Remediation
KMIP registration is not enabled	The following error message is displayed in CipherTrust Records: <i>"errorMessage": "Unregistered client, please register a new client from CLI or API or UI."</i>	Check whether the Autoregistration option is selected in Admin Settings > System > Interfaces > kmip . If it is not selected, turn on the Autoregistration option. Refer to the steps mentioned in Enable KMIP Client Registration .
User corresponding to username location in certificate (example: OU/UID) has not been created	The following error messages are displayed in CipherTrust Records: <i>"errorMessage": "username not found: "</i> <i>"errorMessage": "Could not authenticate certificate user, hence client is not auto registered in mode tls-cert-pw-opt"</i>	Check whether the user corresponding to UID/OU of the node certificates has been created in Keys & Access Management > Users . If the user is not created, create a new user with the same name as the OU/UID field of the node

Issue	Error Message	Remediation
		certificates. After creating the user, add this user to the Key Admins . Refer to steps mentioned in Create a New User .
User has not been added to Key Admin group	The following error message is displayed in CipherTrust Records: <i>"errorMessage": "authorization denied: verdict was deny: CreateKey"</i>	Check whether the user corresponding to UID/OU of the node certificates has been created under Keys & Access Management > Users . If the user is not added, add the user to the Key Admins group.
The Username location in Certificate has been set incorrectly	The following error messages are displayed in CipherTrust Records: <i>"errorMessage": "username not found: "</i> <i>"errorMessage": "Could not authenticate certificate user, hence client is not auto registered in mode tls-cert-pw-opt"</i>	Check whether the Username Location in the Certificate option is set correctly to OU/UID in Admin Settings > System > Interfaces > kmip . If it is not set correctly, set the correct value for the Username Location in the Certificate.

CipherTrust Manager

Version: v2.22 (latest)

4 February 2026

Contents

KMIP Reference 3

KMIP Reference

Note

For integration guides on the respective KMIP clients, refer to [CipherTrust Integrations](#).

The Key Management Interoperability Protocol (KMIP) is a communication protocol that facilitates key management and cryptographic operations on a key management server. This section provides additional user information and specifications applicable to the KMIP interface of CipherTrust Manager.

This section provides the following information:

- [Setting up a KMIP Client](#)
- [KMIP Licensing](#)
- [KMIP Client Registration](#)
- [Supported Objects, Operations, Attributes, and Key Formats](#)
- [Cryptographic Operations for KMIP](#)
- [Recommended Curve Mappings](#)
- [KMIP Interface Mode](#)

Setting up a KMIP Client

Here are the prerequisites for allowing KMIP clients to connect to CipherTrust Manager:

- The CipherTrust Manager server's KMIP port 5696 should be open from the client.
- The CipherTrust Manager server supports the following TLS versions:
 - TLS version 1.0
 - TLS version 1.1
 - TLS version 1.2 (default minimum)
 - TLS version 1.3

Caution

TLS 1.0 and 1.1 are deprecated and support will be discontinued in a future release.

- Configure the KMIP service to trust the external CAs. Refer to [Trusted CAs \(NAE, KMIP, and WEB\)](#) for details.

KMIP Parameter: `kmip_enable_hard_delete`

This optional parameter enables a hard delete of keys on a "KMIP Destroy" operation. This means that both meta-data and material are removed from CipherTrust Manager for the key being deleted. By default, only key material is removed and meta-data is preserved with the updated key state. This setting applies only to the KMIP interface. Should be set to '1' for enabling this feature or '0' for returning to the default behavior.

KMIP Licensing

The KMIP interface is active for a 90-day trial period after CipherTrust Manager is installed. After the trial period expires, a new purchased KMIP license must be installed to use the KMIP interface. Contact [Thales Customer Support](#) for assistance in obtaining a license.

To activate a license using the GUI

Activating a KMIP license requires a license string for the CipherTrust Manager with which the clients will be registered. This string is generated when a license is activated on the Sentinel EMS License Portal.

Refer to [Activating a Connector License](#) for details.

After the KMIP license is activated, its state becomes **Active** on the Features tab of the Licensing page of the CipherTrust Manager GUI. The license is displayed with the feature name **KMIP**.

KMIP Client Registration

CipherTrust Manager recognizes only registered KMIP clients.

For registering a KMIP client, a certificate is required. The certificate facilitates authentication and communication between CipherTrust Manager and the client.

You can register KMIP clients using following methods:

1. Using Auto Registration (using an existing certificate)

Auto registration is useful when the clients are having certificates from the Classic KeySecure, or from older versions of CipherTrust Manager, or certificates issued by External CAs.

If you are already having one of the above certificate, you can utilize it to register your KMIP client, or to upgrade to a newer version of CipherTrust Manager. For detailed steps, refer to the section [KMIP Client Registration for existing CipherTrust Manager and external CA\(s\)](#).

2. Using Manual Registration

Before proceeding to manual registration, make sure that a client profile is created on the CipherTrust Manager. A client profile contains a set of properties, on basis of which, the KMIP client gets registered. KMIP clients can be registered manually by:

- Creating a new certificate using local CA on the CipherTrust Manager.
- Using a certificate signed by an external CA.

Refer to [To Register a new KMIP Client](#) for details.

Note

- CipherTrust Manager 2.2.0 onward, it is mandatory to register the KMIP clients.
- For KMIP client administration, the user must be a member of `Key Users` and `Client Admins` groups.

Specifying LDAP and Multi-Domain Client Usernames in KMIP Certificates

The connection and/or username can be specified in the following formats:

- `<username>` - A local user in the root domain. For example, `joe`.
- `<ldap-connection>|<username>`

An LDAP user in the root domain. For example, `ldap-connection|joe`.

- `<domain>|<ldap-connection>|<username>`

An LDAP user in a specific domain. For example, `domain|ldap-connection|joe`.

- `<domain>||<username>`

A root domain user assigned in a specific domain. For example, `domain||joe`.

- `<domain>|<auth-domain>||<username>`

A local user created inside a specific domain, named "auth-domain". For example, `domain|auth-domain||joe`.

Note

To authenticate a domain user:

- a. Add the trusted CA of the domain to the root domain's external CAs list.
- b. Add that external CA of the root domain to the KMIP interface's trusted external CAs list.

When browsing the GUI, users can be identified from the source property. The user is displayed in either of the formats listed above. A local user is displayed as `local|<username>`.

KMIP Client Registration for existing CipherTrust Manager and external CA(s)

1. Create a registration token to register KMIP clients.

Request

```
ksctl clientmgmt tokens create --configfile config_example.yaml
```

Response

```
{
  "id": "dd8289f4-adbe-412f-9191-320bf2bac847",
  "uri": "kylo:kylo:munshi:tokens:dd8289f4-adbe-412f-9191-320bf2bac847",
  "account": "kylo:kylo:admin:accounts:kylo",
  "application": "ncryptify:gemalto:admin:apps:kylo",
  "devAccount": "ncryptify:gemalto:admin:accounts:gemalto",
  "createdAt": "2019-12-19T05:52:36.590956451Z",
  "updatedAt": "2019-12-19T05:52:36.590956451Z",
  "token": "RwIgd6RfXd7kzri12ydzoeFXsA2R9ju2YDxMv2xM9duQbqAhcKcyMQ020pqZesti",
  "valid_until": "0001-01-01T00:00:00Z",
  "max_clients": -1,
  "cert_duration": 730,
  "clients_registered": 0,
  "ca_id": "713172e0-02be-48c2-be60-6aae964ce943",
  "label": null
}
```

2. Update the KMIP Interface for which you want to allow Auto registration of KMIP clients. For auto registration, the client certificate which is to be registered should be signed by the trusted CA for the interface. To update the KMIP interface, run the `ksctl interfaces modify` command with the following parameters.

- `-a (true | false)` is for enabling or disabling auto registration
- `-r` is for providing registration token as input

If `-a` is set to `true`, then providing registration token in `-r` is mandatory.

Note

A new KMIP interface can also be created with the `-a` and `-r` parameters.

Note

If the client is auto registered using the `tls-pw-opt` mode, then that certificate cannot be used to connect via the other two modes, `tls-cert-pw-opt` and `tls-cert-and-pw`.

Request to update interface with auto registration on:

```
ksctl interfaces modify -n kmip -a true -r RwIgd6RfXd7kzri12ydzoeFXsA2R9ju2YDxMv2xM9duQbqAhcKcyMQ020pqZesti --configfile config_example.yaml
```

Response

```
{
  "id": "54523325-62d0-40d4-a45e-f45b9e1679e7",

  "default_connection": "local_account",
  "port": 5696,
  "network_interface": "all",
  "interface_type": "kmip",
  "minimum_tls_version": "tls_1_2",
  "local_auto_gen_attributes": {
    "cn": "kmip.keysecure.local",

```

```

    "email_addresses": [
        "support@gemalto.com"
    ],
    "names": [
        {
            "C": "US",
            "ST": "MD",
            "L": "Belcamp",
            "O": "Gemalto",
            "OU": ""
        }
    ],
    "generated": false
},
"auto_registration": true,
"registration_token": "RwIgd6RfXd7kzri12ydzoeFXsA2R9ju2YDxMv2xM9duQbqAhcKc
yMQ020pqZesti"
}

```

Note

`cert_user_field` specifies how the user name is extracted from the client certificate. The default value is CN. This user must already exist. This parameter must be one of the following:

- CN: common name
- OU: organizational unit
- SN: surname
- E: Email address
- UID: User ID
- E_ND: Email without domain; the data to the left of the @ sign in the email address is taken as the user name

3. Connect to the KMIP interface using the client certificate you want to register. It will automatically register the KMIP client corresponding to that certificate.

Note

If the client is mistakenly registered without a username, then you need to manually delete the registered client, before creating a new client. To delete a registered client, log into the console, navigate to **KMIP > Registered Clients**, and delete the client.

To Register a new KMIP Client

1. Create a json file for specifying properties to create a KMIP client profile. There are two ways to create a client profile:
 - Using csr
 - Using csr parameter

A detailed explanation of input parameters is provided after the examples.

profile.json: This file is a user input to CLI for providing profile parameters.

Note

The profile.json is just a place holder for name of file, user can choose any name for this file.

Note

- To register a KMIP client using a client certificate generated by an external CA, during profile creation, the `cert_user_field` parameter is mandatory; whereas, the `csr` and `csr` parameters are not required.
- To register a KMIP client in a domain, first, authenticate the client in that domain using any of the domain [authentication methods](#).

The authentication of the registered client certificate is based on the Subject DN of the certificate.

Note

Email ID is also part of subject DN of the certificate. An email ID mismatch can result in subject DN mismatch.

Example 1

```
{
  "cert_user_field": "CN",
  "csr": "-----BEGIN CERTIFICATE REQUEST-----\nMIIBCDCBjwIBADAQM...T0KnChXGc
6JazA==\n-----END CERTIFICATE REQUEST-----\n"
}
```

Example 2

```
{
  "cert_user_field": "CN",
  "csr_cn": "user1",
  "csr_org_name": "Thales",
  "csr_org_unit": "Security",
  "csr_email": "abc@example.com",
  "csr_city": "Noida",
  "csr_state": "UP",
  "csr_country": "IN"
}
```

**** Parameter Explanation****

- **cert_user_field**: Specifies how the user name is extracted from the client certificate. The default value is **CN**. This user must already exist. For more information, click [here](#).

Note

After registering the new KMIP client, cert_user_field setting of profile is used instead of the setting present in the interface.

- **csr**: This is certificate signing request. The common name specified in CSR will be used to authenticate KMIP request.

Note

If the user is not present, then profile registration will fail.

Other parameters

If CSR is not provided, then CipherTrust Manager creates CSR using below input parameters from `profile.json`:

- `csr_cn`: Common Name used to create CSR.
 - `csr_org_name`: Organization name to be used in CSR.
 - `csr_uid`: User ID used to create CSR.
 - `csr_org_unit`: Organizational unit to be used in CSR.
 - `csr_email`: Email address to be used in CSR.
 - `csr_city`: City name to be used in CSR.
 - `csr_state`: State name to be used in CSR.
 - `csr_country`: Country name to be used in CSR.
2. (Optional Step) Create a json file (for example, `device_cred.json`) for specifying device credential properties.

Note

This step is optional and should be performed only when it is desired to authenticate the KMIP Client using device credentials.

Example 1

All fields in the example are optional, however, at least one field must be specified for a successful authentication using device credentials.

```
{
  "serial_no": "12345",
  "password": "example_password_123",
  "device_id": "example_device_ID",
```

```

    "network_id": "sample_Network_ID",
    "machine_id": "MAC123456789",
    "media_id": "Media123456789"
  }

```

Parameters

- **serial_no**: Serial number of the device, for example the hardware serial number of the device.
 - **password**: Password for the device.
 - **device_id**: Device Identifier of the device.
 - **network_id**: Network identifier of the device, for example the MAC address for Ethernet connected devices.
 - **machine_id**: Machine identifier of the device, for example the client aggregator identifier, such as a tape library aggregating tape drives.
 - **media_id**: Media identifier of the device, for example the volume identifier used for a tape cartridge.
3. (Optional Step) Specify **do_not_modify_subject_dn** or **subject_dn_field_to_modify**:
- **do_not_modify_subject_dn**: Specifies whether Subject DN in the CSR is allowed to be modified or not. If this flag is set to **true**, then Subject DN must be unique across all the CipherTrust Manager clients, otherwise client registration will not be allowed. The default value is **false**. For details, refer to [Renew Local CA Client Certificates](#).
 - **subject_dn_field_to_modify**: Makes Subject DN unique so that the client can be identified uniquely. The default value is **UID**. For details, refer to [Renew Local CA Client Certificates](#).

Note

Email ID is also part of subject DN of the certificate. Therefore, an email ID mismatch can result in subject DN mismatch.

Example 1

```

ksctl kmip createprofile -p kmipprofile1 -c profile.json --configfile config_example.yaml --do_not_modify_subject_dn true

```

Example 2

```
ksctl kmip createprofile -p kmipprofile1 -c profile.json --configfile config_example.yaml --subject_dn_field_to_modify 'DNQ'
```

4. Create the KMIP profile using the json file created in step 1.

Request

```
ksctl kmip createprofile -p kmipprofile1 -c profile.json --configfile config_example.yaml
```

Note

When you create a client profile through KMIP, it creates a profile with the reserved prefix `kmip` in the generic client profile.

Example

Profile name provided on KMIP:

Profile name = "test"

Internally generates generic client profile with name:

profile name = "kmip-test"

If the same client profile name already exists (for example, "kmip-test") in the generic client profile section, the KMIP profile naming convention issue occurs and the name conflict error is displayed. For details on generic client profile, refer to [Managing Client Profiles](#).

Note

If using device credentials, use the following request instead:

```
ksctl kmip createprofile -p kmipprofile1 -c profile.json -d device_cred.json --configfile config_example.yaml
```

Here, `device_cred.json` is the device credential file created in previous step.

Response

```
{
  "account": "kylo:kylo:admin:accounts:kylo",
  "application": "ncryptify:gemalto:admin:apps:kylo",
  "createdAt": "2019-12-18T10:19:32.745104774Z",
  "devAccount": "ncryptify:gemalto:admin:accounts:gemalto",
}
```

```
{
  "id": "70d92635-7e9f-4a9b-9161-d7f41b4e0109",
  "name": "kmipprofile1",
  "properties": {
    "csr_cn": "rajesh"
  },
  "updatedAt": "2019-12-18T10:19:32.745104774Z",
  "uri": "kylo:kylo:nae:kmip_profile:kmipprofile1"
}
```

5. Create a registration token using the profile created in the previous step.

If client registration is through local CA:

Request

```
ksctl kmip createkmipregtoken -p kmipprofile1 --configfile config_example.yaml
```

Note

The `profile_name` is required and must be present in the system before creating a registration token.

Response

```
{
  "id": "6b8f5397-b738-4160-8c39-7979bae280aa",
  "uri": "kylo:kylo:munshi:tokens:6b8f5397-b738-4160-8c39-7979bae280aa",
  "account": "kylo:kylo:admin:accounts:kylo",
  "application": "ncryptify:gemalto:admin:apps:kylo",
  "devAccount": "ncryptify:gemalto:admin:accounts:gemalto",
  "createdAt": "2019-12-18T10:29:26.701363932Z",
  "updatedAt": "2019-12-18T10:29:26.701363932Z",
  "token": "LW0heyZNXHE9SEKmu7B0zVqnwHns42tahMVWJYUKP6I5CI67RQLS0EDkZ96Uioc
I",
  "valid_until": "0001-01-01T00:00:00Z",
  "max_clients": -1,
  "cert_duration": 730,
  "clients_registered": 0,
  "ca_id": "efe1d302-7ff4-46ca-a2a4-c4d9236cc0f8",
  "label": {
    "KmiclientProfile": "kmipprofile1"
  }
}
```

```
}
}
```

If client registration is through external CA:

Request

```
ksctl kmip createkmipregtoken -p kmipprofile1 --configfile <config_example.yaml> --ca_id <CA-Id-of-the-External-CA>
```

Note

To register a client using external CA, make sure to upload the external CA to CipherTrust Manager, and the `ca_id` parameter must be set to the ID of the uploaded external CA.

Response

```
{
  "id": "6b8f5397-b738-4160-8c39-7979bae280aa",
  "uri": "kylo:kylo:munshi:tokens:6b8f5397-b738-4160-8c39-7979bae280aa",
  "account": "kylo:kylo:admin:accounts:kylo",
  "application": "ncryptify:gemalto:admin:apps:kylo",
  "devAccount": "ncryptify:gemalto:admin:accounts:gemalto",
  "createdAt": "2019-12-18T10:29:26.701363932Z",
  "updatedAt": "2019-12-18T10:29:26.701363932Z",
  "token": "LW0heyZNXHE9sEKmu7B0zVqnwHns42tahMVWJYUkP6I5CI67RQLS0EDkZ96UiocI",
  "valid_until": "0001-01-01T00:00:00Z",
  "max_clients": -1,
  "cert_duration": 730,
  "clients_registered": 0,
  "ca_id": "efe1d302-7ff4-46ca-a2a4-c4d9236cc0f8",
  "label": {
    "KmipClientProfile": "kmipprofile1"
  }
}
```

6. Register the new KMIP client using the registration token generated in the previous step.

If client registration is through local CA:

Request

```
ksctl kmip register -n Kmiclient2 -t LW0heyZNXHE9sEKmu7B0zVqnwHns42tahMVWJYUk
P6I5CI67RQLS0EDkZ96UiocI --kmipCertOutFile ClientCert.pem --kmipKeyOutFile Cli
entKey.pem --configfile config_example.yaml
```

Response

```
{
  "cert": "-----BEGIN CERTIFICATE-----4xq+8sZ6PuwxePopPD2HWB+uxjLjdaKb01wz5A
Ek...-
N3e2aj0ow/ZC2FxtkipCIyYdlTJ7P\n-----END CERTIFICATE-----\n",
  "client_ca": "-----BEGIN CERTIFICATE-----\kXLCgQWnp2Kp445v2ZAYf3CUwWnBBUzL
ZdpDkUkQpaloJaMkNXU2KFVxjyDT7cXM...
v5jwHaYfqXImDs0bC/UZyEo+bnwFlA==\n-----END CERTIFICATE-----\n",
  "client_id": "ac8c7131-7dc4-4b1e-ab42-3529b4c4a497",
  "csr": "-----BEGIN CERTIFICATE REQUEST-----\nwSnPtpvJZU9kac0...2LfMJxmbnmA
ug2YM/\n-----END CERTIFICATE REQUEST-----\n",
  "key": "-----BEGIN RSA PRIVATE KEY-----zMTurULUu9S9dc89ajkKJ...TlkMA/Gx0IO
kpH1zMbJLf6NEga0ZbC1tCLjxB6YjQIgHfrTqupc=\n-----END RSA PRIVATE KEY-----\n"
}
```

If client registration is through external CA:

Request

```
ksctl kmip register -n Kmiclient2 -t LW0heyZNXHE9sEKmu7B0zVqnwHns42tahMVWJYUk
P6I5CI67RQLS0EDkZ96UiocI --configfile config_example.yaml --cert <Path-to-Exte
rnal-Client-Certificate>
```

Response

```
{
  "cert": "-----BEGIN CERTIFICATE-----4xq+8sZ6PuwxePopPD2HWB+uxjLjdaKb01wz5A
Ek...-
N3e2aj0ow/ZC2FxtkipCIyYdlTJ7P\n-----END CERTIFICATE-----\n",
  "client_ca": "-----BEGIN CERTIFICATE-----\kXLCgQWnp2Kp445v2ZAYf3CUwWnBBUzL
ZdpDkUkQpaloJaMkNXU2KFVxjyDT7cXM...
v5jwHaYfqXImDs0bC/UZyEo+bnwFlA==\n-----END CERTIFICATE-----\n",
  "client_id": "ac8c7131-7dc4-4b1e-ab42-3529b4c4a497",
  "csr": "",
  "key": ""
}
```

Note

To register a client using an external CA, the `cert` parameter should specify the path of the client certificate.

7. Use **Client Certificate** and **Client Private Key** to connect with the server.

User Impersonation

The CipherTrust Manager allows a client to impersonate a user for a client, meaning, the client can connect to the CipherTrust Manager as a user without providing the user credentials, on NAE and KMIP interfaces. By default, the user impersonation functionality is limited to impersonate users of the clients' domain (where the client is registered) only. Hence, user impersonation applies only to the users created in the clients' domain or assigned users (users created in the clients' domain and assigned to some other domain).

If you set the `ALLOW_USER_IMPERSONATION_ACROSS_DOMAIN` property to `true`, clients belonging to the `root` domain are allowed to impersonate the users created within sub-domains. The property is only applicable to NAE and KMIP interfaces. The default value of this property is `false`.

```
ksctl properties modify --name ALLOW_USER_IMPERSONATION_ACROSS_DOMAIN --value true
```

Note

Make sure to restart the NAE service when you change the value of "ALLOW_USER_IMPERSONATION_ACROSS_DOMAIN" property.

KMIP Client Renewal

The CipherTrust Manager allows you to renew the certificate of a registered KMIP Client.

Note

The KMIP clients should use **Admin's Renew Route** for renewal. For details, refer to [Renewing Client Certificates](#).

Supported Objects, Operations, Attributes, and Key Formats

The following KMIP Objects Types, Attributes, and Operations supported on CipherTrust Manager are in accordance with KMIP Specification Version 1.4.

Supported Object Types

Object	Object	Object
Symmetric Key	Public Key	Private Key
Secret Data	Opaque Object	Certificate

Supported Operations

Operation	Operation	Operation	Operation
Activate	Delete Attribute	Get Attributes List	Register
Add Attribute	Destroy	Locate	Re-key
Check	Discover Versions	MAC	Re-key Key Pair
Create	Encrypt	MACV	Revoke
Create Key Pair	Get	Modify Attribute	Sign
Decrypt	Get Attributes	Query	SignV

Note

CipherTrust Manager supports Wrapping and Unwrapping of Keys for Get and Register operations. To read more, go to [Wrap/Unwrap support in KMIP](#) for details.

Supported Attributes

Attribute	Attribute	Attribute
Unique Identifier	Name	Object Type
Cryptographic Algorithm	Cryptographic Length	Cryptographic Parameters
Cryptographic Domain Parameters	Cryptographic Usage Mask	Digital Signature
State	Initial Date	Activation Date
Process Start Date	Protect Stop Date	Deactivation Date
Destroy Date	Compromise Occurrence Date	Compromise Date
Revocation Reason	Link	Application Specific Information
Contact Information	Object Group	Custom Attribute
Fresh Attribute	Alternate Name	Digest Attribute
Certificate Type	Certificate Length	X.509 Certificate Identifier
X.509 Certificate Subject	X.509 Certificate Issuer	Certificate Identifier
Certificate Subject	Certificate Issuer	Never Extractable

Attribute	Attribute	Attribute
Extractable	Operation Policy Name	

Note

For information on the above listed object Types, Operations, and Attributes, refer to the OASIS KMIP Documentation.

Note

The Operation Policy Name attribute supports only 'default' value.

Note

The Fresh Attribute, Custom Attribute, Application Specific Information, and Digest Attribute are stored in the Key Meta.

Example 1

If a custom attribute (for example, `AttributeName : x-attribute1`, `AttributeValue: value1`) is added to the key `k1`, then the attribute is stored in Key Meta as:

```
{
  "kmip": {
    "custom": [
      {
        "type": "TextString",
        "x-attribute1": "Value1"
      }
    ],
    "ownerId": "local|261d8e87-73bb-4106-aa3d-06ed92e2f010",
    "permissions": {}
  }
}
```

Example 2

If an application specific attribute (for example, `application_data": "data"`, `"application_namespace": "Test"`) is added to a key, then the attribute is stored in Key Meta as:

```
{
  "kmip": {
    "app_specific_info": [
```

```

    {
      "application_data": "data",
      "application_namespace": "TestASi"
    }
  ],
  "ownerId": "local|261d8e87-73bb-4106-aa3d-06ed92e2f010",
  "permissions": {}
}

```

Supported Key Formats

Object Type	Key Formats
Symmetric	• Raw • Opaque
Private Key	• PKCS_1 • PKCS_8 • PKCS_12
Public Key	• PKCS_1 • PKCS_8
Certificate	• PKCS_12 • X.509
Opaque	• Raw
Secret	• Opaque

Wrap/Unwrap support in KMIP

Key wrapping is used for encrypting data keys. This provides an additional layer of security in protecting keys when they are at rest or are being transmitted over insecure networks. A variety of key wrapping algorithms can be used to encrypt the data keys. Similarly, unwrap mechanisms are used to decrypting the data keys.

CipherTrust Manager supports wrapping/unwrapping of keys under Get and Register operations.

Note

Only Symmetric and Private keys can be wrapped/unwrapped in KMIP.

Supported wrapping methods are:

- Encrypt
- MACSign

Note

For Encrypt Wrapping Method:

- Only AES and RSA keys can be used to wrap the symmetric keys.
- Only AES-256 keys can be used to wrap private keys.

Note

For MACSign Wrapping Method:

- Only HMAC keys can be used for MAC request.
- Only RSA keys can be used for Sign request.

Encrypt Wrapping Method

Symmetric Data Keys	Symmetric Data Keys	Private Data Keys
Supported BlockCipher Modes for AES wrap keys	Supported padding methods for RSA wrap keys	Supported BlockCipher Mode for AES wrap keys
• NISTKeyWrap (RFC-3394) • AESKeyWrapPadding (RFC-5649)	• PKCS1V1_5 • OAEP Supported Hash Algorithms for OAEP padding method: • SHA_1 • SHA_256 • SHA_384 • SHA_512	• AESKeyWrapPadding (RFC-5649)

MACSign Wrapping Method for Symmetric and Private Keys

MAC Request	Sign Request	Sign Request
Supported HMAC algorithms for HMAC wrap keys	Supported padding methods for RSA wrap keys	Supported DigitalSignatureAlgorithms for RSA wrap keys
• HMAC_SHA_1 • HMAC_SHA_256 • HMAC_SHA_384 • HMAC_SHA_512	• PKCS1V1_5 (Default) • PSS Supported Hash Algorithms for above padding methods: • SHA_1 • SHA_256 • SHA_384 • SHA_512	• SHA_1WithRSAEncryption • SHA_256WithRSAEncryption • SHA_384WithRSAEncryption • SHA_512WithRSAEncryption

Supported Encodings

- NoEncoding
- TTLVEncoding

For more information, visit [OASIS Key Management Interoperability Protocol Documentation](#).

Opaque Key Format for Symmetric Keys

The CipherTrust Manager supports opaque key format type for symmetric keys in the REST/KMIP interface. The opaque key format type can be used during importing keys when key material is not raw. For more details, refer to [OASIS Key Management Interoperability Protocol Documentation](#).

Example Request

```
<RequestMessage>
  <RequestHeader>
    <ProtocolVersion>
      <ProtocolVersionMajor type="Integer" value="1"/>
      <ProtocolVersionMinor type="Integer" value="2"/>
    </ProtocolVersion>
    <BatchCount type="Integer" value="1"/>
  </RequestHeader>
  <BatchItem>
    <Operation type="Enumeration" value="Register"/>
    <RequestPayload>
      <ObjectType type="Enumeration" value="SymmetricKey"/>
      <TemplateAttribute>
        <Attribute>
          <AttributeName type="TextString" value="Name"/>
          <AttributeValue>
            <NameValue type="TextString" value="OpaqueKey_AES128_1"/>
            <NameType type="Enumeration" value="UninterpretedTextString"/>
          </AttributeValue>
        </Attribute>
        <Attribute>
          <AttributeName type="TextString" value="Cryptographic Usage Mask"/>
          <AttributeValue type="Integer" value="Decrypt Encrypt"/>
        </Attribute>
      </TemplateAttribute>
      <SymmetricKey>
        <KeyBlock>
          <KeyFormatType type="Enumeration" value="Opaque"/>
          <KeyValue>
            <KeyMaterial type="ByteString" value="000102030405060708090a0b0c0d0e0f000102030405060708090a0b0c0d0e0f000102030405060708090a0b0c0d0e0f000102030405060708090a0b0c0d0e0f000102030741"/>
          </KeyValue>
          <CryptographicAlgorithm type="Enumeration" value="AES"/>
          <CryptographicLength type="Integer" value="128"/>
        </KeyBlock>
      </SymmetricKey>
    </RequestPayload>
  </BatchItem>
</RequestMessage>
```

Example Response

```
<ResponseMessage>
  <ResponseHeader>
    <ProtocolVersion>
      <ProtocolVersionMajor type="Integer" value="1" />
      <ProtocolVersionMinor type="Integer" value="2" />
    </ProtocolVersion>

    </ResponsePayload>
  </BatchItem>
</ResponseMessage>
```

Cryptographic Operations for KMIP

Using KMIP interface, you can perform following cryptographic operations:

Operations	Algorithms	Modes	Padding
Encrypt/Decrypt	AES	• ECB (default) • CBC • GCM • CTR	• PKCS5 (default) • None
Encrypt/Decrypt	TDES	• ECB (default) • CBC	• PKCS5 (default) • None
Encrypt/Decrypt	RSA	not applicable	• PKCS1V1_5 (default) • OAEP
MAC/MACV	HMAC_SHA1	not applicable	not applicable
MAC/MACV	HMAC_SHA256	not applicable	not applicable
MAC/MACV	HMAC_SHA384	not applicable	not applicable
MAC/MACV	HMAC_SHA512	not applicable	not applicable
MAC/MACV	AES	CMAC	not applicable

Caution

We recommend that you set the **RandomIV** object in the **Cryptographic Parameters** attribute to true for AES CBC, AES GCM, and TDES CBC encryption requests to have CipherTrust Manager generate a unique random IV with each request. The size of a generated random IV is always fixed to the cipher block size. CipherTrust Manager does not use Cryptographic Parameter objects such as **Fixed Field**

Length, Invocation Field Length or Counter Length to construct the random IV.

Otherwise, you can provide your own IV in the Request Payload as an **IV/Counter/Nonce** object. If you or your KMIP vendor are providing IVs, follow [NIST SP800-38A](#) and [NIST SP800-38D](#) to ensure IVs are sufficiently unique and secure.

Recommended Curve Mappings

The recommended Curve mappings along with the respective Curve IDs are listed in the following table.

Curve	Curve ID
P-224	secp224r1
P-256	prime256v1
P-384	secp384r1
P-521	secp521r1

KMIP Interface Mode

The "interface mode" configuration parameter specifies the KMIP Interface mode, and must be one of the following:

- **tls-pw-opt:** TLS, allow anonymous logins.
 - Username is not extracted from the client certificate.
 - If authentication request is sent in KMIP request, Username will be the owner of the key.
 - If authentication request is not sent in KMIP request, the Key Owner will be the 'global' user.
- **tls-cert-pw-opt:** TLS, user name taken from client cert, auth request is optional.
 - Username is extracted from the registered client's Common Name specified during client's registration.
 - If authentication request is sent in KMIP request, then the Username in the authentication request will be the owner of the key.
- **tls-cert-and-pw:** TLS, password is needed, user name specified during client's registration must match user name in authentication request.
 - Username is extracted from the registered client's Common Name specified during client's registration.
 - The inclusion of the authentication request in KMIP request is mandatory.
 - The Username in the authentication request must match with the registered client's Common Name specified during client's registration.

Tip

The interface mode can be changed using the API or the CLI "ksctl interfaces modify" command.

KMIP Interface mode mapping

Following table provides a mapping between the KMIP interfaces mode from SafeNet KeySecure Classic and CipherTrust Manager.

Safenet KeySecure Classic	CipherTrust Manager
Password authentication: Not Used Client cert authentication: SSL only	tls-pw-opt TLS, allow anonymous logins, verify client cert
Password authentication: Optional Client cert authentication: SSL only	tls-pw-opt TLS, allow anonymous logins, verify client cert
Password authentication: Required Client cert authentication: SSL only	tls-pw-req
Password authentication: Not Used Client cert authentication: SSL with CN	tls-cert-pw-opt Verify client cert, user name taken from client cert, auth request is optional
Password authentication: Optional Client cert authentication: SSL with CN	tls-cert-pw-opt Verify client cert, user name taken from client cert, auth request is optional
Password authentication: Required Client cert authentication: SSL with CN	tls-cert-and-pw Verify client cert, password is needed, user name in cert must match user name in authentication request

Managing KMIP Interface

You can add, remove, or modify KMIP interfaces.

To create a new KMIP interface:

Example

```
ksctl interfaces create -o 5697 -y kmip
```

Response

```
{
  "id": "90b3b131-d6d8-4985-abdd-539162c136c3",
  "name": "kmip_all_5697",
  "mode": "tls-cert-pw-opt",
  "cert_user_field": "CN",
  "auto_gen_ca_id": "kylo:kylo:naboo:localca:c729ffe0-f6ad-49ad-8558-2db435b112c7",
}
```

```

    "trusted_cas": {
      "local": [
        "kylo:kylo:naboo:localca:c729ffe0-f6ad-49ad-8558-2db435b112c7"
      ]
    },
    "createdAt": "2019-08-22T10:10:28.05794Z",
    "updatedAt": "2019-08-22T10:10:28.05794Z",
    "default_connection": "local_account",
    "port": 5697,
    "network_interface": "all",
    "interface_type": "kmip"
  }

```

Note

Interface can only be created in Root domain. To use interfaces in other domains, add the domain certificate to the Local Trusted CA of the domain.

Adding domain CA to the interface as external CA

To add domain CA to the interface as external CA:

1. Log on to the CipherTrust Manager GUI.
2. [Switch](#) to the desired domain.

Tip

To create a new domain, click [here](#).

3. Navigate to **CA > Local**. The list of available CAs is displayed.
4. Click the ellipsis icon corresponding to the CA.
5. Click **Copy/Download** the local CA.
6. Switch to **Root** domain.
7. Navigate to **CA > External**.
8. Click **Add External CA**. The Add External Certificate screen appears.
9. Provide **Display name**.
10. Either upload or paste the **Certificate** that you copied/downloaded in the step 5.

11. Click **Add External CA**. The newly created external CA appears on the External Certificate Authorities page.
12. Navigate to **Admin Settings > Interfaces**.
13. Click **kmip** and select the external CA created in step 11 from the **External Trusted CAs** drop-down list.
14. Click **Update**.

To modify TLS version of an interface:

```
ksctl interfaces modify -n <interface name> -e <minimum tls version>
```

Here:

- `<interface name>` is KMIP interface name.
- `<minimum tls version>` can be `tls_1_0`, `tls_1_1`, or `tls_1_2`. `tls_1_1` and `tls_1_0` are deprecated and will be discontinued in a future release.

Example

```
ksctl interfaces modify -n kmip_all_5697 -e tls_1_2
```

Response

```
{
  "id": "6199c8d1-f59a-4bd1-8dfd-cf4d43900264",
  "name": "kmip_all_5697",
  "mode": "tls-cert-and-pw",
  "cert_user_field": "CN",
  "auto_gen_ca_id": "kylo:kylo:naboo:localca:afdebde8-a5ff-4cbd-9bb2-6dc5186e4c03",
  "trusted_cas": {
    "local": [
      "kylo:kylo:naboo:localca:0a4bf97b-1294-41d2-93cd-d19e6290cfa3",
      "kylo:kylo:naboo:localca:b7860db1-b7d1-4163-996e-22b14090d55a",
      "kylo:kylo:naboo:localca:afdebde8-a5ff-4cbd-9bb2-6dc5186e4c03"
    ]
  },
  "createdAt": "2019-08-28T05:21:05.36768Z",
  "updatedAt": "2019-08-28T07:41:38.62511Z",
  "default_connection": "local_account",
  "port": 5697,
  "network_interface": "all",
  "interface_type": "kmip",
  "kmip_enable_hard_delete": 0,
  "minimum_tls_version": "tls_1_2"
}
```

Viewing and Setting Log Level

You can view or change the log level of KMIP service using the "ksctl" CLI tool.

There are two subcommands in the logs command:

- `get level`: used for viewing the current log level of a service
- `set level`: used for setting log level of a service

Using getlevel

To view the current log level for KMIP service, use the following request in CLI:

Request

```
ksctl logs getlevel --service kmip
```

Response

```
{
  "level": "INF",
  "service": "kmip"
}
```

Using setlevel

Note

Debug-level logging can generate a significant amount of detailed information that can impact the application's performance. Therefore, it is recommended **not to** configure the log level to "debug" mode.

To set current log level to debug for KMIP service, use the following request in CLI:

Request

```
ksctl logs setlevel --service kmip --level debug
```

Response

```
{
  "level": "DBG",
  "service": "kmip"
}
```

Supported levels are:

- `error` or `ERR`
- `info` or `INF`

- `debug` or `DBG`

Note

- To view the logs, go to `/opt/keysecure/logs` directory on appliance.
- To download the logs, use `ksctl logs download` command.
- Only users with administrator privileges can change or set the log level.
- When the log level is set to `debug`, sensitive data from `debug` logs is masked. To unmask the sensitive data, contact **Customer Support**.

Note

Any `ssl` connection related error message can be filtered from the log file based on `ERR` and `tls` tags.

Executive Summary

Today, every IT organization is striving to protect valuable digital assets of any enterprise from accidental exposure or intentional misuse by cyber criminals. Many organizations have deployed a variety of point encryption solutions as a primary method of protecting sensitive data to meet various digital privacy regulations and compliance mandates. Unfortunately, the majority of these disparate encryption solutions have fallen short in their ability to address their enterprise key management challenges.

This white paper looks back at the evolution of encryption and key management systems, and examines the key challenges faced by IT teams around encryption systems, including regulation and compliance, complexity, lack of proper management tools. This is followed by a review of the recent industry initiatives and compliance regulations that are shaping the future of key management.

The paper concludes with an introduction to CipherTrust Manager, the next generation enterprise key management offering from Thales, which provides a powerful integrated solution that enables organizations to centrally manage encryption key lifecycle and policies for Thales Data Protection Connectors and third-party KMIP compliant products in the enterprise.

Data Security Challenges

Many organizations are adopting digital transformation and migrating to the cloud to drive operational efficiency into their data-intensive processes. According to the 2020 Thales Data Threat Report, which is based on a global-IDC survey of 1,723 executives who have responsibility or influence over IT and data security, we are at an inflection point with the cloud as half of all data is now stored in cloud environments, and 48% of that data is sensitive. Additionally, most organizations rely on multi-cloud environments to deploy their applications, in order to avoid vendor lock-in.

Data migration to third-party hosted environments and multiple cloud service providers is creating new attack surfaces for cybercriminals to exploit. Hence, data breaches continue to threaten the IT landscape at an increasing rate. All of this adds up to today's data environments becoming even more complex; operation complexity is a top barrier to data security.

" We are at an inflection point with the cloud as half of all data is now stored in cloud environments, and 48% of that data is sensitive."

– 2020 Thales Data Threat Report, IDC Survey

Looking Back at Encryption and Key Management Techniques

The Internet has been the most significant driving force in the evolution of encryption and key management technologies. Providing easy access to a company's data to those who need it- employees, partners, and customers has taken priority, with data security being implemented as an afterthought. This connection of public and private resources over the internet to any company's sensitive data has given rise to the increase in data breaches.

In response, a variety of perimeter and endpoint security controls and security policies have been adopted to defend against these threats. In addition, data privacy regulations and a myriad of compliance requirements have been developed to battle these forces. However, they are not enough to stop cyber theft.

As attacks become more sophisticated, the industry has been improving these early encryption systems, eliminating the difficulties of disparate native key repositories that were then scattered across the various information systems in the enterprise.

Data Encryption Across Disparate Systems – Security Silos

The increased adoption of encryption solutions has improved security for enterprises, but it has made life much more challenging for the IT security team, now tasked with managing a variety of cryptographic keys. Nearly all offline data storage devices and many database management systems (DBMS) include the option of embedded native encryption capability. A challenge with these islands of encryption is that keys and key management software from each provider don't usually interoperate well with one another.

The resulting silos of security, where system administrators and database administrators (DBAs) have to become the managers of the encryption keys for a particular system, distracts them from their primary tasks of IT and database administration. Along with the resource inefficiency of such a methodology, it also puts an enterprise's overall security posture at risk.

Figure 1: 2020 IDC Data Security Survey - Most Critical Assets that Require Protection

According to the 2020 IDC Data Security Survey (shown in Figure 1), both IT and IT Security practitioners rated Secrets, Encryption Keys and Passwords as the most critical assets that requires protection.

The Business Problem - Too Many Silos

Without a centralized encryption key management solution, security administrators are faced with a costly, inefficient and often impossible task managing disparate encryption keys for many different databases accumulated over time from separate vendors. This heterogeneous world means that an enterprise looking to secure databases, such as Oracle and Microsoft SQL Server using native TDE, has to factor in the increased costs and administrative resources required for managing multiple, incompatible encryption solutions. It is costly and complex to manage separate encryption systems required for each data store, without consistent security policies, repeatable processes and error prone, as shown in Figure 2 below.

When each system administrator separately controls encryption keys for each data repository they manage, the keys are generally stored in the same location as encrypted data, it leaves room for security compromises – the electronic equivalent of taping the key to the front door. Manual systems to store and transmit the encryption keys, lack of password control and the failure to revoke keys when an employee leaves the company can result in data breaches waiting to happen. And strict adherence to compliance requirements is nearly impossible in this situation.

Figure 2: Costly and Complex to Manage Too Many Silos

Essentials of Enterprise Key Management

As organizations deploy an ever-increasing number of encryption solutions, they should look for a centralized key management solution that enables them to securely store and backup/restore the encryption keys, define consistent access control policies, audit all key management operations and separate encryption tasks from key management tasks.

Here are the essential elements of a robust enterprise key management solution that can help address the challenges listed in the previous section.

Secure Key Storage

Secure key storage is the foundation for any enterprise key management system. The use of Hardware Security Modules (HSMs) is a well-established approach for protecting encryption keys. Mandated in government and certain financial/payment markets HSMs protect cryptographic keys and perform various cryptographic functions in a secure tamper-resistant environment. Enterprise key management solutions should provide options to support built-in HSMs, external network attached HSM or a cloud-based HSM-as-a-service, based on the level of assurance your company needs

Centralized Key Lifecycle Management

The key management system should be able to centrally manage keys across their entire lifecycle, including secure key generation, backup/restore, clustering, deactivation, and deletion. It should also provide policy-based access control to keys, support various authentication providers including Active Directory and LDAP, and robust auditing of all key management operations.

Enabling Scalability and Flexibility

As the complexity of an organization's IT infrastructure grows from a single data-center to external hosted environments to multiple cloud service providers, so should the ability of enterprise key management solution to adopt to changing requirements.

A flexible key management solution should be able to support both on-premises infrastructure and be deployable as a virtual appliance in public cloud environments, wherever your sensitive data resides, such as AWS, Azure, Google Cloud and more.

Guaranteed Availability

Organizations cannot function without the availability of business critical data, which is most likely encrypted to reduce business risks due to unauthorized exposure. The key management system should support high-availability clustering options, using two or more physical and/or virtual appliances to reduce security lapses.

Interoperability with Third-party Systems

Any enterprise key management solution should support the following three major interoperability standards that enable you to work with multiple server, storage and device vendors, who utilize the keys for authentication, digitally signing or encrypting data.

- **PKCS#11** – Public Key Cryptographic Standard #11 specifies an API for devices to interoperate with hardware security modules (HSM) and smart cards, which hold cryptographic tokens. It is also used to access signing keys from Certification Authorities (CAs) or to enroll user certificates for digital signing and encryption using asymmetric keys. As an example, PKCS#11 is used by Oracle TDE.
- **EKM/MSCAPI** – Extensible Key Management (EKM) using the Microsoft Cryptographic APIs (MSCAPI), enables MS SQL Server to communicate with third-party key management servers. The keys must be exported from a provider before they are stored in the database. This approach enables key management that includes an encryption key hierarchy and key backup for Microsoft SQL Server Transparent Data Encryption.
- **OASIS KMIP** – Key Management Interoperability Protocol (KMIP), maintained by the Organization for Advancing Open Standards for the Information Society (OASIS), defines the standard protocol for any key management server to communicate with clients (e.g. storage devices, databases) that utilize the keys for embedded encryption. KMIP improves interoperability for key lifecycle management between encryption systems and enterprise applications.

Facilitate Governance and Reporting

The most important aspect of governance is a discipline for managing, controlling, and protecting the security and privacy of data. A policy-driven key management system forces the adherence to procedures for separation of duties and user authorization, and it automates all the security processes involved in the key lifecycle. Some of the more notable industry standards and compliance requirements affecting key management today include:

- **General Data Protection Regulations (GDPR)**

Perhaps the most comprehensive data privacy standard to date, GDPR affects any organization that processes the personal data of EU citizens - regardless of where the organization is headquartered. GDPR is designed to improve personal data protections and increase organizational accountability for data breaches. With potential fines of up to four percent of global revenues or 20 million EUR (whichever is higher), the regulation has impact on many businesses.

- **UIDAI's Aadhaar Number Regulation Compliance**

Unique Identification Authority of India (UIDAI) was established under the provisions of India's 2016 Aadhaar Act. UIDAI is responsible for issuing unique identification numbers (UIDs), called Aadhaar, and providing Aadhaar cards to all residents of India. The 12-digit UIDs are generated after the UIDAI verifies the uniqueness of enrollees' demographic and biometric information; UIDAI must protect individuals' identity information and authentication records.

- **Payment Card Industry Data Security Standard (PCI DSS)**

Any organization that plays a role in processing credit and debit card payments must comply with the strict PCI DSS compliance requirements for the processing, storage and transmission of account data. The PCI DSS standard involves assessment against over 200 tests that fall into 12 general security areas representing six core principles. These PCI DSS tests span a wide variety of common security practices along with technologies such as encryption, key management, and other data protection techniques.

- **Gramm Leach Bliley Act (GLBA)**

The United States requires that firms acknowledge publicly when a disclosure event occurs, taking whatever damages to their reputation or market position that such a statement would entail. Led by California's Database Security Breach Notification Act in 2003, more than half of all states have passed additional rules beyond the general notification requirements of GLBA to require firms to notify disclosure victims of the event, with higher associated costs to the business than GLBA exacted.

- **The U.S. Health Information Technology for Economic and Clinical Health (HITECH) Act**

HITECH does not require breach notification if the Protected Health Information (PHI) being exposed in the event of a data breach is already encrypted. For "unsecured PHI data", notification of the breach to every individual affected must be made. With the increasing cost of recovering from a data breach, it is important to invest in a strong encryption strategy for PHI data, and centralized key management system as its underpinning.

Introducing CipherTrust Manager

The Foundation of Thales Key Management Solutions

CipherTrust Manager enables organizations to centrally manage encryption key lifecycles and policies, independent of where the data resides, and help them meet their data privacy and compliance requirements. It simplifies key lifecycle management tasks, including secure key generation, backup/restore, clustering, deactivation, and deletion. It provides role-based access control to keys and policies, multi-tenancy support with ultimate separation of duties, and robust auditing and reporting of all key management operations.

The unified management console in CipherTrust Manager makes it easy to discover and classify data, and protect sensitive data using a comprehensive set of data protection connectors from Thales.

Figure 3: CipherTrust Manager

Key Benefits

Simplified Management

CipherTrust Manager provides a unified management console that enables you to discover and classify sensitive data, and protect data using integrated set of Thales Data Protection connectors across on-premises data stores and multi-cloud deployments. It offers advanced self-service licensing for improved visibility and control of licenses.

Cloud Friendly Deployment

CipherTrust Manager offers users with additional hosting options, and can run as a native virtual machine on AWS, Microsoft Azure, Google Cloud, VMware, Microsoft HyperV, and more. Additionally, native support for CipherTrust Cloud Key Manager is available on CipherTrust Manager, to streamline key management across multiple cloud infrastructures and SaaS applications.

Flexible Form Factors

CipherTrust Manager is available in both virtual and physical form factors and FIPS 140-2 levels. Flexible deployment options can easily scale to provide key management at remote facilities or in cloud infrastructures.

Thales Enterprise Key Management Solutions

Thales Enterprise Key Management solutions are built on CipherTrust Manager. They deliver a robust, standards-based platform for managing encryption keys from disparate sources across the enterprise. It simplifies the administrative challenges around encryption key management to ensure that keys are secure and always provisioned to authorized encryption services.

Figure 4: CipherTrust Enterprise Key Management Solutions

CipherTrust Enterprise Key Management solutions enable organizations to centrally manage and store cryptographic keys and policies for the following third-party products as shown in Figure 4. The following three elements comprise the CipherTrust Enterprise Key Management solution.

- **KMIP Server:** provides a simple interface to the key management functions on the CipherTrust Manager, delivering powerful, centralized key management capabilities for KMIP-compliant applications/systems such as SAN and NAS storage arrays, self-encrypting drives, and hyper-converged infrastructure solutions.
- **TDE Key Agents:** CipherTrust Manager centralizes and simplifies key management across Oracle TDE and Microsoft SQL Server TDE using TDE Key Agents, and keeps the TDE keys separate from your database servers.
- **LUKS Key Agent:** Linux Unified Key Setup (LUKS) provides transparent disk encryption for Linux. The LUKS Key Agents enables you to centrally manage encryption keys for Linux disk partitions.

In addition, CipherTrust Manager integrates with CipherTrust Cloud Key Manager to manage keys for multi-cloud environments, such as AWS, Azure, Salesforce and more.

Thales Hardware Security Module Solutions

Thales offers a variety of hardware security modules (HSMs), which are the highest performing, most secure and easiest to integrate in the market today. They act as trust anchors to protect the master keys that encrypt your data and digital identities in a high assurance FIPS 140-2 Level 3-certified, tamper-resistant appliance. Thales offers the following types of purpose-built HSMs:

- General Purpose HSMs: Luna HSMs come in several form-factors — a network attached appliance, an embedded PCI module, and a portable USB appliance. They can be easily integrated with a wide-range of applications to accelerate general cryptographic operations. The CipherTrust Manager model k570, includes a built-in Luna HSM card.
- Cloud HSMs: Data Protection On Demand (DPoD) is a cloud-based platform that provides a wide range of Cloud HSM and key management services through a simple on-line marketplace.

Summary

Data is only as secure as the system that manages the encryption keys protecting that data. A centralized enterprise key management solution is critical to ensuring all sensitive enterprise data is secure and available. CipherTrust Key Management from Thales help organizations maximize IT efficiency through a centralized, extensible platform based solution, and support the burdens of encryption key management across the enterprise and into the cloud – without disrupting existing application or database environments.

About Thales

The people you rely on to protect your privacy rely on Thales to protect their data. When it comes to data security, organizations are faced with an increasing number of decisive moments. Whether the moment is building an encryption strategy, moving to the cloud, or meeting compliance mandates, you can rely on Thales to secure your digital transformation.

Decisive technology for decisive moments.

Enterprise Key Management for Storage Infrastructure

Security conscious organizations are adopting Key Management Interoperability Protocol (KMIP) compliant integrations of their existing storage infrastructure with Enterprise Key Management (EKM) systems. KMIP simplifies the requirement of separating keys from encrypted data, and allows those keys to be centrally managed with a common set of policies from a corporate perspective. Thales offers CipherTrust Manager as the central enterprise key management solution for an expansive ecosystem of storage and archive infrastructure vendors.

Overview

Encryption is fundamental to any defense-in-depth strategy whether the goal is compliance or securing sensitive data. Purpose built or software defined storage solutions are an effective way to deploy encryption (using either self encrypting drives or controller based) in large-scale storage environments. However, as the number of drives or storage end points increase, so does the complexity with increasing number of encryption keys, key stores, and access policies needing management. To cost-effectively support such an environment and bring it into regulatory compliance, enterprise key management must be part of a secure solution.

Solution

Thales' CipherTrust Manager integrates with a multitude of storage products to provide robust, enterprise-scale key management, ensuring that access keys are managed throughout their lifecycle and properly secured with FIPS 140-2 certified internal or external Hardware Security Module (HSM). CipherTrust Manager is also available as a virtual appliance providing organizations with a scalable less expensive alternative to using a physical appliance.

CipherTrust Manager Integrates with Various Storage Solutions

CipherTrust Manager is pre-integrated with a variety of storage and archive solutions via the Key Management Interoperability Protocol (KMIP) to centrally manage key life-cycle for encrypting/decrypting data. Consolidating the policy and key management of servers, databases, and file storage streamlines security administration. Centralized key management improves security by making key creation, rotation, and deletion easier, while also separating duties so that no single administrator is responsible for the entire environment. Additionally, unifying and centralizing policy management, logging, and auditing makes information more readily accessible which, in turn, makes demonstrating compliance with data governance requirements simple.

Virtual CipherTrust Manager allows organizations to utilize a secure virtual appliance to centrally manage encryption keys and enforce access control across cloud infrastructures. It also ensures that organizations maintain ownership of their encryption keys at all times by hardening the appliance OS and encrypting the entire virtual appliance for enhanced key security and protection against snapshot attacks. CipherTrust Manager provides scalable key management and secure encryption at remote facilities or cloud infrastructures.

Summary of Benefits:

Thales' CipherTrust Manager provides customers with complete control by securing the keys needed to access the storage system. Together, Thales and their storage partners offer a secure and efficient means of protecting data at rest with encryption, and help customers meet data security compliance mandates such as FIPS 140-2, PCIDSS, HIPAA, and GDPR.

Centralized Management of Access Keys

Centralize and simplify key life-cycle management (e.g. key generation, rotation, etc.) for various storage platforms and KMIP-compatible encryption solutions, while improving compliance and auditability.

High-Availability Configurations

Cluster multiple CipherTrust Manager appliances to maintain encrypted data availability, even in geographically dispersed data centers.

Hardware or Software Appliance

CipherTrust Manager is available in both physical and virtual form factors. By utilizing CipherTrust Manager, organizations benefit from its flexible options for secure and centralized key management – deployed in physical, virtualized infrastructure, and public cloud environments.

Separation of Duties

CipherTrust Manager supports segmented key ownership and management based on individuals or group owners. This approach is perfect for dividing large enterprises into multiple administrative domains based on organizational structure.

Ecosystem Support

When there are dispersed data repositories with varying security concerns among lines of businesses consuming these repositories, CipherTrust Manager enables businesses to bring all these disparate efforts under one umbrella from a policy management viewpoint. The CipherTrust Manager EKM solutions including the KMIP technology standard help in providing a consistent interface to applications and appliances interfacing with the external key management system.

Conclusion—Secure the Breach

Encrypting data in the storage environment is critical to ensuring that data is safe in the event of a data breach. Thales has partnered with a number of storage vendors to offer organizations the ability to secure data through encryption without making the management of the necessary encryption keys and policies unwieldy or difficult.

About Thales

The people you rely on to protect your privacy rely on Thales to protect their data. When it comes to data security, organizations are faced with an increasing number of decisive moments. Whether the moment is building an encryption strategy, moving to the cloud, or meeting compliance mandates, you can rely on Thales to secure your digital transformation.

Decisive technology for decisive moments.

Encryption key management solutions for Microsoft® SQL Server® and Oracle® Database

Simplified and protected management for database encryption keys

- Streamlined operations through centralized key management
- Stronger security by separating keys from databases
- Comprehensive key security based on FIPS 140-2 compliant hardware and software solutions

Microsoft SQL and Oracle Database key management challenges

Microsoft SQL Server and Oracle Database solutions provide native transparent database encryption (TDE) that protects the data stored in their customers' enterprise and cloud-hosted databases. And, as with any encryption-based security scheme, securing and managing the encryption keys is critically important for robust data security.

Managing encryption keys presents challenges such as isolating them from the assets they protect and storing them securely—not only a best practice for key management, but a common industry data protection mandate. Encryption key management challenges multiply as organizations use multiple databases for different purposes, each requiring dedicated key management to ensure that keys are securely stored, backed up and available when needed.

Thales key management solutions for transparent database encryption

Thales key management solutions centralize key management for your enterprise and cloud-hosted Microsoft SQL Server and Oracle Database, giving you greater command over the keys while increasing your data security.

CipherTrust key management using the CipherTrust Manager

The CipherTrust Manager centrally manages keys for Microsoft SQL and Oracle TDE keys and Thales Data Protection portfolio.

Microsoft SQL Transparent Data Encryption

Thales key management solutions complement Microsoft native TDE by providing secure storage and management of the keys used in Microsoft's database encryption scheme. Microsoft TDE encrypts the sensitive data in the SQL database using a database encryption key (DEK), and Thales interfaces with Microsoft Extensible Key Management (EKM) to store and manage the DEKs in the FIPS 140-2 compliant CipherTrust Manager.

Oracle Database Transparent Data Encryption

The CipherTrust Manager complements Oracle Database native TDE by centrally storing and managing Oracle Database encryption keys. As a part of the Oracle Advanced Security TDE two-tier key architecture, Oracle Database uses master encryption key (MEKs) to encrypt the database encryption keys (DEKs), which are used to encrypt columns and tablespaces within the databases. Thales key management solutions interface with the Oracle Wallet to protect and manage these MEKs within a secure FIPS-certified boundary.

Enterprise and Cloud Support

Whether your database resides on-premises or in the cloud, Thales solutions provide secure and efficient management of your database encryption keys.

CipherTrust Manager: the foundation for Thales key management solutions

The CipherTrust Manager is a high-availability appliance that centralizes encryption key management for Oracle Database and Microsoft SQL Server TDE as well as a variety of additional Thales and third-party encryption solutions. CipherTrust Manager helps direct key life-cycle tasks including generation, rotation, destruction, import and export as well as provide abilities to manage certificates and secrets.

The CipherTrust Manager is available as either hardware or a virtual appliance:

Either appliance is hardened to ensure protection of its contents and prevents any modification to the underlying operating system. In addition, non-HSM enabled appliances can utilize an external HSM as a root of trust for better security as well as utilize its random number generator for better key entropy.

CipherTrust key management solutions

Centrally managing your keys independently from your database applications will help you streamline operations, fulfill compliance mandates and better protect your sensitive data. And as your needs expand, Thales solutions can grow with you. Below is a summary of key management offerings and related products.

- TDE key management
- Database encryption, file encryption, comprehensive data encryption
- KMIP-compliant applications
- Tokenization
- Cloud key management (CipherTrust Cloud Key Manager)
- Key management through APIs
- Key storage

Enterprise key management solutions

Challenges

Managing encryption keys as a centralized service is essential to the integrity of any enterprise encryption system. Many organizations operate multiple, independent encryption systems resulting in silos, which complicates key management and erodes security. Managing keys for these silos consumes time, resources and budget. It also risks compromising data, if keys are kept local to the encryption systems they protect.

Solution: Thales key management solutions

Thales CipherTrust key management products centralize key management for internal as well as commercial off the shelf (COTS) applications. This gives customers greater command over your keys while increasing encryption data security. Thales CipherTrust key management products connect with your applications through standard interfaces and deliver access to robust key management and encryption functions.

Highly secure and efficient centralized key management

- Streamlined operations through centralized key management
- Improved compliance by separating keys from applications
- Comprehensive key services delivered by dedicated, FIPS-compliant hardware and software solutions

CipherTrust Manager: the foundation for Thales key management solutions

CipherTrust Manager is a high-availability appliance that centralizes encryption key management for the Thales Data Security Portfolio and third-party encryption solutions. CipherTrust Manager helps direct key life-cycle tasks including generation, rotation, destruction, import and export as well as provide abilities to manage certificates and secrets.

CipherTrust Manager enhances key management by delivering strong separation of duties for increased security. Additionally, CipherTrust Manager offers multi-tenancy, or domains, allowing customers and service providers to generate unique key management environments. This provides additional security and ultimate separation of duties, where no single administrator has access to all domains.

CipherTrust Manager is available as either hardware or a virtual appliance. Either appliance is hardened to ensure protection of its contents and prevents any modification to the underlying operating system. In addition, non-HSM enabled appliances can utilize an external HSM as a root of trust for better security as well as utilize its random number generator for better key entropy.

Thales key management solutions

Thales key management solutions support a variety of applications, including:

Key Management Interoperability Protocol (KMIP)

KMIP is an industry-standard protocol for encryption key exchange between clients (appliances and applications) and a server (key store). Standardization facilitates external key management for storage solutions including SAN and NAS storage arrays, self-encrypting drives and hyper-converged infrastructure solutions. KMIP simplifies the requirement of separating keys from the data being encrypted, and allowing those keys to be managed with a common set of policies from a corporate perspective. CipherTrust Manager has already been certified with a number of 3rd party applications utilizing KMIP (as well as other API's).

Database and Linux Key Management

Thales centralized key management solutions for databases and Linux can provide high security while providing enhanced IT efficiency. For both Transparent Database Encryption (TDE) key management and Linux Unified Key Setup (LUKS), a Thales agent on the database or Linux server requests keys from CipherTrust Manager and serves them to TDE or LUKS.

Cloud Key Management using CipherTrust Cloud Key Manager

CipherTrust Cloud Key Manager delivers efficient, secure control over the full lifecycle of software as a service (SaaS) and infrastructure as a service (IaaS) encryption keys, including key creation, uploading, updating, storing, revocation and reporting. It is available as a service in the cloud and as an on-premises deployment using the CipherTrust Manager to securely manage keys.

CipherTrust Cloud Key Manager supported clouds include Microsoft Azure and Office 365, Amazon Web Services, Salesforce.com and IBM Cloud.

CipherTrust Key Management Solutions for Proprietary Applications

For the most convenient integrations into applications that perform encryption but require centralized, key management, the CipherTrust Manager offers PKCS#11, REST, and NAE-XML API's that can be leveraged by any application environment supporting these API's. In addition, for the most performance-sensitive applications, CipherTrust Manager provides application-layer libraries implementing Java, C, C++, .NET and .NET CORE that can be installed on supported application server environments.

About Thales

The people you rely on to protect your privacy rely on Thales to protect their data. When it comes to data security, organizations are faced with an increasing number of decisive moments. Whether the moment is building an encryption strategy, moving to the cloud, or meeting compliance mandates, you can rely on Thales to secure your digital transformation.

Decisive technology for decisive moments.

The Importance of KMIP Standard for
Centralized Key Management

How Thales Trusted Cyber Technologies Can Help

Executive Summary

Today, protecting sensitive data is a fundamental requirement in virtually every business. What's also nearly universal is this: operations and security teams continue to struggle with managing the proliferation of encryption keys that enable in protection of sensitive data.. The Key Management Interoperability Protocol (KMIP) was developed to enable more unified, efficient management of keys from multiple encryption technologies and vendors. This white paper offers a look at the KMIP standard, and it shows how Thales solutions help you maximize the advantages of this standard.

The promise of KMIP

Organizations deploy specific encryption solutions based on their unique use cases, technologies, businesses, security threats and more. To address all their requirements, organizations employ many different solutions from different vendors. Historically these different technologies lacked common standards for key management.

KMIP changed that. KMIP advances interoperability standards for enterprise encryption key management in order to help organizations centrally manage keys from a number of vendors. KMIP represents a comprehensive protocol for communication between a client and a server. In most scenarios, customers will need to integrate a KMIP Client with a KMIP Server. The KMIP Server within the Key Management System (KMS) provides life-cycle management of keys sent by the KMIP Client, as well as perform cryptographic operations whose results can be returned to the client.

The KMIP standard is governed by the Organization for the Advancement of Structured Information Standards, or OASIS, a nonprofit organization that promotes the development, convergence and adoption of open standards. The KMIP standard has been developed with the support of top security experts and leading vendors, including Thales. In fact, Thales was one of the four pioneering vendors responsible for original development of the protocol, and the company's representatives have served in leadership capacities on the OASIS KMIP technical committee since the standard's inception in 2007.

How Thales enables customers to capitalize on the KMIP Standard

With its advanced solutions, deep expertise and extensive partnerships, Thales is uniquely equipped to help organizations quickly, effectively and broadly harness the advantages of the KMIP standard. Through its support of KMIP and other standards, Thales solutions enable more efficient, centralized management of the entire data protection ecosystem.

Thales has a track record of successful KMIP integrations and deployments, and continues to work with technology partners and customers to expand its ecosystem. Our solutions have been proven in organizations with the most stringent security requirements, including financial services institutions, health care organizations, retailers and government agencies.

Solution: CipherTrust Manager

With the CipherTrust Manager from Thales, organizations can maximize the advantages of the KMIP standard. In addition, CipherTrust Manager delivers centralized controls that enable consistent and repeatable management of encryption keys, access policies and improved security intelligence.

CipherTrust Manager makes it easy and efficient to manage data-at-rest security across the entire organization by offering a diverse portfolio of encryption solutions to protect data wherever it resides in the organization.. As a result, security teams can address data security policies, compliance mandates and best practices, while reducing administration effort and total cost of ownership. CipherTrust Manager can be deployed with a physical HSM Root of Trust. Optionally, the virtual appliance can use an external HSM. Both solutions provide improved key security and entropy.

The CipherTrust Manager is uniquely equipped to enable organizations to centralize and streamline key management across an organization. Here's why:

- CipherTrust Manager enables security teams to manage keys and policies for a broad range of data protection solutions from Thales, which feature broad capabilities for protecting and controlling access to databases, files and containers—and securing assets residing in cloud, virtual, big data and physical environments.
- CipherTrust Manager can manage keys and policies for a number of third-party platforms, including Transparent Data Encryption (TDE) products from Microsoft, Oracle and IBM.
- CipherTrust Manager offers comprehensive support for the KMIP standard. Effectively, any device or client software that is KMIP-enabled can communicate with CipherTrust Manager to facilitate management of encryption keys. Examples of KMIP clients include management systems in hyperconverged environments (Nutanix), self-encrypting drives in storage systems (Netapp, Dell, IBM, HPE) and native encryption in next-generation databases and virtualized environments.

Figure 1: Thales CipherTrust Manager serves a variety of applications and client types using KMIP.

Figure 2. KMIP Client-Server Communications

1. Purchase and install KMIP Client licenses on CipherTrust Manager
2. Generate token to register each KMIP Client
3. Add token and restart KMIP service on CipherTrust Manager
4. Sign the KMIP Client Certificate Signing Request (CSR)
5. Upload CipherTrust Manager signed CSR to the KMIP Client

KMIP-based communications: How it works

Following is a high-level overview of how the process works:

- CipherTrust Manager needs to be prepared for KMIP support, which entails adding a KMIP client to the KMIP client list.
- A KMIP client is registered with the CipherTrust Manager
- Trust between the CipherTrust Manager and the KMIP client needs to be established. The KMIP protocol requires a mutually authenticated TLS connection between clients and servers. Once the client is registered with the CipherTrust Manager for secure communications, a certificate for the KMIP client will be created. This certificate will be used by the KMIP client for TLS authentication.

How Thales KMIP support benefits your organization

By leveraging Thales solutions, expertise and partnerships, organizations can realize a number of benefits:

- **Extend and maximize the value of your investments.** Thales support for KMIP allows organizations to more fully take advantage of their existing investments. CipherTrust Manager enables organizations to centrally manage the keys associated with their applications. As the encryption deployments grow, organizations can continue to employ CipherTrust Manager to manage keys for more technologies.
- **Streamline and enhance operations.** When organizations centralize key management on CipherTrust Manager, they can significantly simplify their operations. For example, administrators can centrally establish and enforce controls and policies for a number of systems. In addition, the solution enables centralized reporting for more effective and efficient compliance auditing, monitoring and reporting.
- **Enhance agility.** CipherTrust Manager helps organizations realize simplified operations and greater integration flexibility. As a result, the solution helps organizations adapt more quickly to evolving technologies and objectives. With the solution, organizations can more quickly and broadly leverage the advantages of innovative technologies like hyperconverged infrastructures and next-generation databases.

Technology support: featured KMIP partners and technologies

Today, many leading technology vendors offer encryption within their solutions, including hyperconverged infrastructures, databases, storage systems and more. This technology-centric encryption represents a vital line of defense. However, if keys are managed in a distributed, insecure fashion, it can erode or even eradicate any of the security benefits that can be gained through encryption.

That's why security experts and even the technology vendors themselves strongly recommend the use of purpose-built, centralized key management platforms, which is critically important for effectively safeguarding the keys generated by encryption. In fact, some vendors don't even allow the use of their encryption capabilities in production without the use of a third-party key management platform.

By leveraging CipherTrust Manager and the KMIP standard, customers can employ the encryption capabilities of their preferred technology vendors, while benefitting from a best-of-breed system for managing and securing keys. The CipherTrust Manager KMIP server enables seamless integration with a number of products across several categories. The sections below highlight some of the most important technologies that are currently supported.

Hyperconverged infrastructure

Hyperconverged infrastructures provide packaged, fully integrated technology stacks, including computing, storage, virtualization and networking. By leveraging these solutions, customers can significantly improve the efficiency of up-front deployment and ongoing administration, more quickly adapt to new business and technology requirements and more. The Thales KMIP server offers proven integration with a number of hyperconverged infrastructure technologies, including the following:

- **VMware vSAN and vSphere.** VMware vSAN powers leading hyperconverged infrastructure solutions. vSAN delivers secure, flash-optimized storage for workloads running on vSphere, VMware's virtualization platform. The vSAN solution delivers native encryption of flash devices. In addition vSphere offers encryption capabilities, securing the inputs and outputs from virtual machines before they get stored in disks. Customers can use CipherTrust Manager to manage keys generated by vSAN and vSphere encryption, enabling secure key management and strong role separation.

Storage

Enterprises rely on massive and rapidly growing storage infrastructures to manage data, and these repositories now invariably contain the organization's most sensitive, highly regulated assets. Encryption of these environments therefore represents a bedrock requirement. In response, many storage system vendors have added system-level encryption into their products. By leveraging CipherTrust Manager and the KMIP standard, customers can employ the encryption capabilities of their storage systems, while centralizing key management. Through its KMIP support, CipherTrust Manager enables seamless integration with a number of storage platforms, including the following:

- **NetApp ONTAP.** NetApp ONTAP enables administrators to assign, promote and retire storage resources without disrupting applications or business operations. ONTAP also unifies customers' control of their entire storage infrastructure, offering robust certificate-based authentication for access control and built-in encryption for data confidentiality. CipherTrust Manager and KMIP enables customers to consolidate key manager for ONTAP data encryption.

Next-generation data management

Database management systems very often house some of an organization's most sensitive data assets, and this is particularly true for next-generation database management platforms like MongoDB. Whether organizations are looking to comply with external regulations or internal policies, encryption of data at rest in these platforms is now an absolute mandate. Through its support for KMIP, CipherTrust Manager enables central, efficient and highly secure management of the keys generated by encryption in the following next-generation data management platforms:

- **MongoDB.** MongoDB is a NoSQL database that equips organizations with a number of significant advantages, including agility, scalability and high availability. In the MongoDB use case, the CipherTrust Manager provides high availability, standards-based enterprise encryption key management for MongoDB TDE using the KMIP standard, and offers vaulting and inventory of certificates. Consolidating enterprise encryption key management delivers consistent policy implementation between systems while reducing training and maintenance costs.

Conclusion

As enterprises expand the use of encryption to protect their sensitive data and assets, so grows the need to unify the management of encryption keys throughout their lifecycle. With the CipherTrust Manager from Thales, organizations can centrally manage keys and policies for Thales data protection solutions. Through its leading KMIP support, CipherTrust Manager can manage keys associated with encryption technologies in hyperconverged infrastructures, storage systems and next-generation data management platforms. As a result, organizations can address their most urgent security objectives, while significantly improving the efficiency of their operations.

About Thales Trusted Cyber Technologies

Thales Trusted Cyber Technologies, a business area of Thales Defense & Security, Inc., protects the most vital data from the core to the cloud to the field. We serve as a trusted, U.S. based source for cyber security solutions for the U.S. Federal Government. Our solutions enable agencies to deploy a holistic data protection ecosystem where data and cryptographic keys are secured and managed, and access and distribution are controlled. For more information, visit www.thalestct.com

THALES

CipherTrust Manager

KMIP REFERENCE GUIDE

Key Management Interoperability Protocol

The Key Management Interoperability Protocol (KMIP) is a communication protocol that facilitates key management and cryptographic operations on a key management server. This section provides additional user information and specifications applicable to the KMIP interface of CipherTrust Manager.

Setting up a KMIP Client

Here are the prerequisites for allowing KMIP clients to connect to CipherTrust Manager:

- > The CipherTrust Manager server's KMIP port 5696 should be open from the client.
- > The CipherTrust Manager server supports the following TLS versions:
 - TLS version 1.0
 - TLS version 1.1
 - TLS version 1.2 (default)

KMIP Parameter: `kmip_enable_hard_delete`

This optional parameter enables a hard delete of keys on a "KMIP Destroy" operation. This means that both meta-data and material are removed from CipherTrust Manager for the key being deleted. By default, only key material is removed and meta-data is preserved with the updated key state. This setting applies only to the KMIP interface. Should be set to '1' for enabling this feature or '0' for returning to the default behavior.

KMIP Licensing

The KMIP interface is active for a 90-day trial period after CipherTrust Manager is installed. After the trial period expires, a new purchased KMIP license must be installed to use the KMIP interface. Contact Gemalto Customer Support for assistance in obtaining a license.

To activate a license using the GUI

To install a KMIP license:

1. Log on to the CipherTrust Manager console as administrator.
2. Click **Admin Settings** to open the application.
3. Click **Licensing**, if needed. The **Server Licenses** section is displayed on the right.
4. Copy the **Connector Lock Code**. Every CipherTrust Manager appliance has a unique connector lock code. This lock code is needed to activate a license for the CipherTrust Manager.

NOTE In a CipherTrust Manager cluster, the connector lock code is applicable to all nodes of the cluster to enforce connector licenses across the cluster nodes. When a license is activated for one CipherTrust Manager appliance, the license is replicated on all the nodes of the cluster.

5. Activate the license.

When you purchase a CipherTrust Manager and connectors, you receive an email after the Purchase Order (PO) is processed. Accompanying this email is a PDF attachment that contains the Entitlement ID (EID). This ID is needed to activate your license.

To activate the KMIP license:

- a. Log on to the [Gemalto License Portal](#). Use your EID when logging on for the first time.
- b. Register your account, if not already done. After registration, you can find the details about your EID and your available licenses.
- c. On the **Entitlements** tab, select the KMIP license.
- d. Click **Activate**.
- e. In the **Quantity** field, specify the number of licenses to activate.
- f. In the **License Lock Code** field, paste the [Connector Lock Code](#) copied earlier.
- g. Click **Activate**.

NOTE

- > Based on the requirements, a KMIP license is activated and a license string is generated.
- > The license string generated for one CipherTrust Manager cannot be used on any other CipherTrust Manager.

- h. Copy the **License String**. This license string is needed to install the KMIP license on the CipherTrust Manager.
6. Return to the CipherTrust Manager console.
7. Under the **Add A New License** section, in the **License String** field, paste the copied [License String](#).
8. Click **Add**. The license is now installed. The license appears under the **Installed Licenses** section.

KMIP Client Registration

CipherTrust Manager recognizes only registered KMIP clients.

For registering a KMIP client, a certificate is required. The certificate facilitates authentication and communication between CipherTrust Manager and the client.

You can register KMIP clients using following methods:

1. Using Auto Registration (using an existing certificate)

Auto registration is useful when the clients are having certificates from the Classic KeySecure, or from older versions of CipherTrust Manager, or certificates issued by External CAs.

If you are already having one of the above certificate, you can utilize it to register your KMIP client, or to upgrade to a newer version of CipherTrust Manager. For detailed steps, see ["KMIP Client Registration for existing CipherTrust Manager and external CA\(s\)" below](#).

2. Generating a new certificate

You can create a new certificate using CipherTrust Manager, and use it to register a new KMIP client. For detailed steps, see ["To register a new KMIP Client" on page 6](#).

Specifying LDAP and Multi-Domain Client Usernames in KMIP Certificates

The connection and/or username can be specified in following formats:

> <username> - A local user in the root domain. For example, **joe**.

> <ldap-connection>|<username>

An LDAP user in the root domain. For example, **ldap-connection|joe**.

> <domain-id>|<ldap-connection>|<username>

An LDAP user in a specific domain. For example, **domain-id|ldap-connection|joe**.

> <domain-id>||<username>

A local user in a specific domain. For example, **domain-id||joe**.

When browsing the GUI, users can be identified from the source property. The user is displayed in either of the formats listed above. A local user is displayed as **local|<username>**.

KMIP Client Registration for existing CipherTrust Manager and external CA(s)

1. Create a registration token to register KMIP clients.

Request:

```
ksctl clientmgmt tokens create --configfile config_example.yaml
```

Response:

```
{
  "id": "dd8289f4-adbe-412f-9191-320bf2bac847",
  "uri": "kylo:kylo:munshi:tokens:dd8289f4-adbe-412f-9191-320bf2bac847",
  "account": "kylo:kylo:admin:accounts:kylo",
  "application": "ncryptify:gemalto:admin:apps:kylo",
  "devAccount": "ncryptify:gemalto:admin:accounts:gemalto",
  "createdAt": "2019-12-19T05:52:36.590956451Z",
  "updatedAt": "2019-12-19T05:52:36.590956451Z",
}
```

```

    "token": "RwIgd6RfXd7kzri12ydzoefXsA2R9ju2YDxMv2xM9duQbqAhcKcyMQO2OpqZesti",
    "valid_until": "0001-01-01T00:00:00Z",
    "max_clients": -1,
    "cert_duration": 730,
    "clients_registered": 0,
    "ca_id": "713172e0-02be-48c2-be60-6aae964ce943",
    "label": null
}

```

2. Update the KMIP Interface for which you want to allow Auto registration of KMIP clients. For auto registration, the client certificate which is to be registered should be signed by the trusted CA for the interface. To update the KMIP interface, run the `ksctl interfaces modify` command with the following parameters.

- `-a` (true | false) is for enabling or disabling auto registration
- `-r` is for providing registration token as input

If `-a` is set to true, then providing registration token in `-r` is mandatory

NOTE A new KMIP interface can also be created with the `-a` and `-r` parameters.

NOTE If the client is auto registered using the **tls-pw-opt** mode, then that certificate cannot be used to connect via the other two modes, **tls-cert-pw-opt** and **tls-cert-and-pw**.

Request to update interface with auto registration on:

```

ksctl interfaces modify -n kmip -a true -r
RwIgd6RfXd7kzri12ydzoefXsA2R9ju2YDxMv2xM9duQbqAhcKcyMQO2OpqZesti --configfile config_
example.yaml

```

Response:

```

{
  "id": "54523325-62d0-40d4-a45e-f45b9e1679e7",
  "name": "kmip",
  "mode": "tls-cert-pw-opt",
  "cert_user_field": "CN",
  "auto_gen_ca_id": "kylo:kylo:naboo:localca:713172e0-02be-48c2-be60-6aae964ce943",
  "trusted_cas":
    {
      "local": ["kylo:kylo:naboo:localca:713172e0-02be-48c2-be60-6aae964ce943"]
    },
  "createdAt": "2019-12-13T03:27:28.767622Z",
  "updatedAt": "2019-12-19T05:55:26.362558Z",
  "default_connection": "local_account",
  "port": 5696,
  "network_interface": "all",
  "interface_type": "kmip",
  "minimum_tls_version": "tls_1_2",
  "local_auto_gen_attributes":
    {
      "cn": "kmip.keysecure.local",
      "email_addresses": [
        "support@gemalto.com"
      ],
      "names": [
        {
          "C": "US",

```

```

    "ST": "MD",
    "L": "Belcamp",
    "O": "Gemalto",
    "OU": ""
  }
],
  "generated": false
},
"auto_registration": true,
"registration_token": "RwIgd6RfXd7kzril2ydzoefXsA2R9ju2YDxMv2xM9duQbqAhcKcyMQO2OpqZesti"
}

```

NOTE `cert_user_field` specifies how the user name is extracted from the client certificate. The default value is `CN`. This user must already exist. This parameter must be one of the following:

- **CN**: common name
- **OU**: organizational unit
- **SN**: surname
- **E**: Email address
- **UID**: User ID
- **E_ND**: Email without domain; the data to the left of the @ sign in the email address is taken as the user name

3. Connect to the KMIP interface using the client certificate you want to register. It will automatically register the KMIP client corresponding to that certificate.

NOTE If the client is mistakenly registered without a username, then you need to manually delete the registered client, before creating a new client. To delete a registered client, log into the console, navigate to **KMIP > Registered Clients**, and delete the client.

To register a new KMIP Client

1. Create a json file for specifying properties to create a KMIP Client Profile. A KMIP client profile contains a set of properties, on basis of which, the KMIP client gets registered. There are two ways to create a profile:

- Using `csr`
- Using `csr` parameter

A detailed explanation of input parameters is provided after the examples.

profile.json: This file is a user input to CLI for providing profile parameters.

NOTE `profile.json` is just a place holder for name of file, user can choose any name for this file.

Example 1:

```

{
  "cert_user_field": "CN",
  "csr": "-----BEGIN CERTIFICATE REQUEST-----\nMIIBCDChXGc6JazA==\n-----END\nCERTIFICATE REQUEST-----\n"
}

```

```
}
```

Example 2:

```
{
  "cert_user_field": "CN",
  "csr_cn": "user1",
  "csr_org_name": "Thales",
  "csr_org_unit": "Security",
  "csr_email": "abc@example.com",
  "csr_city": "Noida",
  "csr_state": "UP",
  "csr_country": "IN"
}
```

Parameter Explanation

- **cert_user_field**: Specifies how the user name is extracted from the client certificate. The default value is CN. This user must already exist. For more information, click [here](#).

NOTE After registering the new KMIP client, `cert_user_field` setting of profile is used instead of the setting present in the interface.

- **csr**: This is certificate signing request. The common name specified in CSR will be used to authenticate KMIP request.

NOTE If the user is not present, then profile registration will fail.

Other parameters

If CSR is not provided, then CipherTrust Manager creates CSR using below input parameters from `profile.json` :

- **csr_cn**: Common Name used to create CSR.
 - **csr_org_name**: Organization name to be used in CSR.
 - **csr_uid**: User ID used to create CSR.
 - **csr_org_unit**: Organizational unit to be used in CSR.
 - **csr_email**: Email address to be used in CSR.
 - **csr_city**: City name to be used in CSR.
 - **csr_state**: State name to be used in CSR.
 - **csr_country**: Country name to be used in CSR.
2. **(Optional Step)** Create a json file (for example, *device_cred.json*) for specifying device credential properties.

NOTE This step is optional and should be performed only when it is desired to authenticate the KMIP Client using device credentials.

Example 1:

All fields in the example are optional, however, at least one field must be specified for a successful authentication using device credentials.

```
{
  "serial_no": "12345",
  "password": "example_password_123",
  "device_id": "example_device_ID",
  "network_id": "sample_Network_ID",
  "machine_id": "MAC123456789",
  "media_id": "Media123456789"
}
```

Parameters

- **serial_no**: Serial number of the device, for example the hardware serial number of the device.
 - **password**: Password for the device.
 - **device_id**: Device Identifier of the device.
 - **network_id**: Network identifier of the device, for example the MAC address for Ethernet connected devices.
 - **machine_id**: Machine identifier of the device, for example the client aggregator identifier, such as a tape library aggregating tape drives.
 - **media_id**: Media identifier of the device, for example the volume identifier used for a tape cartridge.
3. Create the KMIP profile using the json file created in [step 1](#).

Request:

```
ksctl kmip createprofile -p kmipprofile1 -c profile.json --configfile config_example.yaml
```

NOTE If using [device credentials](#), use the following request instead:

```
ksctl kmip createprofile -p kmipprofile1 -c profile.json -d device_cred.json
--configfile config_example.yaml
Here device_cred.json is the device credential file created in previous step.
```

Response:

```
{
  "account": "kylo:kylo:admin:accounts:kylo",
  "application": "ncryptify:gemalto:admin:apps:kylo",
  "createdAt": "2019-12-18T10:19:32.745104774Z",
  "devAccount": "ncryptify:gemalto:admin:accounts:gemalto",
  "id": "70d92635-7e9f-4a9b-9161-d7f41b4e0109",
  "name": "kmipprofile1",
  "properties": {
    "csr_cn": "rajesh"
  },
  "updatedAt": "2019-12-18T10:19:32.745104774Z",
  "uri": "kylo:kylo:nae:kmip_profile:kmipprofile1"
}
```

4. Create a registration token using the profile created in the previous step.

Request:

```
ksctl kmip createkmipregtoken -p kmipprofile1 --configfile config_example.yaml
```

NOTE `profile_name` is required and must be present in the system before creating a registration token.

Response:

```
{
  "id": "6b8f5397-b738-4160-8c39-7979bae280aa",
  "uri": "kylo:kylo:munshi:tokens:6b8f5397-b738-4160-8c39-7979bae280aa",
  "account": "kylo:kylo:admin:accounts:kylo",
  "application": "ncryptify:gemalto:admin:apps:kylo",
  "devAccount": "ncryptify:gemalto:admin:accounts:gemalto",
  "createdAt": "2019-12-18T10:29:26.701363932Z",
  "updatedAt": "2019-12-18T10:29:26.701363932Z",
  "token": "LW0heyZNXHE9sEKmu7B0zVqnwHns42tahMVWJYUkP6I5CI67RQLS0EDkZ96UiocI",
  "valid_until": "0001-01-01T00:00:00Z",
  "max_clients": -1,
  "cert_duration": 730,
  "clients_registered": 0,
  "ca_id": "efeld302-7ff4-46ca-a2a4-c4d9236cc0f8",
  "label": {
    "KmiclientProfile": "kmipprofile1"
  }
}
```

5. Register the new KMIP client using the registration token generated in the previous step.

Request:

```
ksctl kmip register -n Kmiclient2 -t
LW0heyZNXHE9sEKmu7B0zVqnwHns42tahMVWJYUkP6I5CI67RQLS0EDkZ96UiocI --kmipCertOutFile
ClientCert.pem --kmipKeyOutFile ClientKey.pem --configfile config_example.yaml
```

Response:

```
{
  "cert": "-----BEGIN CERTIFICATE-----4xq+8sZ6PuwxePopPD2HwB+uxjLjdaKb01wz5AEk...-
N3e2ajOow/ZC2FxtkipCIyYdlTJ7P\n-----END CERTIFICATE-----\n",

PRIVATE KEY-----\n"
}
```

6. Use Client Certificate and Client Private Key to connect with the server.

Supported Objects, Operations, and Attributes

The following KMIP Objects Types, Attributes, and Operations supported on CipherTrust Manager are in accordance with KMIP Specification Version 1.4.

Supported Object Types

Symmetric Key	Public Key	Private Key
Secret Data	Opaque	

Supported Operations

Activate	Delete Attribute	Get Attributes List	Register
Add Attribute	Destroy	Locate	Re-key
Check	Discover Versions	MAC	Re-key Key Pair
Create	Encrypt	MACV	Revoke
Create Key Pair	Get	Modify Attribute	
Decrypt	Get Attributes	Query	

NOTE CipherTrust Manager supports Wrapping and Unwrapping of Keys for Get and Register operations. To read more, go to ["Wrap/Unwrap support in KMIP" on the next page](#)

Supported Attributes

Unique Identifier	Name	Object Type
Cryptographic Algorithm	Cryptographic Length	Cryptographic Parameters
Cryptographic Domain Parameters	Cryptographic Usage Mask	Usage Limits
State	Initial Date	Activation Date
Process Start Date	Protect Stop Date	Deactivation Date
Destroy Date	Compromise Occurrence Date	Compromise Date
Revocation Reason	Link	Application Specific Information
Contact Information	Last Change Date	Custom Attribute
Fresh Attribute	Alternate Name	Digest Attribute

NOTE For information on the above listed object Types, Operations, and Attributes, refer to the [OASIS KMIP Documentation](#).

NOTE Fresh Attribute, Custom Attribute, Application Specific Information, and Digest Attribute are stored in the Key Meta.

Example 1:

If a custom attribute (for example, `AttributeName : x-attribute1`, `AttributeValue: value1`) is added to the key `k1`, then the attribute is stored in Key Meta as:

```
{
  "kmip": {
    "custom": [
      {
        "type": "TextString",
        "x-attribute1": "Value1"
      }
    ],
    "ownerId": "local|261d8e87-73bb-4106-aa3d-06ed92e2f010",
    "permissions": {}
  }
}
```

Example 2:

If an application specific attribute (for example, `application_data": "data"`, `application_namespace": "Test"`) is added to a key, then the attribute is stored in Key Meta as:

```
{
  "kmip": {
    "app_specific_info": {
      "application_data": "data",
      "application_namespace": "TestASi"
    },
    "ownerId": "local|261d8e87-73bb-4106-aa3d-06ed92e2f010",
    "permissions": {}
  }
}
```

Wrap/Unwrap support in KMIP

Key wrapping is used for encrypting data keys. This provides an additional layer of security in protecting keys when they are at rest or are being transmitted over insecure networks. A variety of key wrapping algorithms can be used to encrypt the data keys. Similarly, unwrap mechanisms are used to decrypting the data keys.

CipherTrust Manager supports wrapping/unwrapping of keys under **Get** and **Register** operations.

NOTE Only *Symmetric* and *Private* keys can be wrapped/unwrapped in KMIP

Supported Wrapping Methods

- > Encrypt
- > MACSign

NOTE

- > For Encrypt Wrapping Method:
 - Only AES and RSA keys can be used to wrap the symmetric keys.
 - Only AES-256 keys can be used to wrap private keys.
- > For MACSign Wrapping Method:
 - Only HMAC keys can be used for MAC request.
 - Only RSA keys can be used for Sign request.

Encrypt Wrapping Method		
Symmetric Data Keys		Private Data Keys
Supported BlockCipher Modes for AES wrap keys	Supported padding methods for RSA wrap keys	Supported BlockCipher Mode for AES wrap keys
> NISTKeyWrap (RFC-3394) > AESKeyWrapPadding (RFC-5649)	> PKCS1V1_5 > OAEP Supported Hash Algorithms for OAEP padding method: • SHA_1 • SHA_256 • SHA_384 • SHA_512	> AESKeyWrapPadding (RFC-5649)

MACSign Wrapping Method for Symmetric and Private Keys		
MAC Request	Sign Request	
Supported HMAC algorithms for HMAC wrap keys	Supported padding methods for RSA wrap keys	Supported DigitalSignatureAlgorithms for RSA wrap keys
> HMAC_SHA_1 > HMAC_SHA_256 > HMAC_SHA_384 > HMAC_SHA_512	> PKCS1V1_5 (Default) > PSS Supported Hash Algorithms for above padding methods: • SHA_1 • SHA_256 • SHA_384 • SHA_512	> SHA_1WithRSAEncryption > SHA_256WithRSAEncryption > SHA_384WithRSAEncryption > SHA_512WithRSAEncryption

Supported Encodings

- > NoEncoding
- > TTLVEncoding

For more information, visit [OASIS Key Management Interoperability Protocol Documentation](#).

Cryptographic Operations for KMIP

Using KMIP interface, you can perform following cryptographic operations:

Operations	Algorithms	Modes	Padding
Encrypt/Decrypt	AES	> ECB (default) > CBC > GCM	> PKCS5 (default) > None
	TDES	> ECB (default) > CBC	> PKCS5 (default) > None
	RSA	not applicable	> PKCS1V1_5 (default) > OAEP
MAC/MACV	HMAC_SHA1	not applicable	not applicable
	HMAC_SHA256	not applicable	not applicable
	HMAC_SHA384	not applicable	not applicable
	HMAC_SHA512	not applicable	not applicable

KMIP Interface Mode

The "interface mode" configuration parameter specifies the KMIP Interface mode, and must be one of the following:

- > **tls-pw-opt**: TLS, allow anonymous logins.
 - Username is not extracted from the client certificate.
 - If authentication request is sent in KMIP request, Username will be the owner of the key.
 - If authentication request is not sent in KMIP request, the Key Owner will be the 'global' user.
- > **tls-cert-pw-opt**: TLS, user name taken from client cert, auth request is optional.
 - Username is extracted from the registered client's Common Name specified during client's registration.
 - If authentication request is sent in KMIP request, then the Username in the authentication request will be the owner of the key.
- > **tls-cert-and-pw**: TLS, password is needed, user name specified during client's registration must match user name in authentication request.
 - Username is extracted from the registered client's Common Name specified during client's registration.
 - The inclusion of the authentication request in KMIP request is mandatory.

- The Username in the authentication request must match with the registered client's Common Name specified during client's registration.

TIP The interface mode can be changed using the API or the CLI "ksctl interfaces modify" command.

KMIP Interface mode mapping

Following table provides a mapping between the KMIP interfaces mode from SafeNet KeySecure Classic and CipherTrust Manager.

Safenet KeySecure Classic	CipherTrust Manager
Password authentication: Not Used Client cert authentication: SSL only	tls-pw-opt TLS, allow anonymous logins, verify client cert
Password authentication: Optional Client cert authentication: SSL only	
Password authentication: Required Client cert authentication: SSL only	tls-pw-req
Password authentication: Not Used Client cert authentication: SSL with CN	tls-cert-pw-opt Verify client cert, user name taken from client cert, auth request is optional
Password authentication: Optional Client cert authentication: SSL with CN	
Password authentication: Required Client cert authentication: SSL with CN	tls-cert-and-pw Verify client cert, password is needed, user name in cert must match user name in authentication request

Managing KMIP Interface

You can add, remove, or modify KMIP interfaces.

To create a new KMIP interface:

Example:

```
$ ksctl interfaces create -o 5697 -y kmip
```

Response:

```
{
  "id": "90b3b131-d6d8-4985-abdd-539162c136c3",
  "name": "kmip_all_5697",
  "mode": "tls-cert-pw-opt",
  "cert_user_field": "CN",
  "auto_gen_ca_id": "kylo:kylo:naboo:localca:c729ffe0-f6ad-49ad-8558-2db435b112c7",
  "trusted_cas": {
    "local": [
      "kylo:kylo:naboo:localca:c729ffe0-f6ad-49ad-8558-2db435b112c7"
    ]
  }
}
```

```

    ],
    "createdAt": "2019-08-22T10:10:28.05794Z",
    "updatedAt": "2019-08-22T10:10:28.05794Z",
    "default_connection": "local_account",
    "port": 5697,
    "network_interface": "all",
    "interface_type": "kmip"
}

```

NOTE Interface can only be created in Root domain. To use interfaces in other domains, add the domain certificate to the Local Trusted CA of the domain.

To modify TLS version of an interface:

```
$ ksctl interfaces modify -n <interface name> -e <minimum tls version>
```

Here:

- <interface name> is KMIP interface name.
- <minimum tls version> can be `tls_1_0`, `tls_1_1`, or `tls_1_2`.

Example:

```
$ ksctl interfaces modify -n kmip_all_5697 -e tls_1_0
```

Response:

```

{
  "id": "6199c8d1-f59a-4bd1-8dfd-cf4d43900264",
  "name": "kmip_all_5697",
  "mode": "tls-cert-and-pw",
  "cert_user_field": "CN",
  "auto_gen_ca_id": "kylo:kylo:naboo:localca:afdebde8-a5ff-4cbd-9bb2-6dc5186e4c03",
  "trusted_cas": {
    "local": [
      "kylo:kylo:naboo:localca:0a4bf97b-1294-41d2-93cd-d19e6290cfa3",
      "kylo:kylo:naboo:localca:b7860db1-b7d1-4163-996e-22b14090d55a",
      "kylo:kylo:naboo:localca:afdebde8-a5ff-4cbd-9bb2-6dc5186e4c03"
    ]
  },
  "createdAt": "2019-08-28T05:21:05.36768Z",
  "updatedAt": "2019-08-28T07:41:38.62511Z",
  "default_connection": "local_account",
  "port": 5697,
  "network_interface": "all",
  "interface_type": "kmip",
  "kmip_enable_hard_delete": 0,
  "minimum_tls_version": "tls_1_0"
}

```

Viewing and setting log level

You can view or change the log level of KMIP service using the "ksctl" CLI tool.

There are two subcommands in the `logs` command:

- > `getlevel`: used for viewing the current log level of a service
- > `setlevel`: used for setting log level of a service

Using `getlevel`

To view the current log level for KMIP service, use the following request in CLI:

Request:

```
ksctl logs getlevel --service kmip
```

Response:

```
{
  "level": "INF",
  "service": "kmip"
}
```

Using `setlevel`

To set current log level to debug for KMIP service, use the following request in CLI:

Request:

```
ksctl logs setlevel --service kmip --level debug
```

Response:

```
{
  "level": "DBG",
  "service": "kmip"
}
```

Supported levels are:

- > `error` or `ERR`
- > `info` or `INF`
- > `debug` or `DBG`

NOTE

- > To view the logs, go to `/opt/keysecure/logs` directory on appliance.
- > To download the logs, use `ksctl logs download` command.
- > Only users with administrator privileges can change or set the log level.
- > When log level is set to debug, sensitive data from debug logs is masked.

Support Contacts

If you encounter a problem while installing, registering, or operating this product, please refer to the documentation before contacting support. If you cannot resolve the issue, contact your supplier or Thales Customer Support.

Thales Customer Support operates 24 hours a day, 7 days a week. Your level of access to this service is governed by the support plan arrangements made between Thales and your organization. Please consult this support plan for further information about your entitlements, including the hours when telephone support is available to you.

Customer Support Portal

The Customer Support Portal, at <https://supportportal.thalesgroup.com>, is where you can find solutions for most common problems. The Customer Support Portal is a comprehensive, fully searchable database of support resources, including:

- > Software and firmware downloads
- > Latest product documentation
- > Latest release notes listing known problems and workarounds
- > A knowledge base
- > FAQs
- > Technical notes, and more

You can also use the portal to create and manage support cases.

NOTE You require an account to access the Customer Support Portal. To create a new account, go to the portal and click on the **REGISTER** link.

Telephone Support

If you have an urgent problem, or cannot access the Customer Support Portal, you can contact Thales Customer Support by telephone at [+1 410-931-7520](tel:+14109317520). Additional local telephone support numbers are listed on the support portal.

Email Support

You can also contact technical support by email at technical.support.dis@thalesgroup.com.

Troubleshooting Issues in Conjunction with Customer Support

When making a support call, the CipherTrust Manager System Administrator (ksadmin) may be asked to log in using ssh to retrieve CipherTrust Manager Logs. CipherTrust Manager Logs are located in this directory:

`/opt/keysecure/logs`

NOTE Any ssl connection related error message can be filtered from the log file based on “ERR” and “tls” tags.

CipherTrust Integrations

4 February 2026

Contents

- Bitglass 3
 - Integration with CipherTrust Manager 3
 - Verifying Your Integration 12
 - Appendix. 13

Bitglass

Bitglass enterprise edition allows users to encrypt data at rest in cloud applications (for example, Salesforce, Box, and so on). Keys can be managed in the CipherTrust Manager or the users can add their own KMIP key store to utilize existing key management appliance/servers.

Data is encrypted using 256-bit derived keys which are encrypted by master keys stored in Key Vaults. Master Key is AES 256-bit symmetric key.

If a KMIP CipherTrust Manager becomes inaccessible, Bitglass cannot decrypt any data encrypted by master keys stored in the CipherTrust Manager. It is critical that external KMS infrastructure is deployed in a redundant high-availability architecture.

Supported Product Versions

Note

This integration has been validated in the field by a partner or in a customer environment with the following software versions. It is recommended to test the integration in a non-production environment with desired software versions before deploying it to production. Thales will provide best-effort support.

CipherTrust Manager

- CipherTrust Manager 2.0

Bitglass

- Bitglass

Integration with CipherTrust Manager

This section lists the steps to integrate Bitglass with CipherTrust Manager.

- [Prerequisites](#)
- [Configuration on CipherTrust Manager](#)
- [Configuration on Bitglass](#)

Prerequisites

This section provides the prerequisites for integration of Bitglass with CipherTrust Manager.

- Ensure that the CipherTrust Manager is installed and configured. For more details, refer to the [CipherTrust Manager Documentation](#).
- Bitglass communicates with the CipherTrust Manager using the KMIP interface. Ensure that the KMIP interface is configured on the CipherTrust Manager. Refer to [CipherTrust Manager Administration Guide](#) for details.
- **IP address** of the CipherTrust Manager and **port** of the KMIP interface must be accessible from the Bitglass system.
- CipherTrust Manager recognizes only registered KMIP clients. Ensure that each node of the Bitglass cluster is registered as a KMIP client on the CipherTrust Manager. Refer to [KMIP Client Registration](#) for more details.
- Ensure that Bitglass has proper license for data at Rest Encryption. To check the license information in Bitglass, navigate to **Settings > Software and Licenses > License Information**.
- Ensure that the required licenses are activated on CipherTrust Manager. For more details, refer to the [CipherTrust Manager documentation](#).

Configuration on CipherTrust Manager

To configure the CipherTrust Manager, you need to perform the following steps:

1. [Creating a User](#)
2. [Assigning User to a Group](#)
3. [Creating or Adding a CA \(optional\)](#)
4. [Registering a KMIP Client](#)
5. [Configuring the KMIP Interface](#)

Creating a User

To create a user, perform the following steps:

1. Log on to the CipherTrust Manager GUI.
2. Open the **Access Management** application.
3. On the left navigation pane, click **Users**. The Users page is displayed.
4. On the Users page, click **Add User**.
5. On the **Add User** page, provide the following details:

-
- Select the required **Connection Type**
 - Select the checkbox against the required **Allowed Client Type**.
 - Enter **Full Name**
 - Enter **Username**
 - Enter the desired **Password**. Re-enter the password in the **Password Match** field.

6. Click **Add User**. The newly created user will now appear on the **Users** page.

Assigning User to a Group

Perform the following steps to add user to a group:

1. Navigate to the **Users** page.
2. Click the ellipsis button (...) corresponding to the user that you created in the previous step.
3. Click **Edit/View**.
4. Click **Group Memberships > Add Group**.
5. In the search bar, enter the desired Group name and select the check box corresponding to it. For example, **Key Admins** or **Key Users**.
6. Click **Add Group**.

Creating or Adding a CA (Optional)

Note

Creating a CA is an optional step in this integration. However, it is recommended to select the CA carefully, as it will be used throughout the process.

Select the **Local CA** tab if you want to create a Local CA **OR** select the **External CA** tab if you wish to add the External CA.

Local CA

To create/add a Self-signed local CA, perform the following steps:

1. Navigate to **CA > Local**. Select **Add Local CA**, the **Add Local CA** page appears.
2. Provide the required information and click **Add Local CA**. The created Local CA will appear under **Pending CAs** section.

-
3. Click the ellipsis against the Local CA that you created and select the option **Self-sign**.
 4. Select a valid duration for the Local CA. Click **Save**.

External CA

To add an external CA, perform the following steps:

1. Navigate to **CA > External**. The **External Certificate Authorities** page appears. Select **Add External CA**, the **Add External Certificate** page appears.
2. Provide the required information.
3. If you want to upload the external CA, select the **File Upload** option and click **Upload Certificate**. Browse and select the required External CA.

OR

Select **Text** and paste the contents of External Certificate.

4. Click **Add External CA**.

Registering a KMIP Client

You can register a KMIP client on the CipherTrust Manager through:

- **Auto Registration**
- **Manual Registration**

Auto-Registration

1. Log on to the CipherTrust Manager.
2. Go to **Products > KMIP**.
3. Create Client Profile using the following steps:
 - a. Navigate to **Client Profile** and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Click **Save**. The new profile is created.
4. Create Registration Token using the following steps:
 - a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a **Name Prefix**.
 - c. Specify a Token Lifetime value along with the Client Capacity for the token.

-
- d. Click **Select CA**.
 - e. Select the CA type as Local/External depending on CA that you created [above](#).
 - f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
 - g. Select the Client Profile from the dropdown which you have created in the above step.
 - h. Click **Create Token**.
 - i. Copy the value of the Token created and click **Done**.

Note

If you are using External CA then you can select the external CA that you created and uploaded on the CipherTrust Manager.

5. Turn ON **Auto Registration** using the following steps:
 - a. Go to **Admin Settings > Interfaces**.
 - b. Click the ellipsis button (...) corresponding to the kmip interface.
 - c. Click **View/Edit**.
 - d. On the **Interface Detail** window, perform the following:
 - Select the Interface Mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
 - Select **Auto Registration** checkbox.
 - Paste the **Registration Token**.
 - Add the CA (Local or External) to the list of Trusted CAs. The CA will reflect under the dropdown menu of Local/External Trusted CAs depending upon CA that you created [above](#).
 - Click **Update**.

Manual Registration

1. Log on to the CipherTrust Manager.
2. Go to **Products > KMIP**.
3. Create Client Profile using the following steps:

-
- a. Go to **Client Profile** and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Select **CN** in **Username Location in Certificate**.
 - d. Click **Certificate Details**.
 - e. You can either paste the content of a generated `client.csr` or you can create one, by filling in the required details.
 - f. Click **Save**.
4. Create Registration Token using the following steps:
 - a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a **Name Prefix**.
 - c. Specify a Token Lifetime value along with the Client Capacity for the token.
 - d. Click **Select CA**.
 - e. Select the CA type as Local/External depending on the CA type that you created [above](#).
 - f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
 - g. Select the Client Profile from the dropdown which you have created in the above step.
 - h. Click **Create Token**.
 - i. Copy the value of the Token created and click **Done**.

Note

If you are using External CA then you can select the external CA that you created and uploaded on the CipherTrust Manager.

5. Go to **Registered Clients** and click **Add Client**.
 - Specify client name and paste the **Registration Token** that you generated in the above step.

Note

If you are using external CA then you can either upload the file using **Upload Certificate** option or select the **Text** option to paste the signed client certificate in the **Client Certificate** field.

- Click **Save** to save the **Client Certificate**.

Configuring the KMIP Interface

The KMIP interface can be configured through:

1. Go to **Admin Settings > Interfaces**.
2. On the KMIP Interface, click the ellipsis button (...) and then click **View/Edit**.
3. Select the **Auto Registration** checkbox if you auto-registered your KMIP client and paste the value of the registration token that you created.

Note

By default, the **Auto Registration** is disabled.

4. Select the mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
5. Specify selections for **Local CA for Automatic Server Certificate Generation** as desired.

Note

Local CA for Automatic Server Certificate Generation should be set to **Turn off auto generation from Local CA** in case of External CA.

6. Depending upon the CA that you created [above](#), select an option from the following:
 - If you are using **Local CA** then select the CA under **Local Trusted CAs**
 - If you are using **External CA** then select the CA under **External Trusted CAs** provided you have the external CA that you created and uploaded on the CipherTrust Manager. For more information on creating or uploading CA, refer to [Creating or Adding a CA](#).

Further, you need to configure the following:

1. Creating Key (using API Playground)
2. Update the Key Attributes

Creating Key (using API Playground)

1. At the top right corner of the main toolbar, click **API** to go to the API playground.
2. Click **Authenticate** on the top right corner. Specify username and password, then click **Post**.

Note

The session will be valid for 300 seconds. You can also authenticate later if you are unable to perform the following steps within this time frame.

3. Go to **Keys** section in the left sidebar. Click **Create - Post**.
4. Specify the following content in the body, and click **POST**. Specify a value equal to or less than 60 characters.

```
{
  "idSize": 60
}
```

Here **idSize:60** will be set to the **ID** of the key, which will be further used while configuring the policy file of the Bitglass.

Caution

Specifying a value greater than 60 leads to integration failure. To view the list of possible errors, go to the [Troubleshooting](#) section.

Updating the Key Attributes

1. In the CipherTrust Manager UI, go to **Keys** and click the Key you have created using API.
2. Ensure that **Exportable** option is checked.
3. Select the user [created above](#) as the **Key Owner**.
4. Click **Update**.

Configuration on Bitglass

- Creating a Key Store
- Creating a Key

Creating a Key Store

1. In the Bitglass UI, go to **Settings > Encryption**.
2. Click the Add (+) button and specify the following:
 - Connection name
 - IP Address of the CipherTrust Manager
 - Port of the CipherTrust Manager
 - Username of the CipherTrust Manager. For Example, bitglass
 - Password of the CipherTrust Manager
 - Upload the downloaded CA Certificate

3. Click **Create** to create a key store.

After performing the above steps, you can check the logs under the CipherTrust Manager. A new connection should be generated under logs.

Creating a Key

1. In the Bitglass UI, go to **Settings > Encryption**.
2. Click the Add (+) button and specify the name.

3. Select the Key Store that is created in the [Creating a Key Store](#) section from the Key Store dropdown.
4. Click **Create** to create a key vault.

After creating a key, use the following steps to perform the Rekey operation:

1. From the Key Vaults, choose the key that is created in the [Creating a Key](#) section.
2. Click **Generate New Key** and click **Continue**. A new key will be created.

The status of old key will be **Decrypt only** and the new key is **Active**.

On the CipherTrust Manager, both the keys (new key and old key) are active. Moreover, you can also check the new key in the logs of the CipherTrust Manager.

Verifying Your Integration

Perform the following steps to ensure the integration is successful:

1. Create a test file on any node and then copy it to **/fs0**. Consider that the user created a file **test.txt**, and then copied it to **/fs0**.

```
cp /tmp/test.txt /fs0
```

2. Verify that file is encrypted with the key present in the CipherTrust Manager, using the following commands:

```
[root@ss1 ~]# /usr/lpp/mmfs/bin/mmlsattr -n gpfs.Encryption /fs0/test.txt
```

```
[root@ss1 ~]# /usr/lpp/mmfs/bin/mmlsattr -n gpfs.Encryption /fs0/test.txt
file name:           /fs0/test.txt
gpfs.Encryption:      "EAGC????#???????????????? ?????"??,???????????????? ?6[?6?
?B??d??L??l?????????m??f?test.txt aaaaaaaaaacccccccccceeeeeerrrrrrff?client?"
EncPar 'AES:256:XTS:FEC:HMI
      type: wrapped FEK  wrpPar 'AES:KWRAP'  CmbPar 'XORHMACSHA512'
      aaaaaaaaaacccccccccceeeeeerrrrrrff:client
```

```
[root@ss1 ~]# /usr/lpp/mmfs/bin/mmlsattr -L /fs0/test.txt
```

```
[root@ssl ~]# /usr/lpp/mmfs/bin/mmfsattr -L gpfs.Encryption /fs0/test.txt
gpfs.Encryption: Stat failed: No such file or directory

file name:                /fs0/test.txt
metadata replication: 1 max 2
data replication:         1 max 2
immutable:                no
appendOnly:               no
flags:
storage pool name:        system
fileset name:              root
snapshot name:
creation time:             Wed May 20 07:03:46 2020
Misc attributes:          ARCHIVE
Encrypted:                 yes
[root@ssl ~]#
```

Since the Encryption flag is true (Encrypted: yes), the integration is successful.

Appendix

Troubleshooting

Issue	Error Message	Remediation
KMIP registration is not enabled	The following error message is displayed in CipherTrust Records: <i>"errorMessage": "Unregistered client, please register a new client from CLI or API or UI."</i>	Check whether the Autoregistration option is selected in Admin Settings > System > Interfaces > kmip . If it is not selected, turn on the Autoregistration option. Refer to the steps mentioned in Enable KMIP Client Registration .
User corresponding to username location in certificate (example: OU/UID) has not been created	The following error messages are displayed in CipherTrust Records: <i>"errorMessage": "username not found: "</i> <i>"errorMessage": "Could not authenticate certificate user, hence client is not auto registered in mode tls-cert-pw-opt"</i>	Check whether the user corresponding to UID/OU of the node certificates has been created in Keys & Access Management > Users . If the user is not created, create a new user with the same name as the OU/UID field of the node certificates. After creating the user, add this user to the Key Admins . Refer to steps mentioned in Create a New User .
User has not been added to Key Admin group	The following error message is displayed in CipherTrust Records: <i>"errorMessage": "authorization denied: verdict was deny: CreateKey"</i>	Check whether the user corresponding to UID/OU of the node certificates has been created under Keys & Access Management > Users . If the user is not added, add the user to the Key Admins group.

Issue	Error Message	Remediation
The Username location in Certificate has been set incorrectly	The following error messages are displayed in CipherTrust Records: <i>"errorMessage": "username not found: "</i> <i>"errorMessage": "Could not authenticate certificate user, hence client is not auto registered in mode tls-cert-pw-opt"</i>	Check whether the Username Location in the Certificate option is set correctly to OU/UID in Admin Settings > System > Interfaces > kmip . If it is not set correctly, set the correct value for the Username Location in the Certificate.

 - Appendix. 17

CipherTrust Manager Integration with MongoDB

MongoDB is a document database designed for the ease of development and scaling. The Enterprise Edition of MongoDB lets you encrypt data files such that only users with the decryption key can decode and read the data.

If encryption is enabled, MongoDB Enterprise uses the the AES256-CBC via OpenSSL as default encryption mode. AES-256 uses a symmetric key (same key to encrypt and decrypt the text). CipherTrust Manager can be integrated with MongoDB to act as an external Key Management Server.

Supported Product Versions

Note

The integration is performed and certified on **LTS release versions** of CipherTrust Manager only. Feature releases support the integration and are covered under technical support but will not be explicitly certified. To know more about CipherTrust Manager release versions, click [here](#).

CipherTrust Manager

- CipherTrust Manager 2.4 and higher

MongoDB Version

- MongoDB Enterprise 4.0 and higher

Integration of MongoDB

This section lists the steps to integrate MongoDB with CipherTrust Manager.

- [Prerequisites](#)

-
- [Configuration on CipherTrust Manager](#)
 - [Configuration on MongoDB](#)

Prerequisites

This section provides the prerequisites for integration of MongoDB with CipherTrust Manager.

- Ensure that the CipherTrust Manager is installed and configured. For more details, refer to the [CipherTrust Manager Documentation](#).
- MongoDB communicates with the CipherTrust Manager using the KMIP interface. Ensure that the KMIP interface is configured on the CipherTrust Manager.
- IP address of the CipherTrust Manager and port of the KMIP interface must be accessible from the MongoDB system.
- CipherTrust Manager recognizes only registered KMIP clients. Ensure that each node of the MongoDB cluster is registered as a KMIP client on the CipherTrust Manager. Refer to KMIP Client Registration for more details.

Configuration on CipherTrust Manager

To configure the CipherTrust Manager, you need to perform the following steps:

1. [Creating a Domain \(optional\)](#)
2. [Creating a User](#)
3. [Assigning User to a Group](#)
4. [Creating or Adding a CA \(optional\)](#)
5. [Registering a KMIP Client](#)
6. [Configuring the KMIP Interface](#)

Creating a Domain (Optional)

Perform the following steps to be performed on CipherTrust Manager:

1. Navigate to **Admin Settings > Domains**.
2. Click **Add Domain**. The **Add Domain** page appears.
3. Specify the following information:
 - **Name** - Enter the domain name.
 - **Admins** - Select the admins (one or more) from the list available in the drop down. For example, admin.

- **Parent CA** - Select parent CA as root CA.
- **Allow Subdomain User Management** - Select this check box if you want to enable the sub-domain user management through this domain.

4. Click **Save**.
5. Switch to the newly created domain by clicking the top right on the current Domain Name.

Creating a User

Root Domain

To create a user, perform the following steps:

1. Log on to the CipherTrust Manager GUI.
2. Open the **Keys & Access Management** application.
3. On the left pane, click **Users**. The Users page is displayed.
4. On the Users page, click **Create New User**.
5. On the Create a New User screen provide the following details:
 - Enter Username.
 - Enter Password.
6. Click **Create**. The newly created user is listed on the Users page.

Sub-Domain

Note

To create a user in sub-domain, you must enable **Allow Subdomain User management**.

To create a user, perform the following steps:

1. Log on to the CipherTrust Manager GUI with the User you created within the sub-domain.
2. Open the **Keys & Access Management** application.
3. On the left pane, click **Users**. The Users page is displayed.
4. On the Users page, click **Create New User**.
5. On the **Create a New User** screen provide the following details:

-
- Enter **Username**.
 - Enter **Password**.

6. Click **Create**. The newly created user is listed on the Users page.

Assigning User to a Group

Perform the following steps to add user to a group:

1. Click the ellipsis button (...) corresponding to the user that you created in the previous step.
2. Click **Edit**.
3. Click **Group Memberships > Add Group**.
4. In the search bar, type **Key Admins** and select the check box corresponding to it .
5. Click **Add Group**.

Creating or Adding a CA (Optional)

Local CA

To create/add a Self-signed local CA, perform the following steps:

1. Navigate to **CA > Local**. Select **Add Local CA**, the **Add Local CA** page appears.
2. Provide the required information and click **Add Local CA**. The created Local CA will appear under Pending CAs section.
3. Click the ellipsis against the Local CA that you created and select the option **Self-sign**.
4. Select a valid duration for the Local CA. Click **Save**.

External CA

To add an external CA, perform the following steps:

1. Navigate to **CA > External**. Select **Add External CA**, the **Add External Certificate** page appears.
2. Provide the required information.
3. If you want to upload the external CA, select the **File Upload** option and click **Upload Certificate**. Browse and select the required External CA.

OR

Select **Text** and paste the contents of External Certificate

4. Click **Add External CA**
-

Registering a KMIP Client

Root Domain

You can register a KMIP client on the CipherTrust Manager through:

- **Auto Registration**
- **Manual Registration**

Auto-Registration

1. Create a Registration Token using the following steps:
 - a. Log on to the CipherTrust Manager in root domain.
 - b. Go to **Access Management > Registration Tokens**.
 - c. Click **Create New Registration Token**.

Copy the **Registration Token** once it is created.

2. Turn ON **Auto Registration** using the following steps:
 - a. Go to **Admin Settings > Interfaces**.
 - b. Click the ellipsis button (...) corresponding to the kmip interface.
 - c. Click **Edit**.
 - d. Under **Configure KMIP** window, select **Auto Registration**.
 - e. Paste the **Registration Token**.
 - f. Select the mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
 - g. Click **Update**.

Manual Registration

1. Log on to the CipherTrust Manager.
2. Go to **Products > KMIP**.
3. Create Client Profile using the following steps:
 - a. Go to **Client Profile** and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Select **CN** in **Username Location in Certificate**.

-
- d. Click **Certificate Details**.
 - e. Paste the content of `client.csr`.
 - f. Click **Save**.
4. Create Registration Token using the following steps:
 - a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a Name Prefix.
 - c. Specify a Token Lifetime value along with the Client Capacity for the token.
 - d. Click **Select CA**.
 - e. Select the CA type as Local/External depending on what you are using.
 - f. Select the appropriate CA from the dropdown menu and click Select Profile.
 - g. Select the Client Profile from the dropdown which you have created in the above step.
 - h. Click **Create Token**.
 - i. Copy the value of the Token created and click **Done**.

Note

If you are using External CA then you can select the external CA which was created using openssl and uploaded on the CipherTrust Manager.

5. Go to **Registered Clients** and click **Add Client**.
 - Specify client name and paste the **Registration Token** generated in the above step.

Note

If you are using external CA then you need to paste the signed client certificate in the **Client Certificate** field.

- Click **Save** to save the **client certificate**.

Sub-Domain

You can register a KMIP client on the CipherTrust Manager through:

- **Auto Registration**
- **Manual Registration**

Auto-Registration

1. Create a Registration Token in the sub-domain using the following steps:
 - a. Log on to the CipherTrust Manager in your specified sub-domain.
 - b. Go to **Access Management > Registration Tokens**.
 - c. Click **Add Registration Token > Begin**.
 - d. Add a **Name Prefix**.
 - e. Specify a **Token Lifetime value** along with the **Client Capacity** for the token.
 - f. Copy the value of the Registration Token once it is created.
 - g. Switch to Root Domain.
2. Turn ON Auto Registration using the following steps:
 - a. Log on to the CipherTrust Manager in the root domain.
 - b. Go to **Admin Settings > Interfaces**.
 - c. Click the ellipsis button (...) corresponding to the kmip interface.
 - d. Click **Edit**.
 - e. Under **Configure KMIP** window, select **Auto Registration**.
 - f. Paste the **Registration Token**.
 - g. Select the mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
 - h. Click **Update**.

Manual Registration

1. Log on to the CipherTrust Manager into your domain.
 2. Go to **Products > KMIP**.
 3. Create **Client Profile** using the following steps:
-

-
- a. Go to Client Profile and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Select **CN** in Username Location in Certificate.
 - d. Expand the Certificate Details section.
 - e. You can either paste the content of a generated client.csr or you can create one, by filling in the details.

For domain, the format to enter the Common Name field of the cert is always: `<domain name> | | <Hostname/IP>`

- f. Click **Save**.
4. Create a Registration Token using the following steps:
 - a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a **Name Prefix**.
 - c. Specify a Token Lifetime value along with the Client Capacity for the token.
 - d. Click **Select CA**.
 - e. Select the CA type as **Local/External** depending on what you are using.
 - f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
 - g. Select the Client Profile from the dropdown which you have created in the above step.
 - h. Click **Create Token**.
 - i. Copy the value of the Token created and click **Done**.
 5. If you are using External CA then you can select the external CA which was created using openssl and uploaded on the CipherTrust Manager.
 6. Go to Registered Clients and click **Add Client**.
 - a. Specify client name and paste the Registration Token generated in the above step.

Note

If you are using external CA then you need to paste the signed client certificate in the Client Certificate field.

- b. Click **Save** to save the client certificate.

Configuring the KMIP Interface

The KMIP interface can be configured through:

Root Domain

1. Go to **Admin Settings > Interfaces**.
2. On the KMIP Interface, click the ellipsis button (...) and then click **View/Edit**.
3. Select the **Auto Registration** checkbox if you auto-registered your KMIP client and paste the value of the registration token that you created.

Note

By default, the Auto Registration is disabled.

4. Select the mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
5. Specify selections for **Local CA for Automatic Server Certificate Generation** as desired.

Note

Local CA for Automatic Server Certificate Generation should be set to **Turn off auto generation from Local CA** in case of External CA.

6. Select the CA according to your preference:
 - If you are using **External CA** then select the CA under **External Trusted CAs**
 - If you are using **Local CA** then select the CA under **Local Trusted CAs**
7. If you are using an External CA, expand the **Upload Certificate** section:
 - In the **Certificate** field, paste the contents of Server Certificate, CA, and Server Key file in the same order. **Do not introduce any space or character or symbol between the contents of these files.**
 - Select certificate **Format** as **PEM**.
 - **Password** field is optional and can be skipped.
 - Click **Update**.

Sub-Domain

1. Switch to **Root Domain**.
2. Go to **Admin Settings > Interfaces**.
3. On the KMIP Interface, click the ellipsis button (...) and then click **View/Edit**.
4. Select the **Auto Registration** checkbox if you auto-registered your KMIP client and paste the value of the registration token that you created.

Note

By default, the Auto Registration is disabled.

5. Select the mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
6. Specify selections for **Local CA for Automatic Server Certificate Generation** as desired.

Note

Local CA for Automatic Server Certificate Generation should be set to **Turn off auto generation from Local CA** in case of External CA.

7. Select the CA according to your preference.

Local CA

- a. Login to your sub-domain. Go to **CA > Local**. Click the ellipsis (...) and copy the contents of your CA Certificate.
- b. Logout of your sub-domain and now login to the root domain.
- c. Go to **CA > External > Add External CA**.
- d. Enter a name for this Domain CA and select the text radio button and paste the certificate contents.
- e. Click **Add External CA**.
- f. Go to **Admin Settings > Interfaces**.
- g. Click the **Add** icon to add the External CA.
- h. Click **Update**.

External CA

Note

If you are using an External CA in the root Domain, you need to add the CA as an External CA in both the root domain as well as the sub-domain and modify the interface accordingly.

- a. Go to **Admin Settings > Interfaces**.
- b. Click the **Add** icon to add the External CA.
- c. Click **Update**.
- d. On the **KMIP interface**, click the ellipsis (...) > **Certificate Options > Upload New Certificate > Ok**.
- e. Select the **Certificate Chain** option and click **Build Certificate Chain**.
- f. Click on Text and paste the contents of Server Certificate, CA, and Server Key file in the same order. Do not introduce any space, character or symbol between the contents of these files.
- g. Select certificate Format as **PEM**.
- h. Click on **Upload Certificate**.

Further, You need to perform the following configuration on CipherTrust Manager specific to MongoDB:

Creating a Client Certificate

Note

- This section is applicable to KMIP clients registered using Auto Registration but not to External CA.
- This section is not applicable when using External CA.

1. Log on to the CipherTrust Manager.
2. Navigate to the **CA > Local CA** and click on the name of the CA certificate you need to issue the certificate from.
3. Click on **Issue Certificate**.
4. Enter the **Display Name**, followed by **Common Name**.

Note

The **Common Name** of the certificate should be the Hostname/IP of CipherTrust Manager. In case of domains, the **Common Name** of the certificate should be of the format:

`<domain name> | | <Hostname/IP>`

For more information on the format of **Common Name** of the certificate, refer to [LDAP and Multi-Domain Client Usernames in KMIP Certificates](#).

5. Select the **Algorithm** and **Size**, and click **Issue Certificate**.
6. Save the **Private Key** and the **CSR**.
7. Select the Certificate Purpose as client, specify the validity of the certificate in days, and click **Issue Certificate**.
8. Download a copy of this certificate by clicking the ellipsis next to the certificate name.

Configuration on MongoDB

You can integrate MongoDB with the CipherTrust Manager using either of the following methods:

Note

These options are available with **MongoDB Enterprise** only.

- [Integrate Using a New Key](#)
- [Integrate Using an Existing Key](#)

Integrate Using a New Key

1. Create a client certificate. Refer to [Creating a Client Certificate](#) if you are auto-registering your KMIP client.
2. Concatenate the **clientcertificate.pem** and **clientkey.pem** files into a single file using:

```
cat clientcertificate.pem clientkey.pem > client.pem
```

3. In case of domains, concatenate the Domain CA and Root CA into a single file using:

```
cat domainCA.pem rootCA.pem > ca.pem
```

4. Start MongoDB manually using the following parameters to create an encryption key:

```
mongod --enableEncryption
--kmipServerName <IP/Hostname of the CipherTrust Manager>
--kmipPort <KMIP port number of the CipherTrust Manager>
--kmipServerCAFile ca.pem
--kmipClientCertificateFile client.pem
--dbpath /var/lib/mongodb
```

Note

You will need to add the CipherTrust Manager's hostname to the `/etc/hosts` file on your MongoDB server so that the name can be resolved to the IP address of the CipherTrust Manager.

Integrate Using an Existing Key

1. Create a client certificate. Refer to [Creating a Client Certificate](#) if you are auto-registering your KMIP client.
2. Concatenate the **clientcertificate.pem** and **clientkey.pem** files into a single file using:

```
cat clientcertificate.pem clientkey.pem > client.pem
```

3. In case of domains, concatenate the Domain CA and Root CA into a single file using:

```
cat domainCA.pem rootCA.pem > ca.pem
```

4. Create a key on the CipherTrust Manager using the **AES** Algorithm. Set the state as **Active**.

```
{
  "name": "Test_Key",
  "usageMask": 12,
  "algorithm": "aes",
  "meta": {
    "ownerId": "local|mongodb"
  },
  "state": "Active",
  "deactivationDate": "2023-10-02T14:24:37.436073Z",
  "protectStopDate": "2023-10-02T14:24:37.436073Z",
}
```

```
"aliases": [
  {
    "alias": "altname2",
    "type": "string"
  },
  {
    "alias": "altname2:keysecure:gemalto:com",
    "type": "uri"
  }
]
```

e. Click **POST**.

5. Add the key management security options to `/etc/mongod.conf`.

The MongoDB configuration file contains a security section. In this section, update the KMIP server name, certificate details, KMIP port number, and Key ID to use the CipherTrust Manager as a key management service.

```
security:
enableEncryption: true
kmip:
  serverName: <IP/Hostname of the CipherTrust Manager>
  port: <KMIP port number of the CipherTrust Manager>
  serverCAFile: <Path to the CA certificate>
  clientCertificateFile: <Path to the client.pem>
  keyIdentifier: <ID of the key created on the CipherTrust Manager>
```

6. Start MongoDB manually using the following parameters:

```
mongod --enableEncryption
--kmipServerName <IP/Hostname of the CipherTrust Manager>
--kmipPort <KMIP port number of the CipherTrust Manager>
--kmipServerCAFile ca.pem
--kmipClientCertificateFile client.pem
--kmipKeyIdentifier <ID of the key created on the CipherTrust Manager>
```

Note

You will need to add the CipherTrust Manager's hostname to the `/etc/hosts` file on your MongoDB

server so that the name can be resolved to the IP address of the CipherTrust Manager.

After the service starts successfully, encryption is enabled and the integration is complete.

Verifying Your Integration

Perform the following steps to ensure the integration is successful:

When Integrating Using a New Key

1. Log on to the CipherTrust Manager using your credentials.
2. Navigate to **Keys** and click the first key that you see listed.
3. Copy the **ID** of this key.
4. On the server where MongoDB is installed, navigate to `/var/lib/mongodb/key.store/`.
5. Notice that a directory with the same name as the **ID** of the key that you just copied exists. This verifies that the integration is successful.

When Integrating with an Existing Key

1. Log on to the CipherTrust Manager using your credentials.
2. Navigate to **Keys** and click the key that you created using the API playground.
3. Copy the **ID** of this key.
4. On the server where MongoDB is installed, navigate to `/var/lib/mongodb/key.store/`.
5. Notice that a directory with the same name as the **ID** of the key that you just copied exists. This verifies that the integration is successful.

Appendix

Troubleshooting

You might encounter some issues while performing the integration steps mentioned in the previous sections. Mentioned below are some of the most common issues and the ways you can resolve them:

Issue	Error Message	Remediation
KMIP auto-registration is not	The following error message is	Check whether the Auto registration

Issue	Error Message	Remediation
enabled	displayed in the CipherTrust Manager Records: "errorMessage": "Unregistered client, please register a new client from CLI or API or UI."	option is selected in Admin Settings > System Interfaces > kmip . If it is not selected, turn on the Auto registration option. Refer to Configuration steps for CipherTrust Manager using the GUI or ksctl.
Incorrect KMIP interface mode has been selected	The following error message is displayed in the mongod logs: "initandlisten Unable to retrieve key .system, error: socket exception [CONNECT_ERROR] for The server certificate does not match the host name."	Check whether the mode selected in Admin Settings > System Interfaces > kmip is "TLS, verify client cert, allow anonymous logins" or not. If not, make appropriate changes.
For any errors encountered while enabling the encryption		Clean up the contents in this directory using the command: <code>sudo rm -rf /var/lib/mongodb/*</code> . Now, retry enabling the encryption.

CipherTrust Integrations

Contents

- DataStax Enterprise 3
 - Integration with CipherTrust Manager 3
 - Verifying Your Integration 13
 - Licensing 13
 - Appendix. 13

DataStax Enterprise

DataStax Enterprise (DSE), built on Apache Cassandra™, is the world's most scalable database, well known for 100% uptime, unmatched low latency, and the ability to handle massive data at planetary scale. DSE delivers enterprise capabilities used by the best internet companies, and hardened by demanding, modern use cases in e-commerce, customer loyalty, banking, IoT, supply chain, etc. at global leading companies, including 40 of the Fortune 100. It provides advanced security provides features that allow you to minimize risk, achieve granular access control, and work toward compliance with regulatory standards.

DataStax Enterprise supports using encryption keys from one or more remote Key Management Interoperability Protocol (KMIP) hosts to encrypt or decrypt table data or sensitive properties, or both. You can set up encryption using keys from the CipherTrust Manager to protect sensitive configuration file properties, system resources, and tables.

Supported Product Versions

Note

The integration is performed and certified on **LTS release versions** of CipherTrust Manager only. Feature releases support the integration and are covered under technical support but will not be explicitly certified. To know more about CipherTrust Manager release versions, click [here](#).

This integration is validated on the following software versions:

CipherTrust Manager

- CipherTrust Manager 2.16.1 and higher

DataStax Enterprise

- DataStax Enterprise 6.8 and higher

Operating System

Red Hat Enterprise Linux

Integration with CipherTrust Manager

This section lists the steps to integrate DataStax Enterprise with CipherTrust Manager.

- [Prerequisites](#)
- [Configuration on CipherTrust Manager](#)
- [Configuration on DataStax Cassandra](#)

Prerequisites

This section provides the prerequisites for integration of Datastax with CipherTrust Manager.

- Ensure that the CipherTrust Manager is installed and configured. For more details, refer to the [CipherTrust Manager Documentation](#).
- Datastax communicates with the CipherTrust Manager using the KMIP interface. Ensure that the KMIP interface is configured on the CipherTrust Manager. Refer to [CipherTrust Manager Administration Guide](#) for details.
- **IP address** of the CipherTrust Manager and **port** of the KMIP interface must be accessible from the Datastax system.
- CipherTrust Manager recognizes only registered KMIP clients. Ensure that each node of the Datastax cluster is registered as a KMIP client on the CipherTrust Manager. Refer to [KMIP Client Registration](#) for more details.
- Ensure that Datastax has proper license for data at Rest Encryption. To check the license information in Datastax, navigate to **Settings > Software and Licenses > License Information**.
- Ensure that the required licenses are activated on CipherTrust Manager. For more details, refer to the [CipherTrust Manager documentation](#).

Configuration on CipherTrust Manager

To configure the CipherTrust Manager, you need to perform the following steps:

1. [Creating a Domain \(Optional\)](#)
2. [Creating a User](#)
3. [Assigning User to a Group](#)
4. [Registering a KMIP Client](#)
5. [Configuring the KMIP Interface](#)

Creating a Domain (Optional)

Perform the following steps to be performed on CipherTrust Manager:

1. Navigate to **Admin Settings > Domains**.
2. Click **Add Domain**. The **Add Domain** page appears.
3. Specify the following information:
 - **Name** - Enter the domain name.

-
- **Admins** - Select the admins (one or more) from the list available in the drop down. For example, admin.
 - **Parent CA** - Select parent CA as root CA.
 - **Allow Subdomain User Management** - Select this check box if you want to enable the subdomain user management through this domain.

4. Click **Save**.
5. Switch to the newly created domain by clicking the top right on the current Domain Name.

Creating a User

Root Domain

To create a user, perform the following steps:

1. Log on to the CipherTrust Manager GUI.
2. Open the **Keys & Access Management** application.
3. On the left pane, click **Users**. The Users page is displayed.
4. On the Users page, click **Create New User**.
5. On the Create a New User screen provide the following details:
 - Enter Username.
 - Enter Password.
6. Click **Create**. The newly created user is listed on the Users page.

Sub Domain

To create a user, perform the following steps:

1. Log on to the CipherTrust Manager GUI with the User you created within the Sub Domain.
2. Open the **Keys & Access Management** application.
3. On the left pane, click **Users**. The Users page is displayed.
4. On the Users page, click **Create New User**.
5. On the **Create a New User** screen provide the following details:
 - Enter **Username**.
 - Enter **Password**.

-
6. Click **Create**. The newly created user is listed on the Users page.

Assigning User to a Group

Perform the following steps to add user to a group:

1. Click the ellipsis button (...) corresponding to the user that you created in the previous step.
2. Click **Edit**.
3. Click **Group Memberships > Add Group**.
4. In the search bar, type **Key Admins** and select the check box corresponding to it .
5. Click **Add Group**.

Creating or Adding a CA (Optional)

Local CA

To create/add a Self-signed local CA, perform the following steps:

1. Navigate to **CA > Local**. Select **Add Local CA**, the **Add Local CA** page appears.
2. Provide the required information and click **Add Local CA**. The created Local CA will appear under Pending CAs section.
3. Click the ellipsis against the Local CA that you created and select the option **Self-sign**.
4. Select a valid duration for the Local CA. Click **Save**.

External CA

To add an external CA, perform the following steps:

1. Navigate to **CA > External**. Select **Add External CA**, the **Add External Certificate** page appears.
2. Provide the required information.
3. If you want to upload the external CA, select the **File Upload** option and click **Upload Certificate**. Browse and select the required External CA.

OR

Select **Text** and paste the contents of External Certificate

4. Click **Add External CA**.

Registering a KMIP Client

Root Domain

You can register a KMIP client on the CipherTrust Manager through:

1. Log on to the CipherTrust Manager.
2. Go to **Products > KMIP**.
3. Create Client Profile using the following steps:
 - a. Go to **Client Profile** and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Select **CN** in **Username Location in Certificate**.
 - d. Click **Certificate Details**.
 - e. Paste the content of `client.csr`.
 - f. Click **Save**.
4. Create Registration Token using the following steps:
 - a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a Name Prefix.
 - c. Specify a Token Lifetime value along with the Client Capacity for the token.
 - d. Click **Select CA**.
 - e. Select the CA type as Local/External depending on CA that you created [above](#).
 - f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
 - g. Select the Client Profile from the dropdown which you have created in the above step.
 - h. Click **Create Token**.
 - i. Copy the value of the Token created and click **Done**.

Note

If you are using External CA then you can select the external CA that you created and uploaded on the CipherTrust Manager.

5. Go to **Registered Clients** and click **Add Client**.
-

-
- Specify client name and paste the **Registration Token** generated in the above step.

If you are using external CA then you need to paste the signed client certificate in the **Client Certificate** field.

- Click **Save** to save the **client certificate**.

Sub Domain

You can register a KMIP client on the CipherTrust Manager through:

1. Log on to the CipherTrust Manager into your domain.
2. Go to **Products > KMIP**.
3. Create **Client Profile** using the following steps:
 - a. Go to Client Profile and click **Add Profile**.
 - b. Add a **Profile Name**.
 - c. Select **CN** in Username Location in Certificate.
 - d. Expand the Certificate Details section.
 - e. You can either paste the content of a generated client.csr or you can create one, by filling in the details.

For domain, the format to enter the Common Name field of the cert is always:

`domainName | | domainUser`

- f. Click **Save**.
4. Create a Registration Token using the following steps:
 - a. Go to **Registration Token** and click **New Registration Token > Begin**.
 - b. Add a **Name Prefix**.
 - c. Specify a Token Lifetime value along with the Client Capacity for the token.
 - d. Click **Select CA**.
 - e. Select the CA type as **Local/External** depending on what you are using [above](#).
 - f. Select the appropriate CA from the dropdown menu and click **Select Profile**.
 - g. Select the Client Profile from the dropdown which you have created in the above step.
 - h. Click **Create Token**.
 - i. Copy the value of the Token created and click **Done**.

-
5. If you are using External CA then you can select the external CA which was created using openssl and uploaded on the CipherTrust Manager.
 6. Go to Registered Clients and click **Add Client**.

- a. Specify client name and paste the Registration Token generated in the above step.

If you are using external CA then you need to paste the signed client certificate in the Client Certificate field.

- b. Click **Save** to save the client certificate.

Configuring the KMIP Interface

The KMIP interface can be configured through:

Root Domain

1. Go to **Admin Settings > Interfaces**.
2. On the KMIP Interface, click the ellipsis button (...) and then click **View/Edit**.
3. Select the mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
4. Specify selections for **Local CA for Automatic Server Certificate Generation** as desired.

Local CA for Automatic Server Certificate Generation should be set to **Turn off auto generation from Local CA** in case of External CA.

5. Depending upon the CA that you created [above](#), select an option from the following:
6. If you are using **Local CA** then select the CA under **Local Trusted CAs**
7. If you are using **External CA** then select the CA under **External Trusted CAs** provided you have the external CA that you created and uploaded on the CipherTrust Manager. For more information on creating or uploading CA, refer to [Creating or Adding a CA](#).

Sub Domain

1. Switch to **Root Domain**.
2. Go to **Admin Settings > Interfaces**.
3. On the KMIP Interface, click the ellipsis button (...) and then click **View/Edit**.
4. Select the mode as **TLS, verify client cert, user name taken from client cert, auth request is optional**.
5. Specify selections for **Local CA for Automatic Server Certificate Generation** as desired.

Local CA for Automatic Server Certificate Generation should be set to **Turn off auto generation from**

Local CA in case of External CA.

6. Select the CA according to your preference.

Local CA

- a. Login to your sub-domain. Go to **CA > Local**. Click the ellipsis (...) and copy the contents of your CA Certificate.
- b. Logout of your sub-domain and now login to the root domain.
- c. Go to **CA > External > Add External CA**.
- d. Enter a name for this Domain CA and select the text radio button and paste the certificate contents.
- e. Click **Add External CA**.
- f. Go to **Admin Settings > Interfaces**.
- g. Click the **Add** icon to add the External CA.
- h. Click **Update**.

External CA

Note

If you are using an External CA in the root Domain, you need to add the CA as an External CA in both the root domain as well as the sub-domain and modify the interface accordingly.

- a. Go to **Admin Settings > Interfaces**.
- b. Click the **Add** icon to add the External CA.
- c. Click **Update**.
- d. On the **KMIP interface**, click the ellipsis (...) > **Certificate Options > Upload New Certificate > Ok**.
- e. Select the **Certificate Chain** option and click **Build Certificate Chain**.
- f. Click on Text and paste the contents of Server Certificate, CA, and Server Key file in the same order. Do not introduce any space, character or symbol between the contents of these files.
- g. Select certificate Format as **PEM**.
- h. Click on **Upload Certificate**.

Creating a Client Certificate

1. Log on to the CipherTrust Manager.
2. Navigate to the **CA > Local CA** and click on the name of the CA certificate you need to issue the certificate from.
3. Click on **Issue Certificate**.
4. Enter the **Display Name**, followed by **Common Name**.

The common Name of the certificate should be the same as the name of the user you created on CipherTrust Manager. Refer to [Creating a User](#) section.

For more information on the format of common name of the certificate, refer to [LDAP and Multi-Domain Client Usernames in KMIP Certificates](#).

5. Select the **Algorithm** and **Size**, and click **Issue Certificate**.
6. Save the **Private Key** and the **CSR**.
7. Select the Certificate Purpose as client, specify the validity of the certificate in days, and click **Issue Certificate**.
8. Download a copy of this certificate by clicking the ellipsis next to the certificate name.

Configuration on DataStax Cassandra

1. Verify the installed version of Java.

```
java --version
```

2. Verify that you have python installed:

```
python3 --version
```

3. Download and extract the **tar** file for DataStax Enterprise. Create a new data directory and logging directory or use the existing default data directory and logging directory locations. Create and change ownership for these directories using:

```
sudo mkdir -p /var/lib/cassandra
sudo chown -R $USER:$GROUP /var/lib/cassandra
sudo mkdir -p /var/log/cassandra
sudo chown -R $USER:$GROUP /var/log/cassandra
```

4. To edit the configuration file `cassandra.yaml`, perform the following steps:
-

```
data_file_directories:
  - <installation_location>/dse-data/data

commitlog_directory: <installation_location>/dse-data/commitlog
saved_caches_directory: <installation_location>/dse-data/saved_caches
hints_directory: <installation_location>/dse-data/hints
cdc_raw_directory: <installation_location>/cdc_raw
```

For example:

```
data_file_directories:
  - /root/dse-6.8.53/dse-data/data

commitlog_directory: /root/dse-6.8.53/dse-data/commitlog
saved_caches_directory: /root/dse-6.8.53/dse-data/saved_caches
hints_directory: /root/dse-6.8.53/dse-data/hints
cdc_raw_directory: /root/dse-6.8.53/dse-data/cdc_raw
```

5. Start the Cassandra (DSE) service:

```
bin/dse cassandra -R
```

6. Verify the status:

```
cd <installation_location>/bin
./nodetool status
```

7. Check if the service is up and running, you will get a similar output as mentioned below:

```
Datacenter: Cassandra
=====
Status=Up/Down
|/ State=Normal/Leaving/Joining/Moving
-- Address      Load          Tokens   Owns    Host ID
Rack
UN  127.0.0.1    82.43 KB     128      ?       40725dc8-7843-43ae-9c98-7c532b1f517e
rack1
```

8. Navigate to the `conf` directory.

```
cd <installation_location>/resources/dse/conf
```

- Update the **kmip_hosts** section in the **dse.yaml** file to include the host details.

```
kmip_hosts:
  kmip_group_name:
    hosts: <IP_of_CipherTrust_Manager>
    keystore_path: <installation_location>/certificates/kmip_truststore.jks
    keystore_type: jks
    keystore_password: <keystore_password>
    truststore_path: <installation_location>/certificates/kmip_truststore.jks
    truststore_type: jks
    truststore_password: <truststore_password>
```

Verifying Your Integration

To verify that the integration is successful and DataStax can connect to CipherTrust Manager:

- Create a key by executing the following command:

```
cd <installation_location>/bin
./dsetool createsystemkey 'AES/ECB/PKCS5' 128 -k kmip_group_name
```

- To list the key created above:

```
./dsetool managekmip list kmip_group_name
```

Licensing

This section provides the licensing requirements for KMIP client.

Condition	License Requirement
Encryption per instance	x1 KMIP client license for each instance

Appendix

Troubleshooting

Issue	Error Message	Remediation
KMIP registration is not enabled	The following error message is displayed in CipherTrust Records: <i>"errorMessage": "Unregistered client, please register a new client from CLI or API or UI."</i>	Check whether the Autoregistration option is selected in Admin Settings > System > Interfaces > kmip . If it is not selected, turn on the

Issue	Error Message	Remediation
		Autoregistration option. Refer to the steps mentioned in Enable KMIP Client Registration .
User corresponding to username location in certificate (example: OU/UID) has not been created	The following error messages are displayed in CipherTrust Records: <i>"errorMessage": "username not found: "</i> <i>"errorMessage": "Could not authenticate certificate user, hence client is not auto registered in mode tls-cert-pw-opt"</i>	Check whether the user corresponding to UID/OU of the node certificates has been created in Access Management > Users . If the user is not created, create a new user with the same name as the OU/UID field of the node certificates. After creating the user, add this user to the Key Admins . Refer to steps mentioned in Create a New User .
User has not been added to Key Admin group	The following error message is displayed in CipherTrust Records: <i>"errorMessage": "authorization denied: verdict was deny: CreateKey"</i>	Check whether the user corresponding to UID/OU of the node certificates has been created under Keys & Access Management > Users . If the user is not added, add the user to the Key Admins group.
The Username location in Certificate has been set incorrectly	The following error messages are displayed in CipherTrust Records: <i>"errorMessage": "username not found: "</i> <i>"errorMessage": "Could not authenticate certificate user, hence client is not auto registered in mode tls-cert-pw-opt"</i>	Check whether the Username Location in the Certificate option is set correctly to OU/UID in Admin Settings > System > Interfaces > kmip . If it is not set correctly, set the correct value for the Username Location in the Certificate.

 - Appendix. 9

Dell EMC Unity Storage

Dell EMC Unity Storage helps the organization to solve the data storage needs. It provides the following benefits:

- Simplifies the data landscape. It streamlines the data storage needs with extensive coverage for enterprise workloads.
- Automates data services. It simplifies the storage management with policy-based automation and data mobility capabilities to quickly move data between environments or clouds.
- Extracts insight from data. Dell EMC provides a complete portfolio of solutions to unlock the value of data capital, with tight integration with leading applications and analytics platforms.
- Optimizes any workload at scale. It automate management to control costs and empower end-users with extensive self-service capabilities that lighten the load on IT. Secure your data assets. Significantly reduce application outages and latency issues while reducing storage requirements and network loads with advanced storage and deduplication.

CipherTrust Manager integrates with Dell EMC Unity Storage to act as an external KMS and secure the data when it is at rest. The integration reduces the threat of unauthorized access to the encrypted data.

Supported Product Versions

Note

This integration has been validated in the field by a partner or in a customer environment with the following software versions. It is recommended to test the integration in a non-production environment with desired software versions before deploying it to production. Thales will provide best-effort support.

CipherTrust Manager

- CipherTrust Manager 2.4

Dell EMC Unity

- Dell EMC Unity 480F

Prerequisites

- Ensure that the CipherTrust Manager is installed and configured. For more details, refer to the [CipherTrust Manager documentation](#).
- Dell EMC Unity Storage communicates with the CipherTrust Manager using the KMIP interface. Ensure that the KMIP interface is configured on CipherTrust Manager. Refer to [CipherTrust Manager Administration Guide](#) for details.
- **IP address** of the CipherTrust Manager and **port** of the KMIP interface must be accessible from the Dell EMC Unity Storage.
- CipherTrust Manager recognizes only registered KMIP clients. Ensure that each node of the Unity cluster is registered as a KMIP client on the CipherTrust Manager. Refer to [KMIP Client Registration](#) for more details.
- Ensure that Dell EMC Unity Storage has proper license for Data at Rest Encryption. To check the license in Dell EMC Unity, go to **Settings > Software and Licenses > License information**.
- Ensure that the required licenses are activated. For more details, refer to the [CipherTrust Manager documentation](#).

Steps for Integration

To integrate CipherTrust Manager with Dell EMC Unity Storage:

1. [Configure the CipherTrust Manager](#)
2. [Configure the Dell EMC Unity Storage](#)

Configuring CipherTrust Manager

This section includes the configuration steps for the CipherTrust Manager.

1. Log on to the CipherTrust Manager as admin to root domain (root/admin).
2. Go to **Admin Settings > Interfaces**, ensure that KMIP interface is enabled and check authentication methods and supported cipher-suites.

For more information, refer to [Dell EMC Documentation](#).

3. Go to **KMIP > Client Profile** and click **Add Profile** button to add new client profile, where CN=<user name>.
4. Go to **KMIP > Registration Token** and click **New Registration Token** button to create a Registration Token for the added Client Profile.

Copy the generated Registration Token.

- Go to **KMIP > Registered Clients** and click **Add Client** button to add a new client based on the created Registration Token.

Click **Save Private Key** and **Save Certificate** to download the private key and certificate.

- Go to **CA > Local** and download the Root CA Certificate.

After performing the above steps, move the client certificate and private key for Dell EMC Unity Storage provider in one file (PFX). Refer the following images:

Configuring Dell EMC Unity Storage

This section includes the configuration steps for Dell EMC Unity storage.

1. From the Dell EMC Unity UI, go to **Settings**.
2. Under **External Key Management**, click **Configure**.

3. In the **KMIP Configuration** window, specify the required details and click **Manage Certificates**.

Note

Under **IP Addresses of the KMIP Server Cluster**, you can add one or more than one (cluster) CipherTrust Manager instance.

4. In the **Certificate Management** window, click **Add** button and import the client certificate and the internal root CA of the CipherTrust Manager.
5. In the **Settings** window, click **Enable KMIP**.

After the successful completion of the above steps, Dell EMC Unity:

- Creates keys on the CipherTrust Manager.
- Encrypts drives

Licensing

Number of required KMIP license(s) should be equivalent to the number of available/active controller in all matrix communicating with the CipherTrust Manager.

Appendix

Verifying integration

After successful integration:

- Unity creates keys in the CipherTrust Manager.

Troubleshooting

Issue: KMIP Server is not available for Unity Storage.

Solution: Check the network connectivity and the required licenses.

CipherTrust Integrations

4 February 2026

Contents

- Google Cloud VMware Engine (GCVE) 3
 - Licensing 4
 - Configuring CM on Google Cloud Platform (GCP) 4
 - Enabling vSAN Encryption 7
 - Enabling VMware KMIP Connection 8
 - Registering KMIP Client 14
 - Configuring VMWare VCenter 17

Google Cloud VMware Engine (GCVE)

Google Cloud VMware Engine (GCVE) enables you to migrate or extend your on-premise VMware workloads to Google Cloud without refactoring the applications. This allows you to benefit from increased scale and agility while continuing to leverage the value of your existing VMware investments. Additionally, it helps you to maintain continuity with existing tools, policies, and unify management across environments.

CipherTrust Manager (CM) can be integrated with GCVE to act as an external KMS, as shown in the following diagram.

Supported Product Versions

Note

This integration has been validated in the field by a partner or in a customer environment with the following software versions. It is recommended to test the integration in a non-production environment with desired software versions before deploying it to production. Thales will provide best-effort support.

Google Cloud vSphere

- GCVE 6.7

CipherTrust Manager

- CipherTrust Manager 1.9.1

Prerequisites

- Ensure that the CipherTrust Manager is installed and configured. For more details, refer to the [CipherTrust](#)

Manager documentation.

- GCVE communicates with the CipherTrust Manager using the KMIP interface. Ensure that the KMIP interface is configured on the CipherTrust Manager. Refer to the [CipherTrust Manager Administration Guide](#) for details.
- **IP address** of the CipherTrust Manager and **port** of the KMIP interface must be accessible from GCVE.
- CipherTrust Manager recognizes only registered KMIP clients. Ensure that GCVE is registered as a KMIP client on the CipherTrust Manager. Refer to [KMIP Client Registration](#) for more details.
- Ensure that the required licenses are activated. For more details, refer to the [CipherTrust Manager documentation](#).

Steps for Integration

To integrate GCVE with the CipherTrust Manager:

1. [Configure CM on Google Cloud Platform \(GCP\)](#)
2. [Enable vSAN Encryption](#)
3. [Enable VMware KMIP Connection](#)
4. [Register KMIP Client](#)
5. [Configure VMWare VCenter](#)

Licensing

This section provides the licensing requirements for KMIP client, vSAN, and vCenter.

Condition	License Requirement
Encryption at VM Level	x1 KMIP client license for vCenter
Encryption at vSAN Level	Minimum x2 KMIP client license. x1 for vCenter+ x1 per node/ESXI host

Configuring CM on Google Cloud Platform (GCP)

To configure the CipherTrust Manager on Google Cloud Platform (GCP):

1. [Setup the Google Cloud SDK](#)
2. [Initialize The Google Cloud Project and Select Region](#)
3. [Access and Install the CipherTrust Manager Image](#)

Setup the Google Cloud SDK

To setup the Google Cloud SDK, refer to the [Google Documentation](#).

Initialize The Google Cloud SDK and Select Region

Refer the following Google documentation:

- To initialize the Google Cloud SDK
- To Select Region

Access and Install the CipherTrust Manager Image

Upon successful completion of the purchase order, you will receive an email from Thales. Select **Accept this invitation** to get access privileges to the Google image

Ensure that you have appropriate permissions to access the disk image. You can view the image(s) using the following `gsutil` command:

```
gsutil ls gs://kylo-images
```

Output:

```
gs://kylo-images/k170v-2369-20181008172807.tar.gz
gs://kylo-images/k170v-2411-20181031022613.tar.gz
```

You can also check the version mapping vs packages names using the following command:

```
gsutil cat gs://kylo-images/readme.txt
```

Output:

```
This folder contains k170v images for import into Google Cloud Platform.
This images can be imported into an account with the following command:
gcloud compute images create <image name> --source-uri <source uri>
Example: gcloud compute images create <image name> --source-uri gs://kylo-images/
k170v-4281-
20200227163646.tar.gz
1.6.0: gs://kylo-images/k170v-2689-20190305130140.tar.gz
1.7.0: gs://kylo-images/k170v-3137-20190604023249.tar.gz
1.8.0: gs://kylo-images/k170v-3506-20190927033321.tar.gz
1.9.1: gs://kylo-images/k170v-4281-20200227163646.tar.gz
1.10.0: gs://kylo-images/k170v-4610-20200619081338.tar.gz
2.0.0: gs://kylo-images/k170v-4933-20200909123423.tar.gz
2.1.0: gs://kylo-images/k170v-5170-20201118110327.tar.gz
```

To create an image, run the following `gc loud` command:

```
gcloud compute images create <image name> --source-uri <source uri>
```

Example:

```
C:\Users\username\AppData\Local\Google\Cloud SDK>gcloud compute images create k170v-1-9-1 --source-uri gs://kylo-images/k170v-4281-20200227163646.tar.gz
```

or (for CipherTrust Manager image here)

```
C:\Users\username\AppData\Local\Google\Cloud SDK>gcloud compute images create CPH-ERTRUST-MANAGER --source-uri gs://kylo-images/k170v-5170-20201118110327.tar.gz
```

Generate the CipherTrust Manager Image

To generate the CipherTrust Manager image:

1. In the GCP UI, go to **Compute Engine > Images**.
2. Under **IMAGES** menu, select the CipherTrust (k170v) image.

Note

Version number associated with the image may change.

3. Under **CREATE INSTANCE** menu, select **New VM Instance** and setup the machine configuration.

Thales recommends the following minimum system requirements:

- **Boot Disk:** 1 volume, minimum size: 30 GB for evaluation and 135 GB for production
 - **Memory:** 16 GB
 - **vCPUs:** 2
 - **NICs:** 1
4. Create an SSH Key via PuTTYGen Key Generator. SSH Key allows access to CipherTrust (K170v) CLI via SSH.
 5. Save the SSH Key, Private, and Public key in a secure location.
 6. Copy the output from the Public Key generated via PuTTYGen Key Generator, and paste it under **SSH Keys** in GCP.

7. Click **Create**.

Your CipherTrust Manager (k170v image) is now generated in the designated region.

For clustering, please follow all the above steps to generate a second instance. Further, to create a cluster and add both the instances (nodes) into it, refer to the [CipherTrust Manager Documentation](#).

After configuring CipherTrust Manager on GCP, you need to enable vSAN encryption. For more details, refer to [Enabling vSAN Encryption](#).

Enabling vSAN Encryption

To enable vSAN encryption with a connected CipherTrust Manager cluster:

1. On the CipherTrust Manager UI, configure the following:
 - a. Hostname (mandatory). For more details, refer to the [CipherTrust Manager documentation](#).
 - b. DNS servers (optional). For more details, refer to the [CipherTrust Manager documentation](#).
 - c. NTP server (optional). For more details, refer to the [Google documentation](#).
 - d. Cluster / members (recommended, with at least 2 nodes). For more details, refer to the [CipherTrust Manager documentation](#).
2. Perform the following steps to configure CipherTrust - KMIP Tenant:
 - a. In the CipherTrust UI, create the following users:
 - KMIP_admin: Created by the ROOT admin, this user is dedicated to KMIP administration purpose.
 - KMIP_user: Created by the ROOT admin, this user can operate inside the KMIP domain only, assigned by the KMIP admin.

Note

In this document we have created KMIP_admin and KMIP_user users. However, you can create user as per your convenience.

For more details on creating user, refer to the [CipherTrust Manager documentation](#).

- b. (This is an optional step.) Create domain and assign KMIP_admin under **Admins** option.

For more details on creating domain, refer to the [CipherTrust Manager documentation](#).

- c. Log on as KMIP ADMIN into the KMIP domain as <your domain>|<your user>. In this example: `KMIP_domain|KMIP_admin`.

- d. Go to **Keys & Access Management > CA**.

You can view the Local Certificate Authority created with the KMIP domain.

- e. Download the Local Certificate Authority using the contextual menu.

This domain certificate will be uploaded further, so that the KMIP interface can recognize it.

- f. Go to **Users > Assign User** and assign the KMIP user to the KMIP domain.
- g. Select the user and assign the Key Users group to it.

Repeat this step and assign the Audit group to the user, so that respective user can check the records in the CipherTrust Manager.

Finally, log out from the CipherTrust platform. Now, you are ready to prepare the VMWare client KMIP connection. For more details, refer to [Enabling VMware KMIP Connection](#).

Enabling VMware KMIP Connection

To enable the connection between VMWare client and KMIP create the following objects:

1. A client profile
2. A registration token
3. A registered client

Create a client profile

To create a new client profile:

1. Log on to the CipherTrust Manager as a domain administrator of the KMIP domain (`KMIP_domain` | `KMIP_admin`).
2. Select the **KMIP** menu from the main dashboard.

3. Click **Client Profile** from the left sidebar and click **Add Profile**.

4. Enter `KMIP_domain|KMIP_user` as the **Common Name**.

Add Profile

Profile Name*
vmware_profile

Username Location in Certificate:

CSR
Contents of .csr file

OR

Organization
Organizational Unit
Email
UID
City
State
Country

Common Name
KMIP_domain | KMIP_use

Device Credentials

Save Cancel

5. Click **Save**.

Create a Registration Token

To create a new registration token:

1. Log on to the CiphTrust Manager as a domain administrator of the KMIP domain (KMIP_domain | KMIP_admin).
2. Click **Registration Token** from the left sidebar and then click **New Registration Token**.

- Under **Configure Token** menu, specify **Name Prefix**.

The 'Create New Registration Token' dialog is shown at Step 01: Configure Token. The progress bar indicates the sequence: 01 Configure Token, 02 Select CA, 03 Select Profile, and 04 Create Token. The 'Name Prefix' field contains 'vmware_token'. Below it, 'Token lifetime' is set to 'unlimited' (with a green checkmark), 'Certificate Duration' is '730', and 'Client Capacity' is '100'. 'Back' and 'Select CA' buttons are at the bottom right.

- Under **Select CA** menu, select **Local CAs**.

The 'Create New Registration Token' dialog is shown at Step 02: Select CA. The progress bar shows: 01 Configure Token, 02 Select CA, 03 Select Profile, and 04 Create Token. Under 'Local CAs', the first option is selected: '/C=US/ST=MD/L=Belcamp/Q=Gemalto/OU=NA/CN=KeySecure CA for Domain KMIP_domain'. Under 'External CAs', the second option is listed: '/C=US/ST=MD/L=Belcamp/Q=Gemalto/CN=KeySecure Root CA'. 'Back' and 'Select Profile' buttons are at the bottom right.

- Under **Select Profile** menu, select the profile.

The screenshot shows a dialog box titled "Create New Registration Token" with a close button (X) in the top right corner. A progress bar at the top indicates four steps: 01 Configure Token, 02 Select CA, 03 Select Profile (highlighted in blue), and 04 Create Token. Below the progress bar, the "Client Profile" dropdown menu is open, showing "vmware_profile" as the selected option. At the bottom right, there are two buttons: "Back" and "Create Token".

- Copy the generated token from **Create Token** menu.

The screenshot shows the same dialog box, now at Step 4: Create Token. The progress bar highlights the "04 Create Token" step. Below the progress bar, a text box displays the generated token "oMkRejprTJeqOy3rVpWal" next to a "Copy" button with a clipboard icon. At the bottom right, there is a "Done" button.

Create a Registered Client

To create a registered client:

- Log on to the CipherTrust Manager as a domain administrator of the KMIP domain (`KMIP_domain | KMIP_admin`).
- From the left sidebar, click **Registered Clients** and then click **Add Client**.

3. Enter the name and token string copied in step 6 of [Create a Registration Token](#) section.

Add Client

Name

vmware_client

Registration Token

oMKRejorTUEQOy3rVpWalqhZy65W1nwWavVv2TFuFiOgk9PkkIh7ijfHILZ'

Client certificate (needed only if your registration token uses an external CA)

Client certificate

Save

Cancel

4. Click **Save Private Key** and then click **Save Certificate**.

Add Client

Name

vmware_client

Registration Token

oMKRejorTUeQOy3rVpWalqhZy65W1nwWavVv2TFuFiOgk9PkkIh7ijfHILZ'

Client certificate (needed only if your registration token uses an external CA)

Client certificate

1

2

Save Private Key

Save Certificate

Save CSR

Close

After configuring the VMware KMIP connection, you need to register the KMIP client. For more details, refer to [Registering KMIP Client](#).

Registering KMIP Client

To register KMIP client:

1. In the CipherTrust Manager UI, import the KMIP domain CA.

Note

It is necessary to import the KMIP domain CA, so that the ROOT admin can link it to the KMIP interface of the CipherTrust platform.

- Go to **Keys and Access Management > CA** and paste the CA content in the **Upload External Certificate** field.
- Click **Upload**.

- Go to the **Admin settings > Interfaces** tab and edit the KMIP interface to add/declare the KMIP domain CA.

Configure KMIP

☐ Enable hard delete ⓘ
 ☐ Auto Registration

Mode

TLS, verify client cert, user name taken from client cert, auth request is optional

Local CA for Automatic Server Certificate Generation

/C=US/ST=MD/L=Belcamp/O=Gemalto/CN=KeySecure Root CA

Local Trusted CAs

CA	
/C=US/ST=MD/L=Belcamp/O=Gemalto/CN=KeySecure Root CA	
	

External Trusted CAs

CA	
	
/C=US/ST=MD/L=Belcamp/O=Gemalto/OU=NA/CN=KeySecure CA for Domain KMIP_domain	

Download Certificate

[Download Current Certificate](#)

Upload Certificate

[Update](#) [Cancel](#)

At this stage, CipherTrust Manager is ready to accept KMIP connection from the VMWare client using Private Key & Certificate.

It is recommended to restart the CipherTrust services to take into account the new CA. To do so:

Using ksctl:

Execute the following command:

```
./ksctl services restart
```

Using CipherTrust Manager UI:

Go to **Admin Settings > System > Services** and restart the services.

After registering the KMIP client, you need to configure VMware. For more details, refer to [Configuring VMWare VCenter](#).

Configuring VMWare VCenter

Prerequisite

Ensure that:

- VCenter is up and running.
- CipherTrust Manager cluster is accessible and in good health. You can check it as admin user from **System > Cluster**.

Note

If this is not the case, you should be notified by an alarm under **Keys & Access Management > Alarms**

Declare a KMS cluster in VMware

To declare a KMS in VMware:

1. Go to **Security > Key Providers > Configure** tab.
2. Click **ADD STANDARD KEY PROVIDER**.
3. Specify the following information in **Edit Standard Key Provider** window:
 - a. Name for the cluster
 - b. Host/IP address and port for each KMS node

4. Click **EDIT KEY PROVIDER**.
5. Under **Establish Trust**, click **Make VCenter Trust KMS**.

A popup window is displayed, click **TRUST**.
6. click **TRUST VCENTER** button.
7. From the left sidebar, under **Choose a Method**, select the **KMS certificate and private key** option.
8. From the left sidebar, under **Upload KMS Credentials**, either upload or copy and paste the KMS Certificate and Private Key.

Note

KMS Certificate and Private Key is downloaded previously. Refer to the [Create a Registered Client](#) section.

9. Click **ESTABLISH TRUST**.

At this stage, ensure that the setup looks similar to the following image:

Moreover, you can also check the logs in CipherTrust Manager UI under **Records** tab.

Data Discovery and Classification (DDC)

This document is intended for CipherTrust Data Discovery and Classification (DDC) administrators responsible for configuring Data Stores and running Scans and Reports.

All products manufactured and distributed by Thales Group are designed to be installed, operated, and maintained by personnel who have the knowledge, training, and qualifications required to safely perform the tasks assigned to them. The information, processes, and procedures contained in this document are intended for use by trained and qualified personnel only.

It is assumed that the users of this document are proficient with data security concepts.

Trademarks

- Thales CipherTrust Data Discovery and Classification is powered by Groundlabs.
- DDC ML cloud-enabled solution is powered by Thales.

What's in this document

This guide explains data discovery concepts such as Locations, Classification Profiles, Data Stores and Scans. The document also explains how to generate scan-based reports on the discovered data. Finally, the document describes how to read generated Reports.

Prerequisite

- It is assumed, for this document, that you have already configured the CipherTrust Manager appliance. Refer to the [CipherTrust Manager product documentation](#) for instructions.
- The next step is to activate and install the DDC license. Refer to [Licensing](#) for details.
- After the license is installed, you can configure DDC Agents. Refer to the [Data Discovery and Classification Deployment Guide](#) specific to your platform for details. Installation of the CTE Agents is required for protecting directories and files stored on clients.

Organization

This document contains the following sections:

- [DDC overview](#): Provides a high-level overview of the DDC solution.
- [Concepts](#): Describes DDC concepts such as Information Types, Classification Profile, Data Stores, Scans and Reports.
 - [User groups](#): Describes all predefined groups of DDC users with their rights to use various product features.
 - [Locations](#): Describes how to add a Location.

-
- **Information types:** Describes how to view, customize and edit a Information Type (infotype).
 - **Classification profiles:** Describes how to view, add and edit a Classification Profile.
 - **Scans:** Describes how to view and add a Scan.
 - **Reports:** Describes how to view and add a Report.
 - **Agents:** Describes how to add agents and view the agent list.
 - **Similarity search:** Describes how to run similarity search on DDC ML infotypes.
 - **Discovering sensitive information:** Describes how to view, add, edit and scan different Data Store.
 - **Logging:** Describes most common log messages from DDC.
 - **Operations:** Describes the operations that the DDC Administrator performs on the CipherTrust Manager. In some situations, you must reconfigure DDC Agents with a new hostname, IP address, Agent Memory, CPU, or throughput.
 - **Troubleshooting:** Describes how to handle the issues that you might face when using DDC with the CipherTrust Manager.
 - **Appendix:** Additional useful information and tools related to system administration, such as system error messages, handy commands.
 - **Deployment security:** Information on system messages related to security of the deployment and tips on how to increase it.

DDC overview

This section provides an overview of the Thales CipherTrust Data Discovery and Classification (DDC) solution.

Workflow

This diagram provides a high-level flow of the DDC and DDC ML solution.

DDC**DDC ML**

Solution architecture

DDC solution operates using a standard DDC architecture and a DDC ML architecture. The two architectures differ in types of components included and in the way these components are configured and interact with one another.

DDC architecture

The following image shows the standard DDC architecture.

Architecture components

The following table outlines different architecture components along with their respective roles:

Component	Description
CipherTrust Manager, DDC Server	At the heart of the Data Discovery and Classification solution is CipherTrust Manager on which runs the DDC Server. It is from here that users interact with the DDC GUI or use the DDC APIs to create classification profiles, add data stores, launch scans and generate reports.
TDP (On-prem): Hadoop, Spark, HDFS	TDP (On-prem) is configured to work with Hadoop data clusters. DDC uses Hadoop to generate reports from scans and to store their results (report data). DDC can directly query HDFS but it requires Spark to interface with Hadoop's HBase. For installing TDP (On-prem), see Thales Data Platform Deployment Guide .
TDPaaS	TDPaaS is a server-less, cloud-based service used for storing the scan and report data. It is a SaaS component that offers an alternative to Hadoop services of on-prem TDP. For configuring DDC to use TDPaaS, see Configuring TDPaaS .
DDC Agent	DDC Agents perform the actual scanning jobs and report the results back to the DDC Server for analysis and processing. DDC supports two types of Agent configurations: • Local Agents: Installed and configured directly on the machine that contains sensitive data. • Proxy Agents: Installed and configured on a proxy machine that is used to scan sensitive data on other machines. For detailed information about agents, see Agents.

Component	Description
Data Stores	A data store is where the data actually resides. It can be a file server, a database, or a Hadoop cluster. For more information, see Discovering Sensitive Information .

DDC ML architecture

The following image shows the DDC ML architecture.

Architecture components

The following table outlines different architecture components along with their respective roles:

Component	Description
CipherTrust Manager, DDC Server	At the heart of the Data Discovery and Classification solution is CipherTrust Manager on which runs the DDC Server. It is from here that users interact with the DDC GUI or use the DDC APIs to create classification profiles, add data stores, launch scans and generate reports.
TDPaaS	TDPaaS is a server-less, cloud-based service used for storing the scan and report data. It is a SaaS component that offers an alternative to Hadoop services of on-prem TDP. For configuring DDC to use TDPaaS, see Configuring TDPaaS .

Component	Description
MLaaS	MLaaS (Machine Learning as a Service) is a multi-tenant service on Google Cloud Platform that is completely managed. It offers pre-trained machine learning models to complete tasks like text embedding, document classification, and named entity recognition. MLaaS works with CipherTrust Manager to process scan, index, and search requests. It takes the scan metadata information produced by the DDC ML agent and uploads it to Google Cloud. It then creates an inverted index that connects embedding and document metadata, allowing search for similar items using the k-nearest neighbors algorithm. For configuring DDC to use MLaaS, see Configuring MLaaS . Additionally, see Similarity search for details on semantic features powered by MLaaS.
DDC ML Agent	A unified agent with machine learning capabilities that also encompasses the features of the standard DDC agent. DDC ML agents perform the actual scanning jobs and report the results back to the DDC Server for analysis and processing. For installing DDC ML agent, see DDC ML Agent .
Data Stores	A data store is where the data actually resides. Currently, DDC ML supports only Local and Network data stores. For more information see Discovering Sensitive Information .

Concepts

Location

A location specifies a site where the file servers, databases, and data centers that contain data to scan are located. Locations are used to indicate where different data stores are physically located. For more information see [Locations](#).

Sensitivity levels

A sensitivity level defines how sensitive the data is. Sensitivity levels are required in creating classification profiles and data stores. Prebuilt sensitivity levels are:

- **None:** The sensitivity level for such data has not yet been specified.
- **Public:** Specifies the least sensitive data with no specific need for data security. Such data can be shared with anybody.
- **Internal:** Specifies the data with low sensitivity. Exposure of such data may not affect an organization, but is not meant for public disclosure.
- **Private:** Specifies that the data is personal. Such data should be protected from public viewing.

-
- **Restricted:** Specifies highly sensitive data, for example, customer's personal data and trade secrets etc. This type of data requires the best possible data security. Disclosure of such data can lead to severe financial and legal consequences for an organization. Businesses must prioritize remediation efforts related to this type of data.

Information type

An information type (or infotype) categorizes data to look for during a scan. A large number of predefined information types are available to better categorize the data. For more information see [Information Types](#).

Tag

A tag helps group data together. Tags are used to filter data for generating reports. They can be specified when creating data stores and classification profiles.

Data Discovery and Classification includes a number of predefined Tags, but also provides the ability to create custom Tags when creating data stores and classification profiles.

Predefined tags

The predefined Tags are APA, APPI, CCPA, FINANCIAL, GDPR, GDPR-FINANCIAL, GDPR-HEALTHCARE, GDPR-ID, GDPR-PII, HEALTH, HIPAA, KVKK, LEGAL, LGPD, NYDFS, PCI, PERSONAL, PHI, PII, SHIELD and UK-GDPR.

Classification profile

A classification profile defines what kind of sensitive information to search for during a scan. It includes information such as a sensitivity level, information types, and tags. Classification profiles can be created based on predefined templates or custom templates. For more information see [Classification Profiles](#).

Data object

A file, a database table, and a BLOB in a database table as stored in a data store are called Data Objects.

Sensitive data object

A data object that contains any data match is called a Sensitive Data Object.

Data Match

A concrete instance of any of the infotypes is called a Data Match.

Risk

A risk is the presence of a sensitive data object in a data store. The risk is calculated per the data object and data store. The risk is directly related with the matches found in the data object or data store.

Scan

A scan is an entity that helps in scanning data stores. Each scan specifies the location to scan and what to look for during scanning. Findings of scans can be used to generate reports for different purposes. Scans can be either run manually (any time) or scheduled to run and stop at a specified time.

Note

- DDC supports partial database scanning. To enable this, you need to configure the number of rows to be scanned. When you run a database scan, the scan results included data from the specified number of rows only.
- If you don't specify the number of rows to scan, the entire databases will be scanned.

For more information see [Scans](#).

Labels

Labels in Data Discovery Classification (DDC) are used to categorize and control standard agents. Labels are tags that highlight an agent's specific features, like its ability to scan certain types of data stores or its performance capabilities. An agent can have several labels. Agent labels can only be created in the **Labels** section inside the agents. See [Managing agent labels](#) to learn how to add or edit agent labels.

Labels have following characteristics:

- **Customizable:** There are no pre-defined labels. You can create them based on your requirements. For example, you could label an agent "Paris Data Center" or "AWS" to ensure DDC selects an agent that is co-located with the data store, providing low latency and high bandwidth access. Alternatively, you might use labels like "Critical" for agents dedicated to scanning highly sensitive data.
- **Immutable after creation:** Once a custom label is created, you can't modify it. However, you can always assign new or existing labels to an agent.

Agent labels vs data store labels:

It's important to understand the relationship between agent labels and data store labels:

- **Agent Labels:** These represent an agent's capabilities.
- **Data Store Labels:** These indicate the capabilities required for any agent to scan that specific data store.

For an agent to be selected to scan a particular data store, it must have all the labels defined for that data store. It can, however, have additional labels. See [Automatic agent selection](#) for more information.

You can also use labels to ensure that only the right agents handle your sensitive data, increasing DDC deployment's security. For more information, see [Mitigating security risks](#).

Encryption keys

DDC uses AES256 encryption to protect sensitive data. DDC creates a number of encryption keys that are stored in the CipherTrust Manager. You can find these DDC keys in the **Keys & Access Management** application in the CipherTrust Manager.

- Four encryption keys to protect the Hadoop configuration before storing it inside the DDC database. Each key is used to protect one configuration parameter (HDFS Server, and HDFS credentials).
 - **Encryption key format:** `citrus-<UUID>`. Example:
`citrus-6e0cb668-3a3d-4f2c-8687-17092b83b41b`.
- One encryption key for each data store. Each key is used to encrypt data store credentials before storing it in the DDC database, and encrypt scan results of that data store before storing them in HDFS. Datastore encryption key formats:
 - **For CipherTrust Manager version 2.15 or earlier:** `d<UUID>`. Example:
`d8b2d8404-c9ae-4a34-800a-01258dfaa383`.
 - **For CipherTrust Manager version 2.16 or later:** `DDC-Data-Store-<UUID>`. Example: `DDC-Data-Store-8b2d8404-c9ae-4a34-800a-01258dfaa383`.
- One encryption key for each scan. Each key is used to encrypt the scan data before storing it in HDFS. Scan encryption key formats:
 - **For CipherTrust Manager version 2.15 or earlier:** `s<UUID>`. Example:
`s14912791-bed5-4e73-b733-6a36ecfe338f`.
 - **For CipherTrust Manager version 2.16 or later:** `DDC-Scan-<UUID>`. Example: `DDC-Scan-14912791-bed5-4e73-b733-6a36ecfe338f`.

Warning

Never delete any encryption key. Otherwise, DDC will not be able to process the related datastores and scans properly.

User groups

System predefined groups

DDC has different kinds of users with different responsibilities in administering and using the system. A number of predefined groups are included to ensure that users are granted minimal permissions needed to perform their tasks while ensuring flexibility to meet security requirements across industries.

The table below lists all predefined groups with their rights to use various DDC features. **R/W** in a cell means that the user has **view** and **edit** rights to this aspect of the product. **R** means that the user has only **view** rights.

	Agents	Data Stores	Scans	Profiles	Reports	Sensitivity Levels	Branch Locations	Infotypes	Hadoop Configuration	Similarity Search
Admin ¹	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	
DDC Admins ^{2, 7}	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	
DDC Store Viewers ⁸	R	R				R	R			
DDC Store Admins ⁷	R/W	R/W				R	R/W			
DDC Scan Viewers ⁶			R					R

DDC Similarity Searches Viewers		R						R		R
DDC Similarity Searches Admins		R						R		R/W
DDC V2 Admins	R/W									
DDC V2 Clients	R/W									

[1] **Admins** can see their own and other users' reports. Admins can also decrypt scan packages from the Hadoop database.

[2] **DDC Admins** can only see their own reports.

[3] **DDC Report Admins** can only see their own reports.

[4] **DDC Full Report Admins** can only see their own reports.

[5] The difference between **Report Admins** and **Full Report Admins** is that **Full Report Admins** do not need access to specific user defined groups to be able to view or generate reports that use data stores restricted to user defined groups. For more information, see [User Defined Groups](#) below.

[6] Scan Viewers are allowed to run scans.

[7] Can view the list of the agents, and activate or deactivate the "Local Storage Only" option.

[8] Can view the list of the agents, but are not allowed to activate or deactivate the "Local Storage Only" option.

[9] **DDC Store Viewers**, **DDC Store Admins**, and **DDC L3 Support** do not have access to custom infotypes.

The users belonging to the "L3 Support" group are Data Discovery and Classification support administrators. These users can help identify and troubleshoot issues you may encounter when using DDC. They can also can also decrypt scan packages from the Hadoop database.

User defined groups

Apart from system predefined groups, CipherTrust Manager also allows you to create [User Defined Groups](#). User defined groups can be used to prevent certain users from viewing sensitive information in reports. These groups are defined by the application administrators, please refer to [Managing User Defined Groups](#) for further information. In DDC, they are applicable when creating a data store, in the **Data Store** screen when you are granting access to selected groups. For details, see the **ACCESS: Selected group/s** setting in the "Tags & Access Control" section of any data store in [Discovering Sensitive Information](#).

In other words, a data store that is restricted to a specific user defined group is visible to all the groups with permissions to see data stores, the same goes for scans. However, a user without a permission to see a data store which is restricted to a group, but with a permission to create and generate reports, will not be able to generate reports for those data stores. For this user, the scan executions will not be visible in the **New Report** screen.

Note

The only users that do not have to belong to a specific user defined group to be able to see reports for all the data stores are **Full Report Admins** and **Admins**.

For example, if a user created a report that has Data Store "DS1" but the data store is restricted to a specific group, that user will see the report template, but when he tries to access the report he will get an "insufficient permissions" error.

Locations

You manage locations through the **Locations** page, which is accessed by clicking the **Settings > Locations** link in the **Data Discovery** sidebar on the left.

From the **Locations** page you can:

- View all currently available locations. See [Viewing locations](#).
- Create a new location. See [Adding locations](#).

Viewing locations

The **Locations** page lists available locations. This view also shows the total number of existing locations. The **Locations** page shows the following details:

Item	Description
Location Name	Name of the location.
Country	Name of the country.
State/Province	Name of the state/province. This field is applicable to the United States. For other countries, the field is unavailable, indicated by N/A.
City	Name of the city.
Description	Description of the location.

Tip

Use the **Search** text box to filter locations. Search results display locations that contain the specified text in their names.

Adding locations

Adding a location requires specifying the country and city of the location.

To add a location:

1. Click **+ Add Location**.
2. In the **Add Location** screen, enter the following details:
 - **Location Name** - Specify a unique name for the location. The name must be longer than two characters and up to 64 characters. This field is mandatory.
 - **Country** - Select the country from the drop-down list. This field is mandatory. **State/Province** | Select the state/province from the drop-down list. This field is applicable to the United States. For other countries, the field is unavailable.
 - **City** - Specify name of the city. This field is mandatory.
 - **Description** - Describe the location (up to 250 characters).
3. Click **Save**.

The newly created location appears on the Locations page. By default, locations are sorted in alphabetic order by name.

Information types

An information type (infotype) categorizes data to look for during a scan. A large number of prebuilt information types are available to better categorize the data.

Different regions and countries can have different regulatory requirements, so these information types are

categorized based on geographical regions. These regions are Global, Africa, Americas, Asia, Europe, and Oceania. The information types can be further categorized into:

- **Financial:** Financial data such as credit card numbers and bank account details.
- **Personal Data:** Personal data such as age, gender, race, and religion.
- **Medical:** Medical data such as history of medical problems and disabilities.
- **National ID:** National identity documents such as Social Security Number (SSN).
- **Cryptographical:** Cryptographic keys such as AWS cloud keys.

Refer to [Information types](#) and [DDC ML information types](#) for a list of all available predefined information types.

DDC also allows you to create custom information types. For more information, see [Creating custom infotypes](#).

Creating custom infotypes

You can create a custom information type, if you require one.

To create custom infotype, click **Settings > Infotypes** in the sidebar on the left. The **Infotype** page is displayed.

1. Click the **+Add Infotype** button. The **Add Infotype** screen is displayed.
 - a. In the **General Info** tab, provide the following information:
 - **Name:** Choose a name for your infotype.
 - **Category:** Select a category to which your infotype belongs (Financial, Personal Data, Medical, National, or Cryptographical).
 - **Family:** Select a family for your infotype. A family is a subcategory inside the **Category** and the choice of options depends on what you selected in the **Category** menu. The following families are available inside their corresponding categories:
 - **Financial:** Credit/Debit Cards; Bank Account Info
 - **Medical:** Patient Health Data
 - **National ID:** Personal Identification
 - **Personal Data:** Email addresses; Login credentials; Card Number; Ethnicity; License Number; Roll Number; Passport Number; Date Of Birth; MAC Address; Mailing Address; Telephone Number; Gender; Religion; IP Address; Phone Number; Name
 - **Cryptographical:** AWS Key, RSA Key
 - **Weight:** Set the risk weight for the custom infotype, which will be used to calculate the risk formula per Data Object. Minimum weight is 1 and maximum is 10. That weight can be modified later, if needed, by editing the custom infotype in the **Infotypes** screen.

Note

- You can set a weight only for a custom infotype; built-in and ML infotypes have a pre-defined weight that cannot be changed.
- If you update a custom weight, you need to run a new scan and generate a new report to see the effects of the update. Historical reports will not be updated.

- **Region:** Select the region for your infotype (Global, Africa, Americas, Asia, Europe, and Oceania).

Click **Next** to go to **Infotype Definition** screen.

- In the **Infotype Definition** tab, you configure the rules for your new information type. You can start by configuring the rules on the **Simple View** tab, and then you can view or edit these rules as translated into an expression of the internal language of the Data Discovery and Classification engine on the **Expert View** tab. Each new expression is validated when you select **SAVE**, and errors, if any, are displayed.

Tip

Alternatively, you can directly click the **Expert View** tab ignoring the **Simple View**. If you add any expression not supported by the **Simple View** in the **RULE** text area, this tab will be disabled. For an extended guide on the expressions available in this internal language refer to [DDC GLASS Reference](#).

To configure the rules for your new information type, click to expand the **Add Rules** menu in the **Simple View** tab and select one of the following types:

- **Character:** Search for one or more specific characters as specified in the **Select Rule** menu. If the character is found, the location will be returned as a match. For a list of available character type rules, refer to [Character type rules](#).

Use the **From** and **To**, controls to set the number of consecutive occurrences of the selected character.

- **Phrase:** Search for a specific pattern as defined in the **Phrase** textbox (in layman terms, it is used to look for specific words). Searching for phrases is **case insensitive**.
- **Built-In:** Pre-defined infotypes can be used in combination with other types (Character or Phrase). The complete list of built-in information types is available in the [Appendix](#).

Note

Currently, you cannot use the Indian Passport Number built-in infotype for creating custom infotypes.

Use the **Apply** button to complete your selection. The selection is displayed in the list of defined infotype rules. You can remove it from the list of rules by clicking the **Remove** link on its right.

You can use each of these types on their own, or combine them to form a more complex rule, involving multiple types in various configurations. See [Examples of custom infotypes](#) for some examples.

Note

Due to a known limitation, it is currently not possible to have two built-in infotypes, one after the other. They must be separated by something, such as another type infotype, or even a plain space. For example:

"american express" " " "english name"

Due to a known limitation, when adding a range of characters, all the possible combinations inside the range will appear as matches. For example, for a range of numbers from 1 to 4, when in a document you have a sequence 1234, the search will yield the following matches:

"1", "12", "123" and "1234"

When you introduce spaces at the beginning or the end of the phrase, the spaces are removed. Also, when you introduce more than one space between words, only one space is considered.

- Click **Save** to save your new infotype. Your new information type has been added and is now listed in the **Infotypes** screen, and marked 'Custom' in the **Type** column.

Character type rules

Specific predefined characters are used to create custom infotypes using character based rules. They are explained below:

Rule	Expert View Keyword	Match
Space	SPACE	Any white-space character.
Horizontal space	HSPACE	Tab characters and all Unicode "space separator" characters.
Vertical space	VSPACE	All Unicode "line break" characters.

Rule	Expert View Keyword	Match
Any	BYTE	Wildcard character that will match any character.
Alphanumeric	ALNUM	ASCII numerical characters and letters.
Alphabet	LETTER	ASCII alphabet characters.
Digit	DIGIT	ASCII numerical characters.
Printable	PRINTABLE	Any printable character.
Printable ASCII only	PRINTABLEASCII	Any printable ASCII character, including horizontal and vertical white-space characters.
Printable non-alphabet	PRINTABLENONALPHA	Printable ASCII characters, excluding alphabet characters and including horizontal and vertical white-space characters.
Printable non-alphanumeric	PRINTABLENONALNUM	Printable ASCII characters, excluding alphanumeric characters and including horizontal and vertical white-space characters.
Graphic	GRAPHIC	Any ASCII character that is not white-space or control character.
Same line	SAMELINE	Any printable ASCII character, including horizontal white-space characters but excluding vertical white-space characters.
Non-alphanumeric	NONALNUM	Symbols that are neither a number nor a letter; e.g. apostrophes ', parentheses (), brackets [], hyphens -, periods ., and commas ,.
Non-alphabet	NONALPHA	Any non-alphabet characters; e.g. ~ ` ! @ # \$ % ^ & * () _ - + =
Non-digit	NONDIGIT	Any non-numerical character.

Examples of custom infotypes

Example 1

You want to search for a "Driver License Number" from Illinois, whose format is **M532-4218-1341**. You would then create the following rule:

Character Alphabet From 1 to 1 Times

Character Digit From 3 to 3 Times

Phrase -

Character Digit From 4 to 4 Times

Phrase -**Character Digit From 4 to 4 Times**

The above example will have the following syntax in the **Expert View**:

```
RANGE LETTER TIMES 1-1
THEN RANGE DIGIT TIMES 3-3
THEN WORD NOCASE '-'
THEN RANGE DIGIT TIMES 4-4
THEN WORD NOCASE '-'
THEN RANGE DIGIT TIMES 4-4
```

In this rule, the expression "**Character** Alphabet **From 1 to 1 Times**" means that you only expect one alphabetic character, the expression "**Character** Digit **From 3 to 3 Times**" means that you expect exactly three digits, and the expression "**Phrase -**" means that you expect to find a hyphen (-) in the sequence.

Example 2

You want to search for a name and last name separated by a number of spaces between 1 and 3. To that end you would create the following rule:

Phrase John**Character Space From 1 to 3****Phrase Gordon**

The above example will have the following syntax in the **Expert View**:

```
WORD NOCASE 'John'
THEN RANGE SPACE TIMES 1-3
THEN WORD NOCASE 'Gordon'
```

This rule will allow you to search for a combination of **John** and **Gordon** with one through three spaces between them. By comparison, using the rule **PhraseJohn Gordon** will only allow you to search for a combination **John Gordon**, with only one space. Any additional spaces in the phrase will be truncated.

Example 3

You want to search for the Spanish NIE (foreigner's identity number) preceded by the phrase **NIE:** and a number of spaces between 0 and 5. For example, **NIE X8691474Q**.

Phrase NIE**Character Space From 0 to 5****Built-in Spanish NIE**

The above example will have the following syntax in the **Expert View**:

```
INCLUDE 'DEFINE_NID'
WORD NOCASE 'NIE'
```

```
THEN RANGE SPACE TIMES 0-5
THEN REFER 'NID_SPAIN_NIE'
```

This rule will find both **NIE** X8691474Q and **nie** x8691474q since searching (regardless of the type - Character, Phrase, or Built-in) is case insensitive.

Search precision

Search precision allows you to change the precision level (in other words, the confidence type) for certain infotypes. Search precision is supported for built-in infotypes. [Infotypes that support search precision](#) section lists all built-in infotypes supporting search precision.

Modifying search precision for an infotype

You can change the precision for a infotypes with which you want to scan, before creating a scan. This can be achieved from the **Infotypes** screen.

1. To access it, on the DDC main page click **Classification Profiles** then **Infotypes** in the sidebar on the left.
2. To change the precision value for an infotype, click the toggle switch in the **Search Precision** column - select **LOW** or **HIGH**.
 - **HIGH** - higher search confidence (i.e. precision), in other words, more robust search.
 - **LOW** - lower search confidence, in other words, more relaxed search.

In case an infotype does not support search precision, it will show **N/A** in the **Search Precision** column.

Creating scans with modified search precision

To create a scan with an infotype with a modified search precision, you use the same steps as for creating any scan for any data store. Just make sure that you select the classification profile that uses the infotype that you modified. For more information, see [Adding scans](#).

Reports with modified search precision

- **Scan Trend Report:** When a scan is generated using search precision, the scan trend report will display an asterisk "*" for the scans when the info type Search Precision value was changed.
- **Aggregated Report:** Data objects in aggregated reports will display an asterisk "*" after the infotypes detected where search precision was modified (this only applies to low search precision, as high precision setting will not display asterisks).

For more information on these reports, see [Report details](#).

Infotypes that support search precision

Below, you have a list of all infotypes that support search precision. Within brackets you have the infotype IDs as coded internally by DDC, for example to be used with the REST API.

Note

The API will apparently allow you to change the search precision level for **any** infotype, however, this will not work if that infotype does not support search precision.

- Australian Business Number (BANK_AUSTRALIA_ABN)
- Australian Company Number (BANK_AUSTRALIA_ACN)
- United Kingdom VAT Number (BANK_UNITED_KINGDOM_VAT)
- Australian Bank Account Number (BANK_AUSTRALIA_BANK_ACCOUNT)
- Canadian Bank Account Number (BANK_CANADA_BANK_ACCOUNT)
- Japanese Bank Account Number (BANK_JAPAN_BANK_ACCOUNT)
- South Korean Corporation Registration Number (BANK_SOUTH_KOREA_CRN)
- South Korean Taxpayer Identification Number (BANK_SOUTH_KOREA_TIN)
- South Korean NH Bank Account Number (BANK_SOUTH_KOREA_BANK_ACCOUNT_NH)
- South Korean KB Bank Account Number (BANK_SOUTH_KOREA_BANK_ACCOUNT_KB)
- South Korean KEB Hana Bank Account Number (BANK_SOUTH_KOREA_BANK_ACCOUNT_KEB_HANA)
- South Korean Shinhan Bank Account Number (BANK_SOUTH_KOREA_BANK_ACCOUNT_SHINHAN)
- South Korean Gwangju Bank Account Number (BANK_SOUTH_KOREA_BANK_ACCOUNT_GWANGJU)
- South Korean Jeju Bank Account Number (BANK_SOUTH_KOREA_BANK_ACCOUNT_JEJU)
- South Korean Jeonbuk Bank Account Number (BANK_SOUTH_KOREA_BANK_ACCOUNT_JEONBUK)
- Australian Tax File Number (NID_AUSTRALIA_TFN)
- Austrian SSN (NID_AUSTRIA_SSN)
- Austrian Personalausweis (NID_AUSTRIA_PERSONALAUSSWEIS)
- Belgian eID (NID_BELGIUM_EID)
- Belgian National Number (NID_BELGIUM_NN)
- Brazilian CPF (NID_BRAZIL_CPF)
- Brazilian Registro Geral (NID_BRAZIL_RG)

-
- Bulgarian EGN (NID_BULGARIA_EGN)
 - Canadian Social Insurance Number (NID_CANADA_SIN)
 - Chilean RUN (NID_CHILE_RUN)
 - Croatian OIB (NID_CROATIA_OIB)
 - Czech Republic RC (NID_CZECH_RC)
 - Danish CPR (NID_DENMARK_CPR)
 - French Carte Vitale (NID_FRANCE_CV)
 - French INSEE (NID_FRANCE_INSEE)
 - French CNI (NID_FRANCE_CNI)
 - Greek AFM (NID_GREECE_AFM)
 - German Personalausweis (NID_GERMAN_PERSONALAUSSWEIS)
 - Hong Kong ID (NID_HONGKONG_HKID)
 - Hungarian Personal ID (NID_HUNGARY_PIN)
 - Icelandic Kennitala (NID_ICELAND_ID)
 - Indian Aadhaar Number (NID_INDIA_AADHAAR)
 - Iranian National Identification Number (NID_IRAN_NID)
 - Irish Personal Public Service Number (NID_IRELAND_PPS)
 - Israeli Identity Number (NID_ISRAEL_ID)
 - Italian Codice Fiscale (NID_ITALY_CF)
 - Italian CARTA D'IDENTITÀ (NID_ITALY_CID)
 - Latvian Personas Kods (NID_LATVIA_PK)
 - Luxembourg ID (NID_LUXEMBOURG_ID)
 - Malaysian NRIC (NID_MALAYSIA_NRIC)
 - Maltese eID (NID_MALTA_EID)
 - Dutch Burgerservicenummer (NID_NETHERLANDS_BSN)
 - New Zealand Inland Revenue Number (NID_NEW_ZEALAND_IRD)
-

-
- Portuguese Citizen's Card (NID_PORTUGAL_CC)
 - Portuguese Fiscal Number (NID_PORTUGAL_FN)
 - Portuguese Identity Number (NID_PORTUGAL_IN)
 - Romanian Identity Card (NID_ROMANIA_IDC)
 - Slovakian RC (NID_SLOVAKIA_RC)
 - South African Identity Number (NID_SOUTH_AFRICA_ID)
 - South Korean RRN (NID_SOUTH_KOREA_RRN)
 - South Korean Foreigner Number (NID_SOUTH_KOREA_FRN)
 - Spanish DNI (NID_SPAIN_DNI)
 - Sri Lankan National Identity Card (NID_SRI_LANKA_NIC)
 - Swedish Personnummer (NID_SWEDEN_PIN)
 - Swiss Social Security Number (NID_SWITZERLAND_AVS)
 - United Arab Emirates ID (NID_UAE_IC)
 - United Kingdom NI Number (NID_UNITED_KINGDOM_NINO)
 - United Kingdom Self Assessment UTR Number (NID_UNITED_KINGDOM_SA_UTR)
 - United States Social Security Number (NID_UNITED_STATES_SSN)
 - Australian Medicare Card (PHD_AUSTRALIA_MEDICARE)
 - United Kingdom Health and Care Number (PHD_UNITED_KINGDOM_HCN)
 - United Kingdom National Health Service Number (PHD_UNITED_KINGDOM_NHS)
 - United States Health Insurance Claim Number (PHD_UNITED_STATES_HICN)
 - United States Health Plan Identifier (PHD_UNITED_STATES_HPID)
 - United States Medicare Beneficiary Identifier (MBI) (PHD_UNITED_STATES_MBI)
 - United States National Provider Identifier (PHD_UNITED_STATES_NPI)
 - Australian Telephone Number (PII_AUSTRALIA_PHONE)
 - Austrian Telephone Number (PII_AUSTRIA_PHONE)
 - Canadian Telephone Number (PII_CANADA_PHONE)
-

-
- South Korean Phone Number (PII_SOUTH_KOREA_PHONE)
 - Luxembourg Phone Number (PII_LUXEMBOURG_PHONE)
 - Portuguese Phone Number (PII_PORTUGAL_PHONE)
 - Credentials username (PII_MISC_CREDENTIALS_USERNAME_ASCII)
 - Dutch Driver License Number (PII_NETHERLANDS_DLN)
 - Dutch Telephone Number (PII_NETHERLANDS_PHONE)
 - New Zealand Telephone Number (PII_NEW_ZEALAND_PHONE)
 - United Kingdom Telephone Number (PII_UNITED_KINGDOM_PHONE)
 - United States Telephone Number (PII_UNITED_STATES_PHONE)
 - United States Mailing Address (PII_USA_ADDRESS)
 - Turkish Telephone Number (PII_TURKISH_PHONE)
 - Spanish Driver License Number (PII_SPAIN_DLN)
 - Spanish Telephone Number (PII_SPAIN_PHONE)
 - Belgian Telephone Number (PII_BELGIUM_PHONE)
 - French Telephone Number (PII_FRANCE_PHONE)
 - German Driver License Number (PII_GERMAN_DLN)
 - German Passport Number (PII_GERMAN_PASSPORT)
 - German Telephone Number (PII_GERMAN_PHONE)
 - Irish Driver License Number (PII_IRELAND_DLN)
 - Irish Passport Number (PII_IRELAND_PASSPORT)
 - Irish Telephone Number (PII_IRELAND_PHONE)
 - Italian Telephone Number (PII_ITALY_PHONE)
 - Polish Passport Number (PII_POLAND_PASSPORT)
 - Polish Telephone Number (PII_POLAND_PHONE)
 - Portuguese Driver License Number (PII_POLAND_DLN)
 - Swedish Driver License Number (PII_SWEDEN_DLN)
-

- South Korean Passport (PII_SOUTH_KOREA_PASSPORT)
- South Korean Driver License Number (PII_SOUTH_KOREA_DLN)

For more information on these infotypes, refer to the [Information types](#) section in the appendix.

Classification profiles

You manage classification profiles through the **Classification Profiles** page, which is accessed by clicking the **Classification Profiles** link in the **Data Discovery** sidebar on the left.

From the **Classification Profiles** page you can:

- View all the available classification profiles. See [Viewing classification profiles](#).
- Create a new classification profile. See [Adding classification profiles](#).
- View details of a selected classification profile. See [Viewing details of classification profiles](#).
- Modify an existing classification profile. See [Editing classification profiles](#).
- Create a new classification profile from an existing one. See [Duplicating classification profiles](#).
- Remove a classification profile. See [Removing classification profiles](#).

Viewing classification profiles

The **Classification Profiles** page lists available classification profiles. Initially, the page shows prebuilt classification profile templates only. Newly created and duplicate classification profiles are also shown on this page. Duplicating classification profiles is the process of creating copies of existing profiles with identical properties. Additionally, the page shows the total number of available profiles.

The list view of the **Classification Profiles** page shows the following details:

Item	Description
Name	Name of the classification profile.
Sens. Level	Sensitivity level applied to the profile.
Modified	Time when the profile is modified.
Tags	Number of applied tags.

Tip

Use the **Search** text box to filter classification profiles. Search results display classification profiles that contain specified text in their names.

By default, classification profiles are listed in ascending alphabetic order of their names. Classification profiles can be sorted by their names and percentage of sensitivity levels.

Classification profiles can be filtered using the **Sens. Level** filter.

Note

To run ML scans on data stores, you require classification profiles that include both built-in and machine learning (ML) infotypes.

Classification profile templates

Classification profiles can be created based on predefined templates or custom templates. You can use the following predefined templates:

- **GDPR (General Data Protection Regulation):** Affects organizations that process the personal data of EU citizens, regardless of where the organization is headquartered. Apart from the general GDPR template you can narrow down the scope by selecting one of these specific GDPR templates:
- **GDPR Financial:** Covers a subset of GDPR information related to personal financial data.
- **GDPR Personal Details:** Covers any GDPR personal data not captured by the other GDPR templates.
- **GDPR Healthcare:** Healthcare data related GDPR template.
- **GDPR National ID:** Can be used to create a classification profile related to national ID data.
- **HIPAA (Health Insurance Portability and Accountability Act):** Covers the healthcare information in the US. HIPAA relates to protection, encryption, and key management.
- **PCI DSS (Payment Card Industry):** Affects organizations that play a role in processing credit and debit card payments. These organizations must comply with the strict PCI DSS (Data Security Standard) compliance requirements for the processing, storage, and transmission of data.
- **CCPA (California Consumer Privacy Act):** Affects organizations that process the personal data of a California resident, regardless of where the organization is headquartered.
- **Privacy Shield:** Privacy Shield Framework (US). Regulates transatlantic exchanges of personal data for commercial purposes between the European Union and United States.
- **UK GDPR:** Although EU GDPR no longer applies in the UK after the Brexit, UK's DPA 2018 has already enacted the EU GDPR's requirements into UK law (effective from January 1, 2021). The template captures this new regime known as UK GDPR.
- **LGPD (Brazil):** Brazilian General Data Protection Law.
- **PDP:** The Personal Data Protection Bill.

Adding classification profiles

Use the Add Classification Profile screen to add a classification profile. Adding a classification profile involves the following steps:

Select Profile Template

1. In the **Classification Profiles** page, click the **+ Add Profile** button on the right. The **Add Classification Profile** screen is displayed.

2. In the **Select Profile Template** step, select the required profile template from the available options.

See [classification profile templates](#) for more information about these classification profile templates.

3. Click **Next** to go on to the **Name and Describe** screen.

General Info

1. Specify a **Profile Name**. The name must be longer than two characters and up to 64 characters.

2. Provide a **Description** for the profile (up to 250 characters).

3. Select a **Sensitivity Level** from the drop-down list. A sensitivity level suggests DDC what level of sensitivity is OK to find in this data store. For details, see [Sensitivity Levels](#).

4. Click **Next** to go on to the **Select Infotypes** screen.

Select Infotypes

1. The **Select Infotypes** screen is displayed. The screen shows the list of available [information types](#). The screen shows details such as Infotype Name, Category, and Region. !!! note

Based on the selected profile template, certain information types may already be applied/selected. The applied information types can be viewed by turning on the ****Selected only**** toggle switch.

2. Search for the required infotypes. You can use the following options:

- **Search** text box: Enter text to filter information types. Search results display information types that contain specified text in their names.
- **Category** filter: Click the filter icon, select or clear categories, and click **OK**.
- **Region** filter: Click the filter icon, select or clear categories, and click **OK**.

3. Click **Next** to go on to the **Apply Tags** screen.

Apply Tags

1. The **Apply Tags** screen is displayed.

Note

Based on the selected profile template, certain tags may appear already applied. You can select existing tags, enter new tags, and remove existing tags, as appropriate.

2. Select a tag from the **Add Tags (optional)** drop-down list. Please check the list of prebuilt tags in **Predefined Tags**.

Tip

New tags can also be added. Start typing a new tag, and click the **New:** link that appears below the drop-down list.

Add as many tags as needed.

To remove a tag, click the close icon in the tag name.

3. Click **Save**.

The newly created classification profile appears on the **Classification Profiles** page. By default, profiles are displayed in alphabetic order by name. Depending on the number of entries per page, you might need to navigate to other pages to view the newly created profile.

Viewing details of classification profiles

The default view of the Classification Profiles page lists prebuilt profile templates, created profiles, and duplicate profiles. Names of profiles and their modification times are also shown. Additionally, the view shows infotypes, sensitivity levels, and tags applied to available classification profiles.

The edit view of the page shows additional details of each classification profile. The details include the number of linked scans, profile name, profile description, applied sensitivity level, list of linked infotypes, and applied tags.

To view details of a classification profile:

1. In the left pane of the **Data Discovery** application, click **Classification Profiles**. The **Classification Profiles** page is displayed. This page lists available classification profiles.
2. Click the ellipses icon (**⋮**) corresponding to the desired profile. A shortcut menu appears.
3. Click **View**. The **Classification Profiles** page shows additional details of the profile.

Note

For new and duplicate classification profiles, the button name is **View/Edit**. Clicking this button shows the edit view of the **Classification Profiles** page. The details can be viewed and edited on this page. Refer to [editing classification profiles](#).

Only the users with appropriate rights can see the **View/Edit** button. For all other users, only the **View** button is visible.

Editing classification profiles

Newly created and duplicate classification profiles can be modified to suit your requirements. Use the edit view of the page to modify individual classification profiles. You can edit the profile name, profile description, applied sensitivity level, linked infotypes, and applied tags.

Note

Prebuilt classification profiles cannot be edited. However, you can duplicate them and edit the copy to suit your requirements.

To edit a new or a duplicate classification profile:

1. In the left pane of the **Data Discovery** application, click **Classification Profiles**. The **Classification Profiles** page is displayed. This page lists available classification profiles.
2. Click the ellipses icon () corresponding to the desired profile. A shortcut menu appears.
3. Click **View/Edit**. The edit view of the **Classification Profiles** page appears.

Note

For new and duplicate classification profiles, the button name is **View/Edit**. Clicking this button shows the edit view of the **Classification Profiles** page. The details can be viewed and edited on this page.

Only the users with appropriate rights can see the **View/Edit** button. For all other users, only the **View** button is visible.

4. Expand **GENERAL**. General details are displayed.
5. Modify the required details.

6. Expand **INFOTYPES**. The list of infotypes is displayed.
7. Select or clear infotypes, as required.
8. Expand **TAGS**. The applied tags, if any, are displayed.
9. Add new tags or modify existing tags, as required.
10. Click **Save Changes**.

The list view of the Classification Profiles page shows updated information.

Duplicating classification profiles

Duplicating classification profiles is the process of creating copies of existing profiles with identical properties. This process simplifies the creation of new profiles. Duplicate profiles can be modified later to suit your requirements, if needed.

To duplicate a classification profile:

1. In the left pane of the **Data Discovery** application, click **Classification Profiles**. The **Classification Profiles** page is displayed. This page lists available classification profiles.
2. Click the ellipses icon (**⋮**) corresponding to the desired profile. A shortcut menu appears.
3. Click **Duplicate**.

A message appears stating that the profile has been duplicated successfully. The duplicate profile with the name **< original_profile_name> - Copy** appears on the Classification Profiles page. For example, if the profile **APA - Australia Privacy Amendment** is duplicated, a profile named **APA - Australia Privacy Amendment - Copy** is created.

Removing classification profiles

You can remove a classification profile in the **Classification Profiles** screen. To remove a classification profile follow these steps:

1. Click the ellipses icon (**⋮**) corresponding to the desired classification profile.
2. In the shortcut menu that is displayed, select the **Remove** option.
 - If the classification profile has scans associated with it, a **Remove Classification Profile** message box with the following information will be displayed:

"Are you sure you want to remove this classification profile? This cannot be undone. This classification profile is actively associated with the following scans:..."

The list of associated scans is displayed further down in the message box. **Keep in mind that removing such a classification profile can have a significant effect on the associated scans and reports.**

Confirm the classification profile removal by clicking the **Remove** button or click the **Cancel** button to

cancel the operation.

- If the classification profile has no scans associated with it, you can simply click the **Remove** button to confirm its removal.

Scans

DDC provides pattern-matching scan capabilities based on regular expressions. DDC ML, an extension of DDC, enhances DDC's scan capabilities by using semantic context-based discovery, classification of sensitive entities, and enabling similarity search. Refer to [DDC ML Infotypes](#) for infotypes supported by DDC ML.

DDC ML only supports local and network storage data stores.

You can manage scans using the **Scans** page. The **Scans** page can be accessed by clicking the **Scans** link in the **Data Discovery** sidebar on the left.

From the **Scans** page you can:

- View all currently available scans. See [Viewing scans](#).
- Create a new scan. See [Adding scans](#).
- Run a scan manually. See [Running scans](#).
- Delete a scan. See [Removing scans](#).
- Modify an existing scan. See [Editing scans](#).
- View scan history. See [Viewing scan history](#).
- Create a copy of a scan. See [Duplicating scans](#).

Viewing scans

The graphical view shows the following details:

- **Scan Age:** Displays a pie chart representing the distribution of scans conducted over different periods.
- **Scanned Data Objects:** Displays the count of scanned data objects, distinguishing between sensitive and non-sensitive types.

Click the refresh button to refresh the displayed information.

The list view of the **Scans** page shows the following details:

Item	Description
Scan Name	Name of the scan. Click the scan name to view scan configuration details. See Adding scans to understand details of the configuration section.
Status	Status of the scan. For more information, see Scan Statuses .

Item	Description
Duration	Time taken to complete the run.
Last Scan	Time when the scan last ran.
Schedule	Schedule of the scan.
Profiles	Number of classification profiles.

Tip

If you are planning to perform a CipherTrust Manager upgrade, make sure that you do not have scans in progress.

Use the **Search** text box to filter scans. Search results display scans that contain specified text in their names. By default, scans are listed in ascending order by name, but you can also sort them by last scan time, duration, and status.

Click the expand arrow (▸) next to the scan name to view additional scan details, including the number and list of data stores scanned, and the number of target paths. These details are available for the Completed, Partially Completed, and Failed scans.

In the expanded panel, click **View details** to see the scan status for each target path in the data store. You can hover over the status to see the error message related to the scan failure. Click **Close** to return to the Scans page.

Adding scans

To add a scan, navigate to the **Scans** screen (**Data Discovery > Scans**). Click the **+Add Scan** button to open the **Add Scan** screen.

In the screen, you have to go over these configuration steps for each scan that you add:

1. **General Info** - Name the scan, provide short description, and advance configuration.
2. **Select Data Stores** - Select which data stores will be scanned.
3. **Add Targets** - Narrow down the scan scope by selecting specific scan targets.
4. **Select Profiles** - Choose which Classification Profile you want to scan for.
5. **Apply Filters** - Add a list of rules to filter some targets when the scan is launched.
6. **Schedule Scan** - Configure when you want your scan to run.

General Info

1. In the **General Info** screen, specify a unique name and short description for the scan.
 - **Name** - The name must be longer than two characters and up to 64 characters.

- **Description** - (optional) Description can be of up to 250 characters.

2. Expand **Advanced Configuration** and specify the following details:

Parameter	Description
Scan Priority	Set the scan priority relative to other applications in terms of CPU utilization. You can select Low or Normal. The default setting is Low Priority. It applies only to local storage. If you want to increase the scan performance, set the scan priority to Normal .
Content Supported (Not applicable for DDC ML)	Select content type that the scan will process: ▪ OCR - Scans images for sensitive data using Optical Character Recognition (OCR). By default, it is disabled (the scanning of images will be skipped). For more details, see Using OCR in Scans. ▪ EBCDIC: Scan file systems that use IBM's EBCDIC encoding. By default, it is disabled. Note Use EBCDIC mode only if you are scanning IBM mainframes that use EBCDIC encoded file systems. This mode forces scanning of targets as EBCDIC encoded file systems, which means that it does not detect matches in non-EBCDIC encoded file systems.
Trace Logs	Use toggle switch to enable trace logs and capture detailed scan trace messages when scanning a target. By default, it is disabled. For more information, see Viewing Scan Log. Note ▪ You need to run the scan again after enabling trace logs in order to download them. ▪ Trace logs may take up a large amount of disk space, depending on the size and complexity of the scan, and may impact system performance. Enable this feature only for troubleshooting. ▪ DDC supports trace logs for multiple scan statuses. Refer to Scan Statuses for the list of supported statuses and the supported trace log download formats.
Enable Indexing	Use toggle switch to enable or disable similarity search on the scan results. When it's enabled, the similarity search can be performed on the scan results. This option becomes available after onboarding MLaaS. See Configuring MLaaS .

Parameter	Description
Memory Usage Limit (MB)	Set the maximum memory usage (in MB) that the scanner service can use on the data store host. The default memory usage limit is 2048 MB. If you want to increase the scan performance, set the memory usage limit between 4GB to 8GB.
Throughput (MBps)	Set the maximum I/O rate (in MBps) that the scanner service will use to read data from the data store. By default, it is set to 0 (for unlimited).
Amount of Data Object Volume	Select the amount of data object volume prioritizing either number of data objects or metadata per data object. Choose from: ▪ <i>Low - maximum metadata</i>: Captures maximal detail per file. ▪ <i>Medium - core metadata</i>: Balances quantity of files and matching detail in each file. ▪ <i>High - minimal metadata</i>: Results in a more even spread of match data across a large quantity of files. This is the default option.
Number of Rows (Only for Relational Database DS)	(Optional) Set the number of rows to scan in each relational database table. The maximum number of allowed rows for the database scan is 2147483647. The supported databases are: ▪ IBM DB2 ▪ Oracle ▪ Microsoft SQL ▪ PostgreSQL ▪ SAP HANA ▪ MySQL ▪ Teradata Note ▪ If you don't specify the number of rows to scan, the entire databases will be scanned. ▪ The number of rows to scan for all tables are selected in the descending order of the primary key. ▪ SAP HANA - Rows are selected in the ascending order. ▪ Teradata - Rows are selected randomly, if no primary key is defined.

The **Restore Defaults** button resets the advanced settings to their default values, however, if you already previously modified these settings for a scan and ran it with the changed configuration the **Restore Defaults** button will roll back the changes to the last saved configuration. In other words, the **Restore Defaults** button only reverts the current modifications.

3. Click **Next** to move on to the **Select Data Stores** screen.

Select Data Stores

The **Select Data Stores** screen lists all data stores in tabular form. By default, no data stores are selected. The table has three columns:

- **Data Store Name:** Lists available data stores (with their number).
- **Type:** The type of the data store, such as Local Storage, Network Share, etc.
- **Ready to Scan:** Displays if the agent that is connected to the data store. In this column, you can also see if the Agent is ready (that is, if the data store is ready).

Note

- **Ready/Not Ready data store:** A scan cannot run unless there is an identified Agent for every data store included in the scan. Data store that has an agent associated with it has the status **Ready**. If a scan contains a data store with **Not Ready** state, scan run will fail and display an error. If there are more than one data store with **Not Ready** state associated with a scan, the scan run will fail on the first data store that is in **Not Ready** state and will not scan the remaining data stores.
- **Disabled/Enabled data store:** You can manually deactivate a data store from the Data Store page. Deactivated data store has a status **Disabled** and is not scanned. A scan will successfully run (without an error) if it has at least one enabled data store and several disabled data stores associated with it. However, only the enabled data stores will be scanned. If a scan contains all **Disabled** data stores, then scan will not run at all.

To select a data store to scan:

1. Search for the desired data stores by specifying the search criteria in the **Search** box. The search results will be displayed in the table under it.
2. Select a data store for the scan by selecting the corresponding check box. Similarly, select multiple data stores, if needed.

Tip

Use the **Selected only** toggle switch to display only the selected data stores or all data stores (if the switch is 'off' all data sources are displayed).

3. Click **Next** to move on to the **Add Targets** screen.

Add Targets

In the **Add Targets** screen you can review a list of the data stores that you selected for the scan. By default, the scan will scan the entire data store, and this screen allows you to narrow down the scan scope by selecting specific targets for your selected data stores. The **Add Targets** screen is divided into three columns:

- **Data Store Name:** Lists selected data stores.
- **Add Target:** You can type in the complete target path in the field and add it to the scan parameters. Or, you can use the **Browse** button to navigate the target path from the root level or starting from an initial path and add it to the scan parameters. The scan will be performed only on the selected target paths.

Note

- For SAP HANA, the full data store scan is not supported. You need to specify at least one path.
- When adding Oracle and IBM DB2 targets, specify the table name exactly as in the database. Table names are case-sensitive.
- Any scan target that you add must be **valid**, otherwise the scan will fail. For more information on what a valid scan target is, see [Target Format Limitations](#).
- For performance sake, try running smaller scans and then generate a report in which you aggregate them. You may schedule a different scan per Data Store and/or per Classification Profile and/or subpaths (such as folders and tables) in the original scan path.
- You can scan emails in a Gmail label if you move the emails to the label - otherwise, they will be kept in your inbox. For the default system labels, Gmail creates some folders that do not match the label name. Please refer to the [Gmail documentation](#) to learn the right path to scan a particular system label.
- In the case of a Sharepoint Server data store with an API passwords file configured, you have to use an empty target path.
- To perform a scan on an Office365: OneDrive for Business or Exchange Server data store you **have to specify a scan target path**. For details, see [Target Format Limitations](#).

To add a scan target for a selected data store, do one of the following:

- Type complete scan target path in the **Add Target Path** field and click **Apply**.
- Navigate and add target paths.
 - a. Click **Browse** to navigate target paths from the root level. Alternatively, provide an initial path in the **Add Target Path** field and click **Browse** to navigate targets from that point onward.

Note

Paths are case sensitive. Providing incorrect initial paths may lead to unexpected results. See [issues encountered while browsing target paths](#) for more details.

Tip

Either navigate the target paths from the root level (without specifying any path in the **Add Target Path** field) or make sure you provide the correct path to navigate further locations within it.

- b. In the left pane, navigate and select the desired target path.

Note

To view subfolders within the folder hierarchy of a *SharePoint Online* or *SharePoint Server* data store, select the folder name and click **List**.

- c. Click **Add Path** to add the target path to the right pane. Similarly, add other target paths.
- d. Click **Add**.

To remove a scan target for a selected data store:

1. Click the arrow button next to the data store name for which you want to remove a scan target.
2. Click the **Remove** link on the right of the scan target to remove it.

Once all targets are added, click **Next** to move to the **Select Profiles** screen.

Tip

Make sure that you do not have nested target paths in a scan for the same data store. This can affect the performance of the scan and you can get duplicated data in the reports.

Select Profiles

The **Select Profiles** screen lists all [classification profiles](#) in tabular form. By default, no profiles are selected. The table has two columns:

- **Classification Profile Name:** Lists available profiles. Items marked with a letter "T" are predefined classification profile templates. For more information about these templates, see [Classification Profile Templates](#). The other items are custom classification profiles.

Sensitivity: Displays the sensitivity level assigned to this classification profile. See [Sensitivity Levels](#) for more information.

To select a classification profile for the scan:

1. Use the search box to specify the search criteria for the desired profiles. The search results are displayed in the table under it.
2. Select the check boxes corresponding to desired profiles for selecting the profiles for the scan.

Tip

Use the **Selected only** toggle switch to display only the selected classification profiles or all classification profiles (if the switch is 'off' all classification profiles are displayed).

3. Click **Next**.

Note

The **Next** button remains disabled if any of the selected classification profiles contains only the ML infotype. This button is enabled if all the selected classification profiles contain at least one built-in or custom infotype.

Apply Filters

In the **Apply Filters** screen you can add a list of rules to filter some targets when the scan is launched. By default, there are no filters applied, and in this step you can add specific rules which affect the data stores selected and their targets (if you specified any). You can configure as many filters as you want.

1. Click the **Select Filter** menu to expand it. The menu shows you the filters as follows:

- **Exclude Path/DO by prefix**

This filter excludes search locations with paths that begin with a given string. It can be used to exclude entire directory trees. Example of such a filter: c:\windows\system32

- **Exclude Path/DO by suffix**

This filter excludes search locations with paths that end with a given string. For example, entering led.jnl, excludes files and folders such as canceled.jnl, totaled.jnl.

- **Exclude Path/DO by expression**

This filter excludes search locations by expression. Wildcards "*" and "?" can be used to form expressions for this filter. For example, *data.txt excludes files that end by "data.txt" in any path.

- **Include DO modified recently**

Use this filter to include search locations modified within a given number of days from the current date. For example, enter 14 to display files & folders that have been modified not more than 14 days before the current date.

- **Exclude DO greater than size**

This filter excludes files that are larger than a given file size (in MB).

- **Include DO's within modification date**

Use this filter to include search locations modified within a given range of dates. Files and folders that fall outside of the range set by the selected start and end date are not scanned.

Note

The exclude Path/DO by prefix, suffix, and expression filters support wildcard characters. See [Using wildcard characters](#) to learn how wildcards work.

2. For each new filter added click **Apply** to save and apply its rules.
3. Click **Next** to move on to the **Schedule** screen.

Note

Filters are case insensitive. That is to say, if you have two directories, "TEST" and "test" and apply the filter */test both directories will be excluded as a result. The same goes for filenames.

Depending on the type of data store, some considerations should be taken into account. For more information, see individual data store pages at [Discovering sensitive information](#).

Schedule Scan

Scans can be run either manually or automatically at a scheduled time. To configure this:

1. In the **Schedule** screen select the frequency with which you want the scan to run. The options are:
 - **Manual:** Select to run the scan manually. This is the default setting. In this case the scan will be run

whenever you manually launch it from the **Scans** screen. For more information about running a scan manually, see [Running Scans](#).

- **Automatic Scan Pause** - Use this switch to schedule the time when a scan will pause. For example, you should pause all scans (by using the automatic scan pause) during working hours so they do not affect production servers. Next, use the **Time Zone** and **Select days and time** controls to set the days and time when the scan should pause.
- **Run Now** - If you select this check box, the scan will be run just once after the scan is added successfully.
- **Scheduled**: Select to specify a schedule for the run. The scan will be run automatically on the specified schedule. When **Scheduled** is selected, the following fields appear on the screen:
 - **Increment**: Select the increment pattern of the run. This is a mandatory field. The options are **Daily**, **Weekly**, and **Monthly**. By default, **Daily** is selected.
 - **Every**: Specify when the run should repeat. This is a mandatory field.

For example, if Daily is selected as Increment, enter 2 to run the scan once every two days. If Weekly is selected as Increment, enter 2 to run the scan once every two weeks. Similarly, if Monthly is selected as Increment, enter 2 to run the scan once every two months.

- **Time**: Specify the time when the run should start. This is a mandatory field. Specify the time in 12-hour format.
- **Time Zone**: Select a time zone from the drop-down list.
- **Starting**: Specify the day when the schedule should start. This is a mandatory field. By default, **Today** is selected. To specify a particular start date, select **On this date**, click the calendar icon, and select the date.
- **Ending**: Specify the day when the schedule should end. This is a mandatory field. By default, **No End** is selected. To specify a particular end date, select **On this date**, click the calendar icon, and select the date.
- **Automatic Scan Pause** - Use this switch to schedule the time when a scan will pause. For example, you should pause all scans (by using the automatic scan pause) during working hours so they do not affect production servers. Next, use the **Time Zone** and **Select days and time** controls to set the days and time when the scan should pause.

2. Click **Save** to complete adding the scan.

As a result, the newly created scan appears on the **Scans** page. By default, scans are displayed in alphabetic order by name. Depending on the number of entries per page, you might need to navigate to other pages to view the newly created scan. By default, the Status of a newly created scan is Unscanned.

Note

If your CM system clock does not match the Agent's system clock, your scans will not run as scheduled, so it is highly recommended to set up a NTP server to synchronize the clocks. This can be achieved in CM through the **Admin Settings -> System -> NTP**. For details, refer to the [Thales CipherTrust Manager Administrator Guide](#).

Running scans

To run a scan manually:

1. Navigate to the **Scans** screen (**Data Discovery > Scans**).
2. Search for the scan to run.

Tip

Use the **Search** text box to filter scans. Search results display scans that contain specified text in their names.

By default, scans are listed in ascending alphabetic order of their names. Scans can be sorted by their name, last scan time, duration, and status.

3. Move the mouse pointer to the row that contains the scan. The **Run Now** button appears. This button disappears as soon as the mouse pointer is moved out of the row.
4. Click **Run Now**.

As soon as the scan is initiated, its status changes to **Pending**, then the status changes to **Processing**. If the automatic scan pause is configured for the scan and you are running it within the set time window, the status of that scan will be **Autopaused** throughout the duration of the time window. After that, the scan is resumed. For more details on the scan auto pause feature, refer to the information in [Schedule scan](#).

After running a scan, you can generate aggregate and trend reports for them. See [Reports](#) for more details.

Scan statuses

The status of the scan changes in the sequence: Unscanned > Validating > Pending > Running now / Paused / Stopped > Processing > Completed / Failed / Partially Completed.

The progress of the scan (that is, its current status) is displayed in the **Status** column on the **Scans** screen.

The table below provides information about possible statuses and their log download formats.

Status	Log Download Format	Description
Unscanned	-	By default, the Status of a newly created scan is Unscanned.
Validating	JSON	Checking if all the data stores are ready.
Pending	JSON	Scan is pending and the linked data stores are being contacted. Depending on factors such as the network connectivity, this stage may: • Complete in a flash. You may not see it on the Scans page. • Remain for some time in this state.
Running now, Paused, Stopped	JSON	Scan is running, paused, or stopped. See Scan progress for more information.
Autopaused	JSON	Scan is paused as a result of automatic scan pause.
Uploading	-	Scan results are being uploaded to TDP.
Indexing	JSON	(Applicable to DDC ML scans) Scan is creating entity and document indexes for similarity search.
Processing	JSON	Scan is processing the collected data.
Completed	JSON	Scan was successful.
Failed	JSON	For some reason, the scan failed. Hover the mouse over the "Failed" icon to learn more about the reason why it failed.
Syncing	JSON	DDC is communicating with the agents to sync the status of ongoing scans that were active when Ciphertrust Manager was last stopped. Displays when Ciphertrust Manager starts.
Partially completed	JSON	Scan is partially completed. A scan is partially completed when at least one, but not all, of its target paths have been fully scanned. Note DDC ML currently does not support partial scanning of

Status	Log Download Format	Description
		data stores. This functionality is only available with regex-based scans.

Note

DDC will always select an agent for every data store when the scan execution begins. It could be the same agent as the previously assigned one, or a new one, regardless of the health status of the assigned agent.

Scan progress

The progress status of **Running** and **Paused** scans is displayed in the form of a progress bar accompanied by a numeric percentage value.

Additionally, you can click the *magnifying glass* on the right of the progress bar to see detailed information about the scan progress.

Scan in progress displays the following information:

- **Progress bars:**
 - The **Regex Process** shows the percentage of regular expressions processed by the scan (to check the scan path).
 - The **ML Process** shows the percentage of DDC ML scan (to check the scan path).
- The **Regex Process** and **ML Process** tabs show up to 5 unfinished scan paths per Hostname/IP ("...% completed") with detailed information displayed in a table, in these columns:
 - **Data Store** - Identifier of the data store on which scan is running. Generally, the identifier matches with the data store's Hostname/IP, but depending on the data store type, it might show different value.
 - **Paths** - Currently scanned scan paths.
 - **% completed** - Scan completion of the current scan path in percent.
 - **Matches** - Number of matches (sensitive items) found in the current scan path.
- The **Agents** tab shows details of the standard agents running the scan in the following columns:
 - **Data Stores** - Identifier of the data store on which the scan is running.
 - **Agent Name** - Agents that are executing scan on the data store.
 - **Last Agent Connected** - Time when the agent was last connected. *This value is updated every five*

minutes.

- **Status** - Connectivity status of the agent (Connected or Not Connected).

Note

- For disconnected agents, **Last Agent Connected** column doesn't display the time of disconnection. It only displays the most recent time when agent was connected.
- The **Agents** tab doesn't show details of the ML agents running the scan.

Editing scans

To edit a scan:

1. Log on to the DDC console.
2. Open the **Data Discovery** application.
3. In the left pane, click **Scans**. The **Scans** page is displayed. This page lists available scans.
4. Search for the scan to edit.
5. Use the **Search** text box to filter scans. Search results display scans that contain specified text in their names.

By default, scans are listed in ascending alphabetic order of their names.

Scans can be sorted by their name, last scan time, duration, and status.

6. Click the ellipsis icon () corresponding to the desired scan. A shortcut menu appears.
7. Click **View/Edit** from the shortcut menu.

The selected scan is displayed, with its configuration settings distributed over these sections (which are exactly the same as the steps of the **Add Scan** screen):

- **GENERAL**
- **DATA STORES**
- **TARGETS**
- **CLASSIFICATION PROFILES**
- **APPLY FILTERS**
- **SCHEDULE**

Select **Run Now** to initiate the scan run after any configuration change. This check box is available for scans that are not in the running state.

For more details on these sections, refer to the [Adding scans](#) section.

8. Click **Expand All** to expand all sections or a plus button (+) in the section in which you want to edit the scan configuration to expand just that section. For information on the available settings, refer to [Adding scans](#).
9. Make the desired changes and click **Save Changes** to save the changes.

When you edit a scheduled scan that was disabled, it gets automatically enabled.

When you edit a scan, you must run it again to see the corresponding report.

Viewing scan log

You can download and view a log of a selected scan if it has trace logs enabled in the advanced scan configuration settings. For more information, see the "Advanced Configuration" under the [General Info](#) section.

1. In the **Scans** screen, click the ellipsis icon () corresponding to the desired scan. A context menu is displayed, with the **Download Logs** option available.
2. Click **Download Logs** in the menu. A dialog box with information "Download logs? Logs for scan "Xyz" are available for downloading." is displayed.
3. Click the **Download** button in the dialog box to confirm the download.

DDC supports the JSON format for log download. Refer to [Scan statuses](#) for the supported log download formats for different scan statuses.

Note

- Trace logs are only available for download when Trace Logs toggle in advanced configuration is enabled, otherwise only troubleshooting logs are available for download.
- When you try to download logs of scans in the Running/Stopped/Paused/Autopaused/Interrupted state, latest logs until that point in time are downloaded.
- When the Scan Trace Logs download is in progress for a scan, downloading the trace log for that scan in parallel is not allowed. You can trigger the API again only after the previous request is complete.
- The Scan Trace Logs can be huge in size depending on the amount of data being scanned, and can also take considerable amount of time in processing before the download starts.

The information written to the log has the following format:

For JSON Format

Parameter	Data Type	Description
timestamp	number	Time stamp (Unix time format) for each action that happened on a path or location during a scan.
action	string enum: source, opening, opened, parsing, decoding, decoded, completed, scanning, inaccess	Action performed on a path or location during a scan.
agent_name	string	Name of the Agent that performed the scan.
path	string	Full path where the action happened.

Removing scans

1. In the **Scans** screen, use the **Search** text box to filter scans and search for the scan that you want to remove.
2. Click the ellipsis icon () corresponding to the desired scan. An overflow menu is displayed, with the **Remove** option available.

Note

The **Remove** option is not always available in the menu, only if a scan is **Failed**, **Completed**, **Stopped**, or **Disabled**.

3. Click **Remove** in the menu. As a result, a warning message "Remove Scan? Are you sure you want to remove this scan?" is displayed.
4. Click the **Remove** button in the warning message window to confirm the removal of the selected scan.

Viewing scan history

You can view the history details of past scan executions and download their logs.

To view the history details of a scan execution:

1. On the **Scans** page, click the ellipses icon (...) corresponding to the desired scan.
2. Select **View Executions**.

The **Execution History** page displays the scan execution history in following columns:

Column Name	Description
Scan Executions	Displays scan execution time stamp in descending order.
Status	Displays the status of scan execution (Failed, Completed, or Stopped). Use the filter button to filter scan execution by their status.
Duration	Displays the duration of scan execution
Logs	Allows you to download scan logs. Click the download button to download logs.

Duplicating scans

You can make copies of existing scans for creating new variants and reducing manual effort of creating scans from scratch. All the configuration details, classification profiles, data stores, target locations, filters, access & tags, schedules, and all other details of the existing scan are replicated in the cloned copy.

To make a copy of a scan:

1. Navigate to **Scans** screen (**CipherTrust Manager > Data Discovery and Classification > Scans**).
2. Click the ellipses icon (...) next to the desired scan that you want to clone.
3. Select **Clone**.
4. Provide a unique name for the new scan.
5. Click **Clone**.

Using Optical Character Recognition in scans

DDC features Optical Character Recognition (OCR) on a number of image file formats. The formats that can be recognized are **JPG / JPEG, BMP, PNG, GIF, TIFF**, and **PDF** that contains any of these image formats.

Note

OCR scans will usually have a lower accuracy than raw text data scans. They may not always recognize all characters in an image due to multiple factors such as poor image quality, unusual fonts, and complex layouts. This may cause unexpected data object matches.

OCR caching

The DDC scanning engine caches the result of OCR on an image within a scan, which can then be reused if the same image is later found in multiple locations within the same scan, for example, when scanning data sources like email in which identical images frequently occur in different email messages.

OCR limitations

The OCR mechanism employed by DDC has the following limitations:

- It cannot detect handwritten information - only typed or printed characters.
- It does not find information stored in screenshots or images of lower quality. The images you scan with OCR enabled must have a minimum resolution of 150 dpi (300dpi or higher is recommended).

At the same time, the accuracy of scans involving OCR will depend on:

- The quality of the image. Any noise in the image such as scanner marks, lines or soft color tones, dust from scanned images, etc.
- The format of the image. Some image formats will result in better detection rates (lossless vs lossy compression).
- Font face, font size and context stored in the image. Fonts within scanned images must be at least 10pt in size. Fonts below that size will not be reliably detected. Abnormally styled fonts may not be clear or consistent.

Note

OCR is not supported for HP UX 11.31+ (Intel Itanium) and Solaris 9+ (Intel x86) operating systems.

Reports

This section covers the following topics:

- Viewing reports.
- Viewing versions of a report.
- Report Types
- Configure reports.
- Generating reports.
- Report details.
- Removing reports.
- Exporting report's data objects.
- Exporting report's inaccessible data objects.

You manage reports on the **Reports** page. To access the **Reports** page, click **Data Discovery and**

Classification > Reports from the left sidebar.

Viewing reports

The **Reports** page lists all available reports including the newly configured reports. Additionally, the page shows the total number of available reports.

The page shows the following details:

Column	Description
Report Name	Name of the report.
Status	Status of the report. The status could be Not Generated, In Progress, Completed, or Failed.
Type	Type of the report (Aggregated or Trend).
Last Run	Time when the report was run.
Duration	The duration time of the report run.
Re-generation	Whether to automatically trigger report regeneration on subsequent runs of the linked scans. Select to enable automatic report regeneration, clear to disable.

You can use the **Search** box to filter reports. Search results display reports that contain specified text in their names. Reports can be sorted by their name (Report Name), and the last time that the report was generated (Last Run).

To view the details of a specific report, click the report name.

Alternatively, click the ellipsis icon () corresponding to the report name and select **View** from the context menu. The context menu also provides options to **Generate**, **Export D.O.**, and **Remove** the report.

Viewing versions of a report

DDC supports report regeneration. As a result, multiple versions of a report can be generated. The details view of the **Reports** page shows available versions of a report.

To view details of a report version:

1. Click the report name. The details of the report are displayed.
2. At the top of the detailed view, click the expand icon () to expand the versions list. The available versions of the report is displayed.
3. Click a version link to view its details.

The details view shows the details of the selected report version. To switch to a different version, click its link in the detail view under the expand icon ().

Report types

You can generate two types of reports with DDC.

- **Aggregate report:** Aggregate report displays consolidated information for multiple scan executions. The two ways to generate aggregate reports are:
 - **Scan run on specific date:** A report that is based on a scan run on a specific date. Such a report shows the scan findings on the selected date. In case of multiple executions of the scan for the selected day, the report will include the information for the latest execution on that day.
 - **Latest scan execution:** A report that always shows the information found on the latest scan execution. This way, the results will reflect (or update) the changes in the sensitive data discovered if the underlying data in the Data Store or the Classification Profile is modified. Still, the report will actually get generated when the user chooses to generate it.
- **Trend Report:** The trend report presents information about the trend of the chosen scan over the last 15 scan executions. It includes trends for various elements such as scanned data objects, identified sensitive data objects, and infotypes. This report assists in comprehending how the scan information develops over time.

Note

To see an updated trend or aggregated report, you can manually regenerate the report to see the results of the last scan execution. Alternatively, for aggregated reports, you can select the **Enable Report Regeneration** check box from the [General Info](#) section to automatically generate the updated report for latest scan execution.

Configure reports

You can configure a report to include information of one or more scans. After the report is configured, it can be generated any number of times. The generated report contains the results of the executed scans.

To configure a report:

1. In the **Data Discovery and Classification** application, click **Reports > + Add Report**.
2. Complete the following steps:
 - a. [General Info](#)
 - b. [Configure Content](#)

General Info

1. Specify the following details:
 - **Name:** Provide a unique name for the report. The name must be longer than two characters and up to 64 characters. This field is mandatory.
 - **Description(optional):** Provide a description for the report.

- **Select report type:** Select the type of the report to generate: **Aggregated** or **Trend**.

Note

- For a partially completed scan, only an aggregated report can be generated.
- DDC ML currently does not support partial scanning of data stores. This functionality is only available with regex-based scans.

- **Enable Report Re-generation** (Applicable only for Aggregated reports): Select the check box to trigger automatic report regeneration. The report will be regenerated automatically whenever any scan linked with the report is executed subsequently (that is, when Latest Execution time is changed).

2. Click **Next**.

Configure Content

The **Configure Content** screen shows available scans with their number and the number of selected scans.

For **Aggregated** reports, scans executions identified in this step will be merged in a single report. For **Trend** reports, you can select the desired scan for which you want to analyze the trend.

Tip

To include the removed scans in the list, leave the **Show Removed Scans** check box selected.

1. Use the **Search** box to filter available scans. Search results display scans that contain specified text in their names.
2. Select the desired **Scan Name**.

After selecting the scans, turn the **Selected Only** toggle on to list only the selected scans.

3. (Applicable only for **Aggregated** reports) Select the preferred way for generating the report.
 - A report that is based on a scan run on a specific date. For such a report, click "Latest Execution" and select the date of the scan that you wish to use.

If **Enable Report Re-generation** was selected and:

- An earlier scan run date is selected for the report, the report will not be automatically regenerated.
- The current date is selected, the report will be automatically regenerated for subsequent scan runs for the current day. However, after the date changes, any new scan runs won't trigger report regeneration.

- A report that can change if the underlying data store or protection profile is modified and a scan is run again. For such a report, leave "Scan Execution" as "Latest Execution".

Note

Dates in orange represent partially completed scans, while dates in green represent fully completed scans.

4. Leave the default settings for **Generate Now** check box. This will immediately generate the report after it is configured. Alternatively, you can clear the check box to generate report at later stage. See [Generating reports](#).
5. Click **Save**.

Generating reports

After you have configured a report, it can be generated at anytime and any number of times.

To generate a report:

1. On the **Reports** page, search for the report that you want to generate.

Tip

- Use the **Search** box to filter the reports. Search results display reports that contain specified text in their names.
- By default, reports are listed in ascending alphabetic order of their names. Reports can be sorted by their name (Name), and the last time that the scan was run (Last Run).

2. Click the ellipsis icon () corresponding to the desired report.
3. Click **Generate**.

As soon as the report starts to run, its status becomes **Not Generated**. The status of the report changes in the sequence: Not Generated > In Progress > Completed / Failed.

Note

Permissions to access the data stores accessed by the scans included in a scan-based report are checked every time the report is run. If the current user no longer has the correct permission for any of them, an

error is displayed.

Report details

The report details page displays the detailed information about the configured report. The upper part of the report details page displays general information about the report, such as the report name, version, and the number of scans included in the report. Click the expand arrow (▸) next to *scans* to see details of completed and partially completed scans.

You can use the **Print Preview** button in the top right corner of the page to print the report. See [Printing report details](#).

Cards

The findings from the scan executions is reported on the following four cards:

- **TOTAL DATA OBJECTS SCANNED** - The count of all data data objects that were included in the scan.

Note

- When scanning Exchange Online and Exchange Server notes data objects, DDC counts notes and their associated attachments as separate data objects.

TOTAL DATA OBJECTS SCANNED count is equal to the sum of *number of notes* and *number of attachments linked with each note* in the corresponding target path. For example, if you scan a target path containing 4 notes, one of which includes an image attachment, the TOTAL DATA OBJECTS SCANNED count will be 5.

- Due to a known limitation, in reports for MongoDB, Azure table, Salesforce, and G-Mail data stores, you will see "N/A" for the TOTAL DATA OBJECTS SCANNED values.
- For G-Mail, DDC ignores copies of the emails that were received in the same second, from the same sender, and with the same subject.
- In case of Binary Large Objects (BLOBs), TOTAL DATA OBJECTS SCANNED reports the parent and child data objects in a given blob.

- **SENSITIVE DATA OBJECTS FOUND** - The count of all data objects containing sensitive data identified during the scan run.
- **SENSITIVE DATA MATCHES** - The count of all sensitive pieces of information found inside the sensitive data objects.

-
- **SELECTED INFOTYPES FOUND** - The count of infotypes found during the scan out of those configured for the scan when it was created (" out of ").

The lower part of the report details screen displays the report information in the following tabs.

Scans tab

This tab provides the list of scans that contributed the information for the report. Scans with orange tick next to them represent partially completed scans, while scans with green tick next to them represent completed scans.

Additionally, you can see the report data in graphical format containing the following information.

- Infotypes Discovered
- Sensitive Data Objects by Content
- Sensitive Infotype Distribution
- Sensitive Data Objects

Information about scan filters

You can view the information about filters applied in the scans. On the **Scans** tab, click the expander arrow next to the scan name. This will display the information about the number and types of filters applied.

Example:

1 Scan Filter Exclude DO greater than size 14000 MB_

Data Stores tab

This tab provides the list of data stores included in the report, with the information about their risk score, sensitivity level, scan name, last scan time, targets, infotypes, data objects scanned, and sensitive objects found in each data store that was scanned.

Expand the data store name to see the following information in graphical format.

- Sensitive infotypes
- Sensitive content
- Classification profiles
- Business department (*applicable only for ML infotypes*)

An orange tick next to a data store name indicates a partial scan, while a green tick indicates a complete scan.

Data Objects tab

This tab provides the list of data objects scanned with below details. Only the top 1000 data objects are displayed, sorted by their Risk score. The first 25 data objects are displayed in the list but you can view more by clicking **Show more**.

Column Name	Description
Data Object Name	The name of the data object scanned and listed in the report details. Click the expand icon (▶) next to the data object to see additional scan details and meta data information about data object. For Oracle and IBM DB2 the result will be displayed in uppercase.
Risk	The number of risks found by the report in the given scanned data object. A risk is the presence of a sensitive item of data.
Type	The type of the scanned data object listed in the report details, such as "File" or "Folder".
Path	The path to the object that is listed in the report details.
Data Store	The name of the data store where the object listed in the report details was found.
Infotypes	The number of information types found in the data object that is listed in the report.

Filter Data Objects:

Use the fields of **Filter Data Objects** filter to search for a specific data objects.

Field	Description
Search	Use the search box to search data objects by name or path. The data object search has following characteristics: - Case-sensitivity is applicable - Partial search is conducted. For example, searching for "bal" will include "baseball" and "balloon" in the search results. - Search is performed for the object name and path.
Sort By	Use the Sort By options to sort the search results ascending or descending order by data object name or risk score.
Type	Select the data object type to narrow down search results.
Data Store	Select the associated data store to narrow down search results.

Note

When searching for the first time, the result will take some time (usually 1 to 3 minutes) to display. During this time, you can navigate through the different tabs inside the report, however, if you leave the **Reports** page, you must repeat the search. The results of a successfully completed search are cached and will allow repeating the same search with a response time of a few seconds only. Generating the report after the search is completed will invalidate the cache as it will render the information outdated.

Note

- Details of a data object scanned partially due to any issue are displayed in the **Inaccessible Data Objects** tab.
- A scanned ZIP file is displayed under the Data Objects tab. However, this tab doesn't indicate whether all the files included in the ZIP file are scanned successfully. To confirm this, review the Inaccessible Data Objects tab.

Inaccessible Data Objects tab

This tab is visible for Aggregated reports. This tab shows the list of inaccessible, skipped, or partially scanned data objects.

The table in the report detail lists the following findings distributed among columns:

Column Name	Description
Data Object Name	The name of the data object scanned and listed in the report details.
Data Store	The name of the data store where the object listed in the report details was found.
Path	The path to the object that is listed in the report details.
Severity	The severity of why the listed data object is inaccessible, skipped, or partially scanned. The severity could be Intervention (least severe), Notice, Error, Critical (most severe).
Reason	The reason why the listed data object is inaccessible. Some of the possible reasons could be: ▪ File size is more than 50% of the RAM configured in the scan properties (for example, the file size is more than 1024 MB and the RAM configured in scan is 2 GB (default)). ▪ File is corrupt

Column Name	Description
	- File permission issue - Unsupported file type - File contains encrypted data Resolve the issues that caused skipping of files and retry the scan.
Date	The date and time when the report is generated.

Note

Due to some known limitations, you might see same data objects listed in both Sensitive and Inaccessible tabs of the aggregated reports.

Examples:

- A partially scanned file (possibly, due to insufficient buffer memory).
- A table with partially scanned rows (due to some password protected content).
- Inaccessible, skipped, or partially scanned data objects by DDC ML agent are not listed on the **Inaccessible Data Objects** tab.

Additional metadata fields in reports

For each report, metadata fields of data objects can be displayed on the reports page. To see the metadata fields, go to the **Data Objects** tab and click the expander arrow next to data object name.

Note

- The number of fields displayed on the GUI depends on the level of details selected in the [scan configuration](#), data store, and file types.
- For MongoDB and Azure Table, no metadata is displayed in Aggregated reports.
- Metadata information of the data object is not displayed when the data object contains only ML infotypes.

The following table shows the complete list of metadata fields that can be displayed for the data objects.

Key	Description
Catalog	Name of the database or catalog.
Client Modified	Client modification timestamp.

Key	Description
Category	Category to which the data object belongs. See Category for list of supported categories.
Date	Date for the resource.
Date Modified	Date when the resource is modified.
Document Created	Date when the document is created.
Document Creator	Name of the document creator.
Document Modified	Date when the document is last modified.
Document Modifier	User who last modified the document.
Encoding	Whether the match is found in an EBCDIC-encoded resource.
File Created	Date when the file is created.
File Modified	Date when the file is last modified.
File Owner	Owner of the file.
Filename	File name for the resource.
Folder	Folder name for the resource.
Instance	Name of the database instance.
Key Columns	Name of the column(s) used as a key in the database scan. If multiple columns are used as the key, the column names will be comma-separated.
Key Source	Source of the key used in the "Key" and "Column:Key" metadata (for example, whether the key is obtained from a primary key column, or unique key column etc.). Enum: Primary Key, Integer Unique Column, String Unique Column, Blob *, Integer Non Unique Column, String Non Unique Column • Blob is the default "Key Source" metadata value for matches detected in BLOB objects as no key column information is stored for BLOB objects.
Number of matches	Displays the number of instances of an infotype found in the data object.
Median of score	Displays the median similarity score per data object and infotype.
Object Created	Date when the Google Cloud Storage object is created.
Object Modified	Date when the Google Cloud Storage object is last modified.
Permission Execute	List of groups, users, or user classes that have execute permissions to the matched object.
Permission Full	List of groups, users, or user classes that have full permissions to the matched object.

Key	Description
Permission Modify	List of groups, users, or user classes that have modify permissions to the matched object.
Permission Read	List of groups, users, or user classes that have read permissions to the matched object.
Permission Special	List of groups, users, or user classes that have special permissions to the matched object.
Permission Write	List of groups, users, or user classes that have write permissions to the matched object.
Processed Rows	Number of rows that were scanned for the table in a database scan.
Schema	Name of the database schema.
Server Modified	Date and time of the last modification by the server. Applicable only to the Dropbox Business Target types.
Subcategory	Subcategory to which the data object belongs. See Subcategory for list of supported subcategories.
Table	Name of the database table in a database.
Track 1	Whether a Track 1 data type was detected.
Track 2	Whether a Track 2 data type was detected.

Printing report details

1. On the **Reports** page, click the report name.
2. Click **Print Preview > Print**.
3. Click **Exit Print View** to return to report details page.

Note

- It is **recommended** to use **A3** and **landscape** settings as print settings to avoid printing distorted charts.
- For the best experience of exporting reports to PDF, use Chrome or Firefox.

Risk score

The risk score reflects the level of the risk to the business that would result from the exposure of the sensitive data objects (i.e., sensitive information) found by a scan. A low risk score number represents lower risk. The risk score depends on the type and number of sensitive data objects found. For example, if a risk score for a single email address found during scan is 10, the risk score for a document that contains thousands of such email addresses will be much higher.

Note

Only a complete removal/deletion of a sensitive data object would reduce the risk score to zero.

Removing reports

You can remove a report in the **Reports** screen. Since reports have no dependencies (i.e. do not affect other resources) you can remove them without problems.

Note

Only users with the right permissions can remove reports, that is Admin, DDC Admin, DDC Report Admin, and DDC Full Report Admin.

To remove a report:

1. Click the ellipsis icon () corresponding to the desired report.
2. In the shortcut menu that is displayed, select the **Remove** option.

A warning message "Remove Report? Are you sure you want to remove this report? This cannot be undone." is displayed.

3. Confirm the report removal by clicking the **Remove** button in the warning message dialogue box. To cancel the report removal, click the **Cancel** button.

Note

After deleting a report, you can create another report with the same name as the one that you deleted.

Reports are not deleted from TDP, which means that if you have the URL of the removed report, with the report ID, you can still view the report after you removed it.

Exporting report's data objects

You can export all the data objects of a report as Newline Delimited JSON (NDJSON) format. You can then view the exported NDJSON file in any editor supporting this format.

There are two ways of exporting those data objects.

- From the **Reports** page, using the **Export D.O.** option.

- From the **Report Details** page, using the **Export All Data Objects** button.

To export the data objects from the **Reports** page:

1. Click the ellipsis icon (**⋮**) corresponding to the desired report.
2. Click **Export D.O.**.
3. Choose the target location for the exported file.

To export data objects from the report details page:

1. Click the report name.
2. Go to the **Data Objects** tab.
3. Click **Export All Data Objects** to export the data objects.
4. Choose the target location for the exported file.

Tip

Please check the [ELK Reference](#) to see how to use the exported data.

Note

When you export the data objects of a *database* data store of a report, the exported NDJSON file also contains sensitive columns that were extracted from the scan results. The list of sensitive columns gathered in the exported file could be partial. The number of columns in the list depends on the scan configuration and the number of sensitive data matches found.

Exporting report's inaccessible data objects

You can export the inaccessible data objects of a report as Newline Delimited JSON (NDJSON) format. You can then view the exported NDJSON file in any editor supporting this format.

To export the inaccessible data objects associated with a report from its **Report Details** page:

1. Click the report name.
2. Go to the **Inaccessible Data Objects** tab.
3. Click **Export Data Objects** to export inaccessible data objects.

The inaccessible data objects report is downloaded as a .ndjson file.

Agents

Use the **Agents** page to manage the following types of DDC agents:

- **DDC Standard Agent:** Manage using **Standard Agents** tab.
- **DDC ML Agents:** Manage using **Machine Learning Agents** tab.

See [DDC agents](#) for installing DDC agents. To reconfigure DDC agents, see [Operations](#).

The **Agents** page allows you to:

- View a list of all available agents. See [Viewing list of agents](#).
- Edit the agent information. See [Editing agent information](#).
- Manage the agent's labels. See [Managing agent labels](#).
- View the agent's time difference information. See [Agent time difference information](#).

To access the **Agents** page, click **Data Stores > Agents**.

Viewing list of agents

The **Agents** page lists all available agents on the **Standard Agents** and **Machine Learning Agents** tabs. After a server restart, the list might take a moment to populate.

The page shows the following information about the installed agents:

Header	Description
Agent Name	Name of the agent (automatically assigned).
Operating System	Operating system on which the agent is running.
Version	Agent version from among the supported agent platforms (for example, Linux 2.3).
Connection IP	The IP address of the agent.
Status	The status of the agent - "Connected" or "Not connected".
Data Stores	The number of data stores that the agent is associated with. NOTE: Modifying data store settings after assigning an agent might trigger a new agent search. If multiple compatible agents are available, the same agent isn't guaranteed to be re-selected.
Labels	The number of labels assigned to the agent.
Local Storage Only	When this option is enabled, the agent can only be used with the Local Storage data stores. When disabled (default), the agent can be used as proxy, and can be associated with other data stores (in the same network).

Header	Description
	NOTE: Disabling a currently used agent prevents it from being selected for new data stores, but does not affect its behavior in the existing data stores.

Note

The agents are shown in any domain. The **Local Storage Only** option is managed independently of the domain, that is you can have an agent with the **Local Storage Only** option enabled in *Domain A*, and the same agent with the **Local Storage Only** option disabled in *Domain B*.

Use the **Search** box to search for an agent. Search results display agents that contain specified text in their names. By default, agents are listed in ascending alphabetic order of their names.

Editing agent information

You can edit agents information only for Standard Agents.

1. In the **Standard Agents** tab, click the ellipses icon () for the selected agent.
2. Click the **View/Edit** option that is displayed in the context menu.

The **Standard Agent** details screen displays. It shows the same information as the main **Agents** screen, split in the **GENERAL** and **LABELS** sections.

3. Modify the agent information as desired and click **Save Changes**.

Managing agent labels

You can add or edit labels only for Standard Agents.

A label is a way to mark an agent, for example its special features, such as its data store scanning capabilities and scanning performance.

For example, you could label an agent "Oracle" if it's set up to scan Oracle databases, or "Critical" if it's dedicated to highly sensitive data stores.

There are no predefined labels, but you can make custom labels as needed. After a custom label is created, it cannot be modified. However, you can assign new labels to the agent. An agent can have multiple labels. Agent labels can only be created in the **Labels** section inside the agents.

To add or edit the labels for an agent:

1. In the **Standard Agents** tabs, click the ellipses icon () for the selected agent.
2. Click the **View/Edit** option.
3. Modify the agent labels as desired (add or remove) and click **Save Changes**.

Note

Editing an agent's labels changes which data stores can automatically select it. Adding a label makes that agent available to any data store configured with the same label.

Refer to [Mitigating security risks](#) section to learn how to use agent labels to enhance the security of your environment.

Agent time difference information

When there is a time difference between the scanner service (where CM is deployed) and the agent machine (where the agent is installed) a clock icon is shown with the difference in seconds (always in seconds):

Icon	Description
	This is the kind of warning that you will see if the time is behind the CM clock.
	This is the kind of warning that you will see if the time is ahead of the CM clock.

Tip

When the date/time has been changed in the agent machine, it's necessary to restart the agent service.

Warning

Be careful when the scan is launched and there is a difference between the scanner service and agent machine. If the agent's clock is slower than scanner service, then the scan will start at that time. Furthermore, it will also delay resuming a scan when using the auto-pause functionality.

Note

If your Agent's system clock does not match with a Cloud Data Store's clock, you may hit issues while adding the Cloud Data Store in DDC, so it is highly recommended to set up a NTP server to synchronize the clocks. This can be achieved in the following manner:

- In CM through the **Admin Settings -> NTP**.
- For Windows agents, refer to: <https://docs.microsoft.com/en-us/troubleshoot/windows-server/identity/configure-authoritative-time-server>.
- For RedHat / CentOS agents, refer to: https://access.redhat.com/documentation/en-us/red_hat_enterprise_linux/7/html/system_administrators_guide/ch-configuring_ntp_using_ntpd.
- For Ubuntu agents, refer to: <https://ubuntu.com/server/docs/network-ntp>.

Automatic agent selection

DDC automatically selects agents to scan data stores. For data stores without an agent on the same host, a proxy agent is selected. Proxy DDC agent scans the data residing on the data store. The automatic agent selection process is triggered under the following conditions:

- A new data store is added.
- An existing data store is updated.
- Labels on any associated agent are changed.
- At the start of every scan execution (to ensure agents are valid and up to date).

Once automatic agent selection process is triggered, the DDC server first identifies all the connected DDC agents and excludes any that are disconnected.

Note

To control the agents that can scan a particular data store:

- Allow access to the data store endpoint, so only desired agents can reach it, and other agents are blocked at the network or data store configuration side.
- Use labels, as indicated in the [Managing agent labels](#) section.

Agent selection for Local data store

For Local data store, DDC selects an agent in this specific order:

-
- **Hostname Match:** It looks for a DDC Agent whose hostname matches that of the data store.
 - **IP Address Match:** If no hostname matches, it then looks for an agent with a network interface whose IP address matches the data store's IP.
 - **Failure:** If neither of these conditions is met, the agent selection for that Local Data Store fails.

Agent selection for other types of Data Stores

For all other types of data stores, DDC follows a more detailed process:

- **Configuration Check:** DDC considers the minimum and maximum number of agents configured for that data store.
- **Label Matching:** It checks the labels associated with the data store. Any agent selected must have at least the same set of labels as the data store (it can have additional ones too).

Agent selection for existing data stores (Re-evaluating previously selected agents):

If this isn't the first time DDC is automatically selecting agents for this data store, it will first verify if the agents chosen in the previous execution are still suitable. They must:

- Be connected to the DDC server.
- Have the required set of labels.
- Not have the "Local Storage Only" configuration attribute set.
- Satisfy the minimum and maximum agent requirements.

The automatic agent selection succeeds if all conditions are met and at least the minimum number of DDC agents can connect to the data store endpoint. Otherwise, DDC runs complete agent selection as if it was a newly added data store instance.

Agent selection for new data stores (if previous agents are not reachable or it is a new selection):

If this is the first selection for this data store (or if the previously selected agents don't meet all conditions), the DDC server will:

- Iterate through all connected DDC agents.
- (For each agent) Verifies its suitability by checking whether:
 - It does not have the "Local Storage Only" configuration attribute set.
 - It has all the mandatory labels defined for the data store.
 - It can connect to the data store endpoint.

This iteration stops once the "maximum number of agents" that can connect are found, or when there are no more agents left to try.

The automatic agent selection succeeds if at least the minimum number of DDC agents can connect to the data

store endpoint. Otherwise, it fails.

Data store status

If agent selection for a data store is successful, DDC sets its status to Ready and includes it in the scan.

If DDC cannot find the required agents, it updates the data store status to Failed and that data store will not be included in the scan.

Note

- Instructions to install and configure DDC agents can be found in the [Data Discovery and Classification deployment guide](#).
- Port 11117 on the CipherTrust Manager appliance must be accessible from DDC agent hosts.
- Data store endpoint needs to be accessible from DDC agent hosts.
- Each data store type may require a specific DDC agent (Windows or Linux) to proxy requests. Refer to the [Agent Compatibility Matrix](#) to verify the required agent type for their Data Store.
- Automatic agent selection algorithm only considers DDC agents with "Local Storage Only" enabled for Local Storage Data Stores. Refer to [Viewing List of Agents](#) for details.

Similarity search

Similarity search enables retrieving sensitive information related to DDC ML specific NER infotypes such as email addresses and GPS. See [DDC ML infotypes](#) to check the complete list of scannable NER infotypes.

Similarity search is used to find specific entities in a database, for example finding sensitive information such as names, addresses, and social security numbers using user queries. It also supports searches in multiple languages by using advanced embedding models that are trained on data from many different languages. These models can understand the meaning of terms and concepts across languages and represent them in a common space. This means that when a user searches in one language, the system can still find relevant content written in another language, as long as the information has clear linguistic meaning.

Similarity search uses advanced text vectorization models and indexing algorithms for fast and accurate information retrieval. To perform similarity search, DDC scans the data store to discover and vectorize sensitive entities. It then uses these embeddings to build a vector index to facilitate querying based on nearest neighbor algorithms. Due to the semantic nature of the search model, multilingual search capabilities are also supported.

Each infotype found in the indexed scan is compared to the user's query using a similarity metric like cosine similarity. Filters for the selected infotype, minimum similarity score, and data stores are also applied. Data objects that don't have the required infotypes (as defined in the search setup) are excluded.

The results are grouped first by data object, then by matched infotype within each object. For each group, the system reports the [number of matches](#) and the [median similarity score](#), which are used to rank the results.

Prerequisites

- Ensure that DDC ML agent is installed and configured. See [DDC ML agent](#) for more details.
- Ensure you are using CipherTrust Manager version 2.20 or later.
- Configure TDPaaS.

Note

The Google GCP region associated with TDPaaS is used for onboarding MLaaS as well.

- Onboard MLaaS cloud component.
- Add Local or Network data stores where you want to perform the search.

See adding [Local storages](#) and [Network storages](#) for adding local and network data stores, respectively.
- Configure and execute a scan on the added data store with indexing enabled for a ML classification profile.
 - See [Classification profile](#) to learn how to create an ML classification profile using ML infotypes.
 - See [Scans](#) to learn how to execute a scan with indexing enabled.

Perform similarity search

1. Log on to the CipherTrust Manager console.
2. Click **Search > Add Search**.
3. On the **General Info** screen, provide the name for the search and click **Next**.
4. On the **Configure Search** screen, perform the following tasks:
 - a. In **Subject Search**, select either **Full Name** or **Primary Email** as mandatory infotype.
 - b. Enter the corresponding name or email address.
 - c. Select additional infotypes from the **Add a new optional field** drop-down.
 - a. From the **This field is** drop-down, select **Mandatory** or **Optional** for infotype type.
 - b. Enter the value for the infotype to search for.
 - c. Click **Add**.

Repeat the above steps to add more infotypes.

d. Click **Next**.

5. On the **Configure Accuracy** screen, provide the search accuracy threshold for different infotypes.

See [Refine search result](#) for more details.

Click **Restore Defaults** to restore the accuracy thresholds to the default value of 90.

6. Click **Next**.

7. On the **Select Data Stores** screen, select the target data stores where you want to search for the infotype.

Note

- Currently, only Local and Network data stores are supported.
- Datastore availability will depend on which scans were indexed previously.

8. Click **Save**.

DDC will perform similarity search for the selected infotypes and display results on the **Search** page.

Note

Similarity search depends on the named entities extracted through NER scans, so search effectiveness is limited by the accuracy of the NER process. Only the entities detected in the scan (as visible in the scan report) are indexed as potential matches for future search queries.

View search results

To view search results, click the corresponding search name. Alternatively, click the ellipsis icon (...) corresponding to the search name and select **Show Results**.

Edit search

You can view, edit, or rerun the search with modified parameters.

1. On the **Search** screen, click the ellipsis icon (...) corresponding to the search name.
2. Select **View/Edit**.
3. Expand the **GENERAL** section to edit the search name.
4. Expand the **CONFIGURE SEARCH** section to add or remove infotypes for searching.

5. Expand the **DATA STORES** section to add or remove data stores.
6. Select the **Run Now** check box to rerun the search after making changes.
7. Click **Save Changes**.

Delete search

To delete a previously created similarity search, click the ellipsis icon (...) corresponding to the search name and select **Remove**.

Refine search result

You can thoughtfully refine the search results by adjusting the threshold value and selecting the number of infotypes:

1. **Similarity Threshold:** This is a score from 0 to 100 that shows how similar the search results need to be to what you're looking for. A higher score means you'll get results that are very similar to your search query. Note that this score measures how related the meanings are, not just how many words match. The default settings are usually helpful, but you can adjust them to fit your needs. For example, if you want only very close matches, you can set the threshold between 95 and 100. On the other hand, cross-lingual queries should have their thresholds relaxed, such as ~40-50%, to get appropriate matches. The below table summarizes various settings for the similarity threshold.

Aspect	Default Threshold	Recommended Adjustments
General Use	90%	Standard starting point; adjust for finer control.
Precision Matches	95% - 100%	Higher thresholds for queries like email addresses, URLs, access keys to minimize false positives.
Ambiguous Infotypes	70% - 90%	Lower thresholds for personal names, mailing addresses, etc., due to variations in representation.
Cross-lingual queries	40% and above	Adjust based on vocabulary (lexicon) and word structure variations across languages.

2. **Mandatory vs. Optional Infotypes:** This means that some types of data must be included in your results (mandatory) while others can be included if they are available (optional). According to DDC requirements, either a full name or an email must always be included. If you require too many mandatory types, it could limit your results because fewer items will meet all those criteria.

Apart from the median similarity score, getting multiple matches for a subject search across a variety of infotypes is a positive indicator of relevance and accuracy.

Discovering sensitive information

DDC helps organizations identify and classify sensitive data within the data stores to ensure compliance, security, and data protection. A data store refers to a repository or location where your sensitive data is stored. This could include cloud storage, databases, local and network storages, servers, or any other storage system.

This section provides information on how to add the supported data stores on DDC and configure scans to discover and classify the data.

You can manage data stores through the **Data Stores** page, which is accessed by clicking the **Data Stores** link in the **Data Discovery** sidebar on the left. The list view of the Data Stores page shows the following details:

Column	Description
Data Store Name	Name of the data store.
Type	Type of the data store.
Ready to Scan	Whether the data store is configured successfully for scanning.
Last Agent Check	Time when the Agent was last scanned.
Location	Location of the data store.
Sens. Level	Sensitivity level applied to the data store.
Labels	The number of agent labels that the datastore has.
Status	Status of the data store - enabled or disabled. During a scan, DDC searches for agents in enabled data stores. Click the toggle switch to change the status.

The status of a data store could be disabled while it waits for an Agent or if it fails to select an Agent. Disabled data stores are skipped during the scan.

Note

- Any modifications in the data store will be effective from the subsequent scans.
- If a data store is associated with a scan, it can't be deleted. Disassociate the data store from the scan and try deleting it again.

Supported data stores

- Local Storages
- Network Storages
- Databases
- Big Data

- Servers
- Clouds

Local storage

You can scan Windows and Linux local storage data stores with Data Discovery and Classification application.

Note

- You cannot scan mounted network shares as local storage.
- As DDC uses the Hostname/IP to determine the system for scanning, avoid having multiple hosts with identical Hostname/IP combinations, as DDC may randomly choose one.
- Install DDC ML agent on local host machine to scan local storage data stores for regex and ML infotypes. If you only want to scan regex based infotype, install the DDC agent on the host machine.
- The DDC ML agent runs as a local system. Ensure that the SYSTEM account has appropriate permissions (typically Full Control) for all files and folders within the data store being scanned. Refer to [Microsoft documentation](#) for more information on default SYSTEM account permissions.

This section covers the following topics:

- [Add local storage data store](#)
- [Add local storage scan](#)

Adding local storage data store

To add the local storage data store:

1. Log on to the **CipherTrust Manager** GUI.
2. Open the **Data Discovery & Classification** application.
3. Click **Data Stores > Data Stores > Add Data Store**.
4. Complete the following steps:
 - a. [Select Type & Category](#)
 - b. [General Info](#)
 - c. [Configure Connection](#)
 - d. [Add Access Control & Tags](#)

Select Type & Category

1. Under **Select Data Store Category**, select **Local**.
2. From **Select Data Store Type**, select **Local Storage**.
3. Click **Next**.

General Info

1. Specify the following details:
 - **Data Store Name**: Name for the data store.
 - **Description** (Optional): Description for the data store.
 - **Location Name**: Location of the data store.
 - **Add Location**: Click **Add Location** to add new locations to the **Location Name** drop-down. Refer to [Adding Locations](#) for detailed steps.
 - **Sensitivity Level** (Optional): Sensitivity level for the data store. Refer to [Sensitivity Levels](#) for details.
 - **Enable Data Store**: Whether to enable the newly added data store. Select the check box to enable the data store.
2. Click **Next**.

Configure Connection

1. In the **Hostname/IP** field, specify a valid hostname, IP address, or Uniform Resource Identifier (URI) of the agent running on the machine where the local storage data store resides. Hostname/IP must be longer than two characters. For example, `10.0.0.1` or `agent123`.

Tip

Make sure the agent can resolve its hostname. If it cannot, include the agent name in the operating system's Hosts file. For example, if the agent's hostname is 'agent123', add the entry '127.0.0.1 localhost agent123' in the Hosts file.

2. Click **Next**.

Add Access Control & Tags

1. (Optional) Grant the `All groups (default)` access for reports. Alternatively, select a group.

2. Click **Save**.

The data store is added to the Data Stores page. If the **Ready to Scan** column shows **Ready**, then data store is properly configured.

For more information on Access control and Tags, expand the section below.

Access Control & Tags

The **Access Control & Tags** tab on the **Add Data Store** screen allows you to grant access rights to your data store and add tags. More details below:

- **ACCESS CONTROL** - select user groups that can access the data store. Access to a data store provides ability to see reports that include scans of that data store. The available options are:
 - **All groups:** All groups of users can access the data store through reports. This is the default setting.
 - **Selected group/s:** Specified user defined groups can access the data store through reports. When this option is selected, select a group from the drop-down list. This list shows existing user defined groups. The user defined groups must already exist on CipherTrust Manager. If no user defined groups exist, ask the administrator to create a group. If needed, you can select multiple groups. Start typing the name of the desired group and select from the suggested groups.
- **TAGS** - Select a tag from the **Add Tag** drop-down. See the list of prebuilt tags in [Predefined tags](#) section.

Tip

- New tags can also be added. Start typing a new tag, and click the **New: <new_tag>** link that appears below the drop-down.
- Add as many tags as needed.
- To remove a tag, click the close icon in the tag name.

Adding local storage Scan

To add a scan for local storage:

1. In the **Data Discovery & Classification** application, click **Scans > Add Scan**.
2. Complete the following steps:
 - a. [General Info](#)
 - b. [Select Data Stores](#)
 - c. [Add Targets](#)

- d. [Select Profiles](#)
- e. [Add Filters](#)
- f. [Schedule Run](#)

Refer to [Scans](#) for the description of sections of the Add Scan screen.

General Info

1. Specify a **Name** for the scan.
2. (optional) Add a **Description** for the scan.
3. Expand **Advanced Configuration** and specify advanced configurations such Scan Priority, Memory Usage Limit, and Amount of Data Object Volume. Refer to [Advanced Configuration](#) for details.
4. Click **Next**.

Select Data Stores

1. Under **Data Store Name**, select the local data store that is **Ready** for scanning. You can select multiple data stores, if required.
2. Click **Next**.

Add Targets

Note

If no specific target is added, the entire data store will be scanned.

1. To add a scan target, do one of the following:
 - Under the **Add Target** field, specify the correct target path and click **Apply**.

Note

Ensure that the target path syntax format matches the local storage directory structure. For example, for Windows, use `drive\folder\filename` as the path and for Linux, use `/directory/subdirectory/filename` as the path.

- Navigate and add target paths.

- a. Click **Browse** to navigate target paths from the root level.

Alternatively, provide an initial path in the **Add Target Path** field and click **Browse** to navigate targets from that point onward.

- b. In the left pane, navigate and select the desired target path.
- c. Click **Add Path** to add the target path to the right pane. Similarly, add other target paths.
- d. Click **Add**.

Tip

Either navigate the target paths from the root level (without specifying any path in the **Add Target Path** field) or make sure you provide the correct path to navigate further locations within it.

2. Click **Next**.

Select Profiles

1. Under **Classification Profile Name**, select the desired classification profiles to search for in the data store.
You can select multiple profiles, if required. Refer to [Classification Profiles](#) for details on classification profiles.
2. Click **Next**.

Add Filters

This step is optional.

1. Select the desired filter from the **Select Filter** drop-down.

To filter the locations to scan a local storage data store, consider the following syntax.

Note

Exclude Path/DO by prefix, suffix, and expression filters support wildcard characters. See [Using wildcard characters](#) to learn how wildcards work.

- **Exclude Path/DO by prefix**

Excludes paths or data objects that begin with a given string. It can be used to exclude entire directory trees. Specify `<string>`.

Filter Item	Windows Syntax	Windows Example	Linux Syntax	Linux Example
Folder	<DriveLetter> :\<FolderName>	C:\TestData	<TopLevelDir> /<FolderName>	/mnt/testdata
Sub Folder	<DriveLetter> :\<FolderName> >\<SubFolderName>	C:\TestData\Tests	<TopLevelDir> /<FolderName> /<SubFolderName>	/mnt/testdata/tests
File	<DriveLetter> :\<FolderName> >\<SubFolderName>\<FileName>	C:\TestData\Tests\ Data\file.txt	<TopLevelDir> /<FolderName> /<SubFolderName>/<FileName>	/mnt/testdata/tests/ data/file.txt

- Exclude Path/DO by suffix

Excludes paths or data objects that end with a given string. Specify <string>.

Filter Item	Windows Syntax	Windows Example	Linux Syntax	Linux Example
Folder	<FolderName>\ *	TestData* — Applies all paths starting with 'TestData' as suffix.	<FolderName>*	testdata* — Applies all paths starting with 'testdata' as suffix.
File	<FileName>	file.txt — Applies all paths ending with 'file.txt' as suffix.	<FileName>	file.txt — Applies all paths ending with 'file.txt' as suffix.

- Exclude Path/DO by expression

This filter is majorly used with wildcard characters.

Excludes paths or data objects that match the given expression. Specify <string>.

For example, to exclude locations that contain 'blob' in their path, use expression *blob*.

Filter Item	Windows Syntax	Windows Example	Linux Syntax	Linux Example
Folder	*<FolderName>	*TestData*	*<FolderName>	*testdata*

Filter Item	Windows Syntax	Windows Example	Linux Syntax	Linux Example
	*		*	
File	*<FileName> File within specific folder: *<FolderName> \<FileName>	*file1	*<FileName> File within specific folder: *<FolderName> /<FileName>	*file1

- **Include DO modified recently**

Includes data objects modified within **N** number of days from the current date, where the value of **N** ranges from 1 to 99 days. After selecting this filter, specify **Days from current date**.

- **Exclude DO greater than size**

Excludes data objects that are larger than a given file size (in MB). After selecting this filter, specify the file size in MB.

- **Include DO's within modification date**

Includes data objects modified within a given range of dates. After selecting this filter, specify the **Start** and **End** dates.

2. Click **Apply**.
3. Repeat the above steps to apply multiple filters. Click **Remove** to remove any applied filter.
4. Click **Next**.

Schedule Run

1. Specify the scan run frequency. The two options are:
 - **Manual:** This is the default option. Select this option to run the scan manually. Select the **Run Now** check box to start the scan run after you save the changes.
 - **Scheduled:** Select this option to configure the scan to run automatically at the specified time.

Refer to [Schedule Scan](#) for more details on scheduling scan runs.

2. Click **Save**.

Big data

- Hadoop
- Teradata

Hadoop

This section covers the following topics:

- Prerequisites
- Add Hadoop data store
- Add Hadoop scan
- Generate Kerberos authentication ticket

Prerequisites

- **Supported version:** Hadoop 2.7.3 and above
- **Considerations and Requirements:**
 - **DataNode:** Nodes where data blocks distributed by Hadoop Distributed File System (HDFS) are stored are called DataNodes. DataNodes are treated as “slaves” in a Hadoop cluster.
 - **NameNode:** A node that maintains the index of directories and files and manages data blocks stored on DataNodes is called a NameNode. A NameNode is treated as “master” in a Hadoop cluster.
 - Hadoop is not supported for Debian-based Linux agents.

To scan a Hadoop cluster with HDFS, you must have:

- a. A Target NameNode running Apache Hadoop 2.7.3, Cloudera Distribution for Hadoop (CDH), or similar.
- b. A Proxy host running the Linux 3 Agent with database runtime components for Linux systems.
- c. A valid Kerberos ticket if Kerberos authentication is enabled. See [Generate Kerberos authentication ticket](#).

Add Hadoop data store

To add the Hadoop data store:

1. Log on to the **CipherTrust Manager** GUI.
 2. Open the **Data Discovery and Classification** application.
 3. Click **Data Stores > Data Stores > Add Data Store**. The **Add Data Store** screen is displayed.
-

4. Complete the following steps:
 - a. [Select Type & Category](#)
 - b. [General Info](#)
 - c. [Configure Connection](#)
 - d. [Add Access Control & Tags](#)

Select Type & Category

1. Under **Select Data Store Category**, select **Big Data**.
2. From **Select Server Type**, select **Hadoop Cluster**.
3. Click **Next**.

General Info

1. Specify the following details:
 - **Data Store Name:** Name for the data store.
 - **Description** (Optional): Description for the data store.
 - **Location Name:** Location of the data store.
 - **Add Location:** Click **Add Location** to add new locations to the **Location Name** drop-down. Refer to [Adding Locations](#) for detailed steps.
 - **Sensitivity Level** (Optional): Sensitivity level for the data store. Refer to [Sensitivity Levels](#) for details.
 - **Enable Data Store:** Whether to enable the newly added data store. Select the check box to enable the data store.
2. Click **Next**.

Configure Connection

1. Specify the credentials of the Hadoop domain:

Field	Description
Hostname/IP	Specify Hostname/IP of the Hadoop cluster's active NameNode. Specify a valid hostname, IP address, or Uniform Resource Identifier (URI). The hostname must be longer than two characters. For example, if your HDFS share path is <code>hdfs://hadoop-</code>

Field	Description
	server - name / share - name, the host name of the Name Node is share - name.
Port	The port on which the NameNode is accessed. Default is 8020. This is a mandatory field.

- (Optional) In the **Add Label** field, enter a label to restrict the agents that can scan this specific data store instance. You can also remove an existing label. See [Labels](#) for more details.
- Click **Next**.

Add Access Control & Tags

- (Optional) Grant the **All groups (default)** access for reports. Alternatively, select a group.
- Click **Save**.

The data store is added to the Data Stores page. If the **Ready to Scan** column shows **Ready**, then data store is properly configured.

For more information on Access control and Tags, expand the section below.

Access Control & Tags

The **Access Control & Tags** tab on the **Add Data Store** screen allows you to grant access rights to your data store and add tags. More details below:

- **ACCESS CONTROL** - select user groups that can access the data store. Access to a data store provides ability to see reports that include scans of that data store. The available options are:
 - **All groups:** All groups of users can access the data store through reports. This is the default setting.
 - **Selected group/s:** Specified user defined groups can access the data store through reports. When this option is selected, select a group from the drop-down list. This list shows existing user defined groups. The user defined groups must already exist on CipherTrust Manager. If no user defined groups exist, ask the administrator to create a group. If needed, you can select multiple groups. Start typing the name of the desired group and select from the suggested groups.
- **TAGS** - Select a tag from the **Add Tag** drop-down. See the list of prebuilt tags in [Predefined tags](#) section.

Tip

- New tags can also be added. Start typing a new tag, and click the **New: <new_tag>** link that appears below the drop-down.

- Add as many tags as needed.
- To remove a tag, click the close icon in the tag name.

Add Hadoop scan

To add a scan for the Hadoop:

1. Open the **Data Discovery and Classification** application.
2. Click **Scans > Add Scan**. The **Add Scan** screen is displayed.
3. Complete the following steps:
 - a. [General Info](#)
 - b. [Select Data Stores](#)
 - c. [Add Targets](#)
 - d. [Select Profiles](#)
 - e. [Add Filters](#)
 - f. [Schedule Run](#)

Refer to [Scans](#) for the description of sections of the Add Scan screen.

General Info

1. Specify a **Name** for the scan.
2. (optional) Add a **Description** for the scan.
3. Expand **Advanced Configuration** and specify advanced configurations such as Scan Priority, Memory Usage Limit, and Amount of Data Object Volume. Refer to [Advanced Configuration](#) for details.
4. Click **Next**.

Select Data Stores

1. Under **Data Store Name**, select the desired data store that is **Ready** for scanning. You can select multiple data stores, if required.
2. Click **Next**.

Add Targets

1. To add a scan target, do one of the following:

- Add target path manually.

Under the **Add Target** field, specify the correct target path and click **Apply**.

If no specific target is added, the entire data store will be scanned.

- Navigate and add target paths.
 - a. Click **Browse** to navigate target paths from the root level.

Alternatively, provide an initial path in the **Add Target Path** field and click **Browse** to navigate targets from that point onward.

- b. In the left pane, navigate and select the desired target path.
- c. Click **Add Path** to add the target path to the right pane. Similarly, add other target paths.
- d. Click **Add**.

Tip

Either navigate the target paths from the root level (without specifying any path in the **Add Target Path** field) or make sure you provide the correct path to navigate further locations within it.

2. Click **Next**.

Select Profiles

1. Under **Classification Profile Name**, select the desired classification profiles to search for in the data store. You can select multiple data stores, if required. Refer to [Classification Profiles](#) for details on classification profiles.
2. Click **Next**.

Add Filters

This step is optional.

1. Select the desired filter from the **Select Filter** drop-down list.

To filter the locations to scan an Hadoop data store, consider the following syntax.

Note

Exclude Path/DO by prefix, suffix, and expression filters support wildcard characters. See [Using wildcard characters](#) to learn how wildcards work.

- **Exclude Path/DO by prefix**

Excludes paths or data objects that begin with a given string. It can be used to exclude entire directory trees. Specify `<string>`.

- **Exclude Path/DO by suffix**

Excludes paths or data objects that end with a given string. Specify `<string>`.

- **Exclude Path/DO by expression**

This filter is majorly used with wildcard characters.

Excludes paths or data objects that matches the given expression. Specify `<string>`.

For example, to exclude locations that contain 'blob' in their path, use expression `*blob*`.

- **Include DO modified recently**

Includes data objects modified within **N** number of days from the current date, where the value of **N** ranges from 1 to 99 days. After selecting this filter, specify **Days from current date**.

- **Exclude DO greater than size**

Excludes data objects that are larger than a given file size (in MB). After selecting this filter, specify the file size in MB.

- **Include DO's within modification date**

Includes data objects modified within a given range of dates. After selecting this filter, specify **Start** and **End** dates.

2. Click **Apply**.
3. Repeat the above steps to apply multiple filters. Click **Remove** to remove any applied filter.
4. Click **Next**.

Schedule Run

1. Specify the scan run frequency. The two options are:

- **Manual:** This is the default option. Select this option to run the scan manually. Select the **Run Now** check box to start the scan run after you save the changes.
- **Scheduled:** Select this option to configure the scan to run automatically at the specified time.

Refer to [Schedule Scan](#) for more details on scheduling scan runs.

2. Click **Save**.

Generate Kerberos authentication ticket

To generate a Kerberos authentication ticket for your HDFS cluster, run these commands in a terminal on the designated Proxy Agent host.

1. Check if a valid Kerberos ticket has been issued for the principal user.

```
klint
```

2. Generate a Kerberos ticket as a principal user.

```
# kinit <username>@<domain>  
kinit DDCuser@example.com
```

Teradata

This section covers the following topics:

- [Prerequisites](#)
- [Add Teradata data store](#)
- [Add Teradata scan](#)

Prerequisites

- **Supported version:** Teradata 17.0.0 and above
- **Considerations and Requirements:**
 - Teradata data stores require **Teradata Tools and Utilities 17.00, 17.10, or 17.20** installed on the Agent along with the following utilities:
 - ODBC Driver for Teradata
 - FastExport

You may have to restart the agent after the installation.

- Scanning of large binary objects is now supported for Teradata. For a list of binary file types supported for Teradata scans, refer to the table in [Binary Large Objects](#).

Note

A scan of a Teradata data store may create temporary tables named `erecon_fexp_<YYYYMMDDHHMMSS><PID><RANDOM>`. **Do not remove these tables** while the scan is in progress. They are automatically removed when a scan completes. If a scan fails or is interrupted by an error, the temporary tables may remain in the database. In this case, it is safe to delete the temporary tables.

Add Teradata data store

To add the Teradata data store:

1. Log on to the **CipherTrust Manager** GUI.
2. Open the **Data Discovery and Classification** application.
3. Click **Data Stores > Data Stores > Add Data Store**. The **Add Data Store** screen is displayed.
4. Complete the following steps:
 - a. [Select Type & Category](#)
 - b. [General Info](#)
 - c. [Configure Connection](#)
 - d. [Add Access Control & Tags](#)

Select Type & Category

1. Under **Select Data Store Category**, select **Big Data**.
2. From **Select Server Type**, select **Teradata**.
3. Click **Next**.

General Info

1. Specify the following details:
 - **Data Store Name:** Name for the data store.
 - **Description** (Optional): Description for the data store.

- **Location Name:** Location of the data store.
- **Add Location:** Click **Add Location** to add new locations to the **Location Name** drop-down. Refer to [Adding Locations](#) for detailed steps.
- **Sensitivity Level (Optional):** Sensitivity level for the data store. Refer to [Sensitivity Levels](#) for details.
- **Enable Data Store:** Whether to enable the newly added data store. Select the check box to enable the data store.

2. Click **Next**.

Configure Connection

1. Specify the credentials of the Teradata domain:

Field	Description
Hostname/IP	Specify a valid Hostname of the Teradata server. The hostname must be longer than two characters. This is a mandatory field.
Port	Default is 1111.
User	The name of the Teradata user. Warning Due to known Teradata limitations DDC cannot use the following internal Teradata users to scan: DBC, tdwm, LockLogShredder, External_AP, TDPUSER, SysAdmin, SystemFe, TDMaps, Crashdumps, Sys_Calendar, viewpoint, console.
Password	The password of the Teradata user.

2. (Optional) In the **Add Label** field, enter a label to restrict the agents that can scan this specific data store instance. You can also remove an existing label. See [Labels](#) for more details.

3. Click **Next**.

Add Access Control & Tags

1. (Optional) Grant the **All groups (default)** access for reports. Alternatively, select a group.
2. Click **Save**.

The data store is added to the Data Stores page. If the **Ready to Scan** column shows **Ready**, then data store is properly configured.

For more information on Access control and Tags, expand the section below.

Access Control & Tags

The **Access Control & Tags** tab on the **Add Data Store** screen allows you to grant access rights to your data store and add tags. More details below:

- **ACCESS CONTROL** - select user groups that can access the data store. Access to a data store provides ability to see reports that include scans of that data store. The available options are:
 - **All groups:** All groups of users can access the data store through reports. This is the default setting.
 - **Selected group/s:** Specified user defined groups can access the data store through reports. When this option is selected, select a group from the drop-down list. This list shows existing user defined groups. The user defined groups must already exist on CipherTrust Manager. If no user defined groups exist, ask the administrator to create a group. If needed, you can select multiple groups. Start typing the name of the desired group and select from the suggested groups.
- **TAGS** - Select a tag from the **Add Tag** drop-down. See the list of prebuilt tags in [Predefined tags](#) section.

Tip

- New tags can also be added. Start typing a new tag, and click the **New: <new_tag>** link that appears below the drop-down.
- Add as many tags as needed.
- To remove a tag, click the close icon in the tag name.

Add Teradata scan

To add a scan for the Teradata:

1. Open the **Data Discovery and Classification** application.
2. Click **Scans > Add Scan**. The **Add Scan** screen is displayed.
3. Complete the following steps:

-
- a. [General Info](#)
 - b. [Select Data Stores](#)
 - c. [Add Targets](#)
 - d. [Select Profiles](#)
 - e. [Add Filters](#)
 - f. [Schedule Run](#)

Refer to [Scans](#) for the description of sections of the Add Scan screen.

General Info

1. Specify a **Name** for the scan.
2. (optional) Add a **Description** for the scan.
3. Expand **Advanced Configuration** and specify advanced configurations such as Scan Priority, Memory Usage Limit, and Amount of Data Object Volume. Refer to [Advanced Configuration](#) for details.
4. Click **Next**.

Select Data Stores

1. Under **Data Store Name**, select the desired data store that is **Ready** for scanning. You can select multiple data stores, if required.
2. Click **Next**.

Add Targets

1. To add a scan target, do one of the following:
 - Add target path manually.

Under the **Add Target** field, specify the correct target path and click **Apply**.

If no specific target is added, the entire data store will be scanned.

The following table lists target paths and syntax to specify them with examples.

Target Path to scan	Syntax	Example
All locations	empty path or [:port]	Leave path blank or :1111
Specific user	<user_name[:<port>]>	userX:1111

Target Path to scan	Syntax	Example
Specific table belonging to a user	<code><user_name[:<port>/table]></code>	<code>userX:1111/accounts</code>
Specific database	<code><database[:<port>]></code>	<code>finance</code>
Specific table	<code><database[:<port>]/table></code>	<code>hr/employees</code>

Note

Paths are case-sensitive.

- Navigate and add target paths.

- a. Click **Browse** to navigate target paths from the root level.

Alternatively, provide an initial path in the **Add Target Path** field and click **Browse** to navigate targets from that point onward.

- b. In the left pane, navigate and select the desired target path.
- c. Click **Add Path** to add the target path to the right pane. Similarly, add other target paths.
- d. Click **Add**.

Tip

Either navigate the target paths from the root level (without specifying any path in the **Add Target Path** field) or make sure you provide the correct path to navigate further locations within it.

2. Click **Next**.

Select Profiles

1. Under **Classification Profile Name**, select the desired classification profiles to search for in the data store. You can select multiple data stores, if required. Refer to [Classification Profiles](#) for details on classification profiles.
2. Click **Next**.

Add Filters

This step is optional.

1. Select the desired filter from the **Select Filter** drop-down list.

To filter the locations to scan an Teradata data store, consider the following syntax.

Note

Exclude Path/DO by prefix, suffix, and expression filters support wildcard characters. See [Using wildcard characters](#) to learn how wildcards work.

- **Exclude Path/DO by prefix**

Excludes paths or data objects that begin with a given string. It can be used to exclude entire directory trees. Specify `<string>`.

- **Exclude Path/DO by suffix**

Excludes paths or data objects that end with a given string. Specify `<string>`.

- **Exclude Path/DO by expression**

This filter is majorly used with wildcard characters.

Excludes paths or data objects that matches the given expression. Specify `<string>`.

For example, to exclude locations that contain 'blob' in their path, use expression `*blob*`.

- **Include DO modified recently**

Includes data objects modified within **N** number of days from the current date, where the value of **N** ranges from 1 to 99 days. After selecting this filter, specify **Days from current date**.

- **Exclude DO greater than size**

Excludes data objects that are larger than a given file size (in MB). After selecting this filter, specify the file size in MB.

- **Include DO's within modification date**

Includes data objects modified within a given range of dates. After selecting this filter, specify **Start** and **End** dates.

2. Click **Apply**.

3. Repeat the above steps to apply multiple filters. Click **Remove** to remove any applied filter.
4. Click **Next**.

Schedule Run

1. Specify the scan run frequency. The two options are:
 - **Manual:** This is the default option. Select this option to run the scan manually. Select the **Run Now** check box to start the scan run after you save the changes.
 - **Scheduled:** Select this option to configure the scan to run automatically at the specified time.

Refer to [Schedule Scan](#) for more details on scheduling scan runs.

2. Click **Save**.

Target limitations

Due to known Teradata limitations Data Discovery and Classification cannot scan the following Teradata internal databases:

SYSJDBC	All	TD_SYSXML	DBC
TDStats	TD_SYSGPL	PUBLIC	SQLJ
SYSBAR	Default	SYSLIB	TD_SYSFNLIB
LockLogShredder	tdwm	TDPUSER	External_AP
EXTUSER	dbcmngr	SystemFe	SysAdmin
TDMaps	TDQCD	Crashdumps	Sys_Calendar
viewpoint	TD_SERVER_DB	console	SYSUDTLIB
SYSUIF	SYSSPATIAL		

Network storage

- NFS Share
- SMB/CIFS Share

NFS Share

NFS (Unix Network File System) is a distributed file system protocol allowing a user on a client computer to access files over a computer network as if it were a local storage.

Note

It is not guaranteed that NFS type data stores will work properly on MAC.

This section covers the following topics:

- Prerequisites
- Add NFS Share data store
- Add NFS Share scan

Prerequisites

- Linux proxy agent.
- Mount target path on the Proxy agent host. See [Mounting an NFS Share](#).
- The target credentials must have minimum required permissions to scan target locations. DDC requires read access for scanning data from the targets.

Note

Install the DDC ML agent on the host server to scan network storage data stores for regex and ML infotypes. To scan only regex-based infotypes, install the standard DDC agent instead.

Add NFS Share data store

To add the NFS Share data store:

1. Log on to the **CipherTrust Manager** GUI.
2. Open the **Data Discovery and Classification** application.
3. Click **Data Stores > Data Stores > Add Data Store**. The **Add Data Store** screen is displayed.
4. Complete the following steps:
 - a. [Select Type & Category](#)
 - b. [General Info](#)
 - c. [Configure Connection](#)

d. Add Access Control & Tags

Select Type & Category

1. Under **Select Data Store Category**, select **Network**.
2. From **Select Server Type**, select **NFS Share**.
3. Click **Next**.

General Info

1. Specify the following details:
 - **Data Store Name**: Name for the data store.
 - **Description** (Optional): Description for the data store.
 - **Location Name**: Location of the data store.
 - **Add Location**: Click **Add Location** to add new locations to the **Location Name** drop-down. Refer to [Adding Locations](#) for detailed steps.
 - **Sensitivity Level** (Optional): Sensitivity level for the data store. Refer to [Sensitivity Levels](#) for details.
 - **Enable Data Store**: Whether to enable the newly added data store. Select the check box to enable the data store.
2. Click **Next**.

Configure Connection

1. Specify the credentials of the NFS Share domain:

Field	Description
Hostname/IP	Provide a valid hostname or IP address of the NFS server. Example : If the NFS shared path is <code>server_ip:/srv/nfs/share</code> , then enter <code>server_ip</code> in the field.
Share Path	Provide a valid NFS path beginning with a slash ('/'). This is the path of the shared directory on the NFS server. Example : If the NFS shared path is <code>server_ip:/srv/nfs/share</code> , then enter <code>/srv/nfs/share</code> in this field.
Agent Hostname/IP	Provide a valid hostname or IP address of the host

Field	Description
	where DDC agent resides. It is mandatory to mount the file share on the host for scanning it.
Mount Point (On Proxy Agent)	Provide a valid directory path on the Proxy host where the NFS Shared path is mounted. This is the local directory on the proxy agent where the NFS shared directory will be accessible. The name of the local directory may be different from the Share path.

Warning

Mount the NFS export on the mount point on the proxy agent host before running any NFS scan.

Note

Use consistent values in the **Hostname/IP** field and the mount command on the DDC Proxy Agent. It is not possible to use the server *IP address* to execute the mount command, and then subsequently use the *hostname* to create the data store, or vice-versa.

2. Click **Next**.

Add Access Control & Tags

1. (Optional) Grant the **All groups (default)** access for reports. Alternatively, select a group.
2. Click **Save**.

The data store is added to the Data Stores page. If the **Ready to Scan** column shows **Ready**, then data store is properly configured.

For more information on Access control and Tags, expand the section below.

Access Control & Tags

The **Access Control & Tags** tab on the **Add Data Store** screen allows you to grant access rights to your data store and add tags. More details below:

- **ACCESS CONTROL** - select user groups that can access the data store. Access to a data store provides ability to see reports that include scans of that data store. The available options are:
 - **All groups:** All groups of users can access the data store through reports. This is the default setting.

- **Selected group/s:** Specified user defined groups can access the data store through reports. When this option is selected, select a group from the drop-down list. This list shows existing user defined groups. The user defined groups must already exist on CipherTrust Manager. If no user defined groups exist, ask the administrator to create a group. If needed, you can select multiple groups. Start typing the name of the desired group and select from the suggested groups.
- **TAGS** - Select a tag from the **Add Tag** drop-down. See the list of prebuilt tags in [Predefined tags](#) section.

Tip

- New tags can also be added. Start typing a new tag, and click the **New: <new_tag>** link that appears below the drop-down.
- Add as many tags as needed.
- To remove a tag, click the close icon in the tag name.

Add NFS Share scan

To add a scan for the NFS Share:

1. Open the **Data Discovery and Classification** application.
2. Click **Scans > Add Scan**. The **Add Scan** screen is displayed.
3. Complete the following steps:
 - a. [General Info](#)
 - b. [Select Data Stores](#)
 - c. [Add Targets](#)
 - d. [Select Profiles](#)
 - e. [Add Filters](#)
 - f. [Schedule Run](#)

Refer to [Scans](#) for the description of sections of the Add Scan screen.

General Info

1. Specify a **Name** for the scan.
2. (optional) Add a **Description** for the scan.

3. Expand **Advanced Configuration** and specify advanced configurations such as Scan Priority, Memory Usage Limit, and Amount of Data Object Volume. Refer to [Advanced Configuration](#) for details.
4. Click **Next**.

Select Data Stores

1. Under **Data Store Name**, select the desired data store that is **Ready** for scanning. You can select multiple data stores, if required.
2. Click **Next**.

Add Targets

1. To add a scan target, do one of the following:

- Add target path manually.

Under the **Add Target** field, specify the correct target path and click **Apply**. For example, `<folder_name>/filename.txt`.

- Navigate and add target paths.

- a. Click **Browse** to navigate target paths from the root level.

Alternatively, provide an initial path in the **Add Target Path** field and click **Browse** to navigate targets from that point onward.

- b. In the left pane, navigate and select the desired target path.
- c. Click **Add Path** to add the target path to the right pane. Similarly, add other target paths.
- d. Click **Add**.

Tip

Either navigate the target paths from the root level (without specifying any path in the **Add Target Path** field) or make sure you provide the correct path to navigate further locations within it.

2. Click **Next**.

Select Profiles

1. Under **Classification Profile Name**, select the desired classification profiles to search for in the data store. You can select multiple data stores, if required. Refer to [Classification Profiles](#) for details on classification

profiles.

2. Click **Next**.

Add Filters

This step is optional.

1. Select the desired filter from the **Select Filter** drop-down list.

To filter the locations to scan an NFS Share data store, consider the following syntax.

Note

Exclude Path/DO by prefix, suffix, and expression filters support wildcard characters. See [Using wildcard characters](#) to learn how wildcards work.

- **Exclude Path/DO by prefix**

Excludes paths or data objects that begin with a given string. It can be used to exclude entire directory trees. Specify `<string>`.

- **Exclude Path/DO by suffix**

Excludes paths or data objects that end with a given string. Specify `<string>`.

- **Exclude Path/DO by expression**

This filter is majorly used with wildcard characters.

Excludes paths or data objects that matches the given expression. Specify `<string>`.

For example, to exclude locations that contain 'blob' in their path, use expression `*blob*`.

- **Include DO modified recently**

Includes data objects modified within **N** number of days from the current date, where the value of **N** ranges from 1 to 99 days. After selecting this filter, specify **Days from current date**.

- **Exclude DO greater than size**

Excludes data objects that are larger than a given file size (in MB). After selecting this filter, specify the file size in MB.

- **Include DO's within modification date**

Includes data objects modified within a given range of dates. After selecting this filter, specify **Start** and

End dates.

2. Click **Apply**.
3. Repeat the above steps to apply multiple filters. Click **Remove** to remove any applied filter.
4. Click **Next**.

Schedule Run

1. Specify the scan run frequency. The two options are:
 - **Manual**: This is the default option. Select this option to run the scan manually. Select the **Run Now** check box to start the scan run after you save the changes.
 - **Scheduled**: Select this option to configure the scan to run automatically at the specified time.

Refer to [Schedule Scan](#) for more details on scheduling scan runs.

2. Click **Save**.

SMB/CIFS Share

Common Internet File System (CIFS) is a cross-platform, transport-independent protocol that provides a mechanism for client systems to use file and print services made available by server systems over a network.

Note

SMB/CIFS is supported for Windows only. Currently, the SMB implementation on Linux (Samba) is not supported.

This section covers the following topics:

- [Prerequisites](#)
- [Add SMB/CIFS Share data store](#)
- [Add SMB/CIFS Share scan](#)

Prerequisites

- Use a Windows proxy agent.
- Ensure that the target storage is accessible from the Proxy agent host.

Note

Install DDC ML agent on host server to scan network storage data stores for regex and ML infotypes. To scan only regex based infotype, install the DDC agent on the host server.

Add SMB/CIFS Share data store

To add the SMB/CIFS Share data store:

1. Log on to the **CipherTrust Manager** GUI.
2. Open the **Data Discovery and Classification** application.
3. Click **Data Stores > Data Stores > Add Data Store**. The **Add Data Store** screen is displayed.
4. Complete the following steps:
 - a. [Select Type & Category](#)
 - b. [General Info](#)
 - c. [Configure Connection](#)
 - d. [Add Access Control & Tags](#)

Select Type & Category

1. Under **Select Data Store Category**, select **Network**.
2. From **Select Server Type**, select **SMB/CIFS Share**.
3. Click **Next**.

General Info

1. Specify the following details:
 - **Data Store Name**: Name for the data store.
 - **Description** (Optional): Description for the data store.
 - **Location Name**: Location of the data store.
 - **Add Location**: Click **Add Location** to add new locations to the **Location Name** drop-down. Refer to [Adding Locations](#) for detailed steps.
 - **Sensitivity Level** (Optional): Sensitivity level for the data store. Refer to [Sensitivity Levels](#) for details.

- **Enable Data Store:** Whether to enable the newly added data store. Select the check box to enable the data store.

2. Click **Next**.

Configure Connection

1. Specify the credentials of the SMB/CIFS Share domain:

Field	Description
Hostname/IP	Specify a valid hostname, IP address, or URI of the data store. For example, if Windows share path is <code>\\remote-server-name\share-name</code> , enter <code>remote-server-name</code> in the field.
Share Name	Specify a valid Windows share name. Following characters are not allowed in the Share Name: <code>=*?, <> ; : + [] " / \</code>. caution Do not confuse Share Name with Network Path. In Windows, Share Name is typically set in the Advanced Sharing settings in the folder sharing properties.
User	Specify user name. Use appropriate format for the target Windows hosts credentials. ▪ <code><domain\username></code> - Use this format when Windows target host resides in the same Active Directory domain as Windows proxy agent. ▪ <code><target_hostname\username></code> - Use this format when Windows target host does not reside in the same Active Directory domain as Windows proxy agent. ▪ <code><username></code> - Use this format if none of the above formats work.
Password	Specify password.

Tip

DNS / DNS reverse resolution may increase the time to scan. Make sure that you optimize your DNS resolution or modify the agent's hosts file to skip the external DNS resolution as indicated in this [technical note](#).

2. In the **Select Number of Agents** field, set the minimum and maximum number of agents for the data store. Refer to [Agents](#) for more information.

Warning

- As there is no limit on the number of minimum and maximum agents that you can set, you should exercise caution so that you do not impact the system performance by using too many resources for a single scan.
- You will not be able to add a datastore if the minimum number of agents cannot be assigned.
- A scan will fail if the assigned agent is unavailable after adding the datastore.
- The minimum number of agents must be less than or equal to the maximum number of agents.

3. (Optional) In the **Add Label** field, enter a label to restrict the agents that can scan this specific data store instance. You can also remove an existing label. See [Labels](#) for more details.
4. Click **Next**.

Add Access Control & Tags

1. (Optional) Grant the **All groups (default)** access for reports. Alternatively, select a group.
2. Click **Save**.

The data store is added to the Data Stores page. If the **Ready to Scan** column shows **Ready**, then data store is properly configured.

For more information on Access control and Tags, expand the section below.

Access Control & Tags

The **Access Control & Tags** tab on the **Add Data Store** screen allows you to grant access rights to your data store and add tags. More details below:

- **ACCESS CONTROL** - select user groups that can access the data store. Access to a data store provides ability to see reports that include scans of that data store. The available options are:
 - **All groups:** All groups of users can access the data store through reports. This is the default setting.

- **Selected group/s:** Specified user defined groups can access the data store through reports. When this option is selected, select a group from the drop-down list. This list shows existing user defined groups. The user defined groups must already exist on CipherTrust Manager. If no user defined groups exist, ask the administrator to create a group. If needed, you can select multiple groups. Start typing the name of the desired group and select from the suggested groups.
- **TAGS** - Select a tag from the **Add Tag** drop-down. See the list of prebuilt tags in [Predefined tags](#) section.

Tip

- New tags can also be added. Start typing a new tag, and click the **New: <new_tag>** link that appears below the drop-down.
- Add as many tags as needed.
- To remove a tag, click the close icon in the tag name.

Add SMB/CIFS Share scan

To add a scan for the SMB/CIFS Share:

1. Open the **Data Discovery and Classification** application.
2. Click **Scans > Add Scan**. The **Add Scan** screen is displayed.
3. Complete the following steps:
 - a. [General Info](#)
 - b. [Select Data Stores](#)
 - c. [Add Targets](#)
 - d. [Select Profiles](#)
 - e. [Add Filters](#)
 - f. [Schedule Run](#)

Refer to [Scans](#) for the description of sections of the Add Scan screen.

General Info

1. Specify a **Name** for the scan.
2. (optional) Add a **Description** for the scan.

3. Expand **Advanced Configuration** and specify advanced configurations such as Scan Priority, Memory Usage Limit, and Amount of Data Object Volume. Refer to [Advanced Configuration](#) for details.
4. Click **Next**.

Select Data Stores

1. Under **Data Store Name**, select the desired data store that is **Ready** for scanning. You can select multiple data stores, if required.
2. Click **Next**.

Add Targets

1. To add a scan target, do one of the following:

- Add target path manually.

Under the **Add Target** field, specify the correct target path and click **Apply**. For example, `<folder_name>/filename.txt`.

- Navigate and add target paths.

- a. Click **Browse** to navigate target paths from the root level.

Alternatively, provide an initial path in the **Add Target Path** field and click **Browse** to navigate targets from that point onward.

- b. In the left pane, navigate and select the desired target path.
- c. Click **Add Path** to add the target path to the right pane. Similarly, add other target paths.
- d. Click **Add**.

Tip

Either navigate the target paths from the root level (without specifying any path in the **Add Target Path** field) or make sure you provide the correct path to navigate further locations within it.

2. Click **Next**.

Select Profiles

1. Under **Classification Profile Name**, select the desired classification profiles to search for in the data store. You can select multiple data stores, if required. Refer to [Classification Profiles](#) for details on classification

profiles.

2. Click **Next**.

Add Filters

This step is optional.

1. Select the desired filter from the **Select Filter** drop-down list.

To filter the locations to scan an SMB/CIFS Share data store, consider the following syntax.

Note

Exclude Path/DO by prefix, suffix, and expression filters support wildcard characters. See [Using wildcard characters](#) to learn how wildcards work.

- **Exclude Path/DO by prefix**

Excludes paths or data objects that begin with a given string. It can be used to exclude entire directory trees. Specify `<string>`.

- **Exclude Path/DO by suffix**

Excludes paths or data objects that end with a given string. Specify `<string>`.

- **Exclude Path/DO by expression**

This filter is majorly used with wildcard characters.

Excludes paths or data objects that matches the given expression. Specify `<string>`.

For example, to exclude locations that contain 'blob' in their path, use expression `*blob*`.

- **Include DO modified recently**

Includes data objects modified within **N** number of days from the current date, where the value of **N** ranges from 1 to 99 days. After selecting this filter, specify **Days from current date**.

- **Exclude DO greater than size**

Excludes data objects that are larger than a given file size (in MB). After selecting this filter, specify the file size in MB.

- **Include DO's within modification date**

Includes data objects modified within a given range of dates. After selecting this filter, specify **Start** and

End dates.

2. Click **Apply**.
3. Repeat the above steps to apply multiple filters. Click **Remove** to remove any applied filter.
4. Click **Next**.

Schedule Run

1. Specify the scan run frequency. The two options are:
 - **Manual**: This is the default option. Select this option to run the scan manually. Select the **Run Now** check box to start the scan run after you save the changes.
 - **Scheduled**: Select this option to configure the scan to run automatically at the specified time.

Refer to [Schedule Scan](#) for more details on scheduling scan runs.

2. Click **Save**.

Server

- Exchange Server
- Sharepoint Server

Exchange Server

This section covers the following topics:

- [Prerequisites](#)
- [Configure impersonation](#)
- [Add Exchange Server data store](#)
- [Add Exchange Server scan](#)
- [Scan additional mailbox types](#)
- [Unsupported mailboxes and folders](#)

Prerequisites

Component	Description
Proxy agent	Windows agent

Component	Description
	Note ▪ Agent host architecture (32-bit or 64-bit) must match the Exchange Server. ▪ The Agent host must be able to contact the domain controller (DC). ▪ A valid LDAP over SSL (LDAPS) certificate that is trusted by the DC must be installed on the Agent host. The proxy agent is only required for LDAPS authentication.
TCP allowed connections	▪ Port 443 ▪ Port 389 for LDAP authentication ▪ Port 636 for LDAPS authentication
Version	Exchange Server 2013 and higher.

Configure impersonation

To scan a Microsoft Exchange mailbox, you have the following options:

- Use an existing service account and assign it the ApplicationImpersonation management role.
- (Recommended) Create a new service account and assign it the ApplicationImpersonation management role.

While you *can* assign the ApplicationImpersonation management role to a global administrator and use it for scanning mailboxes, we recommend using a dedicated service account instead. Service accounts are user accounts set up to perform administrative tasks only. Because of the broad permissions granted to service accounts, we recommend that you closely monitor and limit access to these accounts.

Assigning the ApplicationImpersonation role to a service account allows that account to act as the owner of any account that it is allowed to impersonate. DDC uses the permissions granted to this service account to scan those mailboxes.

To assign a service account the ApplicationImpersonation role for all mailboxes:

1. On the Exchange Server, open the Exchange Management Shell and run as administrator:

```
# <impersonationAssignmentName>: Name of your choice to describe the role assigned to the service account.
# <serviceAccount>: Name of the Exchange administrator account used to scan EWS.
```

```
New-ManagementRoleAssignment -Name:<impersonationAssignmentName> -Role:ApplicationImpersonation -User:<serviceAccount>
```

(Advanced) To assign the service account the ApplicationImpersonation role for a limited number of mailboxes, apply a management scope when making the assignment.

To assign a service account the ApplicationImpersonation role with an applied management scope:

1. On the Exchange Server, open the Exchange Management Shell as administrator.
2. Create a management scope to define the group of mailboxes the service account can impersonate:

```
New-ManagementScope -Name <scopeName> -RecipientRestrictionFilter <filter>
```

For more information on how to define management scopes, see Microsoft: [New-ManagementScope](#).

3. Apply the ApplicationImpersonation role with the defined management scope:

```
New-ManagementRoleAssignment -Name:<impersonationAssignmentName> -Role:ApplicationImpersonation -User:<serviceAccount> -CustomRecipientWriteScope:<scopeName>
```

Add Exchange Server data store

To add the Exchange Server data store:

1. Log on to the **CipherTrust Manager** GUI.
2. Open the **Data Discovery and Classification** application.
3. Click **Data Stores > Data Stores > Add Data Store**. The **Add Data Store** screen is displayed.
4. Complete the following steps:
 - a. [Select Type & Category](#)
 - b. [General Info](#)
 - c. [Configure Connection](#)
 - d. [Add Access Control & Tags](#)

Select Type & Category

1. Under **Select Data Store Category**, select **Server**.

2. From **Select Server Type**, select **Exchange Server**.
3. Click **Next**.

General Info

1. Specify the following details:
 - **Data Store Name**: Name for the data store.
 - **Description** (Optional): Description for the data store.
 - **Location Name**: Location of the data store.
 - **Add Location**: Click **Add Location** to add new locations to the **Location Name** drop-down. Refer to [Adding Locations](#) for detailed steps.
 - **Sensitivity Level** (Optional): Sensitivity level for the data store. Refer to [Sensitivity Levels](#) for details.
 - **Enable Data Store**: Whether to enable the newly added data store. Select the check box to enable the data store.
2. Click **Next**.

Configure Connection

1. Specify the credentials of the Exchange Server domain:

Field	Description
Domain	Domain name to scan mailboxes that reside on that domain. This is usually the domain component of the email address, or the Windows domain. Note Using the domain IP instead of the domain name will not work.
User	Service account user name.

Field	Description
	Tip The account used to scan Microsoft Exchange mailboxes must: ▪ Have a mailbox on the target Microsoft Exchange server. ▪ Be a service account assigned the ApplicationImpersonation management role. See Configure impersonation.
Password	Service account password.

2. In the **Select Number of Agents** field, set the minimum and maximum number of agents for the data store. Refer to [Agents](#) for more information.

Warning

- As there is no limit on the number of minimum and maximum agents that you can set, you should exercise caution so that you do not impact the system performance by using too many resources for a single scan.
- You will not be able to add a datastore if the minimum number of agents cannot be assigned.
- A scan will fail if the assigned agent is unavailable after adding the datastore.
- The minimum number of agents must be less than or equal to the maximum number of agents.

3. (Optional) In the **Add Label** field, enter a label to restrict the agents that can scan this specific data store instance. You can also remove an existing label. See [Labels](#) for more details.
4. Click **Next**.

Add Access Control & Tags

1. (Optional) Grant the **All groups (default)** access for reports. Alternatively, select a group.
2. Click **Save**.

The data store is added to the Data Stores page. If the **Ready to Scan** column shows **Ready**, then data store is properly configured.

For more information on Access control and Tags, expand the section below.

Access Control & Tags

The **Access Control & Tags** tab on the **Add Data Store** screen allows you to grant access rights to your data store and add tags. More details below:

- **ACCESS CONTROL** - select user groups that can access the data store. Access to a data store provides ability to see reports that include scans of that data store. The available options are:
 - **All groups:** All groups of users can access the data store through reports. This is the default setting.
 - **Selected group/s:** Specified user defined groups can access the data store through reports. When this option is selected, select a group from the drop-down list. This list shows existing user defined groups. The user defined groups must already exist on CipherTrust Manager. If no user defined groups exist, ask the administrator to create a group. If needed, you can select multiple groups. Start typing the name of the desired group and select from the suggested groups.
- **TAGS** - Select a tag from the **Add Tag** drop-down. See the list of prebuilt tags in [Predefined tags](#) section.

Tip

- New tags can also be added. Start typing a new tag, and click the **New: <new_tag>** link that appears below the drop-down.
- Add as many tags as needed.
- To remove a tag, click the close icon in the tag name.

Add Exchange Server scan

Note

If a mailbox is a member of multiple Groups, it is scanned each time a Group it belongs to is scanned. Mailboxes that are members of multiple Groups still consume only one mailbox license, no matter how many times it is scanned as part of a separate Group.

Example: User mailbox "A" belongs to Groups "A1", and "A2". When Groups "A1" and "A2" are added to the same scan, user mailbox "A" is scanned once when Group "A1" is scanned, and a second time when Group "A2" is scanned. Mailbox "A" consumes only one mailbox license despite having been scanned twice.

To add a scan for the Exchange Server:

1. Open the **Data Discovery and Classification** application.
2. Click **Scans > Add Scan**. The **Add Scan** screen is displayed.

3. Complete the following steps:

- a. [General Info](#)
- b. [Select Data Stores](#)
- c. [Add Targets](#)
- d. [Select Profiles](#)
- e. [Add Filters](#)
- f. [Schedule Run](#)

Refer to [Scans](#) for the description of sections of the Add Scan screen.

General Info

1. Specify a **Name** for the scan.
2. (optional) Add a **Description** for the scan.
3. Expand **Advanced Configuration** and specify advanced configurations such as Scan Priority, Memory Usage Limit, and Amount of Data Object Volume. Refer to [Advanced Configuration](#) for details.
4. Click **Next**.

Select Data Stores

1. Under **Data Store Name**, select the desired data store that is **Ready** for scanning. You can select multiple data stores, if required.
2. Click **Next**.

Add Targets

1. To add a scan target, do one of the following:

- Add target path manually.

Under the **Add Target** field, specify the correct target path and click **Apply**. See [Target limitations](#).

- Navigate and add target paths.

- a. Click **Browse** to navigate target paths from the root level.

Alternatively, provide an initial path in the **Add Target Path** field and click **Browse** to navigate targets from that point onward.

- b. In the left pane, navigate and select the desired target path.
-

- c. Click **Add Path** to add the target path to the right pane. Similarly, add other target paths.
- d. Click **Add**.

Tip

Either navigate the target paths from the root level (without specifying any path in the **Add Target Path** field) or make sure you provide the correct path to navigate further locations within it.

2. Click **Next**.

Select Profiles

1. Under **Classification Profile Name**, select the desired classification profiles to search for in the data store. You can select multiple data stores, if required. Refer to [Classification Profiles](#) for details on classification profiles.
2. Click **Next**.

Add Filters

This step is optional.

1. Select the desired filter from the **Select Filter** drop-down list.

To filter the locations to scan an Exchange Server data store, consider the following syntax.

Note

Exclude Path/DO by prefix, suffix, and expression filters support wildcard characters. See [Using wildcard characters](#) to learn how wildcards work.

- **Exclude Path/DO by prefix**

Excludes paths or data objects that begin with a given string. It can be used to exclude entire directory trees. Specify `<string>`.

- **Exclude Path/DO by suffix**

Excludes paths or data objects that end with a given string. Specify `<string>`.

- **Exclude Path/DO by expression**

This filter is majorly used with wildcard characters.

Excludes paths or data objects that matches the given expression. Specify `<string>`.

For example, to exclude locations that contain 'blob' in their path, use expression `*blob*`.

- **Include DO modified recently**

Includes data objects modified within **N** number of days from the current date, where the value of **N** ranges from 1 to 99 days. After selecting this filter, specify **Days from current date**.

- **Exclude DO greater than size**

Excludes data objects that are larger than a given file size (in MB). After selecting this filter, specify the file size in MB.

- **Include DO's within modification date**

Includes data objects modified within a given range of dates. After selecting this filter, specify **Start** and **End** dates.

2. Click **Apply**.
3. Repeat the above steps to apply multiple filters. Click **Remove** to remove any applied filter.
4. Click **Next**.

Schedule Run

1. Specify the scan run frequency. The two options are:
 - **Manual:** This is the default option. Select this option to run the scan manually. Select the **Run Now** check box to start the scan run after you save the changes.
 - **Scheduled:** Select this option to configure the scan to run automatically at the specified time.

Refer to [Schedule Scan](#) for more details on scheduling scan runs.

2. Click **Save**.

Scan additional mailbox types

The following additional mailbox types are supported:

- **Shared mailboxes:** Shared mailboxes do not have a specific owner. Instead, user accounts that need to access the shared mailbox are assigned "SendAs" or "FullAccess" permissions.
- **Linked mailboxes:** A linked mailbox is a mailbox that resides on one Active Directory (AD) forest, while its associated AD user account (the linked master account) resides on another AD forest.

- **Mailboxes associated with disabled AD user accounts:** Disabled AD user accounts may still be associated with active mailboxes that can still receive and send email. Mailboxes associated with disabled AD user accounts are not the same as disconnected mailboxes.

To scan the above supported mailbox types, use a service account with "FullAccess" rights to the target mailbox.

Grant access rights to mailboxes

Note

Adding "FullAccess" privileges to an existing user account may cause issues with existing user configuration. To avoid this, create a new service account and use only that account for scanning Exchange shared mailboxes with DDC.

Changes may not be immediate. Wait 15 minutes before starting a scan on the exchange server.

After the service account is granted access to the target mailboxes, you can add them as targets.

Note

Linked mailboxes as service accounts

You cannot use a linked master account (the owner of a linked mailbox) to scan Exchange Targets in DDC. To successfully scan an Exchange Target, use a service account that resides on the same AD forest as the Exchange Target.

Shared Mailboxes

To grant a service account "FullAccess" rights to shared mailboxes, run the following commands in the Exchange Management Shell:

Grant full access to a specific shared mailbox:

```
Add-MailboxPermission -Identity <SHARED_MAILBOX> -User <SERVICE_ACCOUNT> -AccessRights FullAccess -Automapping $false
```

Here, <SHARED_MAILBOX> is the name of the shared mailbox, and <SERVICE_ACCOUNT> is the name of the account used to scan the mailbox.

Grant full access to all existing shared mailboxes on the Exchange server:

```
Get-Recipient -Resultsize unlimited | where {$_.RecipientTypeDetails -eq "SharedMailbox"} | Add-MailboxPermission -User <SERVICE_ACCOUNT> -AccessRights FullAccess -Automapping $false
```

Here <SERVICE_ACCOUNT> is the name of the account used to scan the mailboxes.

Linked Mailboxes

To grant a service account "FullAccess" rights to linked mailboxes, run the following commands in the Exchange Management Shell:

Grant full access to a specific shared mailbox:

```
Add-MailboxPermission -Identity <LINKED_MAILBOX> -User <SERVICE_ACCOUNT> -AccessRights FullAccess -Automapping $false
```

Here <LINKED_MAILBOX> is the name of the shared mailbox, and <SERVICE_ACCOUNT> is the name of the account used to scan the mailbox.

Grant full access to all existing shared mailboxes on the Exchange server:

```
Get-Recipient -Resultsize unlimited | where {$_.RecipientTypeDetails -eq "LinkedMailbox"} | Add-MailboxPermission -User <SERVICE_ACCOUNT> -AccessRights FullAccess -Automapping $false
```

Here <SERVICE_ACCOUNT> is the name of the account used to scan the mailboxes.

Mailboxes associated with disabled AD user accounts

To grant a service account "FullAccess" rights to mailboxes associated with disabled AD user accounts, run the following commands in the Exchange Management Shell:

Grant full access to a specific mailbox:

```
Add-MailboxPermission -Identity <USER_DISABLED_MAILBOX> -User <SERVICE_ACCOUNT> -AccessRights FullAccess -Automapping $false
```

Here, <USER_DISABLED_MAILBOX> is the name of the mailbox associated with a disabled AD user account, and <SERVICE_ACCOUNT> is the name of the account used to scan the mailbox.

Unsupported mailboxes and folders

Currently, DDC doesn't support the following mailbox types and folders for the Exchange Server target:

- **Disconnected mailboxes:** Disconnected mailboxes are mailboxes that have been:
 - **Disabled:** Disabled mailboxes are rendered inactive and retained until the retention period expires, while leaving associated user accounts untouched. Disabled mailboxes can only be accessed by reconnecting the owner user account to the mailbox.
 - **Removed:** Removing a mailbox deletes the associated AD user account, renders the mailbox inactive, and retains it until its retention period expires. Removed mailboxes can only be accessed by connecting it to another user account.
 - **Moved to a different mailbox database:** Moving a mailbox from one mailbox database to another leaves the associated user account untouched, but sets the state of the mailbox to "SoftDeleted". "SoftDeleted"

mailboxes are left in place in its original mailbox database as a backup, in case the destination mailbox is corrupted during the move. To access a "SoftDeleted" mailbox, connect it to a different user account or restore its contents to a different mailbox.

- **Resource mailboxes:** Resource mailboxes are mailboxes that have been assigned to meeting locations (room mailboxes) and other shared physical resources in the company (equipment mailboxes). These mailboxes are used for scheduling purposes.
- **Remote mailboxes:** Mailboxes that are set up on a hosted Exchange instance, or on Microsoft 365, and connected to an email user on an on-premises Exchange instance.
- **System mailboxes**
- **Legacy mailboxes**

Note

The following are not mailboxes, and are not supported as scan locations:

- All distribution groups.
- Mail users or mail contacts.
- Public folders.

Target limitations

Scanning the entire data store is not supported, hence you must specify a scan target path.

Sharepoint Server

This section covers the following topics:

- [Prerequisites](#)
- [SharePoint Server resources](#)
- [Add Sharepoint Server data store](#)
- [Add Sharepoint Server scan](#)

Prerequisites

Component	Description
Proxy agent	Windows agent

Component	Description
TCP allowed connections	All TCP ports used by the SharePoint web applications.
Version	SharePoint Server 2013 and higher.

SharePoint Server resources

Sharepoint Server is a web-based collaborative platform integrating natively with Microsoft Office that is provided to organizations seeking greater control over Sharepoint's behavior or design. A SharePoint Server host consists of web applications, site collections, sites, files, and folders as shown below. When a SharePoint Server is added as a scan target, DDC returns all root-level site collections for the SharePoint Server.

Example structure of SharePoint Server Host:

```
SharePoint Server Host (host name: SharePointX)
+- SharePoint Server
  +- Web Application 1 (https://sharepoint.example.com)
    +- Site Collection 1 (https://sharepoint.example.com/)
    +- Site Collection 2 (https://sharepoint.example.com/operations)
    +- Site Collection 3 (https://sharepoint.example.com/marketing)
  +- Web Application 2 (https://sharepoint.example.com:100)
    +- Site Collection 1 (https://sharepoint.example.com:100/)
    +- Site Collection 2 (https://sharepoint.example.com:100/engineering)
```

Example of structure of Web application:

```
Web Application 1 (https://sharepoint.example.com)
+- Site Collection 1 (https://sharepoint.example.com/)
+- Site Collection 2 (https://sharepoint.example.com/operations)
  +- Sub-site 1 (https://sharepoint.example.com/operations/sub-site.aspx)
  +- Folder 1 (https://sharepoint.example.com/operations/myFolder)
    +- File 1 (https://sharepoint.example.com/operations/myFolder/myFile
e.txt)
  +- Lists (https://sharepoint.example.com/operations/Lists)
    +- List 1 (https://sharepoint.example.com/operations/Lists/myList)
      +- Item 1 https://sharepoint.example.com/operations/Lists/myList/
myFile.pptx)
```

Add Sharepoint Server data store

To add the Sharepoint Server data store:

1. Log on to the **CipherTrust Manager** GUI.
2. Open the **Data Discovery and Classification** application.
3. Click **Data Stores > Data Stores > Add Data Store**. The **Add Data Store** screen is displayed.
4. Complete the following steps:
 - a. **Select Type & Category**

- b. General Info
- c. Configure Connection
- d. Add Access Control & Tags

Select Type & Category

1. Under **Select Data Store Category**, select **Server**.
2. From **Select Server Type**, select **Sharepoint Server**.
3. Click **Next**.

General Info

1. Specify the following details:
 - **Data Store Name**: Name for the data store.
 - **Description** (Optional): Description for the data store.
 - **Location Name**: Location of the data store.
 - **Add Location**: Click **Add Location** to add new locations to the **Location Name** drop-down. Refer to [Adding Locations](#) for detailed steps.
 - **Sensitivity Level** (Optional): Sensitivity level for the data store. Refer to [Sensitivity Levels](#) for details.
 - **Enable Data Store**: Whether to enable the newly added data store. Select the check box to enable the data store.
2. Click **Next**.

Configure Connection

1. Specify the credentials of the Sharepoint Server domain:

Field	Description
Hostname	Hostname of the Microsoft SQL Server where the SharePoint Server is hosted.
User	A SQL user configured in the SharePoint and has access to the sites that you want to scan.
Password	Password used for the SQL user.
API Passwords	If multiple credentials are required to access the different site collections or sites, click the Browse

Field	Description
	button and upload the text file containing granular access credentials for sites and site collections. Text file format: Each line in the file defines a credential set for a URL path formatted as <code><url_path> <username> <password></code>. Here, ▪ <code><url_path></code> is the URL path to a Site Collection or Site. If it is left blank, the credentials will be used to access all content in the SharePoint Server. ▪ <code><username></code> is the user name that has access to the URL path. ▪ <code><password></code> is the password for the corresponding user. Note DDC will default to the credentials provided in the User and Password fields for sites or site collections that are not specified in the text file.

Note

Use credentials that have the minimum required privileges to access all the web applications and site collections on the Sharepoint Server for successfully scanning all resources for a Sharepoint Server target. For example, to scan all the Sharepoint site collections in "Sharepoint X", use a credential set that has access to "Web Application 1" and "Web Application 2".

Tip

Windows Authentication for Microsoft SQL

For Windows authentication, enter Windows account credentials as follows:

- **User:** Windows domain and username in the `<domain_name\user_name>` format.

- **Password:** Windows password.

For more information on Windows or SQL Server authentication modes, see [Choose An Authentication Mode](#).

2. In the **Select Number of Agents** field, set the minimum and maximum number of agents for the data store. Refer to [Agents](#) for more information.

Warning

- As there is no limit on the number of minimum and maximum agents that you can set, you should exercise caution so that you do not impact the system performance by using too many resources for a single scan.
- You will not be able to add a datastore if the minimum number of agents cannot be assigned.
- A scan will fail if the assigned agent is unavailable after adding the datastore.
- The minimum number of agents must be less than or equal to the maximum number of agents.

3. (Optional) In the **Add Label** field, enter a label to restrict the agents that can scan this specific data store instance. You can also remove an existing label. See [Labels](#) for more details.
4. Click **Next**.

Add Access Control & Tags

1. (Optional) Grant the **All groups (default)** access for reports. Alternatively, select a group.
2. Click **Save**.

The data store is added to the Data Stores page. If the **Ready to Scan** column shows **Ready**, then data store is properly configured.

For more information on Access control and Tags, expand the section below.

Access Control & Tags

The **Access Control & Tags** tab on the **Add Data Store** screen allows you to grant access rights to your data store and add tags. More details below:

- **ACCESS CONTROL** - select user groups that can access the data store. Access to a data store provides ability to see reports that include scans of that data store. The available options are:
 - **All groups:** All groups of users can access the data store through reports. This is the default setting.
 - **Selected group/s:** Specified user defined groups can access the data store through reports. When this

option is selected, select a group from the drop-down list. This list shows existing user defined groups. The user defined groups must already exist on CipherTrust Manager. If no user defined groups exist, ask the administrator to create a group. If needed, you can select multiple groups. Start typing the name of the desired group and select from the suggested groups.

- **TAGS** - Select a tag from the **Add Tag** drop-down. See the list of prebuilt tags in [Predefined tags](#) section.

Tip

- New tags can also be added. Start typing a new tag, and click the **New: <new_tag>** link that appears below the drop-down.
- Add as many tags as needed.
- To remove a tag, click the close icon in the tag name.

Add Sharepoint Server scan

To add a scan for the Sharepoint Server:

1. Open the **Data Discovery and Classification** application.
2. Click **Scans > Add Scan**. The **Add Scan** screen is displayed.
3. Complete the following steps:
 - a. [General Info](#)
 - b. [Select Data Stores](#)
 - c. [Add Targets](#)
 - d. [Select Profiles](#)
 - e. [Add Filters](#)
 - f. [Schedule Run](#)

Refer to [Scans](#) for the description of sections of the Add Scan screen.

General Info

1. Specify a **Name** for the scan.
2. (optional) Add a **Description** for the scan.

- Expand **Advanced Configuration** and specify advanced configurations such as Scan Priority, Memory Usage Limit, and Amount of Data Object Volume. Refer to [Advanced Configuration](#) for details.
- Click **Next**.

Select Data Stores

- Under **Data Store Name**, select the desired data store that is **Ready** for scanning. You can select multiple data stores, if required.
- Click **Next**.

Add Targets

- To add a scan target, do one of the following:

- Add target paths manually.

Under the **Add Target** field, specify the correct target path and click **Apply**. See [SharePoint Server resources](#) to understand the structure of targets.

If no specific target is added, the entire data store will be scanned.

The following table lists target paths and syntax to specify them with examples.

Target Path to scan	Syntax	Example
Complete data store	Empty path	
Site collection	<code><organization>.sharepoint.com/<site_collection></code>	<code>https://example.sharepoint.com/operations</code>
All lists in a site collection	<code><organization>.sharepoint.com/<site_collection>/<site></code>	<code>https://example.sharepoint.com/operations/my-site</code>
Specific list in a site collection	<code><organization>.sharepoint.com/<site_collection>/:site/:list/<list></code>	<code>https://example.sharepoint.com/operations/:site/:list/my-list</code>
All folders and files in a site collection.	<code><organization>.sharepoint.com/<site_collection>/:site/:file</code>	<code>https://example.sharepoint.com/operations/:site/:file</code>
Specific folder in a site collection.	<code><organization>.sharepoint.com/<site_collection></code>	<code>https://example.sharepoint.com/</code>

Target Path to scan	Syntax	Example
	<code>>/:site/:file/<folder></code>	<code>operations/:site/:file/documents</code>
Specific file in a site collection.	<code><organization>.sharepoint.com/<site_collection>/:site/:file/<file></code>	<code>https://example.sharepoint.com/operations/:site/:file/example-file.txt</code>
Specific file within a folder in a site collection.	<code><organization>.sharepoint.com/<site_collection>/:site/:file/<folder>/<file></code>	<code>https://example.sharepoint.com/operations/:site/:file/documents/example-file.txt</code>

Note

- Target paths are case-sensitive.
- A list item in a specific list cannot be individually added and scanned. You can only scan the entire list.
- While scanning lists, attachments within SharePoint Server lists are not scanned, resulting in no sensitive data objects being detected. To scan the attachments within list, use the following target path: `<organization>.sharepoint.com/sites/<site_collection>/:site/:file/Lists/list_name/attachments`

- Navigate and add target paths.

- Click **Browse** to navigate target paths from the root level.

Alternatively, provide an initial path in the **Add Target Path** field and click **Browse** to navigate targets from that point onward.

- In the left pane, navigate and select the desired target path.
- Click **Add Path** to add the target path to the right pane. Similarly, add other target paths.
- Click **Add**.

Tip

Either navigate the target paths from the root level (without specifying any path in the **Add Target Path** field) or make sure you provide the correct path to navigate further locations within it.

2. Click **Next**.

Select Profiles

1. Under **Classification Profile Name**, select the desired classification profiles to search for in the data store. You can select multiple data stores, if required. Refer to [Classification Profiles](#) for details on classification profiles.
2. Click **Next**.

Add Filters

This step is optional.

1. Select the desired filter from the **Select Filter** drop-down list.

To filter the locations to scan a Sharepoint Server data store, consider the following syntax.

Note

Exclude Path/DO by prefix, suffix, and expression filters support wildcard characters. See [Using wildcard characters](#) to learn how wildcards work.

- **Exclude Path/DO by prefix**

Excludes paths or data objects that begin with a given string. It can be used to exclude entire directory trees. Specify `<string>`.

Filter Item	Syntax
Site collection	<code><organization>.sharepoint.com/<site_collection></code>
Site	<code><organization>.sharepoint.com/<site_collection>/<site></code>
List	<code><organization>.sharepoint.com/<site_</code>

Filter Item	Syntax
	collection>/:site/:list/<list>
Files	<organization>.sharepoint.com/<site_collection>/:site/:file/<file>
Folders	<organization>.sharepoint.com/<site_collection>/:site/:file/<folder>

- **Exclude Path/DO by suffix**

Excludes paths or data objects that end with a given string. Specify <string>.

Filter Item	Example
Site collection	<site_collection>/*
Site	<site>/*
List	<list>/*
Files	<file>/*
Folders	<folder>/*

- **Exclude Path/DO by expression**

This filter is majorly used with wildcard characters.

Excludes paths or data objects that matches the given expression. Specify <string>.

For example, to exclude locations that contain 'blob' in their path, use expression *blob*.

Filter Item	Example
Site collection	*<site_collection>*
Site	*<site>*
List	*<list>*
Files	*<file>*
Folders	*<folder>*

- **Include DO modified recently**

Includes data objects modified within **N** number of days from the current date, where the value of **N** ranges from 1 to 99 days. After selecting this filter, specify **Days from current date**.

- **Exclude DO greater than size**

Excludes data objects that are larger than a given file size (in MB). After selecting this filter, specify the file size in MB.

- **Include DO's within modification date**

Includes data objects modified within a given range of dates. After selecting this filter, specify **Start** and **End** dates.

2. Click **Apply**.
3. Repeat the above steps to apply multiple filters. Click **Remove** to remove any applied filter.
4. Click **Next**.

Schedule Run

1. Specify the scan run frequency. The two options are:
 - **Manual**: This is the default option. Select this option to run the scan manually. Select the **Run Now** check box to start the scan run after you save the changes.
 - **Scheduled**: Select this option to configure the scan to run automatically at the specified time.

Refer to [Schedule Scan](#) for more details on scheduling scan runs.

2. Click **Save**.

Clouds

- [AWS S3](#)
- [Azure Blobs](#)
- [Azure Table](#)
- [Google Workspace: GDrive](#)
- [Google Workspace: Gmail](#)
- [Office 365: Exchange Online](#)
- [Office 365: OneDrive for Business](#)
- [Office 365: Sharepoint Online](#)
- [Salesforce](#)

AWS S3

This section covers the following topics:

- Prerequisites
- Encryption Methods
- Get AWS S3 Access Keys
- Add AWS S3 Data Store
- Add AWS S3 Scan

Prerequisites

Component	Description
Proxy Agent	• Direct Internet Access • Cloud service-specific access key • Recommended Proxy Agents: • Windows Agent • Linux Agent
TCP Allowed Connections	Port 443

Encryption methods

DDC supports Amazon S3 Buckets that use the following encryption methods:

- Server-side encryption with Amazon S3-managed encryption keys (**SSE-S3**)
- Server-side encryption with AWS KMS-managed keys (**SSE-KMS**)

Get AWS S3 access keys

You require AWS S3 account access key (and associated secret access key) to add AWS S3 data store in DDC for scanning.

To get AWS S3 access key:

1. Log on to [AWS Console](#).
2. On the top left corner, click **Services > IAM > Users**.
3. Search and select the IAM user with the following access permissions:
 - ListAllMyBuckets
 - ListBucket
 - GetBucketLocation

-
- `GetObject`

You can check the user's permission under **Permissions** tab. If you cannot find a user with the required permissions, [create a new user](#).

4. Go to **Security Credentials > Access keys** and note down the access key ID.

Each access key has an associated secret access key. The secret access key is provided to the user at the time of key creation.

If there are no access key listed, [create a new access key](#).

Create new user

1. Click **IAM > Users > Create user**.
2. Enter the user name and click **Next**.
3. Under **Permissions options**, select **Attach policies directly** option.
4. Under **Permissions policies**, select an existing policy having required access permissions to the Amazon S3 Buckets. Or, [create a new permission policy](#).
5. Under **Review and create**, click **Create user**.

Create access key

You can have a maximum of two access keys at a time.

To create an access key:

1. In the **Access keys** section, click **Create access key**.
2. Under **Access key best practices & alternatives**, select **Other** and click **Next**.

You can choose any option as per your requirements. In this use case, **Others** is selected for long-term access key.

3. (Optional) Under **Set description tag**, add a description for the access key.
4. Click **Create access key**.

Access and Secret Access keys are created.

5. Click **Download .csv file** to download and save the access key and secret access key.

Caution

Once the **Retrieve access key** page is closed, you cannot access the secret access keys.

6. Click **Done**.

Create policy

1. Click **Create policy**.
2. On the **Specify permissions** page, use the Visual or JSON editor to add the following permissions:
 - ListAllMyBuckets
 - ListBucket
 - GetBucketLocation
 - GetObject

Example:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:ListAllMyBuckets",
        "s3:ListBucket",
        "s3:GetObject",
        "s3:GetBucketLocation"
      ],
      "Resource": "*"
    }
  ]
}
```

3. Click **Next**.
4. On **Review and create** page, enter the policy name and click **Create policy**.

The new user policy is created and will display under **Permissions policies**.

Delete/Deactivate access key

You can deactivate or delete AWS S3 access keys for a user account.

1. In the AWS console, click **Services > IAM service > Users**.
2. Select the desired user and go to **Security Credentials** tab.

The **Access keys** section displays the existing keys.

3. Do one of the following:

- a. To deactivate an access key:

- Select **Deactivate** from the **Actions** drop-down of the desired access key.

Note

A deactivated access key still counts toward your limit of two access keys.

- b. To delete an access key:

- a. Choose **Delete** from the **Actions** drop-down of the desired access key. Follow the instructions in the dialog to first **Deactivate** the key before deleting it.
- b. In the **Delete <Access Key>** dialog, enter the access key ID.
- c. Click **Delete**.

The access key is deleted. This enables the **Create access key** button for adding new access key.

Add AWS S3 online data store

To configure the AWS S3 Online data store:

1. Log on to the **CipherTrust Manager** GUI.
2. Open the **Data Discovery & Classification** application.
3. Click **Data Stores > Data Stores > Add Data Store**. The **Add Data Store** screen is displayed.
4. Complete the following steps:
 - a. [Select Type & Category](#)
 - b. [General Info](#)
 - c. [Configure Connection](#)

d. Add Access Control & Tags

Note

It is recommended to use IAM access keys instead of AWS root credentials.

Select Type & Category

1. Under **Select Data Store Category**, select **Cloud**.
2. From **Select Cloud Type**, select **AWS S3**.
3. Click **Next**.

General Info

1. Specify the following details:
 - **Data Store Name**: Name for the data store.
 - **Description** (Optional): Description for the data store.
 - **Location Name**: Location of the data store.
 - **Add Location**: Click **Add Location** to add new locations to the **Location Name** drop-down. Refer to [Adding Locations](#) for detailed steps.
 - **Sensitivity Level** (Optional): Sensitivity level for the data store. Refer to [Sensitivity Levels](#) for details.
 - **Enable Data Store**: Whether to enable the newly added data store. Select the check box to enable the data store.
2. Click **Next**.

Configure Connection

1. Specify the credentials of the AWS S3:

Field	Description
Access Key ID	Access Key ID obtained from your storage account administrator.
Secret Access Key	Secret Access Key ID obtained from your storage account administrator.

2. (Optional) In the **Select Number of Agents** field, set the minimum and maximum number of agents for the data store. Refer to [Agents](#) for more information.

Warning

- As there is no limit on the number of minimum and maximum agents that you can set, you should exercise caution so that you do not impact the system performance by using too many resources for a single scan.
- You will not be able to add a datastore if the minimum number of agents cannot be assigned.
- A scan will fail if the assigned agent is unavailable after adding the datastore.
- The minimum number of agents must be less than or equal to the maximum number of agents.

3. (Optional) In the **Add Label** field, enter a label to restrict the agents that can scan this specific data store instance. You can also remove an existing label. See [Labels](#) for more details.
4. Click **Next**.

Add Access Control & Tags

1. (Optional) Grant the **All groups (default)** access for reports. Alternatively, select a group.
2. Click **Save**.

The data store is added to the Data Stores page. If the **Ready to Scan** column shows **Ready**, then data store is properly configured.

For more information on Access control and Tags, expand the section below.

Access Control & Tags

The **Access Control & Tags** tab on the **Add Data Store** screen allows you to grant access rights to your data store and add tags. More details below:

- **ACCESS CONTROL** - select user groups that can access the data store. Access to a data store provides ability to see reports that include scans of that data store. The available options are:
 - **All groups:** All groups of users can access the data store through reports. This is the default setting.
 - **Selected group/s:** Specified user defined groups can access the data store through reports. When this option is selected, select a group from the drop-down list. This list shows existing user defined groups. The user defined groups must already exist on CipherTrust Manager. If no user defined groups exist, ask the administrator to create a group. If needed, you can select multiple groups. Start typing the name of the desired group and select from the suggested groups.
- **TAGS** - Select a tag from the **Add Tag** drop-down. See the list of prebuilt tags in [Predefined tags](#) section.

Tip

- New tags can also be added. Start typing a new tag, and click the **New: <new_tag>** link that appears below the drop-down.
- Add as many tags as needed.
- To remove a tag, click the close icon in the tag name.

Add AWS S3 scan

To add a scan for SharePoint Online:

1. Open the **Data Discovery & Classification** application.
2. Click **Scans > Add Scan**. The **Add Scan** screen is displayed.
3. Complete the following steps:
 - a. [General Info](#)
 - b. [Select Data Stores](#)
 - c. [Add Targets](#)
 - d. [Select Profiles](#)
 - e. [Add Filters](#)
 - f. [Schedule Run](#)

Refer to [Scans](#) for the description of sections of the **Add Scan** screen.

General Info

1. Specify a **Name** for the scan.
2. (optional) Add a **Description** for the scan.
3. Expand **Advanced Configuration** and specify advanced configurations such Scan Priority, Memory Usage Limit, and Amount of Data Object Volume. Refer to [Advanced Configuration](#) for details.
4. Click **Next**.

Select Data Stores

1. Under **Data Store Name**, select the desired data store that is **Ready** for scanning. You can select multiple data stores, if required.
2. Click **Next**.

Add Targets

1. To add a scan target, do one of the following:
 - Under the **Add Target** field, specify the correct target path and click **Apply**.

If no specific target is added, the entire data store will be scanned.

The following table lists target paths and syntax to specify them with examples.

Target Path to Scan	Syntax	Example
Full Data Store	<Empty_Path>	
Whole Bucket	<BucketName>	ddc-data
Specific folder in Bucket	<BucketName/folder_name>	ddc-data/test1
Specific file in Bucket	<BucketName/folder_name/ filename>	ddc-data/test1/emp-info.txt

Note

Target paths are case-sensitive, except for the bucket name. Failure to use the correct case will result in a completed scan, but the report will not contain any match count for data objects and sensitive data.

- Navigate and add target paths.
 - a. Click **Browse** to navigate target paths from the root level.

Alternatively, provide an initial path in the **Add Target Path** field and click **Browse** to navigate targets from that point onward.
 - b. In the left pane, navigate and select the desired target path.
 - c. Click **Add Path** to add the target path to the right pane. Similarly, add other target paths.
 - d. Click **Add**.

Tip

Either navigate the target paths from the root level (without specifying any path in the **Add Target Path** field) or make sure you provide the correct path to navigate further locations within it.

2. Click **Next**.

Select Profiles

1. Under **Classification Profile Name**, select the desired classification profiles to search for in the data store.
You can select multiple profiles, if required. Refer to [Classification Profiles](#) for details on classification profiles.
2. Click **Next**.

Add Filters

This step is optional.

1. Select the desired filter from the **Select Filter** drop-down list.

To filter the locations to scan an AWS S3 data store, consider the following syntax.

Note

Exclude Path/DO by prefix, suffix, and expression filters support wildcard characters. See [Using Wildcard Characters](#) to learn how wildcards work.

- **Exclude Path/DO by prefix**

Excludes paths or data objects that begin with a given string. It can be used to exclude entire directory trees. Specify `<string>`.

Filter Item	Syntax	Example
Bucket	<BucketName>	ddtestdata Wildcard usage ddtestdata* — Applies all paths starting with 'ddtestdata' as prefix.
Folder	<BucketName>/<FolderName>	ddtestdata/tests

Filter Item	Syntax	Example
Sub folder	<BucketName>/<FolderName>/<SubFolderName>	ddctestdata/tests/data
File	<BucketName>/<FolderName>/<SubFolderName>/<File>	ddctestdata/tests/data/file.txt

- **Exclude Path/DO by suffix**

Excludes paths or data objects that end with a given string. Specify **<string>**.

Filter Item	Syntax	Example
Bucket	<BucketName>*	ddctestdata* — Applies all paths starting with 'ddctestdata' as suffix
Folder	<BucketName>/<FolderName>*	ddctestdata/tests* — Applies all paths starting with 'ddctestdata/tests' as suffix.
Sub folder	<BucketName>/<FolderName>/<SubFolderName>*	ddctestdata/tests/data* — Applies all paths starting with 'ddctestdata/tests/data' as suffix.
File	<FileName>	file.txt Wildcard usage *.txt — Applies all paths ending with '.txt' as suffix.

- **Exclude Path/DO by expression**

This filter is majorly used with wildcard characters.

Excludes paths or data objects that matches the given expression. Specify **<string>**.

For example, to exclude locations that contain 'blob' in their path, use expression *blob*.

Filter Item	Syntax	Example
Bucket	*<BucketName>*	*ddctestdata*
Folder	*<FolderName>*	*tests*
Sub folder	*<FolderName>/<SubFolderName>*	*tests/data*
File	*<BucketName>/<FolderName>/	*ddctestdata/tests/data/file1* or

Filter Item	Syntax	Example
	<FileName>* or *<FileName>*	*file1*

- **Include DO modified recently**

Includes data objects modified within **N** number of days from the current date, where the value of **N** ranges from 1 to 99 days. After selecting this filter, specify **Days from current date**.

- **Exclude DO greater than size**

Excludes data objects that are larger than a given file size (in MB). After selecting this filter, specify the file size in MB.

- **Include DO's within modification date**

Includes data objects modified within a given range of dates. After selecting this filter, specify the **Start** and **End** dates.

2. Click **Apply**.
3. Repeat the above steps to apply multiple filters. Click **Remove** to remove any applied filter.
4. Click **Next**.

Schedule run

1. Specify the scan run frequency. The two options are:
 - **Manual:** This is the default option. Select this option to run the scan manually. Select the **Run Now** check box to start the scan run after you save the changes.
 - **Scheduled:** Select this option to configure the scan to run automatically at the specified time.

Refer to [Schedule Scan](#) for more details on scheduling scan runs.

2. Click **Save**.

Azure Blobs

This section covers the following topics:

- [Prerequisites](#)
- [Get Azure Account Access Keys](#)
- [Add Azure Blobs Data Store](#)
- [Add Azure Blobs Scan](#)

Prerequisites

Component	Description
Proxy Agent	• Direct Internet Access • Cloud service-specific access key • Recommended Proxy Agents: • Windows Agent • Linux Agent
TCP Allowed Connections	Port 443

Get Azure Account access keys

You require Azure account access keys to add Azure Blobs data store in DDC for scanning.

To get Azure Account Access keys:

1. Log on to your Azure account.
2. Select **All resources**.
3. Use the search explorer to search for *storage account*.
4. Select the desired storage account.
5. Select **Access keys**.
6. Click **Show** to display the key values.

Note down the key values for **key1 (Primary)** and **key2 (Secondary)**.

Note

Only one access key can be active at a time. Ask your Azure Storage account administrator which access key is currently active, and use that key to connect DDC to your Azure Storage account.

Add Azure Blobs data store

To configure the Azure Blobs data store:

1. Log on to the **CipherTrust Manager** GUI.
2. Open the **Data Discovery & Classification** application.
3. Click **Data Stores > Data Stores > Add Data Store**. The **Add Data Store** screen is displayed.
4. Complete the following steps:

-
- a. **Select Type & Category**
 - b. **General Info**
 - c. **Configure Connection**
 - d. **Add Access Control & Tags**

Note

It is recommended to use IAM access keys instead of AWS root credentials.

Select Type & Category

1. Under **Select Data Store Category**, select **Cloud**.
2. From **Select Cloud Type**, select **Azure Blobs**.
3. Click **Next**.

General Info

1. Specify the following details:
 - **Data Store Name**: Name for the data store.
 - **Description** (Optional): Description for the data store.
 - **Location Name**: Location of the data store.
 - **Add Location**: Click **Add Location** to add new locations to the **Location Name** drop-down. Refer to [Adding Locations](#) for detailed steps.
 - **Sensitivity Level** (Optional): Sensitivity level for the data store. Refer to [Sensitivity Levels](#) for details.
 - **Enable Data Store**: Whether to enable the newly added data store. Select the check box to enable the data store.
2. Click **Next**.

Configure Connection

1. Specify the credentials of the Azure Blobs:

Field	Description
Account Name	Azure account name.
User	Azure storage account name.
Active Access Key	Azure storage account access keys (key1 or key2). See Get Azure Account Access keys .

- In the **Select Number of Agents** field, set the minimum and maximum number of agents for the data store. Refer to [Agents](#) for more information.

Warning

- As there is no limit on the number of minimum and maximum agents that you can set, you should exercise caution so that you do not impact the system performance by using too many resources for a single scan.
- You will not be able to add a datastore if the minimum number of agents cannot be assigned.
- A scan will fail if the assigned agent is unavailable after adding the datastore.
- The minimum number of agents must be less than or equal to the maximum number of agents.

- (Optional) In the **Add Label** field, enter a label to restrict the agents that can scan this specific data store instance. You can also remove an existing label. See [Labels](#) for more details.
- Click **Next**.

Add Access Control & Tags

- (Optional) Grant the **All groups (default)** access for reports. Alternatively, select a group.
- Click **Save**.

The data store is added to the Data Stores page. If the **Ready to Scan** column shows **Ready**, then data store is properly configured.

For more information on Access control and Tags, expand the section below.

Access Control & Tags

The **Access Control & Tags** tab on the **Add Data Store** screen allows you to grant access rights to your data store and add tags. More details below:

- ACCESS CONTROL** - select user groups that can access the data store. Access to a data store provides ability to see reports that include scans of that data store. The available options are:
 - All groups:** All groups of users can access the data store through reports. This is the default setting.

- **Selected group/s:** Specified user defined groups can access the data store through reports. When this option is selected, select a group from the drop-down list. This list shows existing user defined groups. The user defined groups must already exist on CipherTrust Manager. If no user defined groups exist, ask the administrator to create a group. If needed, you can select multiple groups. Start typing the name of the desired group and select from the suggested groups.
- **TAGS** - Select a tag from the **Add Tag** drop-down. See the list of prebuilt tags in [Predefined tags](#) section.

Tip

- New tags can also be added. Start typing a new tag, and click the **New: <new_tag>** link that appears below the drop-down.
- Add as many tags as needed.
- To remove a tag, click the close icon in the tag name.

Add Azure Blobs scan

Azure Blobs data store support multi-agent scans.

To add a scan for Azure Blobs:

1. Open the **Data Discovery & Classification** application.
2. Click **Scans > Add Scan**. The **Add Scan** screen is displayed.
3. Complete the following steps:
 - a. [General Info](#)
 - b. [Select Data Stores](#)
 - c. [Add Targets](#)
 - d. [Select Profiles](#)
 - e. [Apply Filters](#)
 - f. [Schedule Run](#)

Refer to [Scans](#) for the description of sections of the **Add Scan** screen.

General Info

1. Specify a **Name** for the scan.

2. (optional) Add a **Description** for the scan.
3. Expand **Advanced Configuration** and specify advanced configurations such Scan Priority, Memory Usage Limit, and Amount of Data Object Volume. Refer to [Advanced Configuration](#) for details.
4. Click **Next**.

Select Data Stores

1. Under **Data Store Name**, select the desired data store that is **Ready** for scanning. You can select multiple data stores, if required.
2. Click **Next**.

Add Targets

1. To add a scan target, do one of the following:
 - Under the **Add Target** field, specify the correct target path and click **Apply**.

If no specific target is added, the entire data store will be scanned.

The following table lists target paths and syntax to specify them with examples.

Target Path to Scan	Syntax	Example
Full Data Store	<Empty>	
Specific folder	<foldername>	test-dataset
Specific file	<folder_name/file_name.txt>	test-dataset/american-express.txt

Note

Target paths are case-sensitive. Incorrect casing will lead to a failed scan.

- Navigate and add target paths.
 - a. Click **Browse** to navigate target paths from the root level.

Alternatively, provide an initial path in the **Add Target Path** field and click **Browse** to navigate targets from that point onward.
 - b. In the left pane, navigate and select the desired target path.
 - c. Click **Add Path** to add the target path to the right pane. Similarly, add other target paths.

- d. Click **Add**.

Tip

Either navigate the target paths from the root level (without specifying any path in the **Add Target Path** field) or make sure you provide the correct path to navigate further locations within it.

2. Click **Next**.

Select Profiles

1. Under **Classification Profile Name**, select the desired classification profiles to search for in the data store.
You can select multiple profiles, if required. Refer to [Classification Profiles](#) for details on classification profiles.
2. Click **Next**.

Apply Filters

This step is optional.

1. Select the desired filter from the **Select Filter** drop-down list.

To filter the locations to scan an Azure Blobs data store, consider the following syntax.

Note

Exclude Path/DO by prefix, suffix, and expression filters support wildcard characters. See [Using Wildcard Characters](#) to learn how wildcards work.

- **Exclude Path/DO by prefix**

Excludes paths or data objects that begin with a given string. Specify `<string>`. It can be used to exclude entire directory trees.

Filter Item	Syntax	Example
Container	<ContainerName>	ddctest Wildcard usage ddtest* — Applies all paths starting with 'ddtest' as prefix.

Filter Item	Syntax	Example
Blob	<ContainerName>/<BlobName>	ddctest/reuters/reut2-012.sgm Wildcard usage *reut2-012.sgm — Applies all paths ending with 'reut2-012.sgm' as prefix.

- **Exclude Path/DO by suffix**

Excludes paths or data objects that end with a given string. Specify <string>.

Filter Item	Syntax	Example
Container	<ContainerName>* or *<ContainerName>*	my_data* — Applies all paths starting with 'my_data' as suffix. *my_data* — Applies all paths containing 'my_data' as suffix.
Blob	<ContainerName>/<BlobName> or <BlobName>	ddctestblob/reut2 or my_data Wildcard usage my_data* — Applies all paths starting with 'my_data' as suffix.

- **Exclude Path/DO by expression**

This filter is majorly used with wildcard characters.

Excludes paths or data objects that matches the given expression. Specify <string>.

For example, to exclude locations that contain 'blob' in their path, use expression *blob*.

Filter Item	Syntax	Example
Container	*<ContainerName>* or <ContainerName>*	ddctestdata* or *test*
Blob	*<BlobName>*	*reut2*

- **Include DO modified recently**

Includes data object modified within **N** number of days from the current date, where the value of **N** ranges from 1 to 99 days. After selecting this filter, specify **Days from current date**.

- **Exclude DO greater than size**

Excludes data objects that are larger than a given file size (in MB). After selecting this filter, specify the file size in MB.

- **Include DO's within modification date**

Includes data objects modified within a given range of dates. After selecting this filter, specify **Start** and **End** dates.

2. Click **Apply**.
3. Repeat the above steps to apply multiple filters. Click **Remove** to remove any applied filter.
4. Click **Next**.

Schedule Run

1. Specify the scan run frequency. The two options are:
 - **Manual:** This is the default option. Select this option to run the scan manually. Select the **Run Now** check box to start the scan run after you save the changes.
 - **Scheduled:** Select this option to configure the scan to run automatically at the specified time.

Refer to [Schedule Scan](#) for more details on scheduling scan runs.

2. Click **Save**.

Azure Table

This section covers the following topics:

- [Prerequisites](#)
- [Get Azure Account Access Keys](#)
- [Add Azure Table Data Store](#)
- [Add Azure Table Scan](#)

Prerequisites

Component	Description
Proxy Agent	• Direct Internet Access • Cloud service-specific access key • Recommended Proxy Agents: • Windows Agent • Linux Agent
TCP Allowed Connections	Port 443

Get Azure Account access keys

You require Azure account access keys to add Azure Table data store in DDC for scanning.

To get Azure Account Access keys:

1. Log on to your Azure account.
2. Select **All resources**.
3. Use the search explorer to search for *storage account*.
4. Select the desired storage account.
5. Select **Access keys**.
6. Click **Show** to display the key values.

Note down the key values for **key1(Primary)** and **key2(Secondary)**.

Note

Only one access key can be active at a time. Ask your Azure Storage account administrator which access key is currently active, and use that key to connect DDC to your Azure Storage account.

Add Azure Table data store

To configure the Azure Table data store:

1. Log on to the **CipherTrust Manager** GUI.
2. Open the **Data Discovery & Classification** application.
3. Click **Data Stores > Data Stores > Add Data Store**. The **Add Data Store** screen is displayed.
4. Complete the following steps:
 - a. [Select Type & Category](#)
 - b. [General Info](#)
 - c. [Configure Connection](#)
 - d. [Add Access Control & Tags](#)

Note

It is recommended to use IAM access keys instead of AWS root credentials.

Select Type & Category

1. Under **Select Data Store Category**, select **Cloud**.
2. From **Select Cloud Type**, select **Azure Table**.
3. Click **Next**.

General Info

1. Specify the following details:
 - **Data Store Name**: Name for the data store.
 - **Description** (Optional): Description for the data store.
 - **Location Name**: Location of the data store.
 - **Add Location**: Click **Add Location** to add new locations to the **Location Name** drop-down. Refer to [Adding Locations](#) for detailed steps.
 - **Sensitivity Level** (Optional): Sensitivity level for the data store. Refer to [Sensitivity Levels](#) for details.
 - **Enable Data Store**: Whether to enable the newly added data store. Select the check box to enable the data store.
2. Click **Next**.

Configure Connection

1. Specify the credentials of the Azure Table:

Field	Description
Account Name	Azure account name.
Authentication User	Azure storage account name.
Password	Azure storage account access keys (key1 or key2). See Get Azure Account Access keys .

2. In the **Select Number of Agents** field, set the minimum and maximum number of agents for the data store.

Refer to [Agents](#) for more information.

Warning

- As there is no limit on the number of minimum and maximum agents that you can set, you should exercise caution so that you do not impact the system performance by using too many resources for a single scan.
- You will not be able to add a datastore if the minimum number of agents cannot be assigned.
- A scan will fail if the assigned agent is unavailable after adding the datastore.
- The minimum number of agents must be less than or equal to the maximum number of agents.

3. (Optional) In the **Add Label** field, enter a label to restrict the agents that can scan this specific data store instance. You can also remove an existing label. See [Labels](#) for more details.
4. Click **Next**.

Add Access Control & Tags

1. (Optional) Grant the **All groups (default)** access for reports. Alternatively, select a group.
2. Click **Save**.

The data store is added to the Data Stores page. If the **Ready to Scan** column shows **Ready**, then data store is properly configured.

For more information on Access control and Tags, expand the section below.

Access Control & Tags

The **Access Control & Tags** tab on the **Add Data Store** screen allows you to grant access rights to your data store and add tags. More details below:

- **ACCESS CONTROL** - select user groups that can access the data store. Access to a data store provides ability to see reports that include scans of that data store. The available options are:
 - **All groups**: All groups of users can access the data store through reports. This is the default setting.
 - **Selected group/s**: Specified user defined groups can access the data store through reports. When this option is selected, select a group from the drop-down list. This list shows existing user defined groups. The user defined groups must already exist on CipherTrust Manager. If no user defined groups exist, ask the administrator to create a group. If needed, you can select multiple groups. Start typing the name of the desired group and select from the suggested groups.
- **TAGS** - Select a tag from the **Add Tag** drop-down. See the list of prebuilt tags in [Predefined tags](#) section.

Tip

- New tags can also be added. Start typing a new tag, and click the **New: <new_tag>** link that appears below the drop-down.
- Add as many tags as needed.
- To remove a tag, click the close icon in the tag name.

Add Azure Table scan

Azure table data store support multi-agent scans.

To add a scan for Azure Table:

1. Open the **Data Discovery & Classification** application.
2. Click **Scans > Add Scan**. The **Add Scan** screen is displayed.
3. Complete the following steps:
 - a. [General Info](#)
 - b. [Select Data Stores](#)
 - c. [Add Targets](#)
 - d. [Select Profiles](#)
 - e. [Apply Filters](#)
 - f. [Schedule Run](#)

Refer to [Scans](#) for the description of tabs of the **Add Scan** screen.

General Info

1. Specify a **Name** for the scan.
2. (optional) Add a **Description** for the scan.
3. Expand **Advanced Configuration** and specify advanced configurations such Scan Priority, Memory Usage Limit, and Amount of Data Object Volume. Refer to [Advanced Configuration](#) for details.
4. Click **Next**.

Select Data Stores

1. Under **Data Store Name**, select the desired data store that is **Ready** for scanning. You can select multiple data stores, if required.
2. Click **Next**.

Add Targets

1. To add a scan target, do one of the following:
 - Under the **Add Target** field, specify the correct target path and click **Apply**.

If no specific target is added, the entire data store will be scanned.

The following table lists target paths and syntax to specify them with examples.

Target Path to Scan	Syntax	Example
Full Data Store	<empty_path>	
Specific table	<tablename>	testdata

Note

Target paths are case-sensitive, except for the bucket name. Failure to use the correct case will result in a successful scan, but the report will not contain any match count for data objects and sensitive data.

- Navigate and add target paths.
 - a. Click **Browse** to navigate target paths from the root level.

Alternatively, provide an initial path in the **Add Target Path** field and click **Browse** to navigate targets from that point onward.
 - b. In the left pane, navigate and select the desired target path.
 - c. Click **Add Path** to add the target path to the right pane. Similarly, add other target paths.
 - d. Click **Add**.

Tip

Either navigate the target paths from the root level (without specifying any path in the **Add Target Path** field) or make sure you provide the correct path to navigate further locations within it.

2. Click **Next**.

Select Profiles

1. Under **Classification Profile Name**, select the desired classification profiles to search for in the data store.
You can select multiple profiles, if required. Refer to [Classification Profiles](#) for details on classification profiles.
2. Click **Next**.

Apply Filters

This step is optional.

1. Select the desired filter from the **Select Filter** drop-down list.

To filter the locations to scan an Azure table data store, consider the following syntax.

Note

Exclude Path/DO by prefix, suffix, and expression filters support wildcard characters. See [Using Wildcard Characters](#) to learn how wildcards work.

- **Exclude Path/DO by prefix**

Excludes paths or data objects that begin with a given string. Specify `<string>`. It can be used to exclude entire directory trees.

Filter Item	Syntax	Example
Table	<code><TableName></code>	ddcdata

- **Exclude Path/DO by suffix**

Excludes paths or data objects that end with a given string. Specify `<string>`.

Filter Item	Syntax	Example
Table	<TableName>*	ddcdata* — Applies all paths starting with 'ddcdata' as suffix.

- **Exclude Path/DO by expression**

This filter is majorly used with wildcard characters.

Excludes paths or data objects that matches the given expression. Specify `<string>`.

For example, to exclude locations that contain 'blob' in their path, use expression `*blob*`.

Filter Item	Syntax	Example
Table	<TableName>*	ddcdata*

2. Click **Apply**.
3. Repeat the above steps to apply multiple filters. Click **Remove** to remove any applied filter.
4. Click **Next**.

Note

Unsupported filters for Azure tables data store:

- Include DO's within modification date
- Exclude DO greater than size
- Include DO modified recently

Schedule Run

1. Specify the scan run frequency. The two options are:
 - **Manual:** This is the default option. Select this option to run the scan manually. Select the **Run Now** check box to start the scan run after you save the changes.
 - **Scheduled:** Select this option to configure the scan to run automatically at the specified time.

Refer to [Schedule Scan](#) for more details on scheduling scan runs.

2. Click **Save**.

Google Workspace: GDrive

This section covers the following topics:

- [Prerequisites](#)
- [Configure Google Workspace Account](#)
- [Add Drive Data Store](#)
- [Add Drive Scan](#)

Prerequisites

Component	Description
Proxy Agent	Proxy Agent host with direct internet access. Recommended Proxy Agents: • Windows Agent • Linux Agent
TCP Allowed Connections	Port 443

Configure Google Workspace account

Before you add Drive targets, you must have:

- A Drive administrator account for the target Drive domain.
- A Drive account. DDC only supports Drive accounts. Personal Google accounts are not supported.

To configure your Google Workspace account for scanning:

1. [Select a Project](#)
2. [Enable APIs](#)
3. [Create a Service Account](#)
4. [Set up Domain-Wide Delegation](#)
5. [Generate a New Key for the Service Account](#)

Select a project

1. Log on to the [Google API Console](#).
2. From the projects list, select the project that you want to scan with DDC. If no project exists, create a new project.

Enable APIs

To scan a Drive account, enable the APIs for it in your selected project.

To enable the APIs:

1. In the left pane, click **Enabled APIs & services**.
2. On the **APIs & Services**, click **+ ENABLE APIS AND SERVICES**.
3. On the **API Library** page, search for the following APIs:

Target Drive	API Library
All	Admin SDK API
Google Drive	Drive API

4. Click **ENABLE** for both the APIs.

Create a service account

Before adding Drive as a target, you must create a Google service account for use with DDC. The service account must have the required permissions to allow DDC to authenticate and access (scan) the resources in your Drive account.

1. Log on to the [Google Cloud Console](#).
2. Select the desired project from the project list.
3. Click the hamburger icon (≡) to expand the navigation menu.
4. Go to **IAM & Admin > Service Accounts**.
5. Click **+CREATE SERVICE ACCOUNT**.
6. In the **Service account details** section, specify the following details:

Field	Description
Service account name	Enter a descriptive name for the service account, for example, ddc-sa .
(Optional) Service account ID	Edit the default ID for the service account, or click the refresh button to generate a service account ID. For example, ddc-sa@project-id.iam.gserviceaccount.com . This will be required when configuring connection for the Drive data store.
(Optional) Description	Provide a description for the new service account.

7. Click **CREATE AND CONTINUE**.
8. In the **Grant this service account access to project** section, from the **Select a role** drop-down list, select **Project > Owner**.
9. Click **CONTINUE** and then **Done**. Your service account is created.
10. Navigate back the **Service accounts** page.
11. Click the newly created service account.
12. Click the **DETAILS** tab.
13. Note down the **Unique ID** (or **OAuth 2 Client ID**) for the service account (for example, **123456789012345678901**). This is required when [setting up domain-wide delegation](#).

Set up domain-wide delegation

After creating a service account, you need to set up and enable domain-wide delegation to allow DDC to access your Drive domain with the service account.

To delegate domain-wide authority to a service account:

1. Log on to [Google Admin Console](#) as a super administrator of the Drive domain.
2. Click the hamburger icon (≡) to expand the navigation menu.
3. Go to **Security > Access and data control > API controls**.
4. Click **MANAGE DOMAIN WIDE DELEGATION**.
5. Click **Add New**. The Add a new customer ID dialog box is displayed.
6. In the **Customer ID** field, enter the service account's **Client ID** or **Unique ID** (for example, **123456789012345678901**).
7. In the **OAuth scopes (comma delimited)** field, enter a comma-separated list of Google API scopes for every Drive service that you want to scan with DDC.

Google Service	Google API OAuth 2.0 Scope
All (required)	https://www.googleapis.com/auth/admin.directory.user.readonly
Google Drive	https://www.googleapis.com/auth/drive.readonly

For example, specify <https://www.googleapis.com/auth/admin.directory.user.readonly>, <https://www.googleapis.com/auth/drive.readonly>.

8. Click **AUTHORIZE**.

Generate a new key for the service account

Credentials for a service account are set to expire in the year 10000, making expiration unlikely. However, a contingency plan exists for regenerating a new key, if needed. If the key is not obtained or expires, it's acceptable to create a new key, although not an ideal practice.

1. Log on to the Google Cloud Platform (GCP) with your credentials.
2. Go to the **DASHHBOARD**.
3. Click the hamburger icon (☰) to expand the navigation menu.
4. Click **IAM & Admin > Service Accounts**.
5. Search for the project in which the required service account is available.
6. Click the ellipses icon (⋮) and click **Manage keys**. The Keys page is displayed.
7. Click **ADD KEY**, then **Create new key** to generate a new key. The Create private key for "<Your service account>" dialog box is displayed.
8. Select **P12** as the **Key type** and click **CREATE**.

The key will be automatically downloaded to your system. Save the created P12 private key file to a secure location on your computer. This will be required when [configuring connection](#) for the Drive data store.

Add Drive data store

To add the Drive data store:

1. Log on to the **CipherTrust Manager** GUI.
2. Open the **Data Discovery & Classification** application.
3. Click **Data Stores > Data Stores > Add Data Store**. The **Add Data Store** screen is displayed.
4. Complete the following steps:
 - a. [Select Type & Category](#)
 - b. [General Info](#)
 - c. [Configure Connection](#)
 - d. [Add Access Control & Tags](#)

Select Type & Category

1. Under **Select Data Store Category**, select **Cloud**.
2. From **Select Cloud Type**, select **G-Drive**.

3. Click **Next**.

General Info

1. Specify the following details:
 - **Data Store Name:** Name for the data store.
 - **Description** (Optional): Description for the data store.
 - **Location Name:** Location of the data store.
 - **Add Location:** Click **Add Location** to add new locations to the **Location Name** drop-down. Refer to [Adding Locations](#) for detailed steps.
 - **Sensitivity Level** (Optional): Sensitivity level for the data store. Refer to [Sensitivity Levels](#) for details.
 - **Enable Data Store:** Whether to enable the newly added data store. Select the check box to enable the data store.
2. Click **Next**.

Configure Connection

1. Specify the credentials of the Google domain.

Field	Description
Google Domain	Google domain that you want to scan. For example, if your Drive administrator email address is <code>admin@example.com</code> , your Google domain is <code>example.com</code> .
User	Email address of the Drive administrator account. For example, <code>admin@example.com</code> .
Service Account ID	Your service account ID or email address. For example, <code>ddc-sa@project-id.iam.gserviceaccount.com</code> . Refer to Create a Service Account to get the service account ID.
Private Key	Private key (*.p12) associated with the Google Workspace service account. Refer to Generate a New Key for the Service Account for the key details.

2. In the **Select Number of Agents** field, set the minimum and maximum number of agents for the data store. Refer to [Agents](#) for more information.

Warning

- As there is no limit on the number of minimum and maximum agents that you can set, you should exercise caution so that you do not impact the system performance by using too many resources for a single scan.
- You will not be able to add a datastore if the minimum number of agents cannot be assigned.
- A scan will fail if the assigned agent is unavailable after adding the datastore.
- The minimum number of agents must be less than or equal to the maximum number of agents.

3. (Optional) In the **Add Label** field, enter a label to restrict the agents that can scan this specific data store instance. You can also remove an existing label. See [Labels](#) for more details.
4. Click **Next**.

Add Access Control & Tags

1. (Optional) Grant the **All groups (default)** access for reports. Alternatively, select a group.
2. Click **Save**.

The data store is added to the Data Stores page. If the **Ready to Scan** column shows **Ready**, then data store is properly configured.

For more information on Access control and Tags, expand the section below.

Access Control & Tags

The **Access Control & Tags** tab on the **Add Data Store** screen allows you to grant access rights to your data store and add tags. More details below:

- **ACCESS CONTROL** - select user groups that can access the data store. Access to a data store provides ability to see reports that include scans of that data store. The available options are:
 - **All groups:** All groups of users can access the data store through reports. This is the default setting.
 - **Selected group/s:** Specified user defined groups can access the data store through reports. When this option is selected, select a group from the drop-down list. This list shows existing user defined groups. The user defined groups must already exist on CipherTrust Manager. If no user defined groups exist, ask the administrator to create a group. If needed, you can select multiple groups. Start typing the name of the desired group and select from the suggested groups.
- **TAGS** - Select a tag from the **Add Tag** drop-down. See the list of prebuilt tags in [Predefined tags](#) section.

Tip

- New tags can also be added. Start typing a new tag, and click the **New: <new_tag>** link that appears below the drop-down.
- Add as many tags as needed.
- To remove a tag, click the close icon in the tag name.

Add Drive scan

To add a scan for Drive:

1. Open the **Data Discovery & Classification** application.
2. Click **Scans > Add Scan**. The **Add Scan** screen is displayed.
3. Complete the following steps:
 - a. [General Info](#)
 - b. [Select Data Stores](#)
 - c. [Add Targets](#)
 - d. [Select Profiles](#)
 - e. [Add Filters](#)
 - f. [Schedule Run](#)

Refer to [Scans](#) for the description of sections of the **Add Scan** screen.

General Info

1. Specify a **Name** for the scan.
2. (optional) Add a **Description** for the scan.
3. Expand **Advanced Configuration** and specify advanced configurations such Scan Priority, Memory Usage Limit, and Amount of Data Object Volume. Refer to [Advanced Configuration](#) for details.
4. Click **Next**.

Select Data Stores

1. Under **Data Store Name**, select the desired data store that is **Ready** for scanning. You can select multiple data stores, if required.
2. Click **Next**.

Add Targets

1. To add a scan target, do one of the following:
 - Under the **Add Target** field, specify the correct target path and click **Apply**.

If no specific target is added, the entire data store will be scanned.

The following table lists target paths and syntax to specify them with examples.

Target Path to Scan	Syntax	Example
Complete data store	<Empty_Path>	
Specific user account	<User_Name>	testuser
Specific folder in user account	<user_name/My Drive/ folder_name>	testuser/My Drive/sensitivedata
Specific file inside a folder	<user_name/My Drive/ folder_name/file_name>	testuser/My Drive/sensitivedata/ foo.txt

- Navigate and add target paths.
 - a. Click **Browse** to navigate target paths from the root level.

Alternatively, provide an initial path in the **Add Target Path** field and click **Browse** to navigate targets from that point onward.
 - b. In the left pane, navigate and select the desired target path.
 - c. Click **Add Path** to add the target path to the right pane. Similarly, add other target paths.
 - d. Click **Add**.

Tip

Either navigate the target paths from the root level (without specifying any path in the **Add Target Path** field) or make sure you provide the correct path to navigate further locations within it.

2. Click **Next**.

Select Profiles

1. Under **Classification Profile Name**, select the desired classification profiles to search for in the data store. You can select multiple data stores, if required. Refer to [Classification Profiles](#) for details on classification profiles.
2. Click **Next**.

Add Filters

This step is optional.

1. Select the desired filter from the **Select Filter** drop-down list.

To filter the locations to scan a Drive data store, consider the following syntax.

Note

Exclude Path/DO by prefix, suffix, and expression filters support wildcard characters. See [Using Wildcard Characters](#) to learn how wildcards work.

▪ Exclude Path/DO by prefix

Excludes paths or data objects that begin with a given string. It can be used to exclude entire directory trees. Specify `<string>`.

Filter Item	Syntax	Example
User	<code><UserName></code>	datastoreiciduser
Folder	<code><UserName>/<FolderName></code>	datastoreiciduser/my drive/sensitivedata
File	<code><UserName>/<FolderName>/<Filename></code>	datastoreiciduser/my drive/sensitivedata/file.txt

▪ Exclude Path/DO by suffix

Excludes paths or data objects that end with a given string. Specify `<string>`.

Filter Item	Syntax	Example
User	<code><UserName>*</code>	datastoreiciduser* — Applies all paths starting with

Filter Item	Syntax	Example
		'datastoreicduser' as suffix.
Folder	<FolderName>*	folder* — Applies all paths starting with 'folder' as suffix.
File	<FileName>	file1 Wildcard usage file1* — Applies all paths starting with 'file1' as suffix.

- **Exclude Path/DO by expression**

This filter is majorly used with wildcard characters.

Excludes paths or data objects that matches the given expression. Specify <string>.

For example, to exclude locations that contain 'blob' in their path, use expression *blob*.

Filter Item	Syntax	Example
User	<UserName>*	datastoreicduser*
Folder	<UserName>/<FolderName>* or *<FolderName>*	datastoreicduser/my drive/some_folder* or *folder*
File	<UserName>/<FolderName>/<FileName>* or *<FileName>*	datastoreicduser/my drive/some/folder/file1* or *file1*

- **Include DO modified recently**

Includes data objects modified within **N** number of days from the current date, where the value of **N** ranges from 1 to 99 days. After selecting this filter, specify **Days from current date**.

- **Exclude DO greater than size**

Excludes data objects that are larger than a given file size (in MB). After selecting this filter,specify the file size in MB.

- **Include DO's within modification date**

Includes data objects modified within a given range of dates. After selecting this filter, specify **Start** and **End** dates.

2. Click **Apply**.

3. Repeat the above steps to apply multiple filters. Click **Remove** to remove any applied filter.

4. Click **Next**.

Schedule Run

1. Specify the scan run frequency. The two options are:
 - **Manual:** This is the default option. Select this option run the scan manually. Select the **Run Now** check box to start the scan run after you save the changes.
 - **Scheduled:** Select this option to configure the scan to run automatically at the specified time.

Refer to [Schedule Scan](#) for more details on scheduling scan runs.

2. Click **Save**.

Google Workspace: Gmail

This section covers the following topics:

- Prerequisites
- [Configure Google Workspace Account](#)
- Add Gmail Data Store
- Add Gmail Scan

Prerequisites

Component	Description
Proxy Agent	Proxy Agent host with direct internet access. Recommended Proxy Agents: • Windows Agent • Linux Agent
TCP Allowed Connections	Port 443

Configure Google Workspace account

Before you add Gmail targets, you must have:

- A Gmail administrator account for the target Gmail domain.
- A Gmail account. DDC only supports Gmail accounts. Personal Google accounts are not supported.

To configure your Google Workspace account for scanning:

1. [Select a Project](#)

2. [Enable APIs](#)
3. [Create a Service Account](#)
4. [Set up Domain-Wide Delegation](#)
5. [Generate a New Key for the Service Account](#)

Select a project

1. Log on to the [Google API Console](#).
2. From the projects list, select the project that you want to scan with DDC. If no project exists, create a new project.

Enable APIs

To scan a Gmail account, enable the APIs for it in your selected project.

To enable the APIs:

1. In the left pane, click **Enabled APIs & services**.
2. On the **APIs & Services**, click **+ ENABLE APIS AND SERVICES**.
3. On the **API Library** page, search for the following APIs:

Target Gmail	API Library
All	Admin SDK API
Google Mail	Gmail API

4. Click **ENABLE** for both the APIs.

Create a service account

Before adding Gmail as a target, you must create a Google service account for use with DDC. The service account must have the required permissions to allow DDC to authenticate and access (scan) the resources in your Gmail account.

1. Log on to the [Google Cloud Console](#).
2. Select the desired project from the project list.
3. Click the hamburger icon (≡) to expand the navigation menu.
4. Go to **IAM & Admin > Service Accounts**.
5. Click **+CREATE SERVICE ACCOUNT**.

6. In the **Service account details** section, specify the following details:

Field	Description
Service account name	Enter a descriptive name for the service account, for example, <code>ddc-sa</code> .
(Optional) Service account ID	Edit the default ID for the service account, or click the refresh button to generate a service account ID. For example, <code>ddc-sa@project-id.iam.gserviceaccount.com</code> . This will be required when configuring connection for the Gmail data store.
(Optional) Description	Provide a description for the new service account.

7. Click **CREATE AND CONTINUE**.
8. In the **Grant this service account access to project** section, from the **Select a role** drop-down list, select **Project > Owner**.
9. Click **CONTINUE** and then **Done**. Your service account is created.
10. Navigate back the **Service accounts** page.
11. Click the newly created service account.
12. Click the **DETAILS** tab.
13. Note down the **Unique ID** (or **OAuth 2 Client ID**) for the service account (for example, `123456789012345678901`). This is required when [setting up domain-wide delegation](#).

Set up domain-wide delegation

After creating a service account, you need to set up and enable domain-wide delegation to allow DDC to access your Gmail domain with the service account.

To delegate domain-wide authority to a service account:

1. Log on to [Google Admin Console](#) as a super administrator of the Gmail domain.
2. Click the hamburger icon (≡) to expand the navigation menu.
3. Go to **Security > Access and data control > API controls**.
4. Click **MANAGE DOMAIN WIDE DELEGATION**.
5. Click **Add New**. The Add a new customer ID dialog box is displayed.
6. In the **Customer ID** field, enter the service account's **Client ID** or **Unique ID** (for example,

123456789012345678901).

7. In the **OAuth scopes (comma delimited)** field, enter a comma-separated list of Google API scopes for every Gmail service that you want to scan with DDC.

Google Service	Google API OAuth 2.0 Scope
All (required)	https://www.googleapis.com/auth/admin.directory.user.readonly
Google Mail	https://mail.google.com/

For example, specify `https://www.googleapis.com/auth/admin.directory.user.readonly,https://mail.google.com/`.

8. Click **AUTHORIZE**.

Generate a new key for the service account

Credentials for a service account are set to expire in the year 10000, making expiration unlikely. However, a contingency plan exists for regenerating a new key, if needed. If the key is not obtained or expires, it's acceptable to create a new key, although not an ideal practice.

1. Log on to the Google Cloud Platform (GCP) with your credentials.
2. Go to the **DASHHBOARD**.
3. Click the hamburger icon (≡) to expand the navigation menu.
4. Click **IAM & Admin > Service Accounts**.
5. Search for the project in which the required service account is available.
6. Click the ellipses icon (⋮) and click **Manage keys**. The Keys page is displayed.
7. Click **ADD KEY**, then **Create new key** to generate a new key. The Create private key for "<Your service account>" dialog box is displayed.
8. Select **P12** as the **Key type** and click **CREATE**.

The key will be automatically downloaded to your system. Save the created P12 private key file to a secure location on your computer. This will be required when [configuring connection](#) for the Gmail data store.

Add Gmail data store

To add the Gmail data store:

1. Log on to the **CipherTrust Manager** GUI.
2. Open the **Data Discovery & Classification** application.

3. Click **Data Stores > Data Stores > Add Data Store**. The Add Data Store screen is displayed.
4. Complete the following steps:
 - a. [Select Type & Category](#)
 - b. [General Info](#)
 - c. [Configure Connection](#)
 - d. [Add Access Control & Tags](#)

Select Type & Category

1. Under **Select Data Store Category**, select **Cloud**.
2. From **Select Cloud Type**, select **Google-workspace: Gmail**.
3. Click **Next**.

General Info

1. Specify the following details:
 - **Data Store Name**: Name for the data store.
 - **Description** (Optional): Description for the data store.
 - **Location Name**: Location of the data store.
 - **Add Location**: Click **Add Location** to add new locations to the **Location Name** drop-down. Refer to [Adding Locations](#) for detailed steps.
 - **Sensitivity Level** (Optional): Sensitivity level for the data store. Refer to [Sensitivity Levels](#) for details.
 - **Enable Data Store**: Whether to enable the newly added data store. Select the check box to enable the data store.
2. Click **Next**.

Configure Connection

1. Specify the credentials of the Google domain.

Field	Description
Google Domain	Google domain that you want to scan. For example, if your Gmail administrator email address is <code>admin@example.com</code> , your Google domain is

Field	Description
	example.com.
User	Email address of the Gmail administrator account. For example, admin@example.com.
Service Account ID	Your service account ID or email address. For example, enterprise-recon-sa@project-id.iam.gserviceaccount.com. Refer to Create a Service Account to get the service account ID.
Private Key	Private key (*.p12) associated with the service account. Refer to Generate a New Key for the Service Account for the key details.

- In the **Select Number of Agents** field, set the minimum and maximum number of agents for the data store. Refer to [Agents](#) for more information.

Warning

- As there is no limit on the number of minimum and maximum agents that you can set, you should exercise caution so that you do not impact the system performance by using too many resources for a single scan.
- You will not be able to add a datastore if the minimum number of agents cannot be assigned.
- A scan will fail if the assigned agent is unavailable after adding the datastore.
- The minimum number of agents must be less than or equal to the maximum number of agents.

- (Optional) In the **Add Label** field, enter a label to restrict the agents that can scan this specific data store instance. You can also remove an existing label. See [Labels](#) for more details.
- Click **Next**.

Add Access Control & Tags

- (Optional) Grant the **All groups (default)** access for reports. Alternatively, select a group.
- Click **Save**.

The data store is added to the Data Stores page. If the **Ready to Scan** column shows **Ready**, then data store is properly configured.

For more information on Access control and Tags, expand the section below.

Access Control & Tags

The **Access Control & Tags** tab on the **Add Data Store** screen allows you to grant access rights to your data store and add tags. More details below:

- **ACCESS CONTROL** - select user groups that can access the data store. Access to a data store provides ability to see reports that include scans of that data store. The available options are:
 - **All groups:** All groups of users can access the data store through reports. This is the default setting.
 - **Selected group/s:** Specified user defined groups can access the data store through reports. When this option is selected, select a group from the drop-down list. This list shows existing user defined groups. The user defined groups must already exist on CipherTrust Manager. If no user defined groups exist, ask the administrator to create a group. If needed, you can select multiple groups. Start typing the name of the desired group and select from the suggested groups.
- **TAGS** - Select a tag from the **Add Tag** drop-down. See the list of prebuilt tags in [Predefined tags](#) section.

Tip

- New tags can also be added. Start typing a new tag, and click the **New: <new_tag>** link that appears below the drop-down.
- Add as many tags as needed.
- To remove a tag, click the close icon in the tag name.

Add Gmail scan

To add a scan for Gmail:

1. Open the **Data Discovery & Classification** application.
2. Click **Scans > Add Scan**. The Add Scan screen is displayed.
3. Complete the following steps:
 - a. [General Info](#)
 - b. [Select Data Stores](#)
 - c. [Add Targets](#)
 - d. [Select Profiles](#)
 - e. [Add Filters](#)

f. Schedule Run

Refer to [Scans](#) for the description of sections of the Add Scan screen.

General Info

1. Specify a **Name** for the scan.
2. (optional) Add a **Description** for the scan.
3. Expand **Advanced Configuration** and specify advanced configurations such Scan Priority, Memory Usage Limit, and Amount of Data Object Volume. Refer to [Advanced Configuration](#) for details.
4. Click **Next**.

Select Data Stores

1. Under **Data Store Name**, select the desired data store that is **Ready** for scanning. You can select multiple data stores, if required.
2. Click **Next**.

Add Targets

1. To add a scan target, do one of the following:
 - Under the **Add Target** field, specify the correct target path and click **Apply**.

If no specific target is added, the entire data store will be scanned.

The following table lists target paths and syntax to specify them with examples.

Target Path to Scan	Syntax
Complete data store	<Empty_Path>
User account	<User_Name>
Folder in user account	<user_name/folder_name>

Note

- Target paths are not case-sensitive.
- To scan the mailbox `user_name@example.com`, enter `user_name`. To scan a specific folder in the mailbox, specify `user_name/<folder>`. For example:

- To scan the **Inbox** folder, enter `user_name/inbox`.
- To scan the **Sent Mail** folder, enter `user_name/sent`.

- Navigate and add target paths.

- a. Click **Browse** to navigate target paths from the root level.

Alternatively, provide an initial path in the **Add Target Path** field and click **Browse** to navigate targets from that point onward.

- b. In the left pane, navigate and select the desired target path.
- c. Click **Add Path** to add the target path to the right pane. Similarly, add other target paths.
- d. Click **Add**.

Tip

Either navigate the target paths from the root level (without specifying any path in the **Add Target Path** field) or make sure you provide the correct path to navigate further locations within it.

2. Click **Next**.

Select Profiles

1. Under **Classification Profile Name**, select the desired classification profiles to search for in the data store. You can select multiple data stores, if required. Refer to [Classification Profiles](#) for details on classification profiles.
2. Click **Next**.

Add Filters

This step is optional.

1. Select the desired filter from the **Select Filter** drop-down list.

To filter the locations to scan a Gmail data store, consider the following syntax.

Note

Exclude Path/DO by prefix, suffix, and expression filters support wildcard characters. See [Using Wildcard Characters](#) to learn how wildcards work.

- **Exclude Path/DO by prefix**

Excludes paths or data objects that begin with a given string. Can be used to exclude entire directory trees. Specify `<string>`.

Filter Item	Syntax	Example
User/Account	<UserName>	datastoreicduser
Folder	<UserName>/<FolderName>	datastoreicduser/inbox Wildcard usage *inbox — Applies all paths ending with 'inbox' as prefix Note Labels are not supported. To filter labels, label ID is required.
File	<UserName>/<FolderName>/<FileNameName>	▪ datastoreicduser/inbox/mydata filter test data/Mon, 23 Aug 2021 10:54:40 +0530/50-contacts.csv ▪ datastoreicduser/inbox/test filter test data ▪ datastoreicduser/Label_4800715244570918733/test filter test data/ Wildcard usage ▪ datastoreicduser/inbox/mydata filter test data/*/50-contacts.csv — Applies all paths starting with 'datastoreicduser/inbox/mydata

Filter Item	Syntax	Example
		filter test data/' and ending with '/50-contacts.csv' as prefix. datastoreicduser/*/mydata filter test data — Applies all paths starting with 'datastoreicduser/' and ending '/mydata filter test data' as prefix

- **Exclude Path/DO by suffix**

Excludes paths or data objects that end with a given string. Specify `<string>`.

Filter Item	Syntax	Example
User/Account	<code><UserName>*</code>	datastoreicduser* — Applies all paths starting with 'datastoreicduser' as suffix.
Folder	<code><FolderName>*</code>	inbox* — Applies all paths starting with 'inbox' as suffix.
File	<code><FileName></code>	50-contacts.csv Wildcard usage datastoreicduser/inbox/mydata filter test data/*/50-contacts.csv — Applies all paths starting with 'datastoreicduser/inbox/mydata filter test data/' and ending with '/50-contacts.csv' as suffix. 50-contacts.csv* — Applies all paths starting with '50-contacts.csv' as suffix.

- **Exclude Path/DO by expression**

This filter is majorly used with wildcard characters.

Excludes paths or data objects that matches the given expression. Specify `<string>`.

For example, to exclude locations that contain 'blob' in their path, use expression `*blob*`.

Filter Item	Syntax	Example
User/Account	<UserName>*	datastorecicduser*
Folder	*<FolderName>*	*folder*
File	<UserName>/<FolderName>/<Subject>/<Date>/<FileName> or <UserName>/<FolderName>/<Subject>*/<FileName>	- datastorecicduser/inbox/mydata filter test data/Mon, 23 Aug 2021 10:54:40 +0530/50-contacts.csv - datastorecicduser/inbox/mydata filter test data/*/50-contacts.csv

- **Include DO modified recently**

Includes data objects modified within **N** number of days from the current date, where the value of **N** ranges from 1 to 99 days. After selecting this filter, specify **Days from current date**.

- **Include DO's within modification date**

Includes data objects modified within a given range of dates. After selecting this filter, specify **Start** and **End** dates.

- **Exclude DO greater than size**

This filter is not supported in this release.

2. Click **Apply**.
3. Repeat the above steps to apply multiple filters. Click **Remove** to remove any applied filter.
4. Click **Next**.

Schedule Run

1. Specify the scan run frequency. The two options are:
 - **Manual:** This is the default option. Select this option run the scan manually. Select the **Run Now** check box to start the scan run after you save the changes.
 - **Scheduled:** Select this option to configure the scan to run automatically at the specified time.

Refer to [Schedule Scan](#) for more details on scheduling scan runs.

2. Click **Save**.

Note

API request default quota for Gmail is **15,000 per minute**. If this limit is exceeded, API request will fail and scan run may encounter different issues.

Office 365: Exchange Online

This section covers the following topics:

- Prerequisites
- Configure Microsoft 365 Account
- Add Exchange Online Data Store
- Add Exchange Online Scan
- Unsupported Mailbox Types and Folders

Prerequisites

Component	Description
Proxy Agent	Proxy Agent host with direct internet access. Recommended Proxy Agents: • Windows Agent • Linux Agent
TCP Allowed Connections	Port 443

Configure Microsoft 365 account

This topic describes how to generate the client ID, tenant key ID, and client secret key. These are required to register DDC with Microsoft 365 account. The topic also describes how to grant API permissions to DDC to access specific resource APIs.

1. Generate Client ID and Tenant ID
2. Generate Client Secret Key
3. Grant API Access

Generate client ID and tenant ID

To generate the client ID and tenant ID:

1. Log on to the [Azure app registration portal](#) as an administrator account. After you log on successfully, you are redirected to the home page.

2. In the left pane, select the **Microsoft Entra ID** service. Alternatively, you can search for **Microsoft Entra ID** in the search bar.
3. Under **Manage**, click **App registrations**. The App registrations page is displayed.
4. Click **+ New registration**. The Register an application page is displayed.
5. Specify the following:
 - **Name:** Display name for your application.
 - **Supported account types:** Select **Accounts in this organizational directory only**.
6. Click **Register**. The Overview page of the newly registered application is displayed.
7. Note down the values of **Application (client) ID** and **Directory (tenant) ID**. These values will be required when [configuring a connection](#) for the data store.

Generate client secret key

1. Under **Manage**, click **Certificates & secrets**.
2. On the **Client secrets** tab, click **+ New client secret**. The Add a client secret dialog box is displayed.
3. Specify the following:
 - **Description:** Description for the client secret key.
 - **Expires:** Validity for the client secret key. The recommended validity is 180 days (6 months).
4. Click **Add**. The client secret key is added. The Value column displays the client secret key.
5. Copy the client secret key and save it to a secure location. This secret key will be required when [configuring a connection](#) for the data store.

Warning

Save the client secret key in a secure location. You cannot access this client secret key after you navigate away from the page.

Grant API access

To scan Exchange Online targets, you need to grant permissions to DDC to access specific resource APIs.

1. Under **Manage**, click **API permissions**.
2. In the **Configured permissions** section, click **+ Add a permission**. The Request API permissions dialog box

is displayed.

3. On the **Microsoft APIs** tab, click **Microsoft Graph > Application permissions**.
4. Select the following API permissions for your app:

Permissions	Description
• Group.Read.All • User.Read.All • Directory.Read.All • Mail.Read • Contacts.Read • Calendars.Read	Permissions required for scanning Exchange Online targets.
• Group.ReadWrite.All • User.ReadWrite.All • Directory.ReadWrite.All • Mail.ReadWrite • Contacts.ReadWrite • Calendars.ReadWrite	Permissions required for remediating Exchange Online targets.

Tip

To add permissions:

- a. In the search box, type the permission you want to add.
- b. Select the check box to the left of the permission. Similarly, select all the required permissions.
- c. Click **Add permissions**.

5. In the **Configured permissions** section, click **Grant admin consent for <organization name>**. The Grant admin consent confirmation dialog box is displayed.
6. Click **Yes**.

The Status column for all the newly added API permissions is updated to **Granted for <organization name>**.

Add Exchange Online data store

To add the Exchange Online data store:

1. Log on to the **CipherTrust Manager** GUI.
2. Open the **Data Discovery & Classification** application.

3. Click **Data Stores > Data Stores > Add Data Store**. The **Add Data Store** screen is displayed.
4. Complete the following steps:
 - a. [Select Type & Category](#)
 - b. [General Info](#)
 - c. [Configure Connection](#)
 - d. [Add Access Control & Tags](#)

Select Type & Category

1. Under **Select Data Store Category**, select **Cloud**.
2. From **Select Cloud Type**, select **Office 365: Exchange Online**.
3. Click **Next**.

General Info

1. Specify the following details:
 - **Data Store Name**: Name for the data store.
 - **Description** (Optional): Description for the data store.
 - **Location Name**: Location of the data store.
 - **Add Location**: Click **Add Location** to add new locations to the **Location Name** drop-down. Refer to [Adding Locations](#) for detailed steps.
 - **Sensitivity Level** (Optional): Sensitivity level for the data store. Refer to [Sensitivity Levels](#) for details.
 - **Enable Data Store**: Whether to enable the newly added data store. Select the check box to enable the data store.
2. Click **Next**.

Configure Connection

1. Specify the credentials of the Exchange Online domain:

Field	Description
Exchange Online Domain	Microsoft 365 domain to scan (for example, <code>example.onmicrosoft.com</code>). Only accounts where the user principal name (UPN)

Field	Description
	shares the same domain as specified in the Exchange Online Domain field will be scanned. For example, if Exchange Online Domain is set to <code>example.onmicrosoft.com</code>, <code>user1@example2.onmicrosoft.com</code> will not be scanned even if the user belongs to a group in the <code>example.onmicrosoft.com</code> domain. To scan multiple domains within your organization's Microsoft 365 environment, add these domains as separate Exchange Online targets.
Client ID	Client ID (application ID) of Exchange Online. For example, <code>clientid-1234-5678-abcd-6d05bf28c2bf</code>. Refer to Generate Client ID and Tenant ID for the client ID.
Client Secret Key	Exchange Online client secret key. For example, <code>client~secret.key-CHvV1B5YQfr~6zDjEyv</code>. Refer to Generate Client Secret Key for the client secret key.
Tenant ID	Tenant ID of Exchange Online. Your Microsoft 365 tenant ID is a globally unique identifier (GUID) that is different than your organization name or domain. For example, <code>tenantid-1234-abcd-5678-02011df316f4</code>. Refer to Generate Client ID and Tenant ID for the tenant ID.

- In the **Select Number of Agents** field, set the minimum and maximum number of agents for the data store. Refer to [Agents](#) for more information.

Warning

- As there is no limit on the number of minimum and maximum agents that you can set, you should exercise caution so that you do not impact the system performance by using too many resources for a single scan.
- You will not be able to add a datastore if the minimum number of agents cannot be assigned.
- A scan will fail if the assigned agent is unavailable after adding the datastore.
- The minimum number of agents must be less than or equal to the maximum number of agents.

- (Optional) In the **Add Label** field, enter a to restrict the agents that can scan this specific data store instance.

You can also remove an existing label. See [Labels](#) for more details.

4. Click **Next**.

Add Access Control & Tags

1. (Optional) Grant the **All groups (default)** access for reports. Alternatively, select a group.
2. Click **Save**.

The data store is added to the Data Stores page. If the **Ready to Scan** column shows **Ready**, then data store is properly configured.

For more information on Access control and Tags, expand the section below.

Access Control & Tags

The **Access Control & Tags** tab on the **Add Data Store** screen allows you to grant access rights to your data store and add tags. More details below:

- **ACCESS CONTROL** - select user groups that can access the data store. Access to a data store provides ability to see reports that include scans of that data store. The available options are:
 - **All groups**: All groups of users can access the data store through reports. This is the default setting.
 - **Selected group/s**: Specified user defined groups can access the data store through reports. When this option is selected, select a group from the drop-down list. This list shows existing user defined groups. The user defined groups must already exist on CipherTrust Manager. If no user defined groups exist, ask the administrator to create a group. If needed, you can select multiple groups. Start typing the name of the desired group and select from the suggested groups.
- **TAGS** - Select a tag from the **Add Tag** drop-down. See the list of prebuilt tags in [Predefined tags](#) section.

Tip

- New tags can also be added. Start typing a new tag, and click the **New: <new_tag>** link that appears below the drop-down.
- Add as many tags as needed.
- To remove a tag, click the close icon in the tag name.

Note

- Only accounts where the user principal name (UPN) shares the same domain as specified in the Exchange Online Domain field will be scanned.
- To scan multiple domains, you need to add the domains in a new data store and add this data store in the scan setting.
- A group can have an email associated with it. If the group has a domain similar to the configured Exchange Online Domain, then only the group will be scanned.
- A group may not have an email configured. The group will be scanned if the users in the group have the same domain as configured in Exchange Online Domain. Users with a different domain won't be scanned.

For example, security groups don't need an email, they will still be scanned. However, the users that belong to this group should have the same domain as the group domain to be scanned. Users that belong to this group, but have a different domain, will not be scanned.

- A group, which has the same email as the group domain, may contain users with different domains. In this case, only the users that share the same domain as the group domain will be scanned.

Add Exchange Online scan

To add a scan for the Exchange Online:

1. Open the **Data Discovery & Classification** application.
2. Click **Scans > Add Scan**. The **Add Scan** screen is displayed.
3. Complete the following steps:
 - a. [General Info](#)
 - b. [Select Data Stores](#)
 - c. [Add Targets](#)
 - d. [Select Profiles](#)
 - e. [Add Filters](#)
 - f. [Schedule Run](#)

Refer to [Scans](#) for the description of sections of the Add Scan screen.

General Info

1. Specify a **Name** for the scan.
2. (optional) Add a **Description** for the scan.
3. Expand **Advanced Configuration** and specify advanced configurations such Scan Priority, Memory Usage Limit, and Amount of Data Object Volume. Refer to [Advanced Configuration](#) for details.
4. Click **Next**.

Select Data Stores

1. Under **Data Store Name**, select the desired data store that is **Ready** for scanning. You can select multiple data stores, if required.
2. Click **Next**.

Add Targets

1. To add a scan target, do one of the following:
 - Under the **Add Target** field, specify the correct target path and click **Apply**.

If no specific target is added, the entire data store will be scanned.

The following table lists target paths and syntax to specify them with examples.

Target Path to Scan	Syntax	Example
Complete data store	<Empty_Path>	
All user accounts in a specific group	<Group Display Name>	TEST_GROUP
Specific user account in group	<Group Display Name>/<User Principal Name>	TEST_GROUP/ user1@example.onmicrosoft.com
Specific folder for user account in group (e.g. Calendar, Contacts, Notes etc.)	<Group Display Name>/<User Principal Name>/<Mailbox Folder>	TEST_GROUP/ user1@example.onmicrosoft.com /Inbox
All user accounts	<All Users>	All Users
Specific user account (Recommended for user accounts that do not belong to any group.)	< All Users/User Principal Name	All Users/ user1@example.onmicrosoft.com
Specific folder for user account	<All Users/<User Principal	All Users/

Target Path to Scan	Syntax	Example
(e.g. Calendar, Contacts, Notes etc.) (Recommended for user accounts that do not belong to any group.)	Name>/<Mailbox Folder>>	user1@example.onmicrosoft.com /Inbox

Note

- Target paths are case-sensitive. Target paths can be groups user principal name and specific folders and files.
- If multiple Microsoft 365 groups with the same display name exist in your domain, then only the first instance of the group will be retrieved. For example, if three groups have the same display name, "TESTGROUP", then the first "TESTGROUP" group for the Exchange Online target will be scanned.

- Navigate and add target paths.

- a. Click **Browse** to navigate target paths from the root level.

Alternatively, provide an initial path in the **Add Target Path** field and click **Browse** to navigate targets from that point onward.

- b. In the left pane, navigate and select the desired target path.
- c. Click **Add Path** to add the target path to the right pane. Similarly, add other target paths.
- d. Click **Add**.

Tip

Either navigate the target paths from the root level (without specifying any path in the **Add Target Path** field) or make sure you provide the correct path to navigate further locations within it.

2. Click **Next**.

Select Profiles

1. Under **Classification Profile Name**, select the desired classification profiles to search for in the data store. You can select multiple data stores, if required. Refer to [Classification Profiles](#) for details on classification profiles.

2. Click **Next**.

Add Filters

This step is optional.

Note

Filters only apply to the scan entities found until the specified folder name in the target path. It doesn't include anything inside that folder or beyond it.

1. Select the desired filter from the **Select Filter** drop-down list.

To filter the locations to scan an Exchange Online data store, consider the following syntax.

Note

Exclude Path/DO by prefix, suffix, and expression filters support wildcard characters. See [Using Wildcard Characters](#) to learn how wildcards work.

- **Exclude Path/DO by prefix**

Excludes paths or data objects that begin with a given string. It can be used to exclude entire directory trees. Specify `<string>`.

Filter Item	Example
Group	All Users
User/Account	All Users/sample@sjcpl.onmicrosoft.com Wildcard usage *sample@sjcpl.onmicrosoft.com — Applies all paths ending with 'sample@sjcpl.onmicrosoft.com' as prefix.
Folder	All Users/sample@sjcpl.onmicrosoft.com/inbox Wildcard usage *inbox — Applies all paths ending with 'inbox' as prefix. Note: Folder name is not case-sensitive.

Filter Item	Example
Attachment	- All Users/sample@sjcpl.onmicrosoft.com/Inbox/Mail a/2021-02-22T06:40:18Z/maildir-a.zip - All Users/sample@sjcpl.onmicrosoft.com/folder_name/subject — This filters out a specific mail and all its content with a corresponding subject name. - All Users/sample@sjcpl.onmicrosoft.com/Inbox/Mail a/2021-02-22T06:40:18Z Wildcard usage - All Users/sample@sjcpl.onmicrosoft.com/Inbox/Mail a/*/maildir-a.zip — Applies all paths starting with 'All Users/sample@sjcpl.onmicrosoft.com/Inbox/Mail a/' and ending with '/maildir-a.zip' as prefix. It is recommended to the use string to avoid manually checking email's date and time and converting it to required format. *maildir-a.zip — Applies all paths ending with 'maildir-a.zip' as prefix. This filters out all data objects with attachment maildir-a.zip. *subject — Applies all paths ending with 'subject' as prefix.

- **Exclude Path/DO by suffix**

Excludes paths or data objects that end with a given string. Specify `<string>`.

Filter Item	Example
Group	All Users* — Applies all paths starting with 'All Users' as suffix.
User/Account	sample@sjcpl.onmicrosoft.com* — Applies all paths starting with 'sample@sjcpl.onmicrosoft.com' as suffix *sample@sjcpl.onmicrosoft.com* — Applies all paths containing 'sample@sjcpl.onmicrosoft.com' as suffix.
Folder	inbox* — Applies all paths starting with 'inbox' as suffix.
Attachment	maildir-a.zip Wildcard usage All Users/sample@sjcpl.onmicrosoft.com/Inbox/

Filter Item	Example
	Mail a/*/maildir-a.zip* — Applies all paths starting with 'All Users/sample@sjcpl.onmicrosoft.com/Inbox/Mail a/' and containing '/maildir-a.zip' anywhere in the followed path as suffix *maildir-a.zip* — Applies all paths containing 'maildir-a.zip' as suffix.

▪ Exclude Path/DO by expression

This filter is majorly used with wildcard characters.

Excludes paths or data objects that matches the given expression. Specify `<string>`.

For example, to exclude locations that contain 'blob' in their path, use expression `*blob*`.

Filter Item	Example
Group	All Users* (Use a trailing * to exclude a given location.)
User/Account	All Users/sample@sjcpl.onmicrosoft.com* or *sample@sjcpl.onmicrosoft.com*
Folder	All Users/sample@sjcpl.onmicrosoft.com/inbox* or *inbox*
Attachment	- All Users/sample@sjcpl.onmicrosoft.com/Inbox/Mail a/2021-02-22T06:40:18Z/maildir-a.zip or - All Users/sample@sjcpl.onmicrosoft.com/Inbox/Mail a/*\maildir-a.zip* or *maildir-a.zip*

▪ Include DO modified recently

Includes data objects modified within **N** number of days from the current date, where the value of **N** ranges from 1 to 99 days. After selecting this filter, specify **Days from current date**.

▪ Exclude DO greater than size

Excludes data objects that are larger than a given file size (in MB). After selecting this filter, specify the file size in MB.

▪ Include DO's within modification date

Includes data objects modified within a given range of dates. After selecting this filter, specify **Start** and **End** dates.

2. Click **Apply**.
3. Repeat the above steps to apply multiple filters. Click **Remove** to remove any applied filter.
4. Click **Next**.

Schedule Run

1. Specify the scan run frequency. The two options are:
 - **Manual**: This is the default option. Select this option run the scan manually. Select the **Run Now** check box to start the scan run after you save the changes.
 - **Scheduled**: Select this option to configure the scan to run automatically at the specified time.

Refer to [Schedule Scan](#) for more details on scheduling scan runs.

2. Click **Save**.

Note

API request default quota for SharePoint Exchange Online is **800 per minute**. If this limit is exceeded, API request will fail and scan run may encounter different issues.

Unsupported mailboxes and folders

Currently, DDC doesn't support the following mailbox types and folders for the Exchange Online target:

- Inactive mailboxes
- Disabled mailboxes
- Unlicensed mailboxes

Office 365: OneDrive for Business

This section covers the following topics:

- [Prerequisites](#)
- [Configure Microsoft 365 Account](#)
- [Add OneDrive for Business Data Store](#)
- [Add OneDrive for Business Scan](#)
- [Unsupported Types and Folders](#)

Prerequisites

Component	Description
Proxy Agent	Proxy Agent host with direct internet access. Recommended Proxy Agents: • Windows Agent • Linux Agent
TCP Allowed Connections	Port 443

Configure Microsoft 365 account

This topic describes how to generate the client ID, tenant key ID, and client secret key. These are required to register DDC with Microsoft 365 account. The topic also describes how to grant API permissions to DDC to access specific resource APIs.

1. [Generate Client ID and Tenant ID](#)
2. [Generate Client Secret Key](#)
3. [Grant API Access](#)

Generate client ID and tenant ID

To generate the client ID and tenant ID:

1. Log on to the [Azure app registration portal](#) as an administrator. After you log on successfully, you are redirected to the home page.
2. In the left pane, select the **Microsoft Entra ID** service. Alternatively, you can search for **Microsoft Entra ID** in the search bar.
3. Under **Manage**, click **App registrations**. The App registrations page is displayed.
4. Click **+ New registration**. The Register an application page is displayed.
5. Specify the following:
 - **Name:** Display name for your application.
 - **Supported account types:** Select **Accounts in this organizational directory only**.
6. Click **Register**. The Overview page of the newly registered application is displayed.
7. Note down the values of **Application (client) ID** and **Directory (tenant) ID**. These values will be required when [configuring a connection](#) for the data store.

Generate client secret key

1. Under **Manage**, click **Certificates & secrets**.
2. On the **Client secrets** tab, click **+ New client secret**. The Add a client secret dialog box is displayed.
3. Specify the following:
 - **Description:** Description for the client secret key.
 - **Expires:** Validity for the client secret key. The recommended validity is 180 days (6 months).
4. Click **Add**. The client secret key is added. The Value column displays the client secret key.
5. Copy the client secret key and save it to a secure location. This secret key will be required when [configuring a connection](#) for the data store.

Warning

Save the client secret key in a secure location. You cannot access this client secret key after you navigate away from the page.

Grant API access

To scan OneDrive for Business targets, you need to grant permissions to DDC to access specific resource APIs.

1. Under **Manage**, click **API permissions**.
2. In the **Configured permissions** section, click **+ Add a permission**. The Request API permissions dialog box is displayed.
3. On the **Microsoft APIs** tab, click **Microsoft Graph > Application permissions**.
4. Select the following API permissions for your app:

Permissions	Description
• Group.Read.All • GroupMember.Read.All • Directory.Read.All • Files.Read.All • Sites.Read.All	Permissions required for scanning OneDrive for Business targets.

Tip

To add permissions:

- a. In the search box, type the permission you want to add.
- b. Select the check box to the left of the permission. Similarly, select all the required permissions.
- c. Click **Add permissions**.

5. In the **Configured permissions** section, click **Grant admin consent for <organization name>**. The Grant admin consent confirmation dialog box is displayed.
6. Click **Yes**.

The Status column for all the newly added API permissions is updated to **Granted for <organization name>**.

Add OneDrive for Business data store

To add the OneDrive for Business data store:

1. Log on to the **CipherTrust Manager** GUI.
2. Open the **Data Discovery & Classification** application.
3. Click **Data Stores > Data Stores > Add Data Store**. The Add Data Store screen is displayed.
4. Complete the following steps:
 - a. [Select Type & Category](#)
 - b. [General Info](#)
 - c. [Configure Connection](#)
 - d. [Add Access Control & Tags](#)

Select Type & Category

1. Under **Select Data Store Category**, select **Cloud**.
2. From **Select Cloud Type**, select **Office 365: OneDrive for Business**.
3. Click **Next**.

General Info

1. Specify the following details:

- **Data Store Name:** Name for the data store.
- **Description** (Optional): Description for the data store.
- **Location Name:** Location of the data store.
- **Add Location:** Click **Add Location** to add new locations to the **Location Name** drop-down. Refer to [Adding Locations](#) for detailed steps.
- **Sensitivity Level** (Optional): Sensitivity level for the data store. Refer to [Sensitivity Levels](#) for details.
- **Enable Data Store:** Whether to enable the newly added data store. Select the check box to enable the data store.

2. Click **Next**.

Configure Connection

1. Specify the credentials of the OneDrive for Business domain:

Field	Description
OneDrive for Business Domain	Microsoft 365 domain to scan (for example, <code>example.onmicrosoft.com</code>). Only accounts where the user principal name (UPN) shares the same domain as specified in the OneDrive for Business Domain field will be scanned. For example, if OneDrive for Business Domain is set to <code>example.onmicrosoft.com</code>, <code>user1@example2.onmicrosoft.com</code> will not be scanned even if the user belongs to a group in the <code>example.onmicrosoft.com</code> domain. To scan multiple domains within your organization's Microsoft 365 environment, add these domains as separate OneDrive for Business targets.
Client ID	Client ID (application ID) of OneDrive for Business. For example, <code>clientid-1234-5678-abcd-6d05bf28c2bf</code>. Refer to Generate Client ID and Tenant ID for the client ID.
Client Secret Key	OneDrive for Business client secret key. For example, <code>client~secret.key-</code>

Field	Description
	CHvV1B5YQfr~6zDjEyv. Refer to Generate Client Secret Key for the client secret key.
Tenant ID	Tenant ID of OneDrive for Business. Your Microsoft 365 tenant ID is a globally unique identifier (GUID) that is different than your organization name or domain. For example, <code>tenantid-1234-abcd-5678-02011df316f4</code> . Refer to Generate Client ID and Tenant ID for the tenant ID.

- In the **Select Number of Agents** field, set the minimum and maximum number of agents for the data store. Refer to [Agents](#) for more information.

Warning

- As there is no limit on the number of minimum and maximum agents that you can set, you should exercise caution so that you do not impact the system performance by using too many resources for a single scan.
- You will not be able to add a datastore if the minimum number of agents cannot be assigned.
- A scan will fail if the assigned agent is unavailable after adding the datastore.
- The minimum number of agents must be less than or equal to the maximum number of agents.

- (Optional) In the **Add Label** field, enter a label to restrict the agents that can scan this specific data store instance. You can also remove an existing label. See [Labels](#) for more details.
- Click **Next**.

Add Access Control & Tags

- (Optional) Grant the **All groups (default)** access for reports. Alternatively, select a group.
- Click **Save**.

The data store is added to the Data Stores page. If the **Ready to Scan** column shows **Ready**, then data store is properly configured.

For more information on Access control and Tags, expand the section below.

Access Control & Tags

The **Access Control & Tags** tab on the **Add Data Store** screen allows you to grant access rights to your data store and add tags. More details below:

- **ACCESS CONTROL** - select user groups that can access the data store. Access to a data store provides ability to see reports that include scans of that data store. The available options are:
 - **All groups:** All groups of users can access the data store through reports. This is the default setting.
 - **Selected group/s:** Specified user defined groups can access the data store through reports. When this option is selected, select a group from the drop-down list. This list shows existing user defined groups. The user defined groups must already exist on CipherTrust Manager. If no user defined groups exist, ask the administrator to create a group. If needed, you can select multiple groups. Start typing the name of the desired group and select from the suggested groups.
- **TAGS** - Select a tag from the **Add Tag** drop-down. See the list of prebuilt tags in [Predefined tags](#) section.

Tip

- New tags can also be added. Start typing a new tag, and click the **New: <new_tag>** link that appears below the drop-down.
- Add as many tags as needed.
- To remove a tag, click the close icon in the tag name.

Note

- Only accounts where the user principal name (UPN) shares the same domain as specified in the OneDrive for Business Domain field will be scanned.
- To scan multiple domains, you need to add the domains in a new data store and add this data store in the scan setting.
- A group can have an email associated with it. If the group has a domain similar to the configured OneDrive for Business Domain, then only the group will be scanned.
- A group may not have an email configured. The group will be scanned if the users in the group have the same domain as configured in OneDrive for Business Domain. Users with a different domain won't be scanned.

For example, security groups don't need an email, they will still be scanned. However, the users that belong to this group should have the same domain as the group domain to be scanned. Users that belong to this group, but have a different domain, will not be scanned.

- A group, which has the same email as the group domain, may contain users with different domains. In this case, only the users that share the same domain as the group domain will be scanned.

Add OneDrive for Business scan

To add a scan for the Exchange Online:

1. Open the **Data Discovery & Classification** application.
2. Click **Scans > Add Scan**. The Add Scan screen is displayed.
3. Complete the following steps:
 - a. [General Info](#)
 - b. [Select Data Stores](#)
 - c. [Add Targets](#)
 - d. [Select Profiles](#)
 - e. [Add Filters](#)
 - f. [Schedule Run](#)

Refer to [Scans](#) for the description of sections of the Add Scan screen.

General Info

1. Specify a **Name** for the scan.
2. (optional) Add a **Description** for the scan.
3. Expand **Advanced Configuration** and specify advanced configurations such Scan Priority, Memory Usage Limit, and Amount of Data Object Volume. Refer to [Advanced Configuration](#) for details.
4. Click **Next**.

Select Data Stores

1. Under **Data Store Name**, select the desired data store that is **Ready** for scanning. You can select multiple data stores, if required.
2. Click **Next**.

Add Targets

1. To add a scan target, do one of the following:
 - Under the **Add Target** field, specify the correct target path and click **Apply**.

If no specific target is added, the entire data store will be scanned.

The following table lists target paths and syntax to specify them with examples.

Target Path to Scan	Syntax	Example
Complete data store	<Empty_Path>	
All user accounts	<All Users>	All Users
All user accounts in a specific group	<Group Display Name>	TEST_GROUP
Specific user account in group	<Group Display Name>/<User Principal Name>	TEST_GROUP/ user1@example.onmicrosoft.com
Specific folder for user account in group	<Group Display Name>/<User Principal Name>/<Folder>	TEST_GROUP/ user1@example.onmicrosoft.com /ProjectA
Specific file for user account in group	<Group Display Name>/<User Principal Name>/<Folder>/<File>	TEST_GROUP/ user1@example.onmicrosoft.com /ProjectA/file.txt

Note

- Target paths are case-sensitive. A target path can be groups user principal name and specific folders and files.
- If multiple Microsoft 365 groups with the same display name exist in your domain, then only the first instance of the group will be retrieved. For example, if three groups have the same display name, "TESTGROUP", then the first "TESTGROUP" group for the OneDrive for Business target will be scanned.

See [Target limitations](#) for more details.

- Navigate and add target paths.

- Click **Browse** to navigate target paths from the root level.

Alternatively, provide an initial path in the **Add Target Path** field and click **Browse** to navigate targets from that point onward.

- In the left pane, navigate and select the desired target path.
- Click **Add Path** to add the target path to the right pane. Similarly, add other target paths.
- Click **Add**.

Tip

Either navigate the target paths from the root level (without specifying any path in the **Add Target Path** field) or make sure you provide the correct path to navigate further locations within it.

2. Click **Next**.

Select Profiles

1. Under **Classification Profile Name**, select the desired classification profiles to search for in the data store. You can select multiple data stores, if required. Refer to [Classification Profiles](#) for details on classification profiles.
2. Click **Next**.

Add Filters

This step is optional.

1. Select the desired filter from the **Select Filter** drop-down list.

To filter the locations to scan a OneDrive for Business data store, consider the following syntax.

Note

Exclude Path/DO by prefix, suffix, and expression filters support wildcard characters. See [Using Wildcard Characters](#) to learn how wildcards work.

- **Exclude Path/DO by prefix**

Excludes paths or data objects that begin with a given string. Can be used to exclude entire directory trees. Specify `<string>`.

Filter Item	Syntax
Group	<code><Group_Name></code>
User	<code><Group_Name>/<user@example.onmicrosoft.com></code>
Folder	<code><Group_Name>/<user@example.onmicrosoft.com>/<foldername></code>

Filter Item	Syntax
File	<Group_Name>/<user@example.onmicrosoft.com>/<foldername>/<filename>

- **Exclude Path/DO by suffix**

Excludes paths or data objects that end with a given string. Specify <string>.

Filter Item	Syntax
Group	<Group_Name>
User	<Group_Name>/<user@example.onmicrosoft.com>
Folder	<Group_Name>/<user@example.onmicrosoft.com>/<foldername>
File	<Group_Name>/<user@example.onmicrosoft.com>/<foldername>/<filename>

- **Exclude Path/DO by expression**

This filter is majorly used with wildcard characters.

Excludes paths or data objects that matches the given expression. Specify <string>.

For example, to exclude locations that contain 'blob' in their path, use expression *blob*.

Filter Item	Syntax
Group	<Group_Name>* (You have to use a trailing * to exclude a given location.)
User	<All Users>/<sample@sjcpl.onmicrosoft.com>* or *<sample@sjcpl.onmicrosoft.com>*
Folder	<All Users>/<sample@sjcpl.onmicrosoft.com>/<folder>* or *<folder>*
File	<All Users>/<sample@sjcpl.onmicrosoft.com>/<folder>/<file>* or *<file>*

- **Include DO modified recently**

Includes data objects modified within **N** number of days from the current date, where the value of **N** ranges from 1 to 99 days. After selecting this filter, specify **Days from current date**.

- **Exclude DO greater than size**

Excludes data objects that are larger than a given file size (in MB). After selecting this filter, specify the file size in MB.

- **Include DO's within modification date**

Includes data objects modified within a given range of dates. After selecting this filter, specify **Start** and **End** dates.

2. Click **Apply**.
3. Repeat the above steps to apply multiple filters. Click **Remove** to remove any applied filter.
4. Click **Next**.

Schedule Run

1. Specify the scan run frequency. The two options are:
 - **Manual:** This is the default option. Select this option run the scan manually. Select the **Run Now** check box to start the scan run after you save the changes.
 - **Scheduled:** Select this option to configure the scan to run automatically at the specified time.

Refer to [Schedule Scan](#) for more details on scheduling scan runs.

2. Click **Save**.

Note

API request default quota for OneDrive is **1000 per minute**. If this limit is exceeded, API request will fail and scan run may encounter different issues.

Unsupported types and folders

Currently, DDC doesn't support the following types and folders for the OneDrive for Business target:

- Notebooks
- OneNote file types and folders stored in OneDrive for Business but outside the default Notebooks folder.

Target limitations

It is not possible to scan all groups from the root location. This is because accounts are located in multiple groups, and scanning all from the root would result in scanning many locations multiple times. For this reason, the user is required to at least specify groups for the scan.

Office 365: SharePoint Online

This section covers the following topics:

- Prerequisites
- Configure SharePoint Online
- Add SharePoint Online Data Store
- Add SharePoint Online Scan
- Deleted SharePoint Online Sites
- Troubleshooting

Prerequisites

Component	Description
Proxy Agent	Recommended Proxy Agents: • Windows Agent • Linux Agent • FreeBSD Agent
TCP Allowed Connections	Port 443

Configure SharePoint Online

These steps need to be performed on Microsoft SharePoint Online.

Before you can add SharePoint Online as a target, you need to register and configure it for use with DDC. Also, grant the necessary permissions to the SharePoint Add-in to authenticate and access (scan) resources within your SharePoint Online environment.

1. Register the SharePoint Add-in
2. Grant Permissions to the SharePoint Add-in

Note

Microsoft has announced the retirement of SharePoint Add-ins as detailed in their [Retirement Announcement for Add-ins](#). From CipherTrust Manager 2.23 onwards, the existing SharePoint Online data store configuration method will no longer be supported, and you must reconfigure the data store according to Microsoft's updated prerequisites and permissions model.

Register the SharePoint Add-in

To register the SharePoint Add-in:

1. Log on to SharePoint Online.
2. Go to the AppRegNew form at `<site collection url>/_layouts/15/AppRegNew.aspx`. For example, `https://mycompany.sharepoint.com/_layouts/15/AppRegNew.aspx`.
3. In the **AppRegNew** form, specify the following:

Field	Description
Client Id	Enter a unique lowercase string. For example, <code>1234abcd-56ef-78gh-90ij-1234clientid</code> . Alternatively, you can click Generate to generate a client ID.
Client Secret	Click Generate to generate a client secret. For example, <code>abcdefghijklmnopqrstuvwxyz0123456789klmnopqrst0clientsecret</code> .
Title	Enter a descriptive name for the add-in. For example, <code>DDC SPO add-in</code> .
App Domain	The hostname of the remote component of the SharePoint Add-in. For example, <code>www.example.com</code> . This field is mandatory when registering the SharePoint Add-in. However, this field is not required for scanning the SharePoint Online Targets.
Redirect URI	The endpoint in the remote application or service to which Azure Access Control service (ACS) sends an authentication code. For example, <code>https://www.example.com/default.aspx</code> . This field is mandatory when registering the SharePoint Add-in. However, this field is not required for scanning the SharePoint Online Targets.

4. Click **Create**. The page reloads and displays the details of the newly registered SharePoint Add-in.
5. Note down the **Client ID** and **Client Secret Key**. These values will be required when configuring a connection for the data store.

Grant permissions to the SharePoint Add-in

1. Log on to SharePoint Online as an administrator.
2. Go to the tenant administration site at `<tenant>-admin.sharepoint.com/_layouts/15/appinv.aspx`. For example, `https://mycompany-admin.sharepoint.com/_layouts/15/appinv.aspx`.

3. In the **App ID** field, enter the Client ID of the registered SharePoint Add-in. This is the Client ID you noted down in [Register the SharePoint Add-in](#).
4. Click **Lookup**. It should fetch and populate the Title, App Domain, and Redirect URL fields.
5. In the **Permission Request XML** field, enter the following permissions:

```
<AppPermissionRequests AllowAppOnlyPolicy="true">
  <AppPermissionRequest Scope="http://sharepoint/content/tenant" Right="FullControl"/>
  <AppPermissionRequest Scope="http://sharepoint/content/sitecollection" Right="Read"/>
  <AppPermissionRequest Scope="http://sharepoint/content/sitecollection/web" Right="Read"/>
</AppPermissionRequests>
```

6. Click **Create**. A permission consent dialog box is displayed.
7. Click **Trust It** to grant permissions to the SharePoint Add-in.
8. Go to the **Site App Permissions** page at `<tenant>-admin.sharepoint.com/_layouts/15/appprincipals.aspx?Scope=Web`. For example, `https://xyz-admin.sharepoint.com/_layouts/15/appprincipals.aspx?Scope=Web`.
9. Under the **App Display Name** column, look for the registered SharePoint Add-In.
10. Note down the value of **Tenant ID** from Application Identifier. This value will be required when configuring SharePoint Online as a Target.

```
# App Identifier format: i:0i.t|ms.sp.ext|<Client ID>@<Tenant ID>
i:0i.t|ms.sp.ext|1234abcd-56ef-78gh-90ij-1234clientid@12345678-abcd-9012-efgh-ijkltenantid
```

Where:

- Client ID = `1234abcd-56ef-78gh-90ij-1234clientid`
- Tenant ID = `12345678-abcd-9012-efgh-ijkltenantid`

Add SharePoint Online data store

To add the SharePoint Online data store:

1. Log on to the **CipherTrust Manager** GUI.
2. Open the **Data Discovery & Classification** application.

3. Click **Data Stores > Data Stores > Add Data Store**. The Add Data Store screen is displayed.
4. Complete the following steps:
 - a. [Select Type & Category](#)
 - b. [General Info](#)
 - c. [Configure Connection](#)
 - d. [Add Access Control & Tags](#)

Select Type & Category

1. Under **Select Data Store Category**, select **Cloud**.
2. From **Select Cloud Type**, select **Office 365: Sharepoint Online**.
3. Click **Next**.

General Info

1. Specify the following details:
 - **Data Store Name**: Name for the data store.
 - **Description** (Optional): Description for the data store.
 - **Location Name**: Location of the data store.
 - **Add Location**: Click **Add Location** to add new locations to the **Location Name** drop-down. Refer to [Adding Locations](#) for detailed steps.
 - **Sensitivity Level** (Optional): Sensitivity level for the data store. Refer to [Sensitivity Levels](#) for details.
 - **Enable Data Store**: Whether to enable the newly added data store. Select the check box to enable the data store.
2. Click **Next**.

Configure Connection

1. Specify the credentials of the SharePoint Online domain:

Field	Description
Domain	Name of the SharePoint Online organization. For example, if you access SharePoint Online at https://mycompany.sharepoint.com , then

Field	Description
	mycompany is the domain.
Client ID	Client ID of the registered SharePoint Add-in. For example, 1234abcd-56ef-78gh-90ij-1234clientid. Refer to Register the SharePoint Add-in for the client ID.
Client Secret Key	Client Secret key of the registered SharePoint Add-in. For example, abcdefghij0123456789klmnopqrst0clientsecret. Refer to Register the SharePoint Add-in for the client secret key.
Tenant ID	Tenant ID of the registered SharePoint Add-in. For example, 12345678-abcd-9012-efgh-ijkltenantid. Refer to Grant Permissions to the SharePoint Add-in for the tenant ID.

- (Optional) In the **Add Label** field, enter a label to restrict the agents that can scan this specific data store instance. You can also remove an existing label. See [Labels](#) for more details.

Note

DDC doesn't support selection of multiple agents for the SharePoint Online data store.

- Click **Next**.

Add Access Control & Tags

- (Optional) Grant the **All groups (default)** access for reports. Alternatively, select a group.
- Click **Save**.

The data store is added to the Data Stores page. If the **Ready to Scan** column shows **Ready**, then data store is properly configured.

For more information on Access control and Tags, expand the section below.

Access Control & Tags

The **Access Control & Tags** tab on the **Add Data Store** screen allows you to grant access rights to your data store and add tags. More details below:

- **ACCESS CONTROL** - select user groups that can access the data store. Access to a data store provides ability to see reports that include scans of that data store. The available options are:
 - **All groups:** All groups of users can access the data store through reports. This is the default setting.
 - **Selected group/s:** Specified user defined groups can access the data store through reports. When this option is selected, select a group from the drop-down list. This list shows existing user defined groups. The user defined groups must already exist on CipherTrust Manager. If no user defined groups exist, ask the administrator to create a group. If needed, you can select multiple groups. Start typing the name of the desired group and select from the suggested groups.
- **TAGS** - Select a tag from the **Add Tag** drop-down. See the list of prebuilt tags in [Predefined tags](#) section.

Tip

- New tags can also be added. Start typing a new tag, and click the **New: <new_tag>** link that appears below the drop-down.
- Add as many tags as needed.
- To remove a tag, click the close icon in the tag name.

Add SharePoint Online scan

To add a scan for SharePoint Online:

1. Open the **Data Discovery & Classification** application.
2. Click **Scans > Add Scan**. The Add Scan screen is displayed.
3. Complete the following steps:
 - a. [General Info](#)
 - b. [Select Data Stores](#)
 - c. [Add Targets](#)
 - d. [Select Profiles](#)
 - e. [Add Filters](#)
 - f. [Schedule Run](#)

Refer to [Scans](#) for the description of sections of the Add Scan screen.

General Info

1. Specify a **Name** for the scan.
2. (optional) Add a **Description** for the scan.
3. Expand **Advanced Configuration** and specify advanced configurations such Scan Priority, Memory Usage Limit, and Amount of Data Object Volume. Refer to [Advanced Configuration](#) for details.
4. Click **Next**.

Select Data Stores

1. Under **Data Store Name**, select the desired data store that is **Ready** for scanning. You can select multiple data stores, if required.
2. Click **Next**.

Add Targets

1. To add a scan target, do one of the following:
 - Under the **Add Target** field, specify the correct target path and click **Apply**.

If no specific target is added, the entire data store will be scanned.

The following table lists target paths and syntax to specify them with examples.

Target Path to Scan	Syntax	Example
Scan all site collections, sites, lists, list items, folders and files.	<Empty_Path>	
Scan a site collection. Includes all sites, lists, list items, folders, and files for the site collection.	<organization>.sharepoint.com/sites/<site_collection>	https://example.sharepoint.com/sites/operations
Scan a site in a site collection.	<organization>.sharepoint.com/sites/<site_collection>/<site>	https://example.sharepoint.com/sites/operations/my-site
Scan all lists in a site collection.	<organization>.sharepoint.com/sites/<site_collection>/:site/:list	https://example.sharepoint.com/sites/operations/:site/:list
Scan a specific list in a site collection.	<organization>.sharepoint.com/sites/<site_collection>/:site/:list/<list>	https://example.sharepoint.com/sites/operations/:site/:list/my-list
Scan all folders and files in a site collection.	<organization>.sharepoint.com/sites/<site_collection>/:site/:file	https://example.sharepoint.com/sites/operations/:site/:file

Target Path to Scan	Syntax	Example
Scan a specific folder in a site collection.	<organization>.sharepoint.com/sites/<site_collection>/:site:/file/<folder>	https://example.sharepoint.com/sites/operations/:site:/file/Shared Documents/documents
Scan a specific file in a site collection.	<organization>.sharepoint.com/sites/<site_collection>/:site:/file/<file>	https://example.sharepoint.com/sites/operations/:site:/file/Shared Documents/my-file.txt
Scan a specific file within a folder in a site collection.	<organization>.sharepoint.com/sites/<site_collection>/:site:/file/<folder>/<file>	https://example.sharepoint.com/sites/operations/:site:/file/Shared Documents/documents/my-file.txt

Note

While scanning lists, attachments within SharePoint Online lists are not scanned, resulting in no sensitive data objects being detected. To scan the attachments within list, use the following target path: <organization>.sharepoint.com/sites/<site_collection>/:site:/file/Lists/list_name/attachments

- Navigate and add target paths.

- a. Click **Browse** to navigate target paths from the root level.

Alternatively, provide an initial path in the **Add Target Path** field and click **Browse** to navigate targets from that point onward.

- b. In the left pane, select the desired target path.

To view subfolders within the folder hierarchy, select the desired folder and click **List**.

- c. Click **Add Path** to add the target path to the right pane. Similarly, add other target paths.
- d. Click **Add**.

Tip

Either navigate the target paths from the root level (without specifying any path in the **Add Target Path** field) or make sure you provide the correct path to navigate further locations within it.

2. Click **Next**.

Select Profiles

1. Under **Classification Profile Name**, select the desired classification profiles to search for in the data store. You can select multiple data stores, if required. Refer to [Classification Profiles](#) for details on classification profiles.
2. Click **Next**.

Add Filters

This step is optional.

1. Select the desired filter from the **Select Filter** drop-down list.

To filter the locations to scan an Office365 SharePoint Online data store, consider the following syntax.

Note

Exclude Path/DO by prefix, suffix, and expression filters support wildcard characters. See [Using Wildcard Characters](#) to learn how wildcards work.

▪ Exclude Path/DO by prefix

Excludes paths or data objects that begin with a given string. It can be used to exclude entire directory trees. Specify `<string>`.

Filter Item	Syntax
Site collection	<code><organization>.sharepoint.com/sites/<site_collection></code>
Site	<code><organization>.sharepoint.com/sites/<site_collection>/<site></code>
List	<code><organization>.sharepoint.com/sites/<site_collection>/<site>/<list></code>
File	<code><organization>.sharepoint.com/sites/<site_collection>/<site>/<list>/<file></code>
Folder	<code><organization>.sharepoint.com/sites/<site_collection>/<site>/<list>/<folder></code>

▪ Exclude Path/DO by suffix

Excludes paths or data objects that end with a given string. Specify `<string>`.

- **Exclude Path/DO by expression**

This filter is majorly used with wildcard characters.

Excludes search locations and nested locations that matches the given expression. Specify **<string>**.

For example, to exclude locations that contain 'blob' in their path, use expression *blob*.

Filter Item	Syntax
Site collection	<organization>.sharepoint.com/<site_collection>* or *<site_collection>*
Site	<organization>.sharepoint.com/<site_collection>/<site>* or *<site>*
List	<organization>.sharepoint.com/<site_collection>/<site>/<list>* or *<list>*
File	<organization>.sharepoint.com/<site_collection>/<site>/<list>/<file>* or *<file>*
Folder	<organization>.sharepoint.com/<site_collection>/<site>/<list>/<folder>* or *<folder>*

- **Include DO modified recently**

Includes data objects modified within **N** number of days from the current date, where the value of **N** ranges from 1 to 99 days. After selecting this filter, specify **Days from current date**.

- **Exclude DO greater than size**

Excludes data objects that are larger than a given file size (in MB). After selecting this filter, specify the file size in MB.

- **Include DO's within modification date**

Includes data objects modified within a given range of dates. After selecting this filter, specify **Start** and **End** dates.

2. Click **Apply**.
3. Repeat the above steps to apply multiple filters. Click **Remove** to remove any applied filter.
4. Click **Next**.

Schedule Run

1. Specify the scan run frequency. The two options are:

- **Manual:** This is the default option. Select this option to run the scan manually. Select the **Run Now** check box to start the scan run after you save the changes.
- **Scheduled:** Select this option to configure the scan to run automatically at the specified time.

Refer to [Schedule Scan](#) for more details on scheduling scan runs.

2. Click **Save**.

Note

API request default quota for SharePoint Online is **600 per minute**. If this limit is exceeded, API request will fail and scan run may encounter different issues.

Deleted SharePoint Online sites

In SharePoint Online, deleted sites or site collections are retained for 93 days in the site Recycle Bin, unless deleted permanently. However, if you try to scan a deleted site, it will result in following error when attempting to scan them:

The target for Data Store Sharepoint Online has not been found.

Troubleshooting

While adding the SharePoint Online data store to DDC, you might encounter the following error:

The target for Data Store SharePoint scan for sites does not have access permissions.

Cause

This error occurs because the `grant app permission` is disabled by default on SharePoint Online.

Solution

For the SharePoint Add-in to work, the `DisableCustomAuthenticationApp` setting for the tenants needs to be set to `false`, as described below:

1. Open PowerShell.
2. Run `Install-Module -Name Microsoft.Online.SharePoint.PowerShell`.
3. Run `$adminUPN="<full email address of a SharePoint administrator account>"`.

For example:

```
$adminUPN="example@democompany.onmicrosoft.com"
```

4. Run `$orgName="<name of your Office 365 organization>"`.

For example:

```
$orgName="democompany"
```

5. Run `$userCredential = Get-Credential -UserName $adminUPN -Message "<password>"`.

For example:

```
$userCredential = Get-Credential -UserName $adminUPN -Message "demopassword@123"
```

6. Run `Connect-SPOService -Url https://$<orgName>-admin.sharepoint.com -Credential $userCredential`.

For example:

```
Connect-SPOService -Url https://$democompany-admin.sharepoint.com -Credential $userCredential
```

Note

The `Connect-SPOService -Url https://$<orgName>-admin.sharepoint.com -Credential $userCredential` command might return the following error. This error occurs when Multifactor Authentication (MFA) is enabled.

```
Connect-SPOService : Identity Client Runtime Library (IDCRL) did not get
a response from the Login server.
At line:1 char:1
+ Connect-SPOService -Url https://trial8349-admin.sharepoint.com -Crede
...
+ CategoryInfo          : NotSpecified: ([Connect-SPOService], IdcrLException
+ FullyQualifiedErrorId : Microsoft.SharePoint.Client.IdcrLException,Mic
rosoft.Online.SharePoint.PowerShell.ConnectSPOService
```

To work around this issue:

- a. Rerun `Connect-SPOService -Url https://$<orgName>-admin.sharepoint.com` (without `-Credential $userCredential`). You will be prompted for the Office 365 authentication.

- b. Enter the Office 365 credentials.

7. Run `set-spotenant -DisableCustomAppAuthentication $false`.

Salesforce

This section covers the following topics:

- [Prerequisites](#)
- [Configure Salesforce Account](#)
- [Add Salesforce Data Store](#)
- [Add Salesforce Scan](#)
- [Salesforce API Limits](#)
- [Unsupported Salesforce Standard Objects](#)

Prerequisites

Component	Description
Proxy Agent	Proxy Agent host with direct internet access. Recommended Proxy Agents: • Windows Agent • Linux Agent
TCP Allowed Connections	Port 443

Configure Salesforce account

This topic describes how to generate a digital certificate and the private key. These are required to register DDC with a Salesforce account.

1. [Generate Certificate and Private Key](#)
2. [Create Connected App](#)

Generate certificate and private key

To scan the Salesforce targets, you need a digital signature associated with a digital certificate and the private key.

To generate the digital certificate and the private key:

1. Open a terminal or the Windows Command prompt.
2. Install the OpenSSL package and run the following command:

```
openssl req -x509 -sha256 -nodes -newkey rsa:2048 -days <number of days> -keyout <*.key private key file> -out <*.crt certificate file> openssl req -x509 -sha256 -nodes -newkey rsa:2048 -days 365 -keyout ddc-salesforce.key -out ddc-salesforce.crt
```

Parameter	Description
(Optional) days	Number of days to certify the certificate for. The default is 30 days.
keyout	Name of the output file to write the private key to. For example, <code>ddc-salesforce.key</code> .
out	Name of the file to write the digital certificate to. For example, <code>ddc-salesforce.crt</code> .

You will be prompted to enter the required details.

3. Specify the following details:

Prompt	Answer
Country Name (2 letter code) [AU]	Your country's two letter country code (ISO 3166-1 alpha-2).
State or Province Name (full name) [Some-State]	State or province name.
Locality Name (for example, city) []	City name or name of region.
Organization Name (for example, company) [Internet Widgits Pty Ltd]	Name of organization.
Organizational Unit Name (for example, section) []	Name of organizational department.
Common Name (for example, server FQDN or YOUR name) []	Fully qualified domain name of the Master Server.
Email Address []	Email address of organization's contact person.

OpenSSL generates two output files:

- The private key (for example, `ddc-salesforce.key`) required to [set up](#) and scan a Salesforce target.
- The digital certificate (for example, `ddc-salesforce.crt`) required to [create a connected app](#) for DDC.

Create connected app

Instructions for the Salesforce Lightning and Salesforce Classic interfaces are different. Click the desired tab to view the instructions.

Salesforce Lightning

To create a connected app for DDC in Salesforce:

1. Log on to your organization's Salesforce site as an administrator.
2. Got to **Setup**.
3. On the **Home** tab, in the **Quick Find** field, enter **App Manager** and select **App Manager**.
4. On the **Lightning Experience App Manager** page, click **New Connected App**.
5. In the **Basic Information** section, specify the following details:

Field	Description
Connected App Name	Descriptive display name for DDC, for example, DDC .
API Name	Unique identifier for referring to the app programmatically, for example, DDC .
Contact Email	Email address that Salesforce can use to contact you about the connected app.

6. In the **API (Enable OAuth Settings)** section, select the **Enable OAuth Settings** check box.
7. In the **Callback URL** field, enter the URL to redirect to after successful authorization of the connected app.

Note

The **Callback URL** is a compulsory field for setting up a connected app but is not required for scanning the Salesforce targets with DDC.

8. Select **Use digital signatures** and click **Choose File** to upload a digital certificate, for example, `er-salesforce.crt`. Refer to [Generate Certificate and Private Key](#) for details.
9. Under **Select OAuth Scopes**, select and **Add** the following permissions for the **DDC** connected app:

Available OAuth Scopes	Description
• Access the identity URL service (id, profile, email,	Required for probing, scanning, and remediating

Available OAuth Scopes	Description
address, phone) • Manage user data via APIs (api) • Perform requests at any time (refresh_token, offline_access)	Salesforce targets.

10. Click **Save** and click **Continue**.

11. On the **Manage Connected Apps** page, go to **API (Enable OAuth Settings) > Consumer Key** and click **Copy**.

A sample consumer key is

1234567890.ThisIsTheConsumerKeyForTheDDCConnectedAppForSalesforce_1234567.

Save the consumer key at a secure location. This key will be required when [configuring the connection](#) for the Salesforce data store.

12. Click **Manage > Edit Policies**.

13. Under **OAuth Policies > Permitted Users**, select **Admin approved users are pre-authorized**.

14. Click **Save**.

15. Return to the **App Manager** page, go to the **Profiles** section, and click **Manage Profiles**.

16. On the **Application Profile Assignment** page, select the profile(s) (for example, **System Administrator**) that you want to allow to access the **DDC** connected app.

Note

The Salesforce account that is specified when you Set Up and Scan a Salesforce Target must be assigned to at least one of the profiles that has:

- Access to the DDC connected app (for example, "DDC"), and
- Minimum "Read" permissions for the Salesforce Objects to be scanned

Refer to [Salesforce Help - Object Permissions](#) for details.

17. Click **Save**.

18. On the **Setup > Home** tab, in the **Quick Find** field, enter **Profiles** and select **Profiles**.

19. Go to the profile you [selected](#) earlier (for example, **System Administrator**) and click **Edit**.

20. In the **Administrative Permissions** section, select the following:

- API Enabled
- Query All Files

Note

Enabling the **Query All Files** permission is an optional step. This permission allows the Salesforce account to scan all files in your organization's Salesforce site, including those owned / managed by other user accounts. You will specify this Salesforce account when [configuring a connection](#) for the data store.

For more information about Salesforce behavior when **Query All Files** is enabled, refer to [ContentVersion](#).

Without the **Query All Files** permission, **DDC** will can only scan the files that are owned by / shared to the specified Salesforce account.

21. Click **Save**.

Salesforce Classic

To create a connected app for DDC in Salesforce:

1. Log on to your organization's Salesforce site as an administrator.
2. Got to **Setup**.
3. In the left pane, under the **Build** section, expand **Create** and click **Apps**.
4. In the **Connected Apps** section, click **New**.
5. In the **Basic Information** section, specify the following details:

Field	Description
Connected App Name	Descriptive display name for DDC, for example, DDC .
API Name	Unique identifier for referring to the app programmatically, for example, DDC .
Contact Email	Email address that Salesforce can use to contact you about the connected app.

6. In the **API (Enable OAuth Settings)** section, select the **Enable OAuth Settings** check box.
7. In the **Callback URL** field, enter the URL to redirect to after successful authorization of the connected app.

Note

The **Callback URL** is a compulsory field for setting up a connected app but is not required for scanning the Salesforce targets with DDC.

8. Select **Use digital signatures** and click **Choose File** to upload a digital certificate, for example, `er-salesforce.crt`. Refer to [Generate Certificate and Private Key](#) for details.
9. Under **Select OAuth Scopes**, select and **Add** the following permissions for the **DDC** connected app:

Available OAuth Scopes	Description
• Access the identity URL service (id, profile, email, address, phone) • Manage user data via APIs (api) • Perform requests at any time (refresh_token, offline_access)	Required for probing, scanning, and remediating Salesforce targets.

10. Click **Save** and click **Continue**. You will be redirected to app details page.
11. Go to **API (Enable OAuth Settings) > Consumer Key and Secret >** and click **Manage Consumer Details > Copy Consumer Key**.

A sample consumer key is
`1234567890.ThisIsTheConsumerKeyForTheDDCConnectedAppForSalesforce_1234567`.
Save the consumer key at a secure location. This key will be required when [configuring the connection](#) for the Salesforce data store.
12. Click **Back to Manage Connected Apps > Manage > Edit Policies**.
13. Under **OAuth Policies > Permitted Users**, select **Admin approved users are pre-authorized**.
14. Click **Save**.
15. Go to the **Profiles** section, and click **Manage Profiles**.
16. On the **Application Profile Assignment** page, select the profile(s) (for example, **System Administrator**) that you want to allow to access the **DDC** connected app.

Note

The Salesforce account that is specified when you set up and scan a Salesforce target must be

assigned to at least one of the profiles that has:

- Access to the DDC connected app (for example, "DDC"), and
- Minimum "Read" permissions for the Salesforce Objects to be scanned

Refer to [Salesforce Help - Object Permissions](#) for details.

17. Click **Save**.
18. Navigate to **Setup**. In the left pane, under the **Administer** section, expand **Manage Users** and select **Profiles**.
19. Go to the profile you [selected](#) earlier (for example, **System Administrator**) and click **Edit**.
20. In the **Administrative Permissions** section, select the following:
 - API Enabled
 - Query All Files

Note

Enabling the **Query All Files** permission is an optional step. This permission allows the Salesforce account to scan all files in your organization's Salesforce site, including those owned / managed by other user accounts. You will specify this Salesforce account when [configuring a connection](#) for the data store.

For more information about Salesforce behavior when **Query All Files** is enabled, refer to [ContentVersion](#).

Without the **Query All Files** permission, **DDC** will can only scan the files that are owned by / shared to the specified Salesforce account.

21. Click **Save**.

Add Salesforce data store

To add the Salesforce data store:

1. Log on to the **CipherTrust Manager** GUI.
2. Open the **Data Discovery & Classification** application.

3. Click **Data Stores > Data Stores > Add Data Store**. The Add Data Store screen is displayed.
4. Complete the following steps:
 - a. [Select Type & Category](#)
 - b. [General Info](#)
 - c. [Configure Connection](#)
 - d. [Add Access Control & Tags](#)

Select Type & Category

1. Under **Select Data Store Category**, select **Cloud**.
2. From **Select Cloud Type**, select **Salesforce**.
3. Click **Next**.

General Info

1. Specify the following details:
 - **Data Store Name**: Name for the data store.
 - **Description** (Optional): Description for the data store.
 - **Location Name**: Location of the data store.
 - **Add Location**: Click **Add Location** to add new locations to the **Location Name** drop-down. Refer to [Adding Locations](#) for detailed steps.
 - **Sensitivity Level** (Optional): Sensitivity level for the data store. Refer to [Sensitivity Levels](#) for details.
 - **Enable Data Store**: Whether to enable the newly added data store. Select the check box to enable the data store.
2. Click **Next**.

Configure Connection

1. Specify the credentials of the Salesforce domain:

Field	Description
Account Name	Email address linked with the Salesforce account to scan. Production

Field	Description
	• Syntax: <code><email_address></code> • Example: <code>admin@example.com</code> Sandbox • Syntax: <code>sandbox:<email_address></code> • Example: <code>sandbox:admin@example.com</code>
Consumer Key	Key obtained when creating the connected app. For example, <code>1234567890.ThisIsTheConsumerKeyForTheDDCConnectedAppForSalesforce_1234567</code> . This key was created when creating the connected app .
Private Key	Cloud service-specific access keys, for example, <code>ddc-salesforce.key</code> . Refer to Generate Certificate and Private Key for the private key.

2. (Optional) In the **Add Label** field, enter a label to restrict the agents that can scan this specific data store instance. You can also remove an existing label. See [Labels](#) for more details.

Note

DDC doesn't support selection of multiple agents for the Salesforce data store.

3. Click **Next**.

Add Access Control & Tags

1. (Optional) Grant the **All groups (default)** access for reports. Alternatively, select a group.
2. Click **Save**.

The data store is added to the Data Stores page. If the **Ready to Scan** column shows **Ready**, then data store is properly configured.

For more information on Access control and Tags, expand the section below.

Access Control & Tags

The **Access Control & Tags** tab on the **Add Data Store** screen allows you to grant access rights to your data store and add tags. More details below:

- **ACCESS CONTROL** - select user groups that can access the data store. Access to a data store provides ability to see reports that include scans of that data store. The available options are:

- **All groups:** All groups of users can access the data store through reports. This is the default setting.
- **Selected group/s:** Specified user defined groups can access the data store through reports. When this option is selected, select a group from the drop-down list. This list shows existing user defined groups. The user defined groups must already exist on CipherTrust Manager. If no user defined groups exist, ask the administrator to create a group. If needed, you can select multiple groups. Start typing the name of the desired group and select from the suggested groups.
- **TAGS** - Select a tag from the **Add Tag** drop-down. See the list of prebuilt tags in [Predefined tags](#) section.

Tip

- New tags can also be added. Start typing a new tag, and click the **New: <new_tag>** link that appears below the drop-down.
- Add as many tags as needed.
- To remove a tag, click the close icon in the tag name.

Add Salesforce scan

To add a scan for the Salesforce:

1. Open the **Data Discovery & Classification** application.
2. Click **Scans > Add Scan**. The Add Scan screen is displayed.
3. Complete the following steps:
 - a. [General Info](#)
 - b. [Select Data Stores](#)
 - c. [Add Targets](#)
 - d. [Select Profiles](#)
 - e. [Add Filters](#)
 - f. [Schedule Run](#)

Refer to [Scans](#) for the description of sections of the Add Scan screen.

General Info

1. Specify a **Name** for the scan.

2. (optional) Add a **Description** for the scan.
3. Expand **Advanced Configuration** and specify advanced configurations such Scan Priority, Memory Usage Limit, and Amount of Data Object Volume. Refer to [Advanced Configuration](#) for details.
4. Click **Next**.

Select Data Stores

1. Under **Data Store Name**, select the desired data store that is **Ready** for scanning. You can select multiple data stores, if required.
2. Click **Next**.

Add Targets

1. To add a scan target, do one of the following:
 - Under the **Add Target** field, specify the correct target path and click **Apply**.

If no specific target is added, the entire data store will be scanned.

The following table lists target paths and syntax to specify them with examples.

Salesforce Object Type	Syntax	Example
Complete data store	<Empty_Path>	
All standard objects	s	s
All custom objects	c	c
All big objects	b	b
Specific standard object	s/<object API name>	s/Account
Specific custom object	c/<object API name>	c/Account__c
Specific big object	b/<object API name>	b/Account__b

Note

Target paths are case-sensitive.

- Navigate and add target paths.
 - a. Click **Browse** to navigate target paths from the root level.

Alternatively, provide an initial path in the **Add Target Path** field and click **Browse** to navigate targets from that point onward.

- b. In the left pane, navigate and select the desired target path.
- c. Click **Add Path** to add the target path to the right pane. Similarly, add other target paths.
- d. Click **Add**.

Tip

Either navigate the target paths from the root level (without specifying any path in the **Add Target Path** field) or make sure you provide the correct path to navigate further locations within it.

2. Click **Next**.

Select Profiles

1. Under **Classification Profile Name**, select the desired classification profiles to search for in the data store. You can select multiple data stores, if required. Refer to [Classification Profiles](#) for details on classification profiles.
2. Click **Next**.

Add Filters

This step is optional.

1. Select the desired filter from the **Select Filter** drop-down list.

To filter the locations to scan an Salesforce data store, consider the following syntax.

Note

Exclude Path/DO by prefix, suffix, and expression filters support wildcard characters. See [Using Wildcard Characters](#) to learn how wildcards work.

- **Exclude Path/DO by prefix**

Excludes paths or data objects that begin with a given string. It can be used to exclude entire directory trees. Specify `<string>`.

Filter Item	Syntax	Example
Folder	<FolderName>	C
Object	<FolderName>/<ObjectName>	c/usecase_data

- **Exclude Path/DO by suffix**

Excludes paths or data objects that end with a given string. Specify **<string>**.

Note

You cannot exclude targets, folders, and objects using suffix filter. To exclude items within any object, provide the complete path or ending string of the item path.

Example - If target path is *c/Usecase_data3__c* and actual path of the object item is *c/Usecase_data3__c/a0H5G00000R5GygUAF/AMX 346761705951424*, then provide **AMX 346761705951424** as suffix to exclude this object item.

- **Exclude Path/DO by expression**

This filter is majorly used with wildcard characters.

Excludes paths or data objects that matches the given expression. Specify **<string>**.

For example, to exclude locations that contain 'blob' in their path, use expression ***blob***.

Filter Item	Syntax	Example
Folder	*<FolderName>*	*C*
Object	*<FolderName>/<ObjectName>*	*c/ddc_c*

- **Include DO modified recently**

Includes data objects modified within **N** number of days from the current date, where the value of **N** ranges from 1 to 99 days. After selecting this filter, specify **Days from current date**.

- **Exclude DO greater than size**

Excludes data objects that are larger than a given file size (in MB). After selecting this filter, specify the file size in MB.

- **Include DO's within modification date**

Includes data objects modified within a given range of dates. After selecting this filter, specify **Start** and

End dates.

2. Click **Apply**.
3. Repeat the above steps to apply multiple filters. Click **Remove** to remove any applied filter.
4. Click **Next**.

Schedule Run

1. Specify the scan run frequency. The two options are:
 - **Manual**: This is the default option. Select this option run the scan manually. Select the **Run Now** check box to start the scan run after you save the changes.
 - **Scheduled**: Select this option to configure the scan to run automatically at the specified time.

Refer to [Schedule Scan](#) for more details on scheduling scan runs.

2. Click **Save**.

Salesforce API limits

Salesforce imposes a limit on the total number of inbound API calls that can be made per 24-hour period for an organization. For every API call to Salesforce, DDC queries and retrieves:

- Up to 2000 records (including Big Objects), or
- A single attachment or file.

If an organization reaches its daily API request limit:

- A critical error is flagged for the Salesforce domain (or location) with the HTTP 403 error - **REQUEST_LIMIT_EXCEEDED. TotalRequest Limit Exceeded**.
- Running Salesforce scans stop executing with the Failed status. A critical error is reflected on the last Object that was scanned when the limit was reached.
- Probing a Salesforce target results in the HTTP 403 error - **REQUEST_LIMIT_EXCEEDED. TotalRequest Limit Exceeded**.

Refer to [Salesforce - API Request Limits and Allocations](#) for details.

Unsupported Salesforce Standard Objects

Currently, DDC doesn't support the following Salesforce Standard Objects:

- AccountUserTerritory2View
 - AppTabMember
-

-
- ColorDefinition
 - ContentDocumentLink
 - ContentFolderItem
 - ContentFolderMember
 - DataStatistics
 - DataType
 - DatacloudAddress
 - EntityParticle
 - FieldDefinition
 - FlexQueueItem
 - FlowVariableView
 - FlowVersionView
 - IconDefinition
 - IdeaComment
 - ListViewChartInstance
 - NetworkUserHistoryRecent
 - OutgoingEmail
 - OutgoingEmailRelation
 - OwnerChangeOptionInfo
 - PicklistValueInfo
 - PlatformAction
 - RelationshipDomain
 - RelationshipInfo
 - SearchLayout
 - SiteDetail
 - UserEntityAccess
-

- UserFieldAccess
- UserRecordAccess
- Vote

Databases

- IBM Db2
- MongoDB
- Microsoft SQL
- MySQL
- Oracle
- PostgreSQL
- SAP HANA

IBM Db2

This section covers the following topics:

- Prerequisites
- Add IBM Db2 Data Store
- Add IBM Db2 Scan

Prerequisites

Component	Description
Proxy Agent	Windows Agent Note Windows Agent built-in drivers are required to connect to a Db2 data store.
Version	IBM Db2 11.1 onwards

Add IBM Db2 data store

To add IBM Db2 data store:

1. Log on to the **CipherTrust Manager** GUI.
2. Open the **Data Discovery & Classification** application.
3. Click **Data Stores > Data Stores > Add Data Store**. The Add Data Store screen is displayed.
4. Complete the following steps:
 - a. [Select Type & Category](#)
 - b. [General Info](#)
 - c. [Configure Connection](#)
 - d. [Add Access Control & Tags](#)

Select Type & Category

1. Under **Select Data Store Category**, select **Database**.
2. From **Select Database Type**, select **IBM DB2**.
3. Click **Next**.

General Info

1. Specify the following details:
 - **Data Store Name**: Name for the data store.
 - **Description** (Optional): Description for the data store.
 - **Location Name**: Location of the data store.
 - **Add Location**: Click **Add Location** to add new locations to the **Location Name** drop-down. Refer to [Adding Locations](#) for detailed steps.
 - **Sensitivity Level** (Optional): Sensitivity level for the data store. Refer to [Sensitivity Levels](#) for details.
 - **Enable Data Store**: Whether to enable the newly added data store. Select the check box to enable the data store.
2. Click **Next**.

Configure Connection

- Specify the credentials for the IBM Db2 data store:

Field	Description
Hostname/IP	Specify a valid hostname or IP address of the database server. Hostname must be more than 2 characters long.
Port	Specify a valid port for connecting to the database server. It must be a valid integer between 1 and 65535. Default port: 50000
Database	Specify the database name. <i>Case sensitivity is applicable.</i>
User	Specify the username of database user.
Password	Specify the user password.

- (Optional) In the **Select Number of Agents** field, set the minimum and maximum number of agents for the data store. Refer to [Agents](#) for more information.

Warning

- As there is no limit on the number of minimum and maximum agents that you can set, you should exercise caution so that you do not impact the system performance by using too many resources for a single scan.
- You will not be able to add a datastore if the minimum number of agents cannot be assigned.
- A scan will fail if the assigned agent is unavailable after adding the datastore.
- The minimum number of agents must be less than or equal to the maximum number of agents.

- (Optional) In the **Add Label** field, enter a label to restrict the agents that can scan this specific data store instance. You can also remove an existing label. See [Labels](#) for more details.
- Click **Next**.

Add Access Control & Tags

- (Optional) Grant the **All groups (default)** access for reports. Alternatively, select a group.
- Click **Save**.

The data store is added to the Data Stores page. If the **Ready to Scan** column shows **Ready**, then data store is

properly configured.

For more information on Access control and Tags, expand the section below.

Access Control & Tags

The **Access Control & Tags** tab on the **Add Data Store** screen allows you to grant access rights to your data store and add tags. More details below:

- **ACCESS CONTROL** - select user groups that can access the data store. Access to a data store provides ability to see reports that include scans of that data store. The available options are:
 - **All groups:** All groups of users can access the data store through reports. This is the default setting.
 - **Selected group/s:** Specified user defined groups can access the data store through reports. When this option is selected, select a group from the drop-down list. This list shows existing user defined groups. The user defined groups must already exist on CipherTrust Manager. If no user defined groups exist, ask the administrator to create a group. If needed, you can select multiple groups. Start typing the name of the desired group and select from the suggested groups.
- **TAGS** - Select a tag from the **Add Tag** drop-down. See the list of prebuilt tags in [Predefined tags](#) section.

Tip

- New tags can also be added. Start typing a new tag, and click the **New: <new_tag>** link that appears below the drop-down.
- Add as many tags as needed.
- To remove a tag, click the close icon in the tag name.

Add IBM Db2 scan

To add a scan for IBM Db2:

1. Open the **Data Discovery & Classification** application.
2. Click **Scans > Add Scan**. The Add Scan screen is displayed.
3. Complete the following steps:
 - a. [General Info](#)
 - b. [Select Data Stores](#)
 - c. [Add Targets](#)

-
- d. [Select Profiles](#)
 - e. [Add Filters](#)
 - f. [Schedule Run](#)

Refer to [Scans](#) for the description of sections of the Add Scan screen.

General Info

1. Specify a **Name** for the scan.
2. (optional) Add a **Description** for the scan.
3. Expand **Advanced Configuration** and specify advanced configurations such as Scan Priority, Memory Usage Limit, and Amount of Data Object Volume. Refer to [Advanced Configuration](#) for details.
4. Click **Next**.

Select Data Stores

1. Under **Data Store Name**, select the desired data store that is **Ready** for scanning. You can select multiple data stores, if required.
2. Click **Next**.

Add Targets

1. To add a scan target, do one of the following:
 - Under **Add Target Path** field, specify the complete target path and click **Apply**.

If no specific target is added, the entire data store will be scanned.

The following table lists different target paths, their syntax, and examples.

Target Path to Scan	Syntax	Example
Full Data Store	<Empty>	
Schema	<SchemaName>	DB2INST1
Table inside schema	<SchemaName>/<TableName>	DB2INST1/TEST1

Note

- Table names are case sensitive but schema names are not case sensitive.
- It is recommended to set the path in **uppercase** if the database is configured as **case-insensitive**.

- Navigate and add target paths.
 - a. Click **Browse** to navigate target paths from the root level. Alternatively, provide an initial path in the **Add Target Path** field and click **Browse** to navigate targets from that point onward.
 - b. In the left pane, navigate and select the desired target path.
 - c. Click **Add Path** to add the target path to the right pane. Similarly, add other target paths.
 - d. Click **Add**.

Tip

Either navigate the target paths from the root level (without specifying any path in the **Add Target Path** field) or make sure you provide the correct path to navigate further locations within it.

2. Click **Next**.

Select Profiles

1. Under **Classification Profile Name**, select the desired classification profiles to search for in the data store.
You can select multiple profiles, if required. Refer to [Classification Profiles](#) for details on classification profiles.
2. Click **Next**.

Add Filters

This step is optional.

1. Select the desired filter from the **Select Filter** drop-down list.

To filter the locations to scan an IBM Db2 data store, consider the following syntax.

Note

Exclude Path/DO by prefix, suffix, and expression filters support wildcard characters. See [Using](#)

Wildcard Characters to learn how wildcards work.

▪ Exclude Path/DO by prefix

Excludes paths or data objects beginning with a given string. It can be used to exclude entire directory trees. Specify `<string>`.

Filter Item	Syntax	Example
Database	<code><DatabaseName>:<Port></code>	testdb:50000
Schema	<code><DatabaseName>:<Port>/<SchemaName></code>	testdb:50000/DB2INST1
Table	<code><DatabaseName>:<Port>/<SchemaName>/<TableName></code>	testdb:50000/DB2INST1/TEST1
Column	<code><DatabaseName>:<Port>/<SchemaName>/<TableName>/<ColumnName></code>	testdb:50000/DB2INST1/TEST1/ DATA Wildcard usage *DATA — Applies all paths ending with 'DATA' as prefix.

▪ Exclude Path/DO by suffix

Excludes paths or data objects ending with a given string. Specify `<string>`.

Filter Item	Syntax	Example
Database	<code><DatabaseName>:<Port>*</code>	testdb:50000* — Applies all paths starting with 'testdb:50000' as suffix.
Schema	<code><SchemaName></code>	testdb Wildcard usage testdb* — Applies all paths starting with 'testdb' as suffix.
Table	<code><TableName></code>	TEST1 Wildcard usage TEST1* — Applies all paths starting with 'TEST1' as suffix.

Filter Item	Syntax	Example
Column	<ColumnName>	DATA Wildcard usage DATA* — Applies all paths starting with 'DATA' as suffix.

- **Exclude Path/DO by expression**

This filter is majorly used with wildcard characters.

Excludes paths or data objects that matches the given expression. Specify **<string>**.

For example, to exclude locations that contain 'blob' in their path, use expression *blob*.

Filter Item	Syntax	Example
Database	<DatabaseName>:<Port>*	testdb:50000*
Schema	<DatabaseName>:<Port>/<SchemaName>/*	testdb:50000/DB2INST1/*
Table	*<TableName>*	*TEST1*
Column	*<ColumnName>*	*DATA*

2. Click **Apply**.
3. Repeat the above steps to apply multiple filters. Click **Remove** to remove any applied filter.
4. Click **Next**.

Note

List of unsupported filters for IBM Db2 data stores:

- Include DO modified recently
- Exclude DO greater than size
- Include DO's within modification date

Schedule Run

1. Specify the scan run frequency. The two options are:

- **Manual:** This is the default option. Select this option to run the scan manually. Select the **Run Now** check box to start the scan run after you save the changes.
- **Scheduled:** Select this option to configure the scan to run automatically at the specified time.

Refer to [Schedule Scan](#) for more details on scheduling scan runs.

2. Click **Save**.

MongoDB

This section covers the following topics:

- [Prerequisites](#)
- [Add MongoDB Data Store](#)
- [Add MongoDB Scan](#)

Prerequisites

Component	Description
Proxy Agent	▪ Windows Agent ▪ Linux Agent
Version	MongoDB 6.0 and above

Add MongoDB data store

To configure MongoDB data store:

1. Log on to the **CipherTrust Manager** GUI.
2. Open the **Data Discovery & Classification** application.
3. Click **Data Stores > Data Stores > Add Data Store**. The Add Data Store screen is displayed.
4. Complete the following steps:
 - a. [Select Type & Category](#)
 - b. [General Info](#)
 - c. [Configure Connection](#)
 - d. [Add Access Control & Tags](#)

Select Type & Category

1. Under **Select Data Store Category**, select **Database**.
2. From **Select Database Type**, select **MongoDB**.
3. Click **Next**.

General Info

1. Specify the following details:
 - **Data Store Name**: Name for the data store.
 - **Description** (Optional): Description for the data store.
 - **Location Name**: Location of the data store.
 - **Add Location**: Click **Add Location** to add new locations to the **Location Name** drop-down. Refer to [Adding Locations](#) for detailed steps.
 - **Sensitivity Level** (Optional): Sensitivity level for the data store. Refer to [Sensitivity Levels](#) for details.
 - **Enable Data Store**: Whether to enable the newly added data store. Select the check box to enable the data store.
2. Click **Next**.

Configure Connection

1. Specify the credentials for the MongoDB data store:

Field	Description
Hostname/IP	Specify a valid hostname or IP address of database server. Hostname must be more than 2 characters long.
Port	Specify a valid port for connecting to database server. It must be a valid integer between 1 and 65535. Default port: 27017
User	Specify the username.
Password	Specify the password.

2. (Optional) In the **Select Number of Agents** field, set the minimum and maximum number of agents for the data store. Refer to [Agents](#) for more information.

Warning

- As there is no limit on the number of minimum and maximum agents that you can set, you should exercise caution so that you do not impact the system performance by using too many resources for a single scan.
- You will not be able to add a datastore if the minimum number of agents cannot be assigned.
- A scan will fail if the assigned agent is unavailable after adding the datastore.
- The minimum number of agents must be less than or equal to the maximum number of agents.

3. (Optional) In the **Add Label** field, enter a label to restrict the agents that can scan this specific data store instance. You can also remove an existing label. See [Labels](#) for more details.
4. Click **Next**.

Add Access Control & Tags

1. (Optional) Grant the **All groups (default)** access for reports. Alternatively, select a group.
2. Click **Save**.

The data store is added to the Data Stores page. If the **Ready to Scan** column shows **Ready**, then data store is properly configured.

For more information on Access control and Tags, expand the section below.

Access Control & Tags

The **Access Control & Tags** tab on the **Add Data Store** screen allows you to grant access rights to your data store and add tags. More details below:

- **ACCESS CONTROL** - select user groups that can access the data store. Access to a data store provides ability to see reports that include scans of that data store. The available options are:
 - **All groups:** All groups of users can access the data store through reports. This is the default setting.
 - **Selected group/s:** Specified user defined groups can access the data store through reports. When this option is selected, select a group from the drop-down list. This list shows existing user defined groups. The user defined groups must already exist on CipherTrust Manager. If no user defined groups exist, ask the administrator to create a group. If needed, you can select multiple groups. Start typing the name of the desired group and select from the suggested groups.
- **TAGS** - Select a tag from the **Add Tag** drop-down. See the list of prebuilt tags in [Predefined tags](#) section.

Tip

- New tags can also be added. Start typing a new tag, and click the **New: <new_tag>** link that appears below the drop-down.
- Add as many tags as needed.
- To remove a tag, click the close icon in the tag name.

Add MongoDB scan

To add a scan for MongoDB:

1. Open the **Data Discovery & Classification** application.
2. Click **Scans > Add Scan**. The Add Scan screen is displayed.
3. Complete the following steps:
 - a. [General Info](#)
 - b. [Select Data Stores](#)
 - c. [Add Targets](#)
 - d. [Select Profiles](#)
 - e. [Add Filters](#)
 - f. [Schedule Run](#)

Refer to [Scans](#) for the description of sections of the Add Scan screen.

General Info

1. Specify a **Name** for the scan.
2. (optional) Add a **Description** for the scan.
3. Expand **Advanced Configuration** and specify advanced configurations such as Scan Priority, Memory Usage Limit, and Amount of Data Object Volume. Refer to [Advanced Configuration](#) for details.
4. Click **Next**.

Select Data Stores

1. Under **Data Store Name**, select the desired data store that is **Ready** for scanning. You can select multiple data stores, if required.
2. Click **Next**.

Add Targets

1. To add a scan target, do one of the following:

- Under **Add Target Path** field, specify the complete target path and click **Apply**.

If no specific target is added, the entire data store will be scanned. *Target paths are case-sensitive.*

The following table lists target paths and syntax to specify them with examples.

Target Path to Scan	Syntax	Example
Full Data Store	<EmptyPath>	
Database	<DatabaseName>	admin
Collection	<DatabaseName>/<CollectionName>	admin/test

- Navigate and add target paths.
 - a. Click **Browse** to navigate target paths from the root level. Alternatively, provide an initial path in the **Add Target Path** field and click **Browse** to navigate targets from that point onward.
 - b. In the left pane, navigate and select the desired target path.
 - c. Click **Add Path** to add the target path to the right pane. Similarly, add other target paths.
 - d. Click **Add**.

Tip

Either navigate the target paths from the root level (without specifying any path in the **Add Target Path** field) or make sure you provide the correct path to navigate further locations within it.

2. Click **Next**.

Select Profiles

1. Under **Classification Profile Name**, select the desired classification profiles to search for in the data store. You can select multiple profiles, if required. Refer to [Classification Profiles](#) for details on classification profiles.

2. Click **Next**.

Add Filters

This step is optional.

1. Select the desired filter from the **Select Filter** drop-down list.

To filter the locations to scan a MongoDB data store, consider the following syntax.

Note

Exclude Path/DO by prefix, suffix, and expression filters support wildcard characters. See [Using Wildcard Characters](#) to learn how wildcards work.

▪ Exclude Path/DO by prefix

Exclude paths or data objects beginning with a given string. It can be used to exclude entire directory trees.

Filter Item	Syntax	Example
Database	<DatabaseName>	admin
Collection	<DatabaseName>/<CollectionName>*	▪ admin/test* — applies all locations that start with 'admin\test' as prefix ▪ *test* —applies all locations that contains "test" as prefix

▪ Exclude Path/DO by suffix

Exclude paths or data objects ending with a given string, specify <string>.

Filter Item	Syntax	Example
Database	<DatabaseName>*	admin* — applies all locations that start with 'admin' as prefix.
Collection	<DatabaseName>/<CollectionName>*	admin/test* — applies all locations that start with 'admin/test' as suffix. *test* — applies all locations that contain 'test' as suffix.

▪ Exclude Path/DO by expression

This filter is majorly used with wildcard characters.

Exclude paths or data objects that matches a given expression.

Filter Item	Syntax	Example
Database	<DatabaseName>*	admin* — excludes all locations that start with 'admin'.
Collection	<DatabaseName>/<CollectionName>*	admin/test* — excludes all locations that start with 'admin\test'. *test* — excludes all locations that contain 'test'.

- Click **Apply**.
- Repeat above steps to apply multiple filters. Click **Remove** to remove any applied filter.
- Click **Next**.

Note

Unsupported filters in MongoDB data stores:

- Include DO modified recently
- Exclude DO greater than size
- Include DO's within modification date

Schedule Run

- Specify the scan run frequency. The two options are:
 - **Manual:** This is the default option. Select this option to run the scan manually. Select the **Run Now** check box to start the scan run after you save the changes.
 - **Scheduled:** Select this option to configure the scan to run automatically at the specified time.

Refer to [Schedule Scan](#) for more details on scheduling scan runs.

- Click **Save**.

Potential problems while scanning MongoDB data store with GridFS

Following are the several known issues specific to MongoDB while scanning GridFS database.

- You cannot specify a GridFS database collection in the scan path, even if the default scan path for MongoDB is of the format `<database/collection>`. If specified, the scan will fail with the error: "Wrong database collection in target path". You should only use the `<database>` in the scan path.
- A scan on a GridFS database only accepts two default collections with a bucket named fs: **fs.files** and **fs.chunks**. If you use another prefix/bucket name, it will not be scanned.
- Scanning with multiple agents will not work.
 - If you run a scan with multiple agents to scan complete data store, the GridFS database will be skipped and will not appear in the report under the data object list.
 - If you run scan with a specific path of the GridFS database, the scan will fail with the error: "Scan results could not be found".
- During a scan of a GridFS database, if multiple files share the same name, the scan report will combine the total number of matches for all those files and list them under that single filename, even if the file contents differ.
- In a report for a scan on a GridFS database, the list of data objects can contain both collections and files.

Microsoft SQL

This section covers the following topics:

- [Prerequisites](#)
- [Add Microsoft SQL Data Store](#)
- [Add Microsoft SQL Scan](#)

Prerequisites

Component	Description
Proxy Agent	Windows Agent Note Microsoft ODBC drivers are required for SQL Server installation on the Windows Proxy Agent, to establish connection between DDC and database. ODBC driver version 17 is required to support TLS 1.2 connections.
Database Credentials	Use the correct syntax for the Username and Password fields according to your Microsoft SQL

Component	Description
	Server authentication method. SQL Server Authentication - Username: <database_user_name> - Password: <database_user_password> Windows Authentication - Username: <Windows_domain>\<Windows_user_name> Note Windows Authentication is supported only when the Windows Proxy Agent and the Microsoft SQL database server reside on the same host.
Version	Microsoft SQL 2012 and above

Add Microsoft SQL data store

To add Microsoft SQL data store:

1. Log on to the **CipherTrust Manager** GUI.
2. Open the **Data Discovery & Classification** application.
3. Click **Data Stores > Data Stores > Add Data Store**. The Add Data Store screen is displayed.
4. Complete the following steps:
 - a. **Select Type & Category**
 - b. **General Info**
 - c. **Configure Connection**
 - d. **Add Access Control & Tags**

Select Type & Category

1. Under **Select Data Store Category**, select **Database**.

2. From **Select Database Type**, select **Microsoft SQL**.
3. Click **Next**.

General Info

1. Specify the following details:
 - **Data Store Name**: Name for the data store.
 - **Description** (Optional): Description for the data store.
 - **Location Name**: Location of the data store.
 - **Add Location**: Click **Add Location** to add new locations to the **Location Name** drop-down. Refer to [Adding Locations](#) for detailed steps.
 - **Sensitivity Level** (Optional): Sensitivity level for the data store. Refer to [Sensitivity Levels](#) for details.
 - **Enable Data Store**: Whether to enable the newly added data store. Select the check box to enable the data store.
2. Click **Next**.

Configure Connection

1. Specify the credentials for the Microsoft SQL data store:

Field	Description
Hostname/IP	Specify a valid hostname or IP address of the database server. Hostname must be more than 2 characters long. <i>Case sensitivity is not applicable.</i>
Port	Specify a valid port for connecting to the database server. It must be a valid integer between 1 and 65535. Default port: 1433
Database	Specify the database name.
User	Specify the username.
Password	Specify the password.

2. (Optional) In the **Select Number of Agents** field, set the minimum and maximum number of agents for the data store. Refer to [Agents](#) for more information.

Warning

- As there is no limit on the number of minimum and maximum agents that you can set, you should exercise caution so that you do not impact the system performance by using too many resources for a single scan.
- You will not be able to add a datastore if the minimum number of agents cannot be assigned.
- A scan will fail if the assigned agent is unavailable after adding the datastore.
- The minimum number of agents must be less than or equal to the maximum number of agents.

3. (Optional) In the **Add Label** field, enter a label to restrict the agents that can scan this specific data store instance. You can also remove an existing label. See [Labels](#) for more details.
4. Click **Next**.

Add Access Control & Tags

1. (Optional) Grant the **All groups (default)** access for reports. Alternatively, select a group.
2. Click **Save**.

The data store is added to the Data Stores page. If the **Ready to Scan** column shows **Ready**, then data store is properly configured.

For more information on Access control and Tags, expand the section below.

Access Control & Tags

The **Access Control & Tags** tab on the **Add Data Store** screen allows you to grant access rights to your data store and add tags. More details below:

- **ACCESS CONTROL** - select user groups that can access the data store. Access to a data store provides ability to see reports that include scans of that data store. The available options are:
 - **All groups:** All groups of users can access the data store through reports. This is the default setting.
 - **Selected group/s:** Specified user defined groups can access the data store through reports. When this option is selected, select a group from the drop-down list. This list shows existing user defined groups. The user defined groups must already exist on CipherTrust Manager. If no user defined groups exist, ask the administrator to create a group. If needed, you can select multiple groups. Start typing the name of the desired group and select from the suggested groups.
- **TAGS** - Select a tag from the **Add Tag** drop-down. See the list of prebuilt tags in [Predefined tags](#) section.

Tip

- New tags can also be added. Start typing a new tag, and click the **New: <new_tag>** link that appears below the drop-down.
- Add as many tags as needed.
- To remove a tag, click the close icon in the tag name.

Add Microsoft SQL scan

To add a scan for Microsoft SQL:

1. Open the **Data Discovery & Classification** application.
2. Click **Scans > Add Scan**. The Add Scan screen is displayed.
3. Complete the following steps:
 - a. [General Info](#)
 - b. [Select Data Stores](#)
 - c. [Add Targets](#)
 - d. [Select Profiles](#)
 - e. [Add Filters](#)
 - f. [Schedule Run](#)

Refer to [Scans](#) for the description of sections of the Add Scan screen.

General Info

1. Specify a **Name** for the scan.
2. (optional) Add a **Description** for the scan.
3. Expand **Advanced Configuration** and specify advanced configurations such as Scan Priority, Memory Usage Limit, and Amount of Data Object Volume. Refer to [Advanced Configuration](#) for details.
4. Click **Next**.

Select Data Stores

1. Under **Data Store Name**, select the desired data store that is **Ready** for scanning. You can select multiple data stores, if required.
2. Click **Next**.

Add Targets

1. To add a scan target, do one of the following:
 - Under **Add Target Path** field, specify the complete target path and click **Apply**.

If no specific target is added, the entire data store will be scanned.

The following table lists different target paths, their syntax, and examples.

Target Path to Scan	Syntax	Example
Full Data Store	<Empty>	
Schema	<SchemaName>	dbo
Table inside schema	<SchemaName>/<TableName>	dbo/sensitive_data

Note

- Table names are case sensitive but schema names are not case sensitive.

- Navigate and add target paths.
 - a. Click **Browse** to navigate target paths from the root level. Alternatively, provide an initial path in the **Add Target Path** field and click **Browse** to navigate targets from that point onward.
 - b. In the left pane, navigate and select the desired target path.
 - c. Click **Add Path** to add the target path to the right pane. Similarly, add other target paths.
 - d. Click **Add**.

Tip

Either navigate the target paths from the root level (without specifying any path in the **Add Target Path** field) or make sure you provide the correct path to navigate further locations within it.

2. Click **Next**.

Select Profiles

1. Under **Classification Profile Name**, select the desired classification profiles to search for in the data store.
You can select multiple profiles, if required. Refer to [Classification Profiles](#) for details on classification profiles.
2. Click **Next**.

Add Filters

This step is optional.

1. Select the desired filter from the **Select Filter** drop-down list.

To filter the locations to scan a Microsoft SQL data store, consider the following syntax.

Note

Exclude Path/DO by prefix, suffix, and expression filters support wildcard characters. See [Using Wildcard Characters](#) to learn how wildcards work.

▪ Exclude Path/DO by prefix

Excludes paths or data objects beginning with a given string. It can be used to exclude entire directory trees. Specify `<string>`.

Filter Item	Syntax	Example
Schema	<code><DatabaseName>:<port>/<SchemaName></code>	ddctest:1433/dbo Wildcard usage */dbo — Applies all paths ending with '/dbo' as prefix.
Table	<code><DatabaseName>:<port>/<SchemaName>/<TableName></code>	ddctest:1433/dbo/test_table Wildcard usage */test_table — Applies all paths ending with '/test_table' as prefix. This filters out all tables with name 'test_table'.
Column	Not supported	

▪ Exclude Path/DO by suffix

Excludes paths or data objects ending with a given string. Specify `<string>`.

Filter Item	Syntax	Example
Schema	<code><SchemaName>*</code>	<code>dbo*</code> — Applies all paths starting with 'dbo' as suffix.
Table	▪ Table from specific schema: <code><SchemaName>/<TableName></code> ▪ Table from all schemas: <code><TableName></code>	<code>dbo/test_table</code> , <code>test_table</code>

▪ Exclude Path/DO by expression

This filter is majorly used with wildcard characters.

Excludes paths or data objects that matches the given expression. Specify `<string>`.

For example to exclude locations that contain 'replica' in their path, use expression `*replica*`.

Filter Item	Syntax	Example
Schema	<code><DatabaseName>:<port>/<SchemaName>*</code>	<code>testddc:1433/dbo*</code>
Table	<code>*<TableName>*</code>	<code>*my_table*</code>

2. Click **Apply**.
3. Repeat the above steps to apply multiple filters. Click **Remove** to remove any applied filter.
4. Click **Next**.

Note

List of unsupported filters for Microsoft SQL data stores:

- Include DO modified recently
- Exclude DO greater than size
- Include DO's within modification date

Schedule Run

1. Specify the scan run frequency. The two options are:

- **Manual:** This is the default option. Select this option to run the scan manually. Select the **Run Now** check box to start the scan run after you save the changes.
- **Scheduled:** Select this option to configure the scan to run automatically at the specified time.

Refer to [Schedule Scan](#) for more details on scheduling scan runs.

2. Click **Save**.

MySQL

This section covers the following topics:

- [Prerequisites](#)
- [Add MySQL Data Store](#)
- [Add MySQL Scan](#)

Prerequisites

Component	Description
Proxy Agent	▪ Windows Agent ▪ Linux Agent Note Built-in drivers for Windows and Linux Agents are required to connect with MySQL data store. Built-in drivers do not support password authentication with 'caching_sha2_password' method.
Database Credentials	Use credentials that have minimum required privileges to access the databases, schemas, and tables you want to scan. Example: To scan a MySQL database, use credentials that have SELECT permissions (read permissions).
Version	MySQL 5.0 and above

Add MySQL data store

To configure MySQL data store:

1. Log on to the **CipherTrust Manager** GUI.
2. Open the **Data Discovery & Classification** application.
3. Click **Data Stores > Data Stores > Add Data Store**. The Add Data Store screen is displayed.
4. Complete the following steps:
 - a. [Select Type & Category](#)
 - b. [General Info](#)
 - c. [Configure Connection](#)
 - d. [Add Access Control & Tags](#)

Select Type & Category

1. Under **Select Data Store Category**, select **Database**.
2. From **Select Database Type**, select **MySQL**.
3. Click **Next**.

General Info

1. Specify the following details:
 - **Data Store Name**: Name for the data store.
 - **Description** (Optional): Description for the data store.
 - **Location Name**: Location of the data store.
 - **Add Location**: Click **Add Location** to add new locations to the **Location Name** drop-down. Refer to [Adding Locations](#) for detailed steps.
 - **Sensitivity Level** (Optional): Sensitivity level for the data store. Refer to [Sensitivity Levels](#) for details.
 - **Enable Data Store**: Whether to enable the newly added data store. Select the check box to enable the data store.
2. Click **Next**.

Configure Connection

1. Specify the credentials for the MySQL data store:

Field	Description
Hostname/IP	Specify valid hostname or IP address of database server. Hostname must be more than 2 characters long. <i>Case sensitivity is not applicable.</i>
Port	Specify a valid port for connecting to database server. It must be a valid integer between 1 and 65535. Default port: 3306
User	Specify the username.
Password	Specify the password.

2. (Optional) In the **Select Number of Agents** field, set the minimum and maximum number of agents for the data store. Refer to [Agents](#) for more information.

Warning

- As there is no limit on the number of minimum and maximum agents that you can set, you should exercise caution so that you do not impact the system performance by using too many resources for a single scan.
- You will not be able to add a datastore if the minimum number of agents cannot be assigned.
- A scan will fail if the assigned agent is unavailable after adding the datastore.
- The minimum number of agents must be less than or equal to the maximum number of agents.

3. (Optional) In the **Add Label** field, enter a label to restrict the agents that can scan this specific data store instance. You can also remove an existing label. See [Labels](#) for more details.

4. Click **Next**.

Add Access Control & Tags

1. (Optional) Grant the **All groups (default)** access for reports. Alternatively, select a group.
2. Click **Save**.

The data store is added to the Data Stores page. If the **Ready to Scan** column shows **Ready**, then data store is properly configured.

For more information on Access control and Tags, expand the section below.

Access Control & Tags

The **Access Control & Tags** tab on the **Add Data Store** screen allows you to grant access rights to your data store and add tags. More details below:

- **ACCESS CONTROL** - select user groups that can access the data store. Access to a data store provides ability to see reports that include scans of that data store. The available options are:
 - **All groups:** All groups of users can access the data store through reports. This is the default setting.
 - **Selected group/s:** Specified user defined groups can access the data store through reports. When this option is selected, select a group from the drop-down list. This list shows existing user defined groups. The user defined groups must already exist on CipherTrust Manager. If no user defined groups exist, ask the administrator to create a group. If needed, you can select multiple groups. Start typing the name of the desired group and select from the suggested groups.
- **TAGS** - Select a tag from the **Add Tag** drop-down. See the list of prebuilt tags in [Predefined tags](#) section.

Tip

- New tags can also be added. Start typing a new tag, and click the **New: <new_tag>** link that appears below the drop-down.
- Add as many tags as needed.
- To remove a tag, click the close icon in the tag name.

Add MySQL scan

To add a scan for MySQL:

1. Open the **Data Discovery & Classification** application.
2. Click **Scans > Add Scan**. The Add Scan screen is displayed.
3. Complete the following steps:
 - a. [General Info](#)
 - b. [Select Data Stores](#)
 - c. [Add Targets](#)
 - d. [Select Profiles](#)
 - e. [Add Filters](#)

f. Schedule Run

Refer to [Scans](#) for the description of sections of the Add Scan screen.

General Info

1. Specify a **Name** for the scan.
2. (optional) Add a **Description** for the scan.
3. Expand **Advanced Configuration** and specify advanced configurations such as Scan Priority, Memory Usage Limit, and Amount of Data Object Volume. Refer to [Advanced Configuration](#) for details.
4. Click **Next**.

Select Data Stores

1. Under **Data Store Name**, select the desired data store that is **Ready** for scanning. You can select multiple data stores, if required.
2. Click **Next**.

Add Targets

1. To add a scan target, do one of the following:
 - Under **Add Target Path** field, specify the complete target path and click **Apply**.

If no specific target is added, the entire data store will be scanned. *Target paths are case-sensitive.*

The following table lists target paths and syntax to specify them with examples.

Target Path to Scan	Syntax	Example
Full Data Store	<EmptyPath>	
Database	▪ Pagination enabled (default): <DatabaseName> ▪ Pagination disabled: <DatabaseName(paged=false)>	test-ddc, test-ddc(paged=false)
Table inside database	<DatabaseName>/<TableName>	test-ddc/sensitive_data

- Navigate and add target paths.
 - a. Click **Browse** to navigate target paths from the root level. Alternatively, provide an initial path in the **Add Target Path** field and click **Browse** to navigate targets from that point onward.
 - b. In the left pane, navigate and select the desired target path.

- c. Click **Add Path** to add the target path to the right pane. Similarly, add other target paths.
- d. Click **Add**.

Tip

Either navigate the target paths from the root level (without specifying any path in the **Add Target Path** field) or make sure you provide the correct path to navigate further locations within it.

2. Click **Next**.

Select Profiles

1. Under **Classification Profile Name**, select the desired classification profiles to search for in the data store. You can select multiple profiles, if required. Refer to [Classification Profiles](#) for details on classification profiles.
2. Click **Next**.

Add Filters

This step is optional.

1. Select the desired filter from the **Select Filter** drop-down list.

To filter the locations to scan a MySQL data store, consider the following syntax.

Note

Exclude Path/DO by prefix, suffix, and expression filters support wildcard characters. See [Using Wildcard Characters](#) to learn how wildcards work.

▪ Exclude Path/DO by prefix

Excludes paths or data objects beginning with a given string. It can be used to exclude entire directory trees. Specify `<string>`.

Filter Item	Syntax	Example
Database/Schema	<code><DatabaseName></code>	testddc
Table	<code><DatabaseName>/<TableName></code>	testddc/sensitive_data Wildcard usage *sensitive_data — Applies all

Filter Item	Syntax	Example
		paths ending with 'sensitive_data' as prefix.
Column	<DatabaseName>/<TableName>/<ColumnName>	testddc/sensitive_data/email Wildcard usage *email — Applies all paths ending with 'email' as prefix.

▪ Exclude Path/DO by suffix

Excludes paths or data objects ending with a given string. Specify `<string>`.

Filter Item	Syntax	Example
Database	<DatabaseName>*	testddc* — Applies all paths starting with 'testddc' as suffix.
Table	▪ Specific table: <TableName> ▪ Table from specific database: <DatabaseName>/<TableName>	sensitive_data, testddc/sensitive_data
Column	▪ Specific column: <ColumnName> ▪ Specific column within table: <DatabaseName>/<TableName>/<ColumnName>	email, test-ddc/sensitive_data/email

▪ Exclude Path/DO by expression

This filter is majorly used with wildcard characters.

Excludes paths or data objects that matches the given expression. Specify `<string>`.

For example, to exclude locations that contain 'blob' in their path, use expression *blob*.

Filter Item	Syntax	Example
Database/Schema	<DatabaseName>*	testddc*
Table	▪ Specific table: *<TableName> ▪ Table from specific database: <DatabaseName>/<TableName>	*sensitive_data, testddc/sensitive_data

Filter Item	Syntax	Example
	<DatabaseName>/<TableName>	
Column	*<DatabaseName>/<TableName>/<ColumnName>	*testddc/sensitive_data/email

- Click **Apply**.
- Repeat the above steps to apply multiple filters. Click **Remove** to remove any applied filter.
- Click **Next**.

Note

Unsupported filters in MySQL data stores:

- Include DO modified recently
- Exclude DO greater than size
- Include DO's within modification date

Schedule Run

- Specify the scan run frequency. The two options are:
 - **Manual:** This is the default option. Select this option to run the scan manually. Select the **Run Now** check box to start the scan run after you save the changes.
 - **Scheduled:** Select this option to configure the scan to run automatically at the specified time.

Refer to [Schedule Scan](#) for more details on scheduling scan runs.

- Click **Save**.

Oracle

This section covers the following topics:

- [Prerequisites](#)
- [Add Oracle Data Store](#)
- [Add Oracle Scan](#)

Prerequisites

Component	Description
Proxy Agent	- Windows Agent - Linux Agent Note Windows and Linux Agent built-in drivers are required to connect to an Oracle data store.
Libraries	Requires <code>libaio1</code> and <code>libaio-dev</code> libraries installed on Linux 3 Agent host. Command: <code>sudo apt-get install libaio1 libaio-dev</code>
Version	Oracle Database 11g and above

Add Oracle data store

To add Oracle data store:

1. Log on to the **CipherTrust Manager** GUI.
2. Open the **Data Discovery & Classification** application.
3. Click **Data Stores > Data Stores > Add Data Store**. The Add Data Store screen is displayed.
4. Complete the following steps:
 - a. **Select Type & Category**
 - b. **General Info**
 - c. **Configure Connection**
 - d. **Add Access Control & Tags**

Select Type & Category

1. Under **Select Data Store Category**, select **Database**.
2. From **Select Database Type**, select **Oracle**.

3. Click **Next**.

General Info

1. Specify the following details:
 - **Data Store Name:** Name for the data store.
 - **Description** (Optional): Description for the data store.
 - **Location Name:** Location of the data store.
 - **Add Location:** Click **Add Location** to add new locations to the **Location Name** drop-down. Refer to [Adding Locations](#) for detailed steps.
 - **Sensitivity Level** (Optional): Sensitivity level for the data store. Refer to [Sensitivity Levels](#) for details.
 - **Enable Data Store:** Whether to enable the newly added data store. Select the check box to enable the data store.
2. Click **Next**.

Configure Connection

1. Specify the credentials for the Oracle data store:

Field	Description
Hostname/IP	Specify a valid hostname or IP address of the database server. Hostname must be more than 2 characters long.
Port	Specify a valid port for connecting to the database server. It must be a valid integer between 1 and 65535. Default port: 1521
Schema	Specify the schema name with service name. Example: Schema with service name: HR(SERVICE_NAME=XE).
User	Specify the username of the database.
Password	Specify the password.

2. (Optional) In the **Select Number of Agents** field, set the minimum and maximum number of agents for the data store. Refer to [Agents](#) for more information.

Warning

- As there is no limit on the number of minimum and maximum agents that you can set, you should exercise caution so that you do not impact the system performance by using too many resources for a single scan.
- You will not be able to add a datastore if the minimum number of agents cannot be assigned.
- A scan will fail if the assigned agent is unavailable after adding the datastore.
- The minimum number of agents must be less than or equal to the maximum number of agents.

3. (Optional) In the **Add Label** field, enter a label to restrict the agents that can scan this specific data store instance. You can also remove an existing label. See [Labels](#) for more details.
4. Click **Next**.

Add Access Control & Tags

1. (Optional) Grant the **All groups (default)** access for reports. Alternatively, select a group.
2. Click **Save**.

The data store is added to the Data Stores page. If the **Ready to Scan** column shows **Ready**, then data store is properly configured.

For more information on Access control and Tags, expand the section below.

Access Control & Tags

The **Access Control & Tags** tab on the **Add Data Store** screen allows you to grant access rights to your data store and add tags. More details below:

- **ACCESS CONTROL** - select user groups that can access the data store. Access to a data store provides ability to see reports that include scans of that data store. The available options are:
 - **All groups:** All groups of users can access the data store through reports. This is the default setting.
 - **Selected group/s:** Specified user defined groups can access the data store through reports. When this option is selected, select a group from the drop-down list. This list shows existing user defined groups. The user defined groups must already exist on CipherTrust Manager. If no user defined groups exist, ask the administrator to create a group. If needed, you can select multiple groups. Start typing the name of the desired group and select from the suggested groups.
- **TAGS** - Select a tag from the **Add Tag** drop-down. See the list of prebuilt tags in [Predefined tags](#) section.

Tip

- New tags can also be added. Start typing a new tag, and click the **New: <new_tag>** link that appears below the drop-down.
- Add as many tags as needed.
- To remove a tag, click the close icon in the tag name.

Add Oracle scan

To add a scan for Oracle:

1. Open the **Data Discovery & Classification** application.
2. Click **Scans > Add Scan**. The Add Scan screen is displayed.
3. Complete the following steps:
 - a. [General Info](#)
 - b. [Select Data Stores](#)
 - c. [Add Targets](#)
 - d. [Select Profiles](#)
 - e. [Add Filters](#)
 - f. [Schedule Run](#)

Refer to [Scans](#) for the description of sections of the Add Scan screen.

General Info

1. Specify a **Name** for the scan.
2. (optional) Add a **Description** for the scan.
3. Expand **Advanced Configuration** and specify advanced configurations such as Scan Priority, Memory Usage Limit, and Amount of Data Object Volume. Refer to [Advanced Configuration](#) for details.
4. Click **Next**.

Select Data Stores

1. Under **Data Store Name**, select the desired data store that is **Ready** for scanning. You can select multiple data stores, if required.
2. Click **Next**.

Add Targets

1. To add a scan target, do one of the following:
 - Under **Add Target Path** field, specify the complete target path and click **Apply**.

If no specific target is added, the entire data store will be scanned.

The following table lists different target paths, their syntax, and examples.

Target Path to Scan	Syntax	Example
Full data store	<Empty>	
Table	<TableName>	TEST1

Note

- Table names are case sensitive.
- It is recommended to set the path in **uppercase** if the database is configured as **case-insensitive**.

- Navigate and add target paths.
 - a. Click **Browse** to navigate target paths from the root level. Alternatively, provide an initial path in the **Add Target Path** field and click **Browse** to navigate targets from that point onward.
 - b. In the left pane, navigate and select the desired target path.
 - c. Click **Add Path** to add the target path to the right pane. Similarly, add other target paths.
 - d. Click **Add**.

Tip

Either navigate the target paths from the root level (without specifying any path in the **Add Target Path** field) or make sure you provide the correct path to navigate further locations within it.

2. Click **Next**.

Select Profiles

1. Under **Classification Profile Name**, select the desired classification profiles to search for in the data store.
You can select multiple profiles, if required. Refer to [Classification Profiles](#) for details on classification profiles.
2. Click **Next**.

Add Filters

This step is optional.

1. Select the desired filter from the **Select Filter** drop-down list.

To filter the locations to scan an Oracle data store, consider the following syntax.

Note

Exclude Path/DO by prefix, suffix, and expression filters support wildcard characters. See [Using Wildcard Characters](#) to learn how wildcards work.

- **Exclude Path/DO by prefix**

Excludes paths or data objects beginning with a given string. Specify `<string>`.

Filter Item	Syntax	Example
Table	<code><SchemaName>(SERVICE_NAME=<sid>:<Port>)/<TableName></code>	<code>DDCADMIN(SERVICE_NAME=DDCTEST):1521/TEST</code>

- **Exclude Path/DO by suffix**

Excludes paths or data objects ending with a given string. Specify `<string>`.

Filter Item	Syntax	Example
Table	<TableName> or end characters of table name	TEST1, T1 (excludes tables ending with 'T1')

- **Exclude Path/DO by expression**

This filter is majorly used with wildcard characters.

Excludes paths or data objects that matches the given expression. Specify `<string>`.

For example, to exclude locations that contain 'replica' in their path, use expression `*replica*`.

Filter Item	Syntax	Example
Table	*<TableName>*	*TEST1*

2. Click **Apply**.
3. Repeat the above steps to apply multiple filters. Click **Remove** to remove any applied filter.
4. Click **Next**.

Note

List of unsupported filters for Oracle data stores:

- Include DO modified recently
- Exclude DO greater than size
- Include DO's within modification date

Schedule Run

1. Specify the scan run frequency. The two options are:
 - **Manual:** This is the default option. Select this option to run the scan manually. Select the **Run Now** check box to start the scan run after you save the changes.
 - **Scheduled:** Select this option to configure the scan to run automatically at the specified time.

Refer to [Schedule Scan](#) for more details on scheduling scan runs.

2. Click **Save**.

Known issues

Issue	Cause
You might encounter following error while configuring Oracle database that requires service name: Cannot find minimum agent for the data store	The service name is missing or incorrect. Solution: Retry configuring the database using correct service name.
Issue when scanning text files as BLOBs in Oracle	DDC can't scan any text file stored as BLOB in Oracle if the file size is greater than 4 KB.

PostgreSQL

This section covers the following topics:

- Prerequisites
- Configure PostgreSQL Server
- Add PostgreSQL Data Store
- Add PostgreSQL Scan

Prerequisites

Component	Description
Proxy Agent	▪ Windows Agent ▪ Linux Agent
Version	PostgreSQL 13 and above

Configure PostgreSQL server

By default, remote connections to the PostgreSQL server are blocked.

To establish connection with PostgreSQL data store, do either of the following:

- Install the DDC agent on the PostgreSQL database server, or
- Configure the PostgreSQL server to allow remote connections (**recommended**).

To configure the PostgreSQL server:

1. Locate the `pg_hba.conf` configuration file on the PostgreSQL database server.

On a Unix-based server, this file is usually found at this location: `/var/lib/postgresql/data directory`.

2. As a root user, open *pg_hba.conf* in a text editor.
3. Append the following lines in the configuration file.

```
# Syntax:  
# host <database_name> <postgresql_user_name> <agent_host_address> <auth-method>  
host all all all md5
```

Above configuration allows any remote client with a valid username and password to connect with the PostgreSQL server. For a more secure configuration, use specific parameter values for database, user, and IP address. For example:

```
host database_A scan_user 172.17.0.0/24 md5
```

4. Save the changes and restart PostgreSQL server.
5. (Optional) Open the *postgresql.conf* file and set the value of `#listen_addresses` parameter to `*` in the Connections and Authentication sections.

```
#listen_addresses = '*'
```

You can also assign a specific IP address of a PostgreSQL server to `listen_addresses` instead of global value (*).

Add PostgreSQL data store

To add PostgreSQL data store:

1. Log on to the **CipherTrust Manager** GUI.
2. Open the **Data Discovery & Classification** application.
3. Click **Data Stores > Data Stores > Add Data Store**. The Add Data Store screen is displayed.
4. Complete the following steps:
 - a. **Select Type & Category**
 - b. **General Info**
 - c. **Configure Connection**
 - d. **Add Access Control & Tags**

Select Type & Category

1. Under **Select Data Store Category**, select **Database**.
2. From **Select Database Type**, select **PostgreSQL**.
3. Click **Next**.

General Info

1. Specify the following details:
 - **Data Store Name**: Name for the data store.
 - **Description** (Optional): Description for the data store.
 - **Location Name**: Location of the data store.
 - **Add Location**: Click **Add Location** to add new locations to the **Location Name** drop-down. Refer to [Adding Locations](#) for detailed steps.
 - **Sensitivity Level** (Optional): Sensitivity level for the data store. Refer to [Sensitivity Levels](#) for details.
 - **Enable Data Store**: Whether to enable the newly added data store. Select the check box to enable the data store.
2. Click **Next**.

Configure Connection

1. Specify the credentials for the PostgreSQL data store:

Field	Description
Hostname/IP	Specify a valid hostname or IP address of the database server. Hostname must be more than 2 characters long.
Port	Specify a valid port for connecting to database server. It must be a valid integer between 1 and 65535. Default port: 5432
Database	Specify the database name. <i>Case sensitivity is applicable.</i>
User	Specify the username.
Password	Specify the password.

2. (Optional) In the **Select Number of Agents** field, set the minimum and maximum number of agents for the data store. Refer to [Agents](#) for more information.

Warning

- As there is no limit on the number of minimum and maximum agents that you can set, you should exercise caution so that you do not impact the system performance by using too many resources for a single scan.
- You will not be able to add a datastore if the minimum number of agents cannot be assigned.
- A scan will fail if the assigned agent is unavailable after adding the datastore.
- The minimum number of agents must be less than or equal to the maximum number of agents.

3. (Optional) In the **Add Label** field, enter a label to restrict the agents that can scan this specific data store instance. You can also remove an existing label. See [Labels](#) for more details.
4. Click **Next**.

Add Access Control & Tags

1. (Optional) Grant the **All groups (default)** access for reports. Alternatively, select a group.
2. Click **Save**.

The data store is added to the Data Stores page. If the **Ready to Scan** column shows **Ready**, then data store is properly configured.

For more information on Access control and Tags, expand the section below.

Access Control & Tags

The **Access Control & Tags** tab on the **Add Data Store** screen allows you to grant access rights to your data store and add tags. More details below:

- **ACCESS CONTROL** - select user groups that can access the data store. Access to a data store provides ability to see reports that include scans of that data store. The available options are:
 - **All groups:** All groups of users can access the data store through reports. This is the default setting.
 - **Selected group/s:** Specified user defined groups can access the data store through reports. When this option is selected, select a group from the drop-down list. This list shows existing user defined groups. The user defined groups must already exist on CipherTrust Manager. If no user defined groups exist, ask the administrator to create a group. If needed, you can select multiple groups. Start typing the name of the desired group and select from the suggested groups.
- **TAGS** - Select a tag from the **Add Tag** drop-down. See the list of prebuilt tags in [Predefined tags](#) section.

Tip

- New tags can also be added. Start typing a new tag, and click the **New: <new_tag>** link that appears below the drop-down.
- Add as many tags as needed.
- To remove a tag, click the close icon in the tag name.

Add PostgreSQL scan

To add a scan for PostgreSQL:

1. Open the **Data Discovery & Classification** application.
2. Click **Scans > Add Scan**. The Add Scan screen is displayed.
3. Complete the following steps:
 - a. [General Info](#)
 - b. [Select Data Stores](#)
 - c. [Add Targets](#)
 - d. [Select Profiles](#)
 - e. [Add Filters](#)
 - f. [Schedule Run](#)

Refer to [Scans](#) for the description of sections of the Add Scan screen.

General Info

1. Specify a **Name** for the scan.
2. (optional) Add a **Description** for the scan.
3. Expand **Advanced Configuration** and specify advanced configurations such as Scan Priority, Memory Usage Limit, and Amount of Data Object Volume. Refer to [Advanced Configuration](#) for details.
4. Click **Next**.

Select Data Stores

1. Under **Data Store Name**, select the desired data store that is **Ready** for scanning. You can select multiple data stores, if required.
2. Click **Next**.

Add Targets

1. To add a scan target, do one of the following:

- Under **Add Target Path** field, specify the complete target path and click **Apply**.

If no specific target is added, the entire data store will be scanned. *Target paths are case-sensitive.*

The following table lists target paths and syntax to specify them with examples.

Target Path to Scan	Syntax	Example
Full Data Store	<EmptyPath>	
Schema	<SchemaName>	public
Table	<SchemaName>/<TableName>	public/test_table

- Navigate and add target paths.
 - a. Click **Browse** to navigate target paths from the root level. Alternatively, provide an initial path in the **Add Target Path** field and click **Browse** to navigate targets from that point onward.
 - b. In the left pane, navigate and select the desired target path.
 - c. Click **Add Path** to add the target path to the right pane. Similarly, add other target paths.
 - d. Click **Add**.

Tip

Either navigate the target paths from the root level (without specifying any path in the **Add Target Path** field) or make sure you provide the correct path to navigate further locations within it.

2. Click **Next**.

Select Profiles

1. Under **Classification Profile Name**, select the desired classification profiles to search for in the data store. You can select multiple profiles, if required. Refer to [Classification Profiles](#) for details on classification profiles.
2. Click **Next**.

Add Filters

This step is optional.

1. Select the desired filter from the **Select Filter** drop-down list.

To filter the locations to scan a PostgreSQL data store, consider the following syntax.

Note

Exclude Path/DO by prefix, suffix, and expression filters support wildcard characters. See [Using Wildcard Characters](#) to learn how wildcards work.

▪ Exclude Path/DO by prefix

Exclude paths or data objects beginning with a given string. It can be used to exclude entire directory trees.

Filter	Syntax	Example
Database	<DatabaseName>	ddc_test
Schema	<DatabaseName>:<Port>/<SchemaName>	ddc_test:5432/public Wildcard usage ddc_test:5432/* — Applies all paths starting with 'ddc_test:5432/' as prefix.
Table	<DatabaseName>:<Port>/<SchemaName>/<TableName>	ddc_test:5432/public/test
Column	*<DatabaseName>:<Port>/<SchemaName>/<TableName>/<ColumnName>*	*ddc_test:5432/public/test/data* — Applies all paths that contains '5432/public/test' as prefix.

▪ Exclude Path/DO by suffix

Exclude paths or data objects ending with a given string, specify <string>.

Filter	Syntax	Example
Database	<DatabaseName>*	ddc_test* — Applies all locations starting with 'ddc_test' as suffix.
Schema	*<Schema>*	*public* — Applies all paths that contain 'public' as suffix.

Filter	Syntax	Example
Table	Table from a specific schema: <DatabaseName>:<Port>/<SchemaName>/<TableName> Table from complete database: <table>	ddc_test:5432/public/test, test
Column	Column from a specific table: <DatabaseName>:<Port>/<SchemaName>/<TableName>/<ColumnName> Column from complete database: <ColumnName>	ddc_test:5432/public/test/data, data

- **Exclude Path/DO by expression**

This filter is majorly used with wildcard characters.

Excludes paths or data objects that matches the given expression.

For example to exclude locations that contain 'blob' in their path, use expression *blob*.

Filter	Syntax	Example
Database	<DatabaseName>	ddc_test*
Schema	<DatabaseName>:<Port>/<SchemaName>/*	ddc_test:5432/public/*
Table	<DatabaseName>:<Port>/<SchemaName>/<TableName>	ddc_test:5432/public/test
Column	*<DatabaseName>:<Port>/<SchemaName>/<TableName>/<ColumnName>*	*ddc_test:5432/public/test/data*

2. Click **Apply**.
3. Repeat above steps to apply multiple filters. Click **Remove** to remove any applied filter.
4. Click **Next**.

Note

Unsupported filters in PostgreSQL data stores:

- Include DO modified recently
- Exclude DO greater than size
- Include DO's within modification date

Schedule Run

1. Specify the scan run frequency. The two options are:

- **Manual:** This is the default option. Select this option to run the scan manually. Select the **Run Now** check box to start the scan run after you save the changes.
- **Scheduled:** Select this option to configure the scan to run automatically at the specified time.

Refer to [Schedule Scan](#) for more details on scheduling scan runs.

2. Click **Save**.

SAP HANA

This section covers the following topics:

- [Prerequisites](#)
- [Add SAP HANA Data Store](#)
- [Add SAP HANA Scan](#)

Prerequisites

Component	Description
Proxy Agent	Windows Agent Note Windows Agent built-in drivers are required to connect to a SAP HANA data store. If SAP HANA ODBC drivers are installed on host agent, the Agent will use these drivers instead of built-in drivers.

Component	Description
Version	SAP HANA 2.0 SPS04 and above

Add SAP HANA data store

To add SAP HANA data store:

1. Log on to the **CipherTrust Manager** GUI.
2. Open the **Data Discovery & Classification** application.
3. Click **Data Stores > Data Stores > Add Data Store**. The Add Data Store screen is displayed.
4. Complete the following steps:
 - a. [Select Type & Category](#)
 - b. [General Info](#)
 - c. [Configure Connection](#)
 - d. [Add Access Control & Tags](#)

Select Type & Category

1. Under **Select Data Store Category**, select **Database**.
2. From **Select Database Type**, select **SAP HANA**.
3. Click **Next**.

General Info

1. Specify the following details:
 - **Data Store Name:** Name for the data store.
 - **Description** (Optional): Description for the data store.
 - **Location Name:** Location of the data store.
 - **Add Location:** Click **Add Location** to add new locations to the **Location Name** drop-down. Refer to [Adding Locations](#) for detailed steps.
 - **Sensitivity Level** (Optional): Sensitivity level for the data store. Refer to [Sensitivity Levels](#) for details.
 - **Enable Data Store:** Whether to enable the newly added data store. Select the check box to enable the data store.

- Click **Next**.

Configure Connection

- Specify the credentials for the SAP HANA data store:

Field	Description
Hostname/IP	Specify valid hostname or IP address of database server. Hostname must be more than 2 characters long. <i>Case sensitivity is applicable.</i>
Port	Specify a valid port for connecting to database server. It must be a valid integer between 1 and 65535. Default port: 30015
Database	Specify the database name.
User	Specify the username.
Password	Specify the password.

- (Optional) In the **Select Number of Agents** field, set the minimum and maximum number of agents for the data store. Refer to [Agents](#) for more information.

Warning

- As there is no limit on the number of minimum and maximum agents that you can set, you should exercise caution so that you do not impact the system performance by using too many resources for a single scan.
- You will not be able to add a datastore if the minimum number of agents cannot be assigned.
- A scan will fail if the assigned agent is unavailable after adding the datastore.
- The minimum number of agents must be less than or equal to the maximum number of agents.

- (Optional) In the **Add Label** field, enter a label to restrict the agents that can scan this specific data store instance. You can also remove an existing label. See [Labels](#) for more details.

- Click **Next**.

Add Access Control & Tags

- (Optional) Grant the **All groups (default)** access for reports. Alternatively, select a group.
- Click **Save**.

The data store is added to the Data Stores page. If the **Ready to Scan** column shows **Ready**, then data store is properly configured.

For more information on Access control and Tags, expand the section below.

Access Control & Tags

The **Access Control & Tags** tab on the **Add Data Store** screen allows you to grant access rights to your data store and add tags. More details below:

- **ACCESS CONTROL** - select user groups that can access the data store. Access to a data store provides ability to see reports that include scans of that data store. The available options are:
 - **All groups:** All groups of users can access the data store through reports. This is the default setting.
 - **Selected group/s:** Specified user defined groups can access the data store through reports. When this option is selected, select a group from the drop-down list. This list shows existing user defined groups. The user defined groups must already exist on CipherTrust Manager. If no user defined groups exist, ask the administrator to create a group. If needed, you can select multiple groups. Start typing the name of the desired group and select from the suggested groups.
- **TAGS** - Select a tag from the **Add Tag** drop-down. See the list of prebuilt tags in [Predefined tags](#) section.

Tip

- New tags can also be added. Start typing a new tag, and click the **New: <new_tag>** link that appears below the drop-down.
- Add as many tags as needed.
- To remove a tag, click the close icon in the tag name.

Add SAP HANA scan

To add a scan for SAP HANA data store:

1. Open the **Data Discovery & Classification** application.
2. Click **Scans > Add Scan**. The Add Scan screen is displayed.
3. Complete the following steps:
 - a. [General Info](#)
 - b. [Select Data Stores](#)
 - c. [Add Targets](#)

- d. [Select Profiles](#)
- e. [Add Filters](#)
- f. [Schedule Run](#)

Refer to [Scans](#) for the description of sections of the Add Scan screen.

General Info

1. Specify a **Name** for the scan.
2. (optional) Add a **Description** for the scan.
3. Expand **Advanced Configuration** and specify advanced configurations such as Scan Priority, Memory Usage Limit, and Amount of Data Object Volume. Refer to [Advanced Configuration](#) for details.
4. Click **Next**.

Select Data Stores

1. Under **Data Store Name**, select the desired data store that is **Ready** for scanning. You can select multiple data stores, if required.
2. Click **Next**.

Add Targets

1. To add a scan target, do one of the following:
 - Under **Add Target Path** field, specify the complete target path and click **Apply**.

If no specific target is added, the entire data store will be scanned. *Target paths are case-sensitive.*

The following table lists target paths and syntax to specify them with examples.

Target Path to Scan	Syntax	Example
Schema	<SchemaName>	system
Table	<SchemaName>/<TableName>	system/test_table

Note

Entire data store scan is not supported for SAP HANA. You must provide at least one path to initiate a scan.

- Navigate and add target paths.
 - a. Click **Browse** to navigate target paths from the root level. Alternatively, provide an initial path in the **Add Target Path** field and click **Browse** to navigate targets from that point onward.
 - b. In the left pane, navigate and select the desired target path.
 - c. Click **Add Path** to add the target path to the right pane. Similarly, add other target paths.
 - d. Click **Add**.

Tip

Either navigate the target paths from the root level (without specifying any path in the **Add Target Path** field) or make sure you provide the correct path to navigate further locations within it.

2. Click **Next**.

Select Profiles

1. Under **Classification Profile Name**, select the desired classification profiles to search for in the data store.
You can select multiple profiles, if required. Refer to [Classification Profiles](#) for details on classification profiles.
2. Click **Next**.

Add Filters

This step is optional.

1. Select the desired filter from the **Select Filter** drop-down list.

To filter the locations to scan a SAP HANA data store, consider the following syntax.

Note

Exclude Path/DO by prefix, suffix, and expression filters support wildcard characters. See [Using Wildcard Characters](#) to learn how wildcard characters function.

- **Exclude Path/DO by prefix**

Exclude paths or data objects beginning with a given string. It can be used to exclude entire directory trees.

Filter Item	Syntax	Example
Database	<DatabaseName>	ddc_test

Filter Item	Syntax	Example
Schema	<DatabaseName>:<Port>/<SchemaName>	ddc_test:5432/system
Table	<DatabaseName>:<Port>/<SchemaName>/<TableName>	ddc_test:5432/system/table Wildcard usage ddc_test:5432/*table — Applies all locations starting with 'ddc_test:5432/' and ending with '/table' as prefix
Column	*<DatabaseName>:<Port>/<SchemaName>/<TableName>/<ColumnName>*	*ddc_test:5432/system/table/col* — Applies all paths containing 'ddc_test:5432/system/table/col' as prefix. *col* — Applies all paths containing 'col' as prefix.

- **Exclude Path/DO by suffix**

Exclude paths or data objects ending with a given string, specify `<string>`.

Filter Item	Syntax	Example
Database	<DatabaseName>*	ddc_test* —Applies all locations starting with 'ddc_test' as suffix.
Schema	*<SchemaName>*	*system* — Applies all locations containing 'system' as suffix.
Table	▪ Specific table: <TableName> ▪ Table from specific schema: <Schema>/<TableName>	test, public/test
Column	▪ Specific column: <ColumnName> ▪ Specific column in specific table: <DatabaseName>:<Port>/<SchemaName>/<TableName>/<ColumnName>	data, test/data,ddc_test:5432/public/test/data

- **Exclude Path/DO by expression**

This filter is majorly used with wildcard characters.

Excludes paths or data objects that matches the given expression. For example to exclude locations that

contain 'blob' in their path, use expression `*blob*`.

Filter Item	Syntax	Example
Database	*<DatabaseName>*	*testddc*
Schema	*<SchemaName>*	*system*
Table	*<TableName>*	*table*
Column	*<ColumnName>*	*email*, *table/col*

- Click **Apply**.
- Repeat above steps to apply multiple filters. Click **Remove** to remove any applied filter.
- Click **Next**.

Note

Unsupported filters in SAP HANA data stores:

- Include DO modified recently
- Exclude DO greater than size
- Include DO's within modification date

Schedule Run

- Specify the scan run frequency. The two options are:
 - **Manual:** This is the default option. Select this option to run the scan manually. Select the **Run Now** check box to start the scan run after you save the changes.
 - **Scheduled:** Select this option to configure the scan to run automatically at the specified time.

Refer to [Schedule Scan](#) for more details on scheduling scan runs.

- Click **Save**.

Logging

Data Discovery and Classification prints its log messages to the CipherTrust Manager logs. DDC logs are located at `/opt/keysecure/logs`. The CipherTrust Manager System administrator (**ksadmin**) can log in using SSH to retrieve CipherTrust Manager logs. Also, the DDC application administrators have access to the logs.

For more details on collecting DDC logs, refer to [Troubleshooting issues in conjunction with customer support](#).

Default logging level

By default, log level setting for DDC is INFO. With this log level set DDC prints out the INFO and ERROR level messages to the log. Among the various messages that DDC prints to the logs, the error messages and security audit messages are the most useful for troubleshooting DDC issues and securing the deployment.

Identifying DDC log messages

The microservices behind DDC are `oleander` and `sundew` and the messages coming to the CipherTrust Manager log from DDC can be identified by those names.

Additionally, `oleander` has these three modules:

- Clustering
- Agent_Selection
- Scan_watcher

Each of these modules will generate its own error messages, each in its separate log.[] log file.

The logging service responsible for collecting and processing these messages is FLUENTD. It is capable of displaying those messages to the terminal through the log command. Here's an example of such a command:

```
log | grep oleander | grep "clustering"
```

This command would display all messages coming from the `oleander`'s Clustering module.

For a complete list of error messages that DDC sends to the CipherTrust Manager logs, see the [Error Log Messages](#).

Modifying DDC ML agent log levels

The DDC ML agent generates the following logs:

Log Type	Description
<code>MLAgentReg.log</code>	ML agent registration logs
<code>agent.{timestamp}</code>	ML library logs
<code>ddc_agent_spark.log</code>	Spark logs generated during scan
<code>service.log</code>	ML Agent service logs

You can change the log level of the DDC ML agent by adding following entries in the `<INSTALL_DIR>/conf/service.conf` file and restarting the DDC ML Agent service.

- To set log level to Warning, add the `AGENT_LOG_CONFIG='{ "level": "WARN", "levels": "*=WARN", "development": false }'` entry in the file.

- To set log level to Error, add the `AGENT_LOG_CONFIG={'level':"ERR", "levels":"*=ERR", "development":false}` entry in the file.
- To set log level to Info, add the `AGENT_LOG_CONFIG={'level':"INF", "levels":"*=INF", "development":false}` entry in the file.

Security audit log messages

The DDC security audit messages can be identified by the `Oleander | INFO [security]` bit that they contain. The full format of such a log message (or log line) is:

```
<date> | Oleander | INFO [security] <event> <error (if any)> <details (if any)>
```

For example:

```
2020-06-29 | Oleander | INFO | [security] DDCScanClientUnexpectedErrorProbe "error: error probing scan client" "details: [scan_id:5432-5432-543254-2-5432]"
```

Usually, only the event type is printed out to the log (in the example above, it would be `DCScanClientUnexpectedErrorProbe`).

Enabling Syslog logging

Audit records are logged to a local database by default. This is suitable for production systems and clusters with a limited load. However, for clusters that support a large number of transactions, it is recommended to configure the CM to disable logging to a local database and enable logging using a remote Syslog server. This significantly reduces cluster traffic and disk usage. For more information, refer to the following sections in the [Thales CipherTrust Manager Administrator Guide](#):

- "Disabling local database audit logging"
- "Configuring remote Syslog server"
- [Configuring Connection to a Syslog Server](#)

Logging troubleshooting information

In addition to including INFO and ERROR log messages in CipherTrust Manager logs, DDC can generate local logs to record interactions between different components during scan run. These logs contain useful technical information that can help [Thales Customer Support](#) in identifying and resolving scan-related issues.

In case the scan fails, is stuck in the running state, or experiences any unexpected issues, you can download and share these logs with [Thales Customer Support](#) to address scan-related issues.

Note

Before running the scan, enable the [Trace logs](#) scan parameter to capture detailed scan execution information for each file.

You can download the logs starting from the scan initiation, throughout its execution, and after it finishes. These log files are encrypted and require decryption before you can share them with [Thales Customer Support](#).

To download and decrypt the logs files:

1. In the **Scans** screen, click the ellipses icon (...) corresponding to the desired scan name.
2. Select the **Download Logs** option.
3. Click **Download**.

An encrypted .tar file containing all the necessary logs will be downloaded.

4. Run the following `ksctl` command to decrypt the .tar file. See [CLI Toolkit](#) to learn how to install and run `ksctl`.

```
ksctl ddc raw-data decrypt [flags]
```

Examples

```
ksctl ddc raw-data decrypt -i /tmp/ScanReport1.tar
ksctl ddc raw-data decrypt -i /tmp/ScanReport1.tar -o /tmp/DecryptedScanReport1.zip
```

Scan logs will be decrypted to a .zip file containing readable files.

Operations

This section provides information on operations that the DDC administrator performs on the CipherTrust Manager.

Reconfiguring DDC agents

In some situations, for example, if the hostname or IP address of the CipherTrust Manager appliance changes, Agents' connection with DDC must be reconfigured with the new hostname or IP address.

Reconfiguring DDC agents on Windows

To reconfigure a DDC Agent:

1. Log on to the host machine as administrator.

2. Open Enterprise Recon Configuration Tool (**er2_config_cmd.exe**).

By default, the tool is available at `C:\Program Files (x86)\Ground Labs\Enterprise Recon 2\`.

3. In the **Master server IP address or host name** field, specify the new hostname or IP address of the CipherTrust Manager.
4. Click **Test Connection**. A message stating "Connectivity test is successful" confirms successful reconfiguration.
5. Click **Finish**.

Reconfiguring DDC agents on Debian

To reconfigure a DDC Agent:

1. Log on to the host machine as a user with root privileges.
2. Reconfigure connection with DDC on the CipherTrust Manager appliance.

```
sudo er2-config -i <hostname|ip_address>
```

Here, `<hostname|ip_address>` represents the new IP address or hostname of the CipherTrust Manager appliance.

3. Restart the Agent service. Configuration settings will be effective after the Agent restarts.

```
sudo /etc/init.d/er2-agent -restart
```

Reconfiguring DDC agents on RHEL

To reconfigure a DDC Agent:

1. Log on to the host machine as a user with root privileges.
2. Reconfigure connection with DDC on the CipherTrust Manager appliance.

```
er2-config -i <hostname|ip_address>
```

Here, `<hostname|ip_address>` represents the new IP address or hostname of the CipherTrust Manager appliance.

3. Restart the Agent service. Configuration settings will be effective after the Agent restarts.

```
sudo /etc/init.d/er2-agent restart
```

Tuning scan settings

You can customize system parameters for all the DDC Agents by using the `ksctl` tool. The following system parameters can be modified this way:

- Agent Memory (in MB)
- CPU used
- Throughput

The `ksctl` command to use to this end is `ksctl ddc settings scan modify`.

Command syntax:

```
ksctl ddc settings scan modify [flags]
```

Flags:

Flag	Usage
<code>--agent-memory int</code>	Setting for the maximum memory usage that the scanner service can use on the agent host, in MB. Default value: 1024.
<code>-h, --help</code>	Help on the command's usage
<code>--jsonfile string</code>	JSON format to create resources in DDC endpoints.
<code>--max-scan-throughput int</code>	Max I/O rate the scanner service will use to read data from the data store, in MBps. Set to 0 for unlimited. Default value is 0.
<code>--scan-cpu string</code>	CPU priority set for the agent used in the scan. The possible values are 'low' and 'normal'. Default value is 'low'.

Global Flags:

Flag	Usage
<code>--configfile string</code>	Full path and name to a file that contains the configuration parameters (optional).
<code>--connection string</code>	The friendly name of the server you want to authenticate against. (default "local_account")
<code>--domain string</code>	The CipherTrust Manager domain that the command will operate in. Can be used only with user/password and not with token. By default the command will operate in the root domain or the domain the user is logged-in.
<code>--jwt string</code>	The JSON Web Token (JWT). It is the access token that can be passed instead of user/password (optional). The command <code>ksctl tokens create</code> creates a JWT.

Flag	Usage
<code>--nossllverify</code>	Do not verify the certificate for SSL/HTTPS authentication (not recommended).
<code>--password string</code>	CipherTrust Manager server user password. Do not use this flag to enter the password (masked) from terminal.
<code>--respfmt string</code>	Response Output format (json is the only supported value at present, optional) (default "json")
<code>--timeout int</code>	Timeout in seconds for TCP connection attempts.
<code>--token string</code>	The refresh token returned from the login command to be passed instead of user/password (optional). The command <code>ksctl login</code> creates a token and writes it to the config file.
<code>--url string</code>	CipherTrust Manager server URL.
<code>--user string</code>	CipherTrust Manager server user name.
<code>-v, --verbose</code>	Provide verbose output while executing command (optional).

Examples:

```
ksctl ddc settings scan modify --agent-memory 1024 --scan-cpu normal --max-sc
an-throughput 2
ksctl ddc settings scan modify --jsonfile scansettings.json
```

Warning

The `ksctl ddc settings scan` command will be deprecated in the coming release.

Restarting DDC agents

Restarting agents on Windows

To restart a DDC Agent, run the following commands:

```
net stop "Enterprise Recon 2 Agent (&lt;ARCH>)"
net start "Enterprise Recon 2 Agent (&lt;ARCH>)"
```

Here, <ARCH> represents the Windows architecture - x32 or x64.

Restarting agents on Debian

To restart a DDC Agent, run:

```
sudo /etc/init.d/er2-agent restart
```

Alternatively, restart the Agent service by stopping it and again starting it manually. Run the following commands:

```
sudo /etc/init.d/er2-agent stop
sudo /etc/init.d/er2-agent start
```

Restarting agents on RHEL

To restart a DDC Agent, run:

```
sudo /etc/init.d/er2-agent restart
```

Alternatively, restart the Agent service by stopping it and again starting it manually. Run the following commands:

```
sudo /etc/init.d/er2-agent stop
sudo /etc/init.d/er2-agent start
```

Renewing DDC ML agent certificate

DDC ML agents are linked with CipherTrust Manager either through client certificates or server certificates for web interface. Certificate renewal is necessary under the following scenarios:

- When client certificate is near expiry
- When signer CA of client certificate is renewed or updated in CipherTrust Manager
- When server certificate is renewed or updated

Note

Only local CAs are supported for issuing certificate for agents. See [Certificate Authority](#) to learn more about local CA certificates.

Renewing client certificate

Client certificate is renewed when the DDC ML agent certificate is about to expire or when its signing CA (Certificate Authority) is modified in the CipherTrust Manager. *The DDC ML agent automatically handles renewal of client certificates.*

- **Agent certificate or its signing CA is near expiry**

When the agent certificate (*with a valid signing CA*) is about to expire, the agent initiates the renewal process sixty days before the expiry. It requests the CipherTrust Manager to issue new certificates. The new certificates are automatically downloaded and saved on the agent host machine.

If the *agent certificate's signing CA* is about to expire, the agent requests CipherTrust Manager to issue a new certificate. This process continues until the expiration or update of the agent certificate's signing CA.

When the signing CA is renewed or updated, CipherTrust Manager sends renewal notifications to the agent, as described in the next section. However, if the signing CA is expired, you must re-install the agent to reestablish communication with CipherTrust Manager.

▪ **Signing CA of agent certificate is updated**

In CipherTrust Manager, each DDC client is associated with a Client Profile. Further, each Client Profile has a CA associated with it, which acts as the signing CA for the agent certificate.

When the signing CA is updated or renewed, CipherTrust Manager sends renewal notification to all the clients associated with the Client Profile.

Upon receiving the notification, DDC ML agents set a flag in their configuration file and within the next 12 hours, the agent certificates are renewed.

When certificate renewal is successful, a message *Updated Agent and signer CA certificates* is added in the log files and the agent continues to function normally.

Note

- If the agent is down or unavailable, CipherTrust Manager will continue to send notifications of CA changes until the agent is accessible again.
- In the event of agent certificate expiring unexpectedly, you need to reinstall the agent to restore communication with CipherTrust Manager.

Renewing server certificate

When a server certificate or one of its signing CAs is renewed or updated, a notification is sent to all the agents registered with the CipherTrust Manager for renewal.

You can renew server certificate either through the CipherTrust Manager API or GUI.

See [Get certificate for NAE, KMIP, and WEB interfaces](#) to issue web interface certificate and use them during renewing.

API

1. Add the new certificate to the list of upcoming sever certificates using the below API.

```
put /v1/configs/interfaces/web/renewal-certificate
```

Parameter	Description
<code>certificate</code>	Specify the certificate chain having the primary certificate, the CA, and its private key.
<code>format</code>	Specify the certificate format.

- Restart the web interface services using the below API.

```
post /v1/system/services/restart
```

Parameter	Description
<code>delay</code>	Specify the delay vale. Default value is 5 seconds.
<code>services</code>	Specify the interface service you want to restart. Enter 'web' as the parameter value.

After upcoming renewal certificate is updated successfully, following events occur at the agent side:

- Active agents receive notification about the update from CipherTrust Manager and updates the trust store with the new certificate chain.

Note

If the agent is down or unavailable, CipherTrust Manager continues to send notifications until the agent is accessible again.

- Old and new certificates are stored on the agent side at `$INSTALL_DIR/Certificates/trustStore.pem` and `$INSTALL_DIR/Certificates/trustStore.0` locations, respectively.
- Agent log displays the *Server CA certificate renewal completed successfully* message.
- Agent trusts both old and new certificates until the former one expires.

- Fetch the upcoming renewal certificate using the below API.

```
get /v1/configs/interfaces/web/renewal-certificate
```

The API returns the public key and CA chain of the upcoming renewal certificate in the PEM format.

- When the current web interface certificate is about to expire, apply the new certificate using the below API.

```
post /v1/configs/interfaces/{interface}/renewal-certificate/apply
```

Note

If the new certificate is not applied manually, it will be automatically applied on expiration of the current certificate.

GUI

1. Upload the upcoming renewal certificate
 - a. Go to **Admin Settings > Interfaces**.
 - b. Click the ellipses icon (...) next to the web interface.
 - c. Select **Renewal Certificate Options**.
 - d. Click **Upload/Generate** to upload a new server certificate.
 - e. Click **OK**.
 - f. Select an upload option.
 - **File Upload:** Use this option to upload the certificate file.
 - **Text:** Use this option to paste the signed certificate and its private key content.
 - g. Select PEM as Format.
 - h. Click **Upload Certificate**.
 - i. Go to **Admin Settings > Services** and click the **Restart** button next to web services.

After the upcoming renewal certificate is uploaded successfully, following events occur at the agent side:

- Active agents receive notification of this update from the CipherTrust Manager and updates the trust store with the new certificate chain.

Note

If the agent is down or unavailable, CipherTrust Manager continues to send notifications until the agent is accessible again.

- Old and new certificates are stored on the agent side at `$INSTALL_DIR/Certificates/trustStore.pem` and `$INSTALL_DIR/Certificates/trustStore.0` locations, respectively.

- Agent log displays the *Server CA certificate renewal completed successfully* message
- Agent trusts both old and new server certificates until the former one expires.

2. Apply the upcoming renewal certificate

When the current interface certificate is about to expire, you need to apply the newly uploaded upcoming renewal certificate for the interface.

- Click the ellipses icon (...) next to the web interface.
- Click **Renewal Certificate Options**.
- Select **Apply** and click **Ok** to apply the upcoming renewal server certificate.

The existing server certificate is replaced with the newly uploaded server certificate.

Note

If the new certificate is not applied manually, it will be automatically applied on expiry of the current certificate.

DDC ML agent configuration parameters

The configuration parameters are available in the `<INSTALL_DIR>/conf/ddc_agent.conf` file.

Performance log settings

Parameters	Default	Description
<code>ddc_agent_extraction_log_threshold</code>	None	This is the elapsed time threshold in milliseconds to log text extraction call. A call will be logged if the elapsed time is equal to or greater than the threshold.
<code>ddc_agent_prediction_log_threshold</code>	None	This is the elapsed time threshold in milliseconds to log ML model prediction call. A call will be logged if the elapsed time is equal to or greater than the threshold.
<code>ddc_agent_archive_log</code>	None	This is the boolean flag on whether to log messages for archive extraction.

Request configuration settings

Parameters	Default	Description
<code>ddc_prediction_worker</code>	(host cpu number) / 4	This is the number of threads to call the ML model prediction interface concurrently.
<code>ddc_prediction_queue</code>	20	This is the maximum number of texts that can be queued for prediction.
<code>ddc_prediction_batch_memory</code>	1 megabytes	ML model has prediction call to accept an array of texts, and this parameter just hints the maximum memory size of the text array in bytes.
<code>ddc_prediction_batch_number</code>	10	ML model has prediction call to accept an array of texts, and this parameter specifies the maximum number of texts in the array.
<code>ddc_parse_worker</code>	(host cpu number) / 4	This is the number of threads to call Apache Tika parser interface concurrently.
<code>ddc_parse_queue</code>	20	This is the maximum number of files can be queued for parsing.
<code>ddc_parser_chunk_size</code>	10 megabytes	When the ML Agent calls Apache Tika to parse a big file, it can receive result texts chunk by chunk and call the ML model prediction interface with those chunks. This parameter specifies the chunk size in bytes.
<code>ddc_prediction_report_threshold</code>	100	This is the frequency for the ML agent to report prediction progress. The default value is 100, which means the ML agent reports progress when every 100 number of files are processed and predicted.
<code>ddc_scan_report_threshold</code>	10000	This is the frequency for the ML agent to report progress of scan file list generation. The default value is 10000, which means the ML agent reports progress when every 10000 files are written into the scan file list.
<code>ddc_java_options</code>	No default	This is the JVM options list separated by comma, for example <code>-Xmx8g, -XX:+UseG1GC</code> .

Model driver

Parameters	Default	Description
<code>ddc_ml_log_level</code>	info	Represent the log level for the model driver. Possible values: info, warn, or error.

TDPaaS retention policy

A retention policy allows you to store data on the cloud TDP (TDPaaS) for a definite amount of time. This feature is useful if there is a need to delete the stored information after a definite amount of time to comply with some regulations and policies.

After the retention policy is enabled, information removal is automatically handled by DDC through scrub jobs. The scrub jobs operate automatically at regular intervals, and you can view the complete details on the **Operations** tab. The scrubbing process clears the scan executions and reports from the cloud storage and CipherTrust Manager database, ensuring they don't show up in the list of executions.

After the scrub job is completed, scrubbed data is no longer accessible for report generation or scan executions, and it can't be restored.

Note

A retention policy is only available when TDPaaS is provisioned. Refer to [TDPaaS Deployment Guide](#) to learn how to provision TDPaaS.

Key features

- **Enable/Disable Flexibility:** Activate or deactivate the Retention Policy at any time.
- **Automatic Scrubbing Jobs:** Scrubbing jobs operate automatically at regular intervals to effectively manage data.
- **Retention Period:** Flexibility to select the retention duration in the range of 3 to 60 months. If the retention period exceeds 60 months, it's recommended to avoid enabling the retention policy.
- **Data Management:** Scrubbing job eliminates scan executions and reports from the cloud storage and the CipherTrust Manager database, ensuring they are no longer visible in the execution list.
- **View Job Details:** Access information about scrub jobs, including:
 - Execution ID - Displays the execution ID of the scrub job.
 - Execution Started - Displays the timestamp when scrub job execution started.
 - Duration - Displays the duration of the scrub job execution.

- **Status** - Displays the current status.
- **Space Freed** - Displays the amount of space freed from cloud storage and CipherTrust Manager databases in MBs.
- **Retention Period** - Displays the retention period in months.
- **Filtering Options**: Filter scrub job data based on the status of job executions and chosen date ranges.

Enabling retention policy

1. Log on to CipherTrust Manager.
2. Go to **Settings > Cloud Management**.
3. Select the **Retention Policy** tab.
4. Turn on the **Retention Policy** toggle.
5. Enter **Retention Period** in the range of 3 to 60 months. By default, it is set to 12 months.
6. Click **Apply**.

Note

If you enable retention policy and switch back to on-premises TDP, then retention policy doesn't disable automatically but remains ineffective.

Viewing Scrub job executions

After enabling the retention policy:

1. Go to the **Operations** tab.

This tab displays all scrub job executions up to the current date. Scrub jobs run automatically at a reasonable frequency.
2. Use the date filter to narrow down job executions to a specific date range.
3. Use the status filter to filter job executions as per Running, Completed, or Failed statuses.

Troubleshooting

Error messages

This section lists the various error messages that the system can display, with explanations and solutions (if

available).

Locations

Error Message	Explanation
"Branch Location name already exists" (message on toast)	You tried to create a location with a name that is already taken by another location. SOLUTION: Choose another name.

Data stores

Error Message	Explanation
"Data Store name already exists" (message on toast)	You tried to create a data store with a name that is already taken by another data store. SOLUTION: Choose another name.
"A valid agent could not be found" (Agent selection - on mouse-over on the data store)	There is no active agent for this data store that the automatic agent selection process has been able to detect. SOLUTION: This requires additional research, such as checking if the agent is installed on the data store, if it has the right type (local/proxy), if it is of the right OS "flavor" (Linux, Windows), or of the right type (e.g. database). Refer to the Data Discovery and Classification Deployment Guide for more information on troubleshooting this issue.
"One of the Oracle Data Stores has been configured with a wrong schema."	SOLUTION: Check the Oracle schema that you used and change it if necessary. For more information, see Configure Connection .
"The target for Data Store SharePoint scan for sites does not have access permissions"	If DDC returns this error while adding a SharePoint Online data store, it is because "grant app permission" is disabled by default on SharePoint Online. SOLUTION: For the SharePoint Add-In to work, the DisableCustomAuthenticationApp setting for the tenants needs to be set to "false". Follow the steps in Configure SharePoint Online .

Scans

Error Message/Issue	Explanation
"Scan name already exists" (message on toast)	You tried to create a scan with a name that is already taken by another scan. SOLUTION: Choose another name.
"All Data Stores are disabled" (message on toast)	You attempted to run a scan that has all data stores disabled. SOLUTION: Enable at least one data store for the scan. Refer to the Scans for instructions.
"The following Data Stores are not accessible: xyz" (message on toast)	You tried to scan a data store that is not accessible. The scan is marked as Failed, and includes a warning

Error Message/Issue	Explanation
	icon with the message "The data store xyz included in the scan is not accessible" on mouse-over. SOLUTION: Verify the connectivity from the agent to the data store. Verify the data store configuration.
"One or more Data Stores are not accessible." (on mouse-over on the scan fail icon)	The scan failed because the data store that is configured is inaccessible. The data store failed after the scan was launched. SOLUTION: There may be a number of reasons for this. To troubleshoot a failed data store refer to Discovering Sensitive Information.
"The following Data Stores have no agent available: xyz" (on mouse-over on the scan fail icon)	You tried to scan a data store that had no agent available when the scan was executed. There is a problem with the agent. The data stores that failed are listed. SOLUTION: This requires additional research, such as checking if the agent is installed on the data store, if it has the right type (local/proxy), if it is of the right OS "flavor" (Linux, Windows), or of the right type (e.g. database). Refer to the Data Discovery and Classification Deployment Guide for more information on troubleshooting this issue.
"Data Store has incorrect credentials" (on mouse-over on the scan fail icon)	Data store credentials provided are incorrect so the scan cannot be executed. These data stores are listed. SOLUTION: Update the server credentials for the data store.
"One or more Data Stores have incorrect credentials" (message on toast)	The credentials for one or more data stores are no longer valid (credentials modified, user deleted, and so on) preventing the scan from completing. SOLUTION: Reconfigure the data store and re-launch the scan.
"The scanner service is not available" (message on toast)	You tried to run a scan with the scan engine unavailable. SOLUTION: Check the status of the scan engine (the CipherTrust Manager server).
"The following Data Stores have missing agents: xyz" (message on toast)	This happens when an agent was assigned to the listed data store(s) and then when a scan was launched, for some reason the assigned agent could not be found on the server. SOLUTION: Try to re-assign the agent in the data stores screen. If this does not work, check the agent assigned to the xyz data store.
"The following Data Stores have agent errors: xyz" (message on toast)	This happens when a management request for an agent fails (for example, at verification or when setting it as a proxy) during the scan execution. SOLUTION: It is usually a transient issue. Wait a few minutes and run the scan again. If it still fails, check the agent status.
"Error processing scan" (message on toast)	This happens when the scan fails in the processing stage, that is when the scan results are being processed by DDC. SOLUTION: Run the scan again. If the error persists,

Error Message/Issue	Explanation
	contact Thales Customer Support .
"Error connecting to HDFS" (message on toast)	This happens when the scan fails because there is no HDFS connectivity. SOLUTION: Check the HDFS configuration in DDC (Hadoop Services). Refer to the Data Discovery and Classification Deployment Guide for information on configuring the DDC-HDFS connection.
"Error connecting to PQS" (on mouse-over on a failed scan status)	A scan failed because there is no PQS connectivity. SOLUTION: Check the HDFS configuration in DDC (Hadoop Services) or PQS/Hadoop configuration in your Hadoop deployment. Refer to the Data Discovery and Classification Deployment Guide for information on configuring the DDC-PQS connection.
"The Knox logs directory has been filled."	SOLUTION: Change the Knox log level or purge the logs directory. Refer to Changing Knox Log Level in the Thales Data Platform Deployment Guide for details.
"Error checking the data allowance" (message on banner)	This happens when DDC is not licensed. DDC sends a request for data allowance to the license server and the server responds that there is no license. SOLUTION: Obtain and install a valid DDC license. Refer to DDC Licensing for licensing information.
"One target path is missing" (on mouse-over on the scan fail icon)	A scan failed because one or more target paths are missing. SOLUTION: Open the scan for editing, by following the Edit link embedded in the error message, and check which target path is missing (it will be indicated by a yellow exclamation mark in the Targets section).
"One database target has incorrect schema" (on mouse-over on the scan fail icon)	A scan failed because one or more database targets have an incorrect schema. SOLUTION: Open the scan for editing, by following the Edit link embedded in the error message, and check which target has an incorrect schema (it will be indicated by a yellow exclamation mark in the Targets section).
"One database target has incorrect table" (on mouse-over on the scan fail icon)	A scan failed because one or more database targets have an incorrect table. SOLUTION: Open the scan for editing, by following the Edit link embedded in the error message, and check which target has an incorrect table (it will be indicated by a yellow exclamation mark in the Targets section).
"One target has incorrect file extension" (on mouse-over on the scan fail icon)	A scan failed because one or more targets have an incorrect file extension. SOLUTION: Open the scan for editing, by following the Edit link embedded in the error message, and check which target has an incorrect file extension (it will be indicated by a yellow exclamation mark in the Targets section).
"One target has nested paths" (on mouse-over on	A scan failed because one or more targets have

Error Message/Issue	Explanation
the scan fail icon)	nested paths. SOLUTION: Open the scan for editing, by following the Edit link embedded in the error message, and check which target has a nested path (it will be indicated by a yellow exclamation mark in the Targets section).
"The target for Data Store is a file" (on mouse-over on the scan fail icon)	A file cannot be a target of a data store. SOLUTION: Open the scan for editing, by following the Edit link embedded in the error message, and put a directory as the target path (the failing target path will be indicated by a yellow exclamation mark in the Targets section).
"The target for Data Store is not a valid directory" (on mouse-over on the scan fail icon)	The specified directory used as the target path is invalid. SOLUTION: Open the scan for editing, by following the Edit link embedded in the error message, and check the directory. The invalid directory will be indicated by a yellow exclamation mark in the Targets section.
"The target for Data Store cannot be accessed" (on mouse-over on the scan fail icon)	The specified path used as the target path in inaccessible. SOLUTION: Open the scan for editing, by following the Edit link embedded in the error message, and check the path. The inaccessible path will be indicated by a yellow exclamation mark in the Targets section.
"Data Allowance is exhausted" (on mouse-over on the scan status)	A scan was run that exceeded the Data Allowance. All scans running when the Data Allowance gets exhausted (or after that) will fail. From that moment on, you cannot launch new scans. SOLUTION: Contact Thales Customer Support and upgrade your DDC license. Refer to DDC Licensing for licensing information.
"Too many sensitive Data Objects found" (on mouse-over on the scan fail icon)	Scan results have a limit on the amount of information (Sensitive Data Object found, infotypes and matches found on each Sensitive Data Object, etc.) and the scan results exceeded this limit. MongoDB data stores are particularly prone to this error. SOLUTION: Split the original scan into multiple smaller scans, re-launch the scans and generate a single report combining the results from all the scans. To reduce the resulting scan size consider scheduling a different scan per Data Store and/or per Classification Profile and/or subpaths (such as folders and tables) in the original scan path.
"Error validating Target Paths" (on mouse-over on the scan fail icon)	The target paths validation failed for some reason. SOLUTION: Go to the scan view and verify that the target paths exist, and that the guard points exist and are enabled.
"There was a fatal error in scan service" (on mouse-over on the scan fail icon)	Unknown error condition on the scan service. Mainly seen when a Database server becomes inaccessible for the scan agent halfway through the scan due to

Error Message/Issue	Explanation
	network issues or DB server crash.
"Scan RAM exhausted" (on mouse-over on the scan fail icon)	A G-mail scan with a large amount of sensitive data fails with this error. SOLUTION: Increase the Agent's RAM using the ksctl tool. For details refer to Tuning Scan Settings .
"Scan results could not be found" (on mouse-over on the scan fail icon)	The scan failed because two independent sub-scans completed in the same second. DDC schedules sub-scans for every path added to the scan. If multiple agents scan a single path, each of them will perform an independent sub-scan. SOLUTION: 1) If the scan failed because of multiple scans finishing in the same second - re-launch the failing scan. 2) If the scan includes multiple agents - reduce the number of agents assigned to Data Stores in the scan. 3) If the scan includes multiple scan paths for a single Data Store - reduce the number of scan paths by scheduling independent scans or by scanning a parent folder that includes multiple scan paths.
"Status of one or more Data Stores is failed, go to Data Store list to resolve the issue" (on mouse-over on the failed scan icon)	The agent assigned to one of the data stores used in the scan has failed or could not be found and no alternative agent was found. SOLUTION: Follow the "Data Store list" link embedded in the error message, locate and fix the agent that has failed. Then, go back to the scans page and relaunch the scan.
Scan run fails after few minutes with error: "Scan result could not be found" Scan run gets stalled for hours or days	Agent is disconnected. SOLUTION: Identify the agent running the scan and try reconnecting the agent. API request quota limit for the data store is exhausted. SOLUTION: Verify quota usage from cloud provider logs. See API Request Quota Limit to check quota limit for different DS.
data store path not accessible	This error indicates an issue with Hadoop file access permissions. It occurs when scanning a Hadoop data store and the configured scan target is a Hadoop file for which you don't have access rights.
table or schema not accessible	This error occurs when scanning an IBM, Oracle, or MS-SQL data store that contains an empty table.
Scanning a Gmail label did not find any results	You can scan emails in a Gmail label if you move the emails to the label, otherwise, the emails will be kept in inbox folder. For the default system labels, Gmail creates some folders that do not match the label name. Solution: Refer to the Gmail documentation to learn the right path to scan a particular system label.
Exchange Online scan completes faster than expected without any matches	A full data store scan is executed successfully even with an incorrect domain name, without triggering any errors or matches. Solution: Verify that the provided domain name is

Error Message/Issue	Explanation
	valid.

Reports

Error Message	Explanation
"Report name already exists" (message on toast)	You tried to create a report with a name that is already used in another report. SOLUTION: Choose another name.
"The version of the scan that was used to generate the report can no longer be found." (message on toast)	The report execution information in TDP references some resource version that is no longer available inside the DDC Database, such as Data Store, Custom Infotype, Classification Profile, or other, probably after restoring DDC from a backup that was taken before the referenced resource was created or modified. SOLUTION: Please restore CipherTrust Manager from a newer backup that includes the referenced resource version, or update the report template to stop referencing the missing resource.
"The report template is configured with a scan execution that can no longer be found." (message on toast)	The report template references a concrete scan execution that is no longer found in TDP, probably after restoring TDP from a backup that was taken before the referenced scan execution was completed. SOLUTION: Please restore TDP from a newer backup that includes the information of the referenced scan execution, or edit the report template to reference a valid scan execution date.
Empty report created for large ML scan runs.	Empty reports may be created for these reasons: - The data file contains a very high number of sensitive entity objects, usually more than 4 million. - There may be constraints with cloud resources, like limited bandwidth between the Machine Learning as a Service (MLaaS) and the agents, or instability issues with Google Cloud Platform (GCP). Workaround: Check the agent log to identify the flagged data object that has high number of scanned entities. To fix the issue, divide the files to ensure match entities remain under the 4 million limit.

Classification Profiles

Error Message	Explanation
"Classification Profile name already exists" (message on toast)	You tried to create a classification profile with a name that is already taken by another classification profile. SOLUTION: Choose another name.

Licensing

Error Message	Explanation
"DDC License not found - try again in a few minutes if you recently inserted one" (message on banner)	Any action performed in the UI results in this message, because there is no valid DDC license installed. SOLUTION: Obtain and install a valid license. Refer to DDC Licensing for licensing information.
"DDC License expired" (message on banner)	Any action performed in the UI results in this message, because your DDC license has expired. SOLUTION: Obtain and install a valid license. Refer to DDC Licensing for licensing information.

DDC ML agent

This section lists various error messages related to the DDC ML agent with explanations and solutions (if available).

Error Message/Issue	Explanation
none Notice: Connection Info - new 0.0.0.0.0: Data connection failed: Connection refused	Possible Causes: ▪ CipherTrust Manager IP/hostname is not correct. ▪ There is an issue with the DDC license. Solution: ▪ Provide a correct CipherTrust Manager IP/hostname. ▪ Ensure DDC license is present on CipherTrust Manager and is in active state.
DDC ML unified agent installation fails without generating logs.	Log directory was not set up during agent installation. Solution: Ensure that the directory <code>C:\ProgramData\thales\ddc_agent</code> exists.
DDC ML unified agent registration fails.	Check error details in <code>MLAgentReg.log</code> at <code>C:\ProgramData\thales\ddc_agent</code>.
Client with name " already exists."	The agent is already registered with CipherTrust Manager. Solution: Re-register the agent using a new hostname/IP or existing hostname/IP. To use existing hostname/IP, you must perform clean up on CipherTrust Manager. See Re-register DDC ML Agent to learn how to remove the existing agent from CipherTrust Manager.
No registered agents available	Check the <code>ML_Reg.log</code> file of the agent that is expected to be selected to identify the issue details.

Error Message/Issue	Explanation
Cannot find minimum agents for the datastore	For SMB scan, there are no agents available to run the scan. Solution: Verify that the Windows agent is registered with CipherTrust Manager. If there is an issue with registration, then re-register the agent, and refresh the datastore from CipherTrust Manager GUI.
Agent status is "Not Connected"	Agent's service is down. Check the agent's service.log file for error details.
Internal error	Displayed when a scan fails. Check the agent and ddc_agent_spark.log files for error details.

TDP (On-prem)

Error Message/Issue	Explanation
"Hadoop is not active. Please go to DDC Settings --> Hadoop" (message on toast)	Problem communicating with Hadoop or DDC has not been configured with Hadoop. SOLUTION: Assuming that you have Hadoop deployed in your environment, configure DDC to use it (DDC Settings --> Hadoop in the CipherTrust UI). For a detailed procedure, refer to the Data Discovery and Classification Deployment Guide .
"Error connecting to the PQS database" (message on toast)	Problem communicating with the Phoenix Query Server database (i.e. HBase). SOLUTION: Check the PQS configuration in DDC (Hadoop Services) or PQS/Hadoop configuration in your Hadoop deployment. Refer to the Data Discovery and Classification Deployment Guide for information on configuring the DDC-PQS connection.
"Error creating the PQS database schema" (message on toast)	Problem communicating with the Phoenix Query Server database. SOLUTION: Check the PQS configuration in DDC (Hadoop Services) or PQS/Hadoop configuration in your Hadoop deployment. Refer to the Data Discovery and Classification Deployment Guide for information on configuring the DDC-PQS connection.
"Error using the PQS database schema" (message on toast)	Problem communicating with the Phoenix Query Server database. SOLUTION: Check the PQS configuration in DDC (Hadoop Services) or PQS/Hadoop configuration in your Hadoop deployment. Refer to the Data Discovery and Classification Deployment Guide for information on configuring the DDC-PQS connection.
"Error connecting to HDFS" (message on toast)	SOLUTION: Check the HDFS configuration in DDC (Hadoop Services). Refer to the Data Discovery and Classification Deployment Guide for information on configuring the DDC-HDFS connection.
"Invalid HDFS directory path: Not a directory" (message on toast)	SOLUTION: Check the HDFS configuration in DDC (Hadoop Services). Refer to the Data Discovery and Classification Deployment Guide for information on configuring the DDC-HDFS connection.

Error Message/Issue	Explanation
	Classification Deployment Guide for information on configuring the DDC-HDFS connection.
"Incorrect credentials in the HDFS connection" (message on toast)	SOLUTION: Check the HDFS configuration in DDC (Hadoop Services). Refer to the Data Discovery and Classification Deployment Guide for information on configuring the DDC-HDFS connection. Check that the authentication service is up and running.
"Incorrect HDFS URI" (message on toast)	SOLUTION: Check the HDFS configuration in DDC (Hadoop Services). Refer to the Data Discovery and Classification Deployment Guide for information on configuring the DDC-HDFS connection.
"Invalid HDFS folder: the path to the folder does not exist" (message on toast)	SOLUTION: Check the HDFS configuration in DDC (Hadoop Services). Refer to the Data Discovery and Classification Deployment Guide for information on configuring the DDC-HDFS connection.
"Invalid server certificate in the HDFS request" (message on toast)	SOLUTION: Check the HDFS configuration in DDC (Hadoop Services). Refer to the Data Discovery and Classification Deployment Guide for information on configuring the DDC-HDFS connection.
"PQS incorrect credentials or authentication service not available" (message on toast)	SOLUTION: Check the PQS configuration in DDC (Hadoop Services) or PQS/Hadoop configuration in your Hadoop deployment. Refer to the Data Discovery and Classification Deployment Guide for information on configuring the DDC-PQS connection. Check that the authentication service is up and running.
"Invalid server certificate in the PQS request" (message on toast)	SOLUTION: Check the PQS configuration in DDC (Hadoop Services) or PQS/Hadoop configuration in your Hadoop deployment. Refer to the Data Discovery and Classification Deployment Guide for information on configuring the DDC-PQS connection.
"Your system does not meet the 16GB RAM minimum" (message displayed across the top of all DDC screens)	DDC requires at least 16GB of RAM to be able to run properly. SOLUTION: Increase the RAM memory on board to at least the required minimum of 16GB.
Knox connection is not configured (message on toast)	Displayed when the user tries to run a scan without setting the Hadoop Knox connection of Hadoop Service. Solution: Configure the Hadoop Knox connection of Hadoop Services under the Access Management > Connection Management tab of CipherTrust Manager.
Invalid Knox connection	Displayed when the user tries to run a scan with an invalid Hadoop Knox connection of Hadoop Services. Solution: Verify and reconfigure the Hadoop Knox connection of Hadoop Services under the Access Management > Connection Management tab of

Error Message/Issue	Explanation
	CipherTrust Manager.
HDFS settings don't exist	Displayed when the user tries to run a scan without configuring the HDFS settings of Hadoop Services. Solution: Configure the HDFS settings under Settings > Hadoop Services in DDC.
Livy settings don't exist	Displayed when the user tries to run a scan without configuring the Livy settings of Hadoop Services. Solution: Configure the Livy settings under Settings > Hadoop Services Settings in DDC.
--Pending-- (message on toast)	Displayed when a user tries to save the HDFS settings but the hostname or port from the connection created in Connections Management are wrong or not reachable.
Livy connection refused (message on toast)	Displayed when a user tries to save the Livy settings but the hostname or port from the connection created in Connections Management are wrong or not reachable.
Invalid Knox server certificate (message on toast)	Displayed when a user tries to save the HDFS or Livy settings but the certificate is invalid.
Invalid HDFS URI path (message on toast)	Wrong parameter added in the DDC Hadoop settings.
Invalid HDFS folder (message on toast)	Wrong parameter added in the DDC Hadoop settings.
Invalid Livy URI path (message on toast)	Wrong parameter added in the DDC Hadoop settings.
503 Service Unavailable (message when configuring HDFS/Livy)	If you are using the CipherTrust Manager's proxy feature, make sure it is properly configured. It should be possible to directly access TDP, to resolve its name, and to allow HTTPS connections to port 8443. Check your proxy software manual to get those rules configured.
Connection error "[SSL: CERTIFICATE_VERIFY_FAILED] certificate verify failed (_ssl.c:618)." (message in ambari-agent.log) Server lost heartbeat from all nodes (message on Ambari UI)	Ambari CA certificate is corrupted or has expired. Solution: See Expired/Corrupted Ambari CA Certificates to resolve this issue.
TDP silent installation failure	Occasionally, TDP silent installation may fail when setting up node cluster. Solution: See TDP Silent Installation Failed to resolve this issue.

TDPaaS

The below sections list various error messages that you may encounter when working with TDPaaS, with their explanations and possible solutions.

Scans & Reports

Error Message	Explanation
No valid Hadoop Knox or Data Management Service connection exist	Displayed when the user tries to run a scan with an invalid Hadoop Knox connection of Hadoop Services. Solution: Verify and reconfigure the Hadoop Knox connection of Hadoop Services under the Access Management > Connection Management tab of CipherTrust Manager.
None of Hadoop Knox & Data Management Service connection exist	Displayed when the user tries to run a scan without configuring either Hadoop Knox or Data Management Service connection. Solution: Configure the Hadoop Knox connection of Hadoop Services under the Access Management > Connection Management tab of CipherTrust Manager or Provision Data Management Service settings under Settings > Cloud Management > Data Management tab in DDC.
The Data Management Service settings don't exist	Displayed when the user tries to run a scan without configuring the Data Management Service settings. Solution: Configure Data Management Service under Settings > Cloud Management > Data Management tab in DDC.
None of Data Management Service & Hadoop Services settings exist	Displayed when the user tries to run a scan without configuring the HDFS & Livy settings of Hadoop Services and Data Management Service. Solution: Configure the HDFS & Livy settings under Settings > Hadoop Services in DDC or provision Data Management Service under Settings > Cloud Management > Data Management tab in DDC.
Connection is Lost: Data Management Service connection is not responding.	Displays when the connection to the Data Management Service is interrupted. Soluton: Ensure Data Management Service are correctly configured in the Settings tab.

Data Management Service Settings & Provisioning

Error Message	Explanation
Error: URL param is invalid	Invalid URL value was mentioned inside OIDC Connection Details of Data Management Service settings used for provisioning. Solution: Try provisioning again after updating the URL field with a valid value.
Error: Data Management Service was previously provisioned with a region. It cannot be changed.	The user tried to reconfigure Data Management Service settings with a different region.

Error Message	Explanation
	Solution: This action is not allowed. Data Management Service settings are already provisioned with a region. After successful provisioning, region cannot be modified.
Error: Hdfs Settings can't be changed	Data platform was switched from Data Management Service to Hadoop Services after a successful scan execution. Solution: This action is not allowed. After executing a scan with Data Management Service, you can't switch to Hadoop Services.
Error: Livy Settings can't be changed	Data platform was switched from Data Management Service to Hadoop Services after a successful scan execution. Solution: This action is not allowed. After executing a scan with Data Management Service, you can't switch to Hadoop Services.
Error: Tdpaas Settings can't be changed	Data platform was switched from Hadoop Services to Data Management Service after a successful scan execution. Solution: This action is not allowed. After executing a scan with Hadoop Services, you can't switch to Data Management Service.
TDPaaS Provision Data can't have empty fields	Data Management Service provisioning returned empty fields in response. Solution: Retry Data Management Service provisioning.
Error: region param is invalid	Data Management Service was provisioned with an invalid or unsupported region. Solution: Try provisioning with another supported region.
Error: missing field %s	Data Management Service configuration was attempted with a missing value for a mandatory field. Solution: Specify the missing field value and reconfigure the service.
Error: Data Management Service Settings could not get provisioned	Data Management Service provisioning failed to create and fetch the Data Management Service settings. Solution: Retry Data Management Service provisioning.
Error: Operation forbidden, cannot change settings - scan is running	Switched the data platform from Hadoop Services to Data Management Service or from Data Management Service to Hadoop Services while scan execution was in progress.

Error Message	Explanation
	Solution: Switch the data platform after scan execution gets failed. After a scan is successfully completed, you can't switch the data platform type.
Error: Operation forbidden, cannot change settings - TDPaaS settings is fixed	Switched the data platform from Hadoop Services to Data Management Service after a successful scan execution. Solution: This action is not allowed. After a successful scan execution with Data Management Service, you can't switch the data platform.
Error: Operation forbidden, cannot change settings - TDP-OnPrem settings is fixed	Switched the data platform from Data Management Service to Hadoop Services after a successful scan execution. Solution: This action is not allowed. After a successful scan execution with Hadoop Services, you can't switch to Data Management Service.

Other errors

Error Message	Explanation
DDCTDPaaSDataProcLaunchJobOperation	Error relates to starting the scan job while using Data Management Service. Solution: This is an unexpected error. Details about the specific cause of error are logged in the Loki Audit records, for each failed attempt of starting the scan job. Please contact customer support to resolve this issue.
DDCTDPaaSDataProcGetJobStatusOperation	Error in performing the get scan job status while using Data Management Service. Solution: This is an unexpected error. Details about the specific cause of error are logged in the Loki Audit records, for each failed attempt of getting the scan job. Please contact customer support to resolve this issue.
Error: Both LivySettings & Data Management Service are set	Livy Settings of the Hadoop Services and Data Management Service settings are set concurrently. Solution: This is an unexpected error. Please contact customer support to resolve this issue.
Error: Neither Livy nor Data Management Service is set	Neither Livy Settings of Hadoop Services nor Data Management Service settings are set. Solution: Ensure Hadoop Services or Data Management Service is correctly configured on the DDC Settings tab.
Error: cannot initialize StorageConnector, Hdfs & Data Management Service are set	Both HDFS Settings of the Hadoop Services and Data Management Service settings are set concurrently.

Error Message	Explanation
	Solution: This is an unexpected error. Please contact customer support to resolve this issue.
Error: Neither HDFS nor Data Management Service is set	Neither HDFS Settings of Hadoop Services nor Data Management Service settings are set. Solution: Ensure Hadoop Services or Data Management Service is correctly configured on the DDC Settings tab.

Info log messages

This section lists the various **information** messages that Data Discovery and Classification sends to CipherTrust Manager log.

OLEANDER INFO

Error Message	Explanation
"[Background-Processes] This node was NOT selected as active node. Turning off background processes"	Related to clustering, self-explanatory error.
"[Background-Processes] This node was selected as active node. Turning on background processes"	Related to clustering, self-explanatory error.
"[Background-Processes] Recovering collectors"	Oleander has received a valid license and recovers the collector processes that were stopped.
"[Background-Processes] Updating license from DMV"	Oleander is requesting from DMV the licenses available for DDC.
"[Background-Processes] Global license status set to nil"	Oleander is unlicensed.
"[Background-Processes] Global license status set to ", "newLicenseStatus", *newLicenseStatus"	Oleander license status is whatever <i>newLicenseStatus</i> is.
"[Background-Processes] Checking HDFS connectivity"	Oleander is sending a ping to HDFS to check the connectivity.
"[Background-Processes] Cannot connect with HDFS", "error", err	Oleander's ping against HDFS has failed. Oleander has no connectivity with HDFS.
"[Background-Processes] HDFS connectivity successful"	Oleander has successfully performed a ping against HDFS. Oleander has connectivity with HDFS.
"[Background-Processes] Checking PQS connectivity"	Oleander is sending a ping to PQS to check the connectivity.
"[Background-Processes] Cannot connect with PQS", "error", err	Oleander's ping against PQS has failed. Oleander has no connectivity with PQS.
"[Background-Processes] PQS connectivity successful"	Oleander has successfully performed a ping against PQS. Oleander has connectivity with PQS.
"[Background-Processes] License status has changed"	Oleander license status has changed since the last license cron execution.

Error Message	Explanation
"[Background-Processes] Initializing fast cron: Oleander unlicensed", "UnlicensedCronFrequency", o.Config.UnlicensedCronFrequency	Oleander is unlicensed so the license cron (which asks DMV for a DDC license) increments its frequency. The frequency is defined in the docker-compose file.
"[Background-Processes] Initializing fast cron: waiting for Hadoop connectivity", "HadoopConnectivityCronFrequency", o.Config.HadoopConnectivityCronFrequency	Oleander has a valid license but does not have connectivity with Hadoop.
"[Background-Processes] Initializing slow cron: Oleander licensed and Hadoop connectivity successful", "RunningCronFrequency", o.Config.RunningCronFrequency	Oleander has a valid license and has connectivity with Hadoop, the license cron decrements its frequency. The frequency is defined in the docker-compose file.
"[Background-Processes] About to run NO LICENSE scenario"	Oleander has no valid license so it will stop all running scan watchers, automatic agent selections and scan schedules.
"[Background-Processes] About to run VALID LICENSE scenario"	Oleander didn't have a valid license but now it has one so all scan watchers, automatic agent selections and scan schedules that were stopped are being resumed.
"[Background-Processes] Recovering automatic agent selection"	Part of the VALID LICENSE scenario above.
"[Background-Processes] Starting automatic agent selection for pending datastores", "pending datastores", strings.Join(ds, ", ")	Part of the VALID LICENSE scenario above.
"[Background-Processes] Recovering watchers"	Part of the VALID LICENSE scenario above.
"[Background-Processes] Starting watchers for ongoing scans", "ongoing scans", strings.Join(ss, ", ")	Part of the VALID LICENSE scenario above.
"[Background-Processes] Recovering scan schedules"	Part of the VALID LICENSE scenario above.
"[Background-Processes] Migrating PQS database"	Self-explanatory message.
"[Background-Processes] Deleting background process for scan", "name", sc.Scan.Name	Oleander has no valid license so all scans are being stopped as well as their corresponding background processes.
"[Background-Processes] Updating status to FAILED for scan", "name", sc.Scan.Name	Oleander has no valid license so all scans are being stopped (with status FAILED).
"Cannot connect to HDFS", "settings", hdfsSettings, "error", err	Oleander's ping against HDFS has failed. Oleander has no connectivity with HDFS.
"Cannot connect to PQS", "Settings", pqsSettings, "error", err	Oleander's ping against PQS has failed. Oleander has no connectivity with PQS.
"[Datastores] Agent selected: ", "Name", a.Name	Oleander has found and assigned a suitable agent for the mentioned data store.
"Unable to connect with datastore", "datastore name", d.Name, "error", err	A probe against the mentioned data store has failed during a test connectivity check.
"Instantiating new scrim helper"	Oleander is instantiating a new ScrimHelper object which is used for communication with Scrim, Minerva, Sallyport and DMV.
"Instantiating new hdfs scan collector"	Oleander is instantiating a new HDFSCollector object

Error Message	Explanation
	which is used for communication and processing with HDFS.
"Instantiating scheduler cron"	Oleander is instantiating a new SchedulerCron and starting the background processes.
"[WARNING] PQS connector can not be closed in GetSummaryReport service"	Oleander was unable to close the PQS connector while executing a GetSummaryReport operation.
"[WARNING] PQS connector can not be closed in GetDatastoresDetailsReport service"	Oleander was unable to close the PQS connector while executing a GetDatastoresDetailsReport operation.
"[WARNING] PQS connector can not be closed in GetReportTemplate service"	Oleander was unable to close the PQS connector while executing a GetReportTemplate operation.
"[Scan-Actions] [WARNING] PQS connector can not be closed in GetScanExecutions service"	Oleander was unable to close the PQS connector while executing a GetScanExecutions operation.
"[Scan-Watchers] Stop watcher signal received", "scan", sc.Scan.Name	A running scan watcher has received a STOP signal and the current execution is cancelled.
"[Scan-Watchers] Watcher has failed stopping scan from scanned service"	The scan has been in an INTERRUPTED status for too long so Oleander has tried to stop the scan in ER2 but the request was unsuccessful.
"[Scan-Watchers] Watcher has detected different status", "scan", sc.Scan.Name, "current status", sc.Scan.ScanProcess.Status, "scan service status", er2MappedStatus	The scan watcher has detected a change in the scan status, scan status will be updated in DDC.
"[Scan-Watchers] Interrupted status received", "MaxTimeInterruptedState", o.Config.Er2MaxInterruptedTime, "scan", sc.Scan.Name, "current status", sc.Scan.ScanProcess.Status, "scan service Mapped status", er2MappedStatus, "scan service status", er2Status, "InterruptedTimestamp", sc.InterruptedTimestamp	The scan watcher has received an INTERRUPTED status for the scan, the scan watcher will continue asking until the status changes or the timeout is exceeded.
"[Scan-Watchers] Scan has finished... collector starting", "scan", sc.Scan.Name	The scan watcher has received a COMPLETED status for the scan, the scan status is set to PROCESSING in DDC and the scan collector starts.
"DDCScanActionComplete"	Scan audit record, logged after a successful scan execution.
"DDCScanActionFail"	Scan audit record, logged after a failed scan execution.
"AggregatedReportOperationCompleteDDC"	Report audit record, logged after a successful aggregated report generation.
"ScanTrendReportOperationCompleteDDC"	Report audit record, logged after a successful scan trend report generation.

SUNDEW INFO

Error Message	Explanation
"Asking for license status"	Sundew is requesting from Oleander the DDC license status.
"Active license information received", "http ret code", c	Sundew has received a valid license status from Oleander.
"Starting scan service..."	Sundew is launching ER2.
"Connectivity test successful, scan service is up"	Sundew confirms that ER2 is up-and-running.
"Generating scan service license...", "ID", s.er2Status.lastIssuedLicenseID	Sundew is generating a license for ER2.
"Injecting license into scan service"	Sundew is injecting the generated license into ER2.
"License won't be generated/refreshed in this iteration", "ID", s.er2Status.lastIssuedLicenseID, "checks (intervals)", s.Config.GeneratingLicenseInterval-s.er2Status.lastIssuedLicense	No action is required from Sundew for this iteration regarding licensing.
"Not active license or product not licensed response received", "http ret code", c	Sundew has received an invalid license status from Oleander.
"Scan service stopped"	Sundew is stopping ER2.
"Unexpected error code in response for /license/status", "http ret code", c	Sundew asked Oleander for the license status but got an unexpected response.

Error log messages

This section lists the various **error** messages that Data Discovery and Classification sends to CipherTrust Manager log.

OLEANDER ERROR

Error Message	Comment/Explanation
Error connecting to the scan service	This error means a connectivity issue between the oleander and the sundew/ER2.
DDC Error creating the database schema.: error executing http request. Code: 500	To check the connectivity with Hadoop external data base a schema is created. So this means that there is no connectivity with Hadoop. (also, possibly related to "Error creating the PQS database schema" in the UI)
"CLIENT_CREDENTIAL_PARTITION is not set"	CLIENT_CREDENTIAL_PARTITION variable is not set in the config object.
"[Background-Processes] Error retrieving license from DMV", "error", err	Oleander GetLicenses request against DMV has failed. This error could have been caused by DMV being down.
"[Background-Processes] Error killing all agents selections"	When the oleander instance loses its license or the current license expires, all ongoing agent selections

Error Message	Comment/Explanation
	will stop. This error is caused by an internal Oleander issue while this agent selections are being shut down.
"[Background-Processes] Error killing all scan watchers"	When the oleander instance loses its license or the current license expires, all ongoing scan tracking will stop. This error is caused by an internal Oleander issue during this scan tracking shut down.
"[Background-Processes] Error removing all scan schedules due to DDC not licensed"	When the oleander instance loses its license or the current license expires, all scheduled scans will be stopped. This error is caused by an internal Oleander issue during this scheduled scans stopping.
"[Background-Processes] Error starting agent selection for datastores"	The listed Data Stores have no agent available.
"[Background-Processes] Error starting scans watchers"	When the oleander instance receives a valid license from DMV, all stopped agent selections must be resumed. This error is caused by an internal Oleander issue during this agent selections resuming.
"[Background-Processes] Error starting cron schedules"	When the oleander instance receives a valid license from DMV, all stopped scheduled scans must be resumed. This error is caused by an internal Oleander issue during this scheduled scans resuming.
"[Background-Processes] Error trying to migrate the PQS database"	During the PQS configuration, an error occurred trying to apply the changesets to update the Database, create the tables, etc...
"[Background-Processes] Error creating cron", "error", err	Background_processes service constantly creates crons for license status checking against DMV, this error is caused by an internal Oleander issue during the creation of one of this crons.
"[Background-Processes] Error with unmarshal."	Any "unmarshal/unmarshalling" error is caused by an internal Oleander issue converting a golang object to JSON format or vice versa.
"[Background-Processes] Error while trying to update status to FAILED for datastore.", "name", ds.Name, "error", err	When background_process services gets an invalid or expired license from DMV all running scans must be stopped and set as FAILED, this message indicates an internal Oleander error changing the scan status for some scan.
"[Background-Processes] Error while trying to retrieve scans from background processes table"	When the oleander instance receives a valid license from DMV, all stopped normal scans must be resumed. This error is caused by an internal Oleander issue accessing the background processes table, which contains all the information for the scans resuming.
"[Background-Processes] Watcher has failed updating scan status for scan", "name", sc.Scan.Name, "error", err	background_processes service has the responsibility to track the running scans and update their Oleander status, this error message indicates an internal Oleander issue updating the scan_process table.
"Cannot retrieve the HDFS settings", "error", err	Connectivity or internal Oleander error trying to retrieve HDFS settings from Citrus.
"Cannot retrieve the PQS settings", "error", err	Connectivity or internal Oleander error trying to

Error Message	Comment/Explanation
	retrieve PQS settings from Citrus.
"Cannot find the country", "error", err	When a user creates a location and he sets a country that is not registered in our DB.
"Cannot find the state", "error", err	When a user creates a location and he sets a state ID that is not registered in our DB.
"Trying to verify if the country has states", "error", err	When a user creates a location and he sets a state "Name" that is not registered in our DB.
"Missing tag %s for the default classification profiles", r	When inserting default classification profiles, there is no tag that matches the correct Regulation
"[Datastores] Error encrypting connection for datastore: ", "Name", d.Name	Error when calling Scrim Helper for the encryption of the Connection field for a data store.
"[Datastores] Error while trying to create background process resource for datastore: ", "Name", d.Name	When a datastore is created, a new row is inserted into the Background Processes table for further tracking, this error message indicates an internal Oleander issue inserting that row.
"[Datastores] Error selecting agent for datastore ", "Name", dsAAS.Name, "error", err	No suitable agent has been found for this data store.
"[Datastores] Error while trying to retrieve datastore for background process, agent selection might fail: ", "error", err	Error retrieving a data store from DB for background processes purposes in a data store.update operation.
"[Datastores] Error running automatic agent selection", "error", errAgentUpdate	An internal Oleander error has occurred while trying to update the status of a data store during the automatic agent selection.
"[Datastores] Error while trying to unmarshal datastore from background processes"	An internal Oleander error has occurred while trying to translate a JSON object to a golang object while recovering the automatic agent selections.
"Error closing the json file", "error", err	Oleander failed trying to close a JSON file.
"Error trying to close the families json file"	Oleander reads a families JSON file for tartup DB population. This error message indicates an internal Oleander error while closing this file.
"Error initializing the account", "error", *errPtr	Oleander failed trying to set the initialization status to the accounts map.
"Error closing oleander", "error", err	Oleander service could not be closed.
"Error starting background processes", "error", err	Some error has occurred trying to execute all background processes.
"Error connecting to HDFS", "error", err	This happens when the scan fails because there is no HDFS connectivity.
"Error trying to close the info types json file"	Oleander reads an infotypes JSON file for startup DB population. This error message indicates an internal Oleander error while closing this file.
"Error connecting to PQS", "error", err	This happens when the scan fails because there is no PQS connectivity.
"Error closing the temporary file", "FileName",	Oleander failed closing the temporary file used for

Error Message	Comment/Explanation
f.Name(), "error", err	decrypting the raw data file.
"Error deleting the temporary file", "FileName", f.Name(), "error", err	Oleander failed deleting the temporary file used for decrypting the raw data file.
"Error trying to close the zip file", "error", merry.Wrap(err).WithHTTPCode(http.StatusBadRequest)	Oleander failed closing the zip file used for decrypting the raw data file.
"Error changing the scan status", "error", err	Internal Oleander error while trying to update the scan status in the Scan Process table.
"[Scan-Launcher] Error while trying to create background process resource for datastore", "name", rsc.Name	Oleander inserts a row in the Background Processes table for further scan tracking - this message indicates an internal Oleander error while performing this insert.
"[Scan-Launcher] The scan watcher returned an error", "error", err	Generic error message for any issue during the scan watcher process.
"[Scan-Launcher] Agent not found for datastore", "DS name", s.ScanDatastores[i].Datastore.Name, "error", err	The listed Data Stores have no agent available.
"[Scan-Launcher] Error getting absolute paths", "DS name", s.ScanDatastores[i].Datastore.Name, "error", err	Oleander was unable to retrieve the absolute paths of the mentioned data store for further scan execution.
"[Scan-Launcher] Error getting connection path", "DS name", s.ScanDatastores[i].Datastore.Name, "error", err	Oleander was unable to retrieve the connection paths of the mentioned data store for further scan execution.
"[Scan-Launcher] Error retrieving the oleander context"	Error while generating the Oleander service user. (this is the context for executing actions on behalf of the itself, instead of a specific user).
"[Scan-Launcher] Error while validating the scan"	This is a generic error, one of the steps of the validation has failed. (could be that some data stores are not ready, a probe has failed, etc)
"[Scan-Launcher] Error while retrieving extensions"	The extensions necessary for the scan execution could not be retrieved from the DB.
"[Scan-Launcher] Unable to initialize background process"	The background process object could not be initialized so the scan watcher cannot start.
"[Scan-Actions] Error found while trying to delete background process resource"	When Oleander has finished tracking a scan it removes the corresponding row from background processes table - this error message indicates an internal Oleander issue removing that row.
"[Scan-Actions] Error trying to execute the Scan scheduled run", "error", err	Oleander failed trying to add a scan schedule for a scan.
"Error changing the scan status", "error", err	Generic error message for an issue during the update of the scan status.
"[Scan-Watchers] Watcher has failed getting scan status from scanned service", "scan", sc.Scan.Name, "error", err	This indicates an underlying connectivity issue with Sundew.
"[Scan-Watchers] Watcher has failed updating scan"	Error updating the scan status in the scan process

Error Message	Comment/Explanation
status", "scan", sc.Scan.Name, "error", err	table.
"[Scan-Watchers] Error processing the report: ", "error", err	Oleander scan collector has failed trying to create the scan collector background process for the mentioned scan.
"[Scan-Watchers] Scan aborted, maximum wait for scan results exceeded", "MaxTimeInterruptedState(minutes)", o.Config.Er2MaxInterruptedTime/60, "scan", sc.Scan.Name, "current status", sc.Scan.ScanProcess.Status, "scan service status", er2MappedStatus	The scan has been in INTERRUPTED er2 state for too long, when it exceeds the timeout the status is changed to FAILED in DDC.
"Error trying to parse er2 polling frequency from env"	Oleander failed trying to read the ER2 POLLING FREQUENCY env variable from the config object.
"Error while trying to retrieve scans from background processes table", "error", err	Oleander tried to retrieve all SCAN rows in the background processes table but it failed.
"Error trying to recover the scan watchers", "error", err	One of the scan watchers instantiated by the recovery system has returned an error and stopped working.
"Wrong datastore credentials"	Oleander was unable to reach a data store due to credentials failure.
"Wrong target path defined"	A scan has failed because the target path defined was not valid.
"Wrong db schema in target path"	A scan has failed because the db schema defined was not valid.
"Wrong db table in target path"	A scan has failed because the DB defined was not valid.
"Wrong defined file extension in target path"	A scan has failed because a file was specified without an extension.
"Error connecting to the scan service"	Oleander is unable to connect with ER2.
"Error processing the scan reports"	Generic error while trying to process a scan report.
"No Data Allowance Licensing detected"	Oleander does not have a Data Allowance record.
"Error reading the scan report"	Generic error while trying to read a scan report.
"Probing path can be launched only on folders. Files are not supported"	Scan failed because a file was specified as target instead of a folder.
"Probing a File or Directory that does not exist"	Scan failed because the specified directory does not exist.

SUNDEW ERROR

Error Message	Explanation
"CLIENT_CREDENTIAL_PARTITION is not set."	CLIENT_CREDENTIAL_PARTITION variable is not set in the config object.
"Error trying to ask for license status", "error", err	Sundew failed trying to request DDC status from

Error Message	Explanation
	Oleander.
"Error trying to start the scan service", "error", err	Sundew failed trying to start ER2.
"Connectivity test to the scan service failed", "error", conErr	Sundew failed trying to ping ER2. ER2 is down.
"Error during validation of received license", "error", err	Sundew failed trying to validate the DDC license retrieved from Oleander.
"Error parsing the license ID", "error", err	Sundew failed trying to parse the DDC license ID received from Oleander.
"Error while injecting license inside scan service", "error", err	Sundew failed trying to inject the generated license into ER2.
"Error stopping scan service", "error", err	Sundew failed trying to stop ER2.
"Error closing the response body", "error", err	Sundew failed trying to close the HTTP response body from a request.
"Error closing sundew", "error", err	Error when trying to close the Sundew service.

Checking the system health

If you run into a problem with DDC, use this procedure to check the system health before you report anything to [Thales Customer Support](#).

1. (if CM is clustered) Check there is a defined DDC active node and check if it is part of the cluster.

Refer to the information in [Identifying the Active DDC Node](#) for details.

2. Check the available disk space using Linux console or disk-usage API. If DDC node free disk space below 20% the scan service will not be available.

Disk usage API

Use the GET disk-usage API as described in the [CipherTrust Manager API Guide](#).

API: /v1/ddc/server-statistics/disk-usage

Description: Returns disk usage statics of scanner service.

Sample response

```
{
  "diskUsage": 82.23,
  "degradedMode": false,
  "error": ""
}
```

Linux console

- a. Access the Linux console (of the DDC active node in case of a CM cluster) as the user **ksadmin**.
- b. Run the `df -h` command and verify that the "Use%" value for the "/" partition is under 80%.

```
ksadmin@ciphertrust:~$ df -h

Filesystem Size Used Avail Use% Mounted on
udev 7.8G 0 7.8G 0% /dev
tmpfs 1.6G 3.7M 1.6G 1% /run
/dev/sda2 49G 12G 35G 26% /
tmpfs 7.9G 0 7.9G 0% /dev/shm
tmpfs 5.0M 0 5.0M 0% /run/lock
tmpfs 7.9G 0 7.9G 0% /sys/fs/cgroup
/dev/sda1 464M 130M 307M 30% /boot
tmpfs 1.6G 0 1.6G 0% /run/user/0
```

3. Check the status of the DDC License.

Refer to the information in [Viewing the license status](#) for details.

4. Check the configuration and status of the TDP connection.

Refer to the information in [Configuring TDP](#) for details.

5. Check TDP health status.

Refer to the [Thales Data Platform Documentation](#) for details.

6. Check the CipherTrust Manager logs and look for messages related to Oleander and Sundew.

- a. Access to the linux console of the DDC active node as the **ksadmin** user.

- b. To see the DDC logs in real time, run the following command:

```
tail -f /opt/keysecure/logs/keysecure.system.log | egrep "\| (oleander|sundew)"
```

- c. To copy all the ddc logs into a single file, run:

```
> /tmp/ddc.log
ls -r /opt/keysecure/logs/keysecure.system.log* | while read FILE; do ext="${FILE##*.}"; if [ "$ext" = "gz" ]; then CMD="zcat"; else CMD="cat"; fi; $CMD $FILE | egrep "\| (oleander|sundew)" >> /tmp/ddc.log; done
```

- d. To copy the ddc logs filtered by a specific date (YYYY-MM-DD), run:

```
> /tmp/ddc-YYYY-MM-DD.log
ls -r /opt/keysecure/logs/keysecure.system.log* | while read FILE; do ext="${FILE##*.}"; if [ "$ext" = "gz" ]; then CMD="zcat"; else CMD="cat"; fi; $CMD $FILE | egrep "^YYYY-MM-DD" | egrep "\| (oleander|sundew)" >> /tmp/ddc-YYYY-MM-DD.log; done
```

Tip

Replace the *YYYY-MM-DD* bit with the date that you want to filter by.

7. Agent connectivity and clock.

▪ All agents

- Go to the Agents page, by clicking the Data Discovery and Classification panel in the CipherTrust Manager dashboard, then click to expand the Data Stores menu in the navigation panel on the left, then click Agents.
- Check whether agents are listed there with right status.
- Check if agent clocks are ok.

For more details please refer to information in [Agents](#).

▪ Specific Agent

- a. Verify the logs generated by the DDC agent.
 - In Linux: `/var/lib/er2/agent.log`
 - In Windows: `C:\Program Files (x86)\Ground Labs\Enterprise Recon 2\agent.log`
- b. Verify the connection from the agent to the CM server.
 - In Linux:

Run the `er2-config -t` command:

```
root@agent1:~# er2-config -t
Master server is not specified, using the default master server: sundew
Testing connection setting...
```

```
Test SUCCESS. Saving settings
Target initial group is not specified, using the default public key [prei
nstalled]
Configuration updated, please restart agent service
The configuration has been saved. Please restart the agent for the change
s to take effect.
```

- In Windows:
 - Open the **Configure Agent** application.
 - Ensure it has the correct server IP or hostname (DDC active node in case of a CM cluster).
 - Click the **Test Connection** button.
- c. Verify the disk space.

Resolving high disk usage issues

DDC performs automatic disk clean up in the backend when a scan run is complete or stopped. However, this process is skipped for a failed scan and all other subsequent scans, whether they fail or succeed. As a result, disk consumption may increase over time, potentially exceeding threshold levels.

Tip

Use the Linux console or disk-usage API to regularly monitor disk usage, and take proactive measures to prevent disk consumption from exceeding threshold levels. See step 2 under [Checking the System Health](#) for details.

DDC continuously monitors disk usage and displays alert banners when disk consumption reaches a certain threshold value.

Warning banner

DDC displays a warning banner when disk usage reaches 60% or above.

When you see a warning banner, perform the following tasks to manage disk space:

- Start the disk clean up process via warning banner.
 - a. Click **Start Clean Up Process**.
 - b. In the consent dialog, click **Clean Up**.

This action will stop all running scans and initiate the clean-up process. After the clean up process is

complete, you can rerun the scans manually.

Alternatively, click **Cancel** and allow the scan runs to complete or stop them manually, before restarting the clean-up process.

Note

After performing cleanup, it takes some time for DDC to synchronize and reflect the actual disk space, and stop displaying the warning banner.

- Delete backup files to reduce disk consumption.
- Increase the disk space.

Degraded banner

DDC enters the degraded mode when disk usage reaches 85% or above and displays a degraded banner with an option to initiate clean up process. DDC exits the degraded mode when the disk space is reduced to 70% or below.

Note

When degraded mode is reached, DDC becomes inoperable and all the APIs related to Scans, Datastores, Agents, Classification Profiles, Infotypes, and Report will not function.

When you see a degraded banner, perform the following tasks to manage disk space:

- Start the disk clean up process via degraded banner.
 - a. Click **Start Clean Up Process**.
 - b. In the consent dialog, click **Clean Up**.

During the clean up process:

- All the running, paused, and auto-paused scans will fail.
- No trace logs will be available for the failed scans.

Note

After performing cleanup, it takes some time for DDC to synchronize and reflect the actual disk space, and stop displaying the degraded banner.

- Delete backup files to reduce disk consumption.
- Increase the disk space.

Note

When disk cleanup is performed by increasing the disk space and/or deleting backup files, all running scans will continue to proceed uninterrupted. Additionally, if a scan was paused, it can be manually resumed.

Appendix

Information types

Infotype Name	Category	Region
AES Key	Personal Data	Global

Supported formats for standard agent

Files

Type	Format
Compressed	bzip2, Gzip (all types), TAR, Zip (all types)
Databases	Access, DBase, SQLite, MSSQL MDF & LDF
Images	BMP, FAX, GIF, JPG, PDF (embedded), PNG, TIF
Microsoft Backup Archive	Microsoft Binary / BKF
Microsoft Office	v5, 6, 95, 97, 2000, XP, 2003 onwards
Open Source	Star Office / Open Office / Libre Office
Open Standards	PDF, RTF, HTML, XML, CSV, TXT

Office files

WORD

- **Legacy:** Legacy filename extensions denote binary Microsoft Word formatting that became outdated with the release of Microsoft Office 2007. Although the latest version of Microsoft Word can still open them, they are no longer developed. Legacy filename extensions include:
 - .doc – Legacy Word document; Microsoft Office refers to them as "Microsoft Word 97 – 2003 Document"
 - .dot – Legacy Word templates; officially designated "Microsoft Word 97 – 2003 Template"
 - .wbk – Legacy Word document backup; referred as "Microsoft Word Backup Document"
- **OOXML:** Office Open XML (OOXML) format was introduced with Microsoft Office 2007 and became the default format of Microsoft Word ever since. Pertaining file extensions include:
 - .docx – Word document
 - .docm – Word macro-enabled document; same as docx, but may contain macros and scripts
 - .dotx – Word template
 - .dotm – Word macro-enabled template; same as dotx, but may contain macros and scripts
 - .docb – Word binary document introduced in Microsoft Office 2007

EXCEL

- **Legacy:** Legacy filename extensions denote binary Microsoft Excel formats that became outdated with the release of Microsoft Office 2007. Although the latest version of Microsoft Excel can still open them, they are no longer developed. Legacy filename extensions include:
 - .xls – Legacy Excel worksheets; officially designated "Microsoft Excel 97-2003 Worksheet"
 - .xlt – Legacy Excel templates; officially designated "Microsoft Excel 97-2003 Template"
 - .xlm – Legacy Excel macro
- **OOXML:** Office Open XML (OOXML) format was introduced with Microsoft Office 2007 and became the default format of Microsoft Excel ever since. Excel-related file extensions of this format include:
 - .xlsx – Excel workbook
 - .xlsm – Excel macro-enabled workbook; same as xlsx but may contain macros and scripts
 - .xltx – Excel template
 - .xltm – Excel macro-enabled template; same as xltx but may contain macros and scripts

POWERPOINT

- **Legacy:**

- .ppt – Legacy PowerPoint presentation
- .pot – Legacy PowerPoint template
- .pps – Legacy PowerPoint slideshow

- **OOXML:**

- .pptx – PowerPoint presentation
- .pptm – PowerPoint macro-enabled presentation
- .potx – PowerPoint template
- .potm – PowerPoint macro-enabled template
- .ppam – PowerPoint add-in
- .ppsx – PowerPoint slideshow
- .ppsm – PowerPoint macro-enabled slideshow
- .sldx – PowerPoint slide
- .sldm – PowerPoint macro-enabled slide

ACCESS

- **Legacy:**

- .ade – Protected Access Data Project (not supported in 2013)
- .adp - Access Data Project (not supported in 2013)
- .mdb - Access Database (2003 and earlier)
- .cdb - Access Database (Pocket Access for Windows CE)
- .mda - Access Database, used for addins (Access 2, 95, 97), previously used for workgroups (Access 2)
- .mdt - Access Add-in Data (2003 and earlier)
- .mdf - Access (SQL Server) detached database (2000)
- .mde - Protected Access Database, with compiled VBA and macros (2003 and earlier)
- .ldb - Access lock files (associated with .mdb)

- **Available formats since Access 2007:**

-
- .accdb – The file extension for the new Office Access 2007 file format. This takes the place of the MDB file extension
 - .accde – The file extension for Office Access 2007 files that are in "execute only" mode. ACCDE files have all Visual Basic for Applications (VBA) source code hidden. A user of an ACCDE file can only execute VBA code, but not view or modify it. ACCDE takes the place of the MDE file extension
 - .accdt – The file extension for Access Database Templates
 - .accdr – is a new file extension that enables you to open a database in runtime mode. By simply changing a database's file extension from .accdb to .accdr, you can create a "locked-down" version of your Office Access database. You can change the file extension back to .accdb to restore full functionality

OUTLOOK

- .pst - Outlook
- .ost - Outlook
- .msg - Outlook
- .dbx - Outlook

OTHER

- .pub – a Microsoft Publisher publication
- .xps – a XML-based document format used for printing (on Windows Vista and later) and preserving documents

Databases

- Microsoft SQL
- Oracle
- IBM DB2
- PostgreSQL
- SAP HANA
- MySQL
- MongoDB

Big Data

- Hadoop

- Teradata

Binary Large Objects

Database	Object Type
Oracle	BLOB, CLOB
Microsoft SQL Server	VARBINARY, Filestream
PostgreSQL	bytea, text, Large Objects(oid)
MySQL	BLOB, TINYBLOB, MEDIUMBLOB, LONGBLOB
IBM DB2	BLOBs, CLOB, DBCLOB
Teradata	BLOBs
MongoDB	GridFS
SAP HANA	BLOB, NCLOB

Supported file formats for DDC ML

- Unstructured
 - DOCX
 - PDF
 - RTF
 - TXT
 - ZIP (contains the supported file format)
- Semi-structured
 - HTML
 - DOCX (Key-value pairs)
 - PDF (Key-value pairs)
 - RTF (Key-value pairs)
 - TXT (Key-value pairs)
 - ZIP (Key-value pairs)

Unsupported file formats for DDC ML

- All structured file formats including CSV, XLSX, and database files (RDBMS).

-
- Semi-structured file formats such as JSON, XML, and YAML.
 - Unstructured file formats such as PPT, PPTX, HEIC, and MPS.
 - All image, audio, and video file formats.
 - All formats not included in [supported list](#).
 - Files with bad or inappropriate context.

Configuration backup

You can back up and restore the DDC configuration by using the Backup/Restore functionality available in CipherTrust Manager. Such a backup will include the following elements:

- Data Stores
- Locations
- Classification Profiles
- Infotypes
- Report definitions

This backup **will not include** the information about the **scan executions**.

Creating/Restoring the configuration backup

To create or restore a backup of your DDC configuration:

1. Log in to CipherTrust Manager.
2. Click the **Admin Settings** link on the dashboard.
3. Select **Backups** from the sidebar on the left. This will display the **Backups** screen.
4. To create a backup of your DDC configuration, click the **Create Backup** button.
5. To restore your DDC configuration from a backup, click the **Upload Backup** button.

For more details refer to these sections of the CipherTrust Manager documentation:

- [CipherTrust Manager backup](#)
- [CipherTrust Manager scheduling backups](#)
- [CipherTrust Manager scheduler](#)

Configuration backup limitations

- The configuration backup references the DDC Active Node. Restoring the backup to a different CipherTrust Manager cluster leaves DDC referencing an invalid node, and therefore without any valid active node.
- The configuration backup contains the definition of the DDC resources (such as the Scan or Data Store definitions). Restoring from a backup that does not contain a certain resource (for example, a Custom Classification Profile) or a resource version after a scan had been completed causes a TDP scan execution data to point to an invalid resource identifier.

If you generate a report that points to the missing resource you may display incomplete data (such as not being able to display the resource name) and/or fail.

Creating/Restoring backup of scan executions

To back up or restore the your Data Discovery and Classification scan executions data you need to access the DDC data stored in Hadoop. For details, refer to the [Thales Data Platform Hadoop backup](#) section in the [Thales Data Platform Administrator Guide](#).

Mounting an NFS share

To mount an NFS share on a Proxy agent, run this command as root:

```
sudo mount <nfs-server-hostname|nfs-server-ipaddress>:</target/directory/share-name>
```

Issues encountered while browsing target paths

You may encounter following issues while trying to navigate target paths using **Browse** button.

Datastore	Scenario	Issue
AWS	Path inside Add Target Path field contains invalid folder name within valid Bucket name Example: <valid_bucket>/<invalid_folder>	No error toast message shows up. File browser displays " No paths to display ".
GMail	Path inside Add Target Path field contains invalid folder name within valid user account Example: <valid_useraccount>/<invalid_folder>	No error toast message shows up. File browser displays " No paths to display ".
GMail, Google Drive	Add Target Path field is empty or contains a path to a valid folder	User accounts are listed correctly, but targets within it are not displayed.
NFS	Add Target Path field contains	No error toast message shows up.

Datastore	Scenario	Issue
	invalid path	File browser displays "No paths to display" .
SharePoint Online, SharePoint Server	Add Target Path field contains: - Invalid folder in valid site collection - Invalid file within valid site collection - Invalid file with valid folder in a site collection Examples: <valid_site_collection>/:site:/file/<valid_folder>/<invalid_file> <valid_site_collection>/:site:/file/<invalid_folder> <valid_site_collection>/:site:/file/<invalid_file>	No error toast message shows up. File browser displays "No paths to display" .
SharePoint Online, SharePoint Server	Add Target Path field contains incorrect site collection	Arbitrary folders and files may get displayed without any error. Selecting these results as target leads to a failed scan.
Exchange Online	Add Target Path field is empty	System default groups are listed. Upon selecting one or more default groups, the scan is executed successfully without any matches. <i>System default groups cannot undergo scanning. Targets must be valid email or email groups.</i>

API request quota limit

Datastore	Quota Limit (per minute request count)
Gmail	15000
SharePoint Online	600
Exchange Online	800
OneDrive	1000

Using wildcard characters

Asterisk (*) and question mark (?) are two most popular wildcard characters that you can use to traverse locations without providing absolute paths.

In DDC, you can use these characters while applying scan filters to scan selective locations instead of recursively scanning entire directory structures of data store.

Wildcard	Meaning	Examples
*	Matches zero or more characters	- D:/A/* will traverse all locations starting with D:/A - D:/A/*/F/E will traverse all locations starting with D:/A and ending with /F/E */A/E will traverse all locations ending with /A/E *A/E* will traverse all locations that contains A/E - D:/A/*/B/C/* will traverse all locations that starts with D:/A/ and contains /B/C/ in the followed path.
?	Matches exactly one character	D:/A??? will traverse all locations starting with D:/A followed by any three characters.

Deployment Security

Security audit log event messages

The following table contains a complete list of security audit log event messages that DDC prints in the log file.

Message	Explanation
DDCScanClientInvalidCredentialsProbe	A probe with invalid credentials.
DDCScanClientUnexpectedErrorProbe	An unknown probe error.
DDCHDFSUpdateHDFSSettingsAuthenticationError	A failed authentication against HDFS updating HDFS
DDCHDFSBackgroundProcessAuthenticationError	A failed authentication against HDFS in background
DDCUnauthorizedCloneRequest	An unauthorized CLONE request.
DDCUnauthorizedGetRequest	An unauthorized GET request.
DDCUnauthorizedListRequest	An unauthorized LIST request.
DDCUnauthorizedListPaginatedRequestWithContext	An unauthorized LIST PAGINATED request with
DDCUnauthorizedCreateRequest	An unauthorized CREATE request.
DDCUnauthorizedUpdateRequest	An unauthorized UPDATE request.
DDCUnauthorizedListProvisionedRequest	An unauthorized LIST PROVISIONED request.
DDCUnauthorizedGetProvisionedRequest	An unauthorized GET PROVISIONED request.
DDCUnauthorizedGetActiveNodeRequest	An unauthorized GET ACTIVE NODE request.

Message	Explanation
DDCUnauthorizedTestConnectivityRequest	An unauthorized TEST CONNECTIVITY request.
DDCUnauthorizedGetLicenseRequest	An unauthorized GET LICENSE request.
DDCUnauthorizedDecryptRawDataFileRequest	An unauthorized DECRYPT RAW DATA FILE request.
DDCUnauthorizedGetDatastoreReportRequest	An unauthorized GET DATASTORE REPORT request.
DDCUnauthorizedFindScanRequest	An unauthorized FIND SCAN request.
DDCUnauthorizedScanActionRequest	An unauthorized SCAN ACTION request.
DDCResourceRetrievalGenericCloneError	A GENERIC CLONE request.
DDCResourceRetrievalGenericGetError	A GENERIC GET request.
DDCResourceRetrievalGenericListError	A GENERIC GET request.
DDCResourceRetrievalGenericListPaginatedRequest Error	A GENERIC LIST PAGINATED request.
DDCResourceRetrievalGenericCreateError	A GENERIC CREATE request.
DDCResourceRetrievalGenericUpdateError	A GENERIC UPDATE request.
DDCResourceRetrievalGenericListProvisionError	A GENERIC LIST PROVISION request.
DDCDatastoreDecryptDataEncryptionKeyNotFoundErr or	A GET KEY request.
DDCDatastoreEncryptDataError	An ENCRYPT DATA request.
DDCScanWatcherInterruptedTimeout	An INTERRUPTED TIMEOUT request.
DDCScanClientRetrieveScanTimeout	A RETRIEVE SCAN TIMEOUT request.
DDCScanActionRequest	A SCAN ACTION request.
DDCDatastoreUpdateRequest	A DATASTORE UPDATE request.
DDCDatastoreCreateRequest	A DATASTORE CREATE request.
DDCScanDeleteRequest	A SCAN DELETE request.
DDCSummaryReportGetRequest	A GET SUMMARY REPORT request.
DDCDatastoreDetailReportGetRequest	A GET DATASTORE DETAILS REPORT request.
DDCDataObjectsDetailReportGetRequest	A GET DATASTORE DETAILS REPORT request.
DDCInfotypesSummaryReportGetRequest	A GET INFOTYPES SUMMARY REPORT request.
DDCDataObjectsSummaryReportGetRequest	A GET DATAOBJECTS SUMMARY REPORT request.
DDCScanDetailsReportGetRequest	A GET SCAN DETAILS REPORT request.

Mitigating security risks

DDC provides you a handy method of mitigating security risks by means of the Agent and Data Store labels. In this section you can find a few procedures that you can use to improve the security of your DDC deployment.

In short, agent labels represent the capabilities and Data Store labels indicate the capabilities required by any agent to scan it. Therefore, in order to scan a particular Data Store, an agent must define all the labels defined for

that Data Store, but it may contain additional labels. You can leverage this functionality to mitigate the following security risks:

1. Ensure that only some hand-picked agents, strongly hardened and monitored, can access your sensitive Data Stores.
2. Ensure that attackers cannot access the Data Store credentials by registering a new agent that they control.
3. Respect network segmentation policies.

Restrict access to sensitive data stores

The default DDC behavior is to share the Data Store credentials with every agent to identify those with connectivity. In order to minimize the attack surface, restrict the agents receiving the credentials to access sensitive Data Stores to those that are properly hardened and monitored by your IT / security department.

1. Reserve a label to identify sensitive Data Stores. For example: SENSITIVE
2. Assign this label to any Data Store containing sensitive information.
3. Assign the SENSITIVE label to the selected agents.

Effect: DDC will only share the Data Store credentials with manually whitelisted agents.

Whitelist vetted agents

DDC identifies any agent installed as legitimate, so attackers that already control a host in the network can leverage this behavior to receive the Data Store credentials even if this host does not have network connectivity to the Data Stores. In order to minimize the attack surface, you may configure DDC to consider only vetted agents.

1. Reserve a DDC-wide label to identify vetted agents. For example: VETTED_AGENT
2. Assign the label to all Data Stores to ensure DDC only considers them to complete the scans.
3. Assign the label to all valid agents displayed in the agent list.

Effect: If an attacker registers a new agent, the attacker-controlled agent will not be considered by DDC to complete any scan nor will receive any Data Store credential.

Respect network segmentation

Companies usually segment the network and define policies restricting data movement between network security zones. As DDC considers all agent with connectivity to the Data Store to complete a scan, data may cross the boundaries and violate the company policies. In order to prevent this, ensure DDC uses agents on the same network security zone the data resides.

1. Ensure that you have labels matching the security zones defined by your corporate security policy. For example: SECURITY_LEVEL_1, SECURITY_LEVEL_2, SECURITY_LEVEL_3
 2. Assign each Data Store to the label indicating the security zone that they reside on.
 3. Deploy (at least) one agent in each security zone, and assign it the label representing the security zone they reside on.
-

Effect: When DDC selects the agent to complete any scan, it will only consider agents that reside in the same network security zone, so your data will never cross the security zone boundaries.

Executive summary

The rapid, often exponential, growth of data year-on-year in organizations like yours makes effective data management an extremely challenging proposition. An increasing switch to remote working raises the bar even higher with many data storage areas or volumes coming into play which are outside your IT team's direct control.

As part of the broader group within your organization responsible for data privacy and security compliance, ensuring no vulnerable areas are overlooked when implementing your data protection strategy is of paramount importance. After all, a data breach will inevitably cause severe business disruption in addition to large fines incurred for non-compliance with the seemingly endless stream of new or enhanced data privacy laws and regulations. Failing to prepare properly is definitely not a viable option for you.

A significant weakness often seen in typical data management implementations is the lack of visibility into the precise types of data being held across various local servers, network drives and increasingly cloud storage locations. Many organizations have been breached already, some have encountered near misses and others are migrating large workloads to the cloud without fully understanding the fundamental nature of the data itself and the exposure risks involved – situations for you to avoid.

Historically staff knowledge was sufficient and simple 'off-the-shelf' encryption methods from database vendors would satisfy needs – no longer with the vast data footprint that is widely dispersed and growing by the second. You inevitably need assistance to take control and keep your organization safe.

Thales CipherTrust Data Discovery and Classification is...

A tool that is significantly more effective and efficient than manual methods for data discovery as it scans the whole targets and not just sampling the data. It helps classify all your data, while supporting every mainstream operating system, data storage type, structured and unstructured data you are likely to possess. Existing processes and tools are supplemented, rather than replaced, providing high levels of automation in your search for sensitive data, wherever it resides. Ultimately, it can help you become more agile and support better data management decisions.

It finds sensitive data that you may not realize even exists in your organization, helping you eliminate threats to your business continuity and reduce your data footprint

It enables you quickly to assess your risks of non-compliance and determine the appropriate protection actions to take

It provides confidence that you are protecting the right assets, including proprietary data or intellectual property, across all your data storage locations including the cloud

The role of CipherTrust Data Discovery and Classification (DDC)

DDC offers a more streamlined, accurate and unattended (or automated) approach in comparison to sensitive data searches using manual methods. DDC stands out from competitive products as it covers additional data storage types, extending the range of structured and unstructured data that can be analyzed while offering higher levels of accuracy by finding sensitive data other tools often miss.

Sensitive items found by DDC are not just restricted to data privacy laws and regulations. Fine tuning using custom infotypes (which you define) facilitates visibility on where data sensitive to your organization is present. By enabling critical assets (such as internal financial data, trade secrets, intellectual property and confidential business plans for example) to be located, their current levels of protection and associated risks of unintended exposure can be better understood. Considerable flexibility comes from running multiple scans simultaneously, each looking for different types of information (if desired) to create a faster and more efficient way to analyze your complete data footprint across a diverse range of storage locations. It is the ability to create multiple classification profiles (customized where needed) that underpins such performance and efficiency benefits that never could be achieved in a comparable timeframe using manual methods or less capable tools.

Discovering the data is only part of the task in hand – classification is equally important, providing deeper understanding of the types of data and their footprint in your organization. DDC does not move or modify your data, merely summarizing what it uncovers during scans in a non-intrusive manner.

You can see **exactly how your data is split** between the personal, financial, medical and national ID categories – you may be surprised that some of this even exists. At least now you will have insight into precisely where it resides to manage the business risk appropriately.

The insights available after scans have been performed provide **important guidance** on what you may need to do next, especially related to protection. You can choose how many scans you wish to incorporate in any given report. Each report improves data visibility, providing detailed insight into:

The names of the infotypes found together with the number of sensitive data matches

The risk associated with each of the data objects analyzed during the scan in question

DDC provides options to run scans at any time, over and over again if desired. The tool is intended to be used regularly to keep your insight up to date rather than just being a one-off activity. Since data is always in a state of flux, DDC is ready to convey the latest true representation of what you have and what you might need to do to keep your business safe.

Secrets discovery is a critical component of cybersecurity and data protection. It involves identifying sensitive information, such as API keys, passwords, and social security numbers, that can be inadvertently exposed within systems or applications.

Secrets are difficult to gain visibility to as they reside in so many different places. Developers often scatter them in code repositories, configuration files and personal devices making both the discovery and management of them challenging. Older systems, false positives, and human error make discovering secrets a challenge, especially with cyberattackers constantly coming up with new ways to exploit these vulnerabilities. When secrets such as tokens, API keys, passwords, or usernames are discovered by threat actors, they can be used to break into IT systems. CipherTrust Data Discovery and Classification, using AI, proactively scans code for specific patterns, making developers aware of them before they become security threats. Secrets Discovery is a feature of Thales CipherTrust Data Discovery and Classification product and is the most comprehensive and reliable secrets discovery tool in the marketplace today. It proactively helps stop malicious actors before they gain unauthorized access to your data. Although there are other vendors for secrets discovery, they cannot tell the full story of Discover, Protect, Control like Thales can. The Thales solution is comprehensive, and doesn't require piecing together solutions, like many competitive solutions do.

How it all fits together

DDC is configured using a graphical user interface (launched from within the CipherTrust Manager console) or via the REST API. It offers a simple and intuitive workflow, enabling you to define data locations for interrogation, specify the types of data you wish to discover and decide when and how often you wish to repeat the scanning process. Ultimately the rich views provide a deep dive into the sensitive data matches, the associated protection status and risk assessment of the data locations in question. The main features are summarized in the sections below, providing a high level insight into the power, flexibility and control available to you.

The workflow for DDC is easy to follow via the user interface. **Three main ingredients** help define your environment – **data stores, classification profiles** and **infotypes**.

Typically, you might adopt the following sequence when using DDC for the first time:

Select and configure **data stores** of interest – we recommend concentrating on the most frequently accessed data stores first and a selected path rather than the whole store.

Choose one or more **classification profiles** – create custom classification profiles if necessary. During this process, select one or more **infotypes** of interest - use the custom infotype capability if the prebuilt list is insufficient.

Configure and start the scan – consider just selecting one data store for your first scan to test your configuration.

Data stores		
Local storage	SharePoint On Prem Exchange Server Local Windows and Linux	
Network Storage	Windows Share (CIFs/SMB) Unix File System (NFS)	
Database	IBM DB2 Microsoft SQL MongoDS MySQL	Oracle DB PostgreSQL SAP HANA SQL
Big Data	Hadoop clusters	Teradata
Cloud	AWS S3 Buckets Azure Blog Google Workspace (Gmail and Gdrive)	Azure Table Office 365 (Exchange, SharePoint, & OneDrive) SalesForce

The structured and unstructured data coverage provided by DDC is frequently being updated with new capabilities - check out the latest specifications [here](#).

Types of file supported

Databases	Access Dbase	SQLite MSSQL MDF & LDF	Microsoft Office	v5 6 95 97 2000	XP 2003 onwards Office Files: Word, Excel, PowerPoint, Access, Outlook, Other (.pub & .xps)
Images	BMP FAX GIF JPG	PDF (embedded) PNG TIF	Open Source	Star Office / Open Office / Libre Office	
Compressed	Bzip2 Gzip (all types)	TAR ZIP (all types)	Open Standards	PDF RTF HTML	XML
Microsoft Backup Archive	Microsoft Binary / BKF				CSV TXT

Regulations Supported

APA	Australia Privacy Amendment	HIPAA	Health Insurance Portability and Accountability Act
APPI	Act on Protection of Personal Information	KVKK	Turkish Personal Data Protection Law
CCPA	California Consumer Privacy Act	LGPD	General Data Protection Law (Brazil)
GDPR	Financial	NYDFS	New York State Department of Financial Services
GDPR	General Data Protection Regulation	PCI DSS	Payment Card Industry Data Security Standard
GDPR	Healthcare	SHIELD	Privacy Shield Framework
GDPR	National ID	UK-GDPR	General Data Protection Regulation (UK)
GDPR	Personal Details		

Core classification profiles are prebuilt and aligned with major data laws and regulations, both regional and global. You can make changes to these or add totally new profiles if required. Various shortcuts are provided in terms of editing and copying so that you can quickly create and test your own profiles. There is full flexibility in specifying various parameters including sensitivity levels and infotypes.

Sensitivity Levels Supported		
None	Public	Internal
Private	Restricted	

Categorizing sensitive data

DDC is prebuilt with various infotypes, over 250 and counting, covering the vast majority of regional and global data privacy laws and regulations. When a prebuilt classification profile template is selected, the appropriate subset of infotypes is added automatically. You can modify or extend this list by creating your own custom infotypes, allowing rules to be defined which describe precisely how the scanning engine should look for the data strings in question. Full access to the groups and categories is available as part of the definition so that data matches can be displayed in the appropriate sections of the scan results.

Infotype categories (prebuilt)		
Financial	Credit/ debit cards	Bank account info
Personal data	Email addresses Login credentials Card number Ethnicity License number Roll number Passport number Date of birth MAC address	Mailing address Telephone number Gender Religion IP address Phone number Name Profanity
Medical	Patient health data	
National ID	Personal identification	
Secrets	Secrets: Keys, credentials, others	

Using agents for discovery

Detailed data analysis is carried out by discovery agents which perform the scanning and report the results back to the DDC Connector for analysis and processing. Two types of agents exist – local and proxy. You would normally install local agents on data store locations (for which you have the appropriate access rights) to ensure the data never leaves the server for security or performance reasons. In contrast, proxy agents are used for network or remote data stores where a separate proxy server hosts the agent.

Type of agent	Pros	Cons
Local	Faster scan Data remains local No need for credential	Longer deployment time More complex management Only supports local data stores
Proxy	Faster to deploy and scale Ability to scan multiple data stores Supports multiple datastore types No resources consumed on target host	Data sent over network to agent prior to scanning Increased network load and data footprint Ideally should be located on same virtual LAN (VLAN)

Common benefits apply to both types of agent:

An **unlimited number** of agents is available for deployment at no additional cost since licensing is based on the volume of new data scanned

Multiple simultaneous sub-scans can be launched to reduce the time required for the overall scan

TLS encryption is available for all communications between data stores and agents to protect sensitive data from eavesdropping

Source data is untouched as agents only access a temporary data copy in internal memory during the scan

No sensitive data is stored during the process as only a summary of the scan results is sent to the DDC Connector

Scans can **still proceed** and record results even when connection to the DDC Connector is lost

With your agents installed, you can then start to think about what and how you wish to scan. We provide a great deal of flexibility in how scans are configured, managed and operated. Important parameters configurable for each scan independently include:

- Name (up to 64 characters)
- Description (up to 250 characters)
- One or more data stores (where to scan)
- One or more classification profiles (what to look for)
- Manual or scheduled operation (when to activate)

On completion of any given scan, it is added to a list of all scans that have been performed. Next, you would use the reporting tool to view detailed results from the scan. Depending on what is found you may make changes to the scan configuration and rerun the scan which is beneficial when working on different data stores or new types of compliance regulations for the first time.

Analyzing scan results

The results from historical and new scans are available for use with the built-in reporting tool. Three main views for scan reports are offered:

- **Scans**
- **Data stores**
- **Data objects**

Before detailed information is available, a report is generated which aggregates the results from one or more successful scans. Often for logistical, security or performance reasons you may wish to use multiple scans (each looking for different types of regulated data) to analyze your entire data footprint. With our flexible approach you can still do this and fine-tune each scan as required using multiple iterations, before generating a final report which can represent the current status of all your data. It is also easy to understand your organizational posture from a single regulation point of view.

Each tab within the report module offers an insight into slightly different aspects of your data – all however have a common goal in helping you identify quickly any sensitive data at risk.

Scans view

Provides a high level, aggregated scan view of the infotypes found (broken down by percentage in each category present) together with three other charts representing the presence of sensitive data objects in terms of category distribution, content types and file types in question.

Data stores view

Provides a list of the data stores with details including the risk, sensitivity level, infotypes found and the number of sensitive data objects present for each data store – this provides a rapid means of assessing at a high level whether or not sensitive data is at risk and which data stores are involved.

Data objects view

Provides a detailed list of all data objects scanned containing sensitive data, sorted in descending order of risk of exposure. For each sensitive data object in question, you can see where it is located, the data store in which it resides and the individual names and data matches for all of the associated infotypes found. Remediation status information is also present which provides a deeper insight into your sensitive data, confirming whether or not an encryption policy is active. No sensitive data is stored as part of the reporting process.

Exporting data

In addition to viewing objects using the built-in reporting tool, you can also export data in a NDJSON format for analysis by an external reporting tool such as one from Elastic used in Thales demonstrations

Reasons for our choice of architecture

Single integrated platform

We decided to make DDC an integral part of the Thales CipherTrust Data Security Platform because, in our experience, data discovery is the foundation of any effective data security strategy. This integrated platform approach enables CipherTrust Manager to act as the central management console for various connectors including data discovery, transparent encryption and tokenization. If you are using CTE already, you will be familiar with the console and will benefit from consistency in how common management tasks such as user groups, data policies, access control and logging are implemented.

Accurate pattern matching

Thales performed an extensive investigation to determine the best data discovery technology in the market. After much research and bench testing, the team experienced a significant difference using GLASS Technology™ over regex. GLASS is a proprietary market-leading technology from Ground Labs (a Thales Technology Partner) for defining and matching simple and complex patterns of data at scale as opposed to a developer code language not built specifically for purpose. It was designed from the ground up with the express purpose of finding patterns of data in modern data sets across both structured and unstructured data storage scenarios.

High performance discovery

An important goal was to provide a highly efficient and accurate discovery engine. Most data discovery solutions available today use the regular expression (regex) language (originating from the 1950's) to search for patterns inside text strings. This approach requires extensive developer knowledge to implement and the syntax is not based on English grammar. The biggest enemy of regex is performance – as pattern concurrency and complexity increases, the slower the performance achieved. Regex has limits to the patterns it can match accurately, making it far from ideal in the modern world where there are hundreds of different privacy regulations and a broad range of data management issues to address.

Easy customization capabilities

Customization support was another important criteria to supplement the comprehensive prebuilt templates. To address proprietary needs, GLASS data patterns can be written by non-developers using English-style grammar to express how a piece of data or pattern exists. Detailed analysis shows it has overcome all important regex limitations for pattern matching techniques, especially its ability to operate across multiple platform and cloud environments, while being very frugal in terms of CPU overhead. This made GLASS an ideal core component for embedding inside DDC, working efficiently and transparently as part of the CipherTrust platform in identifying and securing critical data.

Flexible licensing model

A consumption model based on total data scanned is used to license DDC, providing close alignment with many cloud subscription models and offering an unlimited number of discovery agents without incurring any additional fees. This makes it much easier for all your teams to have access to the data discovery capabilities, with the only real decision to make is how much overall data discovery capacity is required for your organization. Re-scanning existing data does not subtract from your remaining allowance, only new data scanned is counted.

Security first

Naturally as a market leading security company we design and implement secure solutions. DDC is no exception with strong emphasis on ensuring no sensitive data is stored or vulnerable to exposure:

- Ensuring that all data flowing between your data stores and the agents is protected using strong encryption
- Providing granular access controls so that you can tailor the solution to your exact needs

Integrating with other solutions

CipherTrust DataSecurity Platform

DDC is optimized for use as part of the CipherTrust Data Security Platform, an integrated suite of data-centric security products and solutions that unify data discovery, protection and control in one platform. Consequently you can cover all data protection needs using a single platform from one vendor, in this case Thales. This provides you with a full suite of data protection capabilities including key management, user access control, file-level encryption, application-layer encryption, database encryption, format-preserving encryption, tokenization and data masking.

CipherTrust Manager

All components utilize CipherTrust Manager as their management console, delivering central management of encryption keys, granular access control and security policy configuration. One key advantage is that our solution is designed to protect your data wherever it resides, on-premises or in the cloud and whatever storage mechanism is in use, such as files, databases, big data or containers. Ultimately you will end up requiring fewer resources dedicated to data security operations, meet your compliance obligations with greater confidence and reduce the business risk to your organization.

It is also possible to deploy DDC alongside other third party data protection tools, such as those supporting data encryption or tokenization for example. It is non-intrusive, complementing tools you have already, rather than replacing them. However, CipherTrust Manager is still necessary since it provides the sole method to launch the data discovery capability and to manage the licenses required for its operation together with keys required for encrypting sensitive data.

Some of the main reasons Thales customers have been using DDC in conjunction with third party products include:

We often get asked... **'What is the difference between CipherTrust Data Discovery and Classification and other Data Loss Prevention (DLP) solutions?'**

The DLP solutions focus on preventing sensitive data from leaving the organization's perimeter. DDC focuses on data privacy - identifying sensitive data, and getting a clear understanding of data and its risk. This enables appropriate steps to be taken to protect data and comply with data privacy and data security regulations.

- Trying to fill gaps in coverage since their existing discovery tool cannot scan all their structured and unstructured data
- Seeking higher accuracy with data matches to eliminate the limitations they are experiencing with regex technology
- Supporting a wider range of operating systems and platforms to interrogate more of their data footprint

Key takeaways

CipherTrust Data Security Platform

Discover

Protect

Control

Your data management and protection strategy can ultimately be improved significantly using CipherTrust Data Discovery and Classification. In conjunction with CipherTrust Manager and CipherTrust Transparent Encryption it provides considerable visibility and insight into your sensitive data while offering quick and effective protection options. It enables you to:

Block unnecessary data access to reduce risk of data breaches

Keep up to date with the evolving regulatory landscape to remain in compliance

Address digital transformation concerns relating to cloud security to support business and technology goals

****Try our free 90 day evaluation to see for yourself how it can help your organization now***

Abbreviations

ACL	Access Control List
CDSP	CipherTrust Data Security Platform

NAS	Network-attached Storage
REST API	Representational State Transfer Application Programming Interface
TDP	Thales Data Platform
NAS	Network-attached Storage

Glossary

Classification profile	A classification profile uses a list of infotypes to define what kind of sensitive information to search for during a scan
Connector	A connector is a generic term which relates to the different licensable products or components (which includes DDC and CTE) that are managed using the CipherTrust Manager console
CTE agent	A CTE agent is a software component that is used to encrypt data associated with GuardPoints defined using CTE policies
Data match	A data match occurs during a scan when a qualified instance of an infotype actively included in the scope of the search is found
Data object	A file or database table located inside a data store is known as a data object
Data store	A data store is the entity where the data is actually stored, with DDC supporting various types - local, network, database, Big Data and cloud
DDC agent	A DDC agent is a software component that is used to scan a data store for specific types of data defined using infotypes in the associated
Discovery	classification profile
False negatives	Data discovery is the process of mapping an organization's data assets including their locations, types and sensitivity levels
False positives	False negatives are where the discovery process fails to identify one or more valid instances of sensitive data
GuardPoint	A GuardPoint specifies the list of folders or paths to be protected –access to files and encryption of files under the GuardPoint is controlled by security policies
Infotype	An infotype is used to categorize specific data (such as passport numbers or email addresses) to look for during a discovery scan, forming an integral component in the definition of a classification profile
Policy	A policy is a collection of rules that govern data access and encryption
Remediation	Remediation refers to the process of protecting (or securing) data that has been identified as vulnerable as the result of a scan – typical remediation methods include encryption, tokenization, data masking and access control
Resource set	A resource set refers to the files or directories to which the policy will apply together with the associated governing key rules
Risk	A risk is the presence of a sensitive data object in a data store and is directly related to the data matches found in the data object or data store
Scan	A scan is part of the discovery process that is used to search for sensitive data within data stores using criteria defined in classification profiles
Sensitive data object	A data object that contains any data match is known as a sensitive data object

Sensitivity level	The sensitivity level is a mandatory parameter (when defining data stores and classification profiles) relating to the degree of potential vulnerability of any given data object if exposed
Structured data	Structured data is highly organized and easily understood by machine language – examples include names, dates, addresses, credit card numbers, stock information, geolocation and more
Tag	A tag helps group data together and can be specified when creating data stores and classification profiles
Thales Data Platform	The Thales Data Platform (TDP) is a Big Data platform based on Hadoop technology which is used by DDC for various tasks including storage of scan results
Unstructured data	Unstructured data is information that either does not have a pre-defined data model (or schema) or is not organized in a pre-defined manner, making it unsuitable for storage in a relational database

Sumário executivo

O crescimento rápido, muitas vezes exponencial, de dados ano a ano em empresas como a sua torna o gerenciamento eficaz de dados uma proposta extremamente desafiadora. A crescente mudança para o trabalho remoto eleva ainda mais o nível de exigência, com muitas áreas ou volumes de armazenamento de dados que estão fora do controle direto da sua equipe de TI.

Como parte do grupo mais amplo de sua empresa responsável pela conformidade com a privacidade e a segurança dos dados, é de suma importância garantir que nenhuma área vulnerável seja negligenciada ao implementar sua estratégia de proteção de dados. Afinal de contas, uma violação de dados inevitavelmente causará graves interrupções nos negócios, além de grandes multas incorridas pela não conformidade com o fluxo aparentemente interminável de leis e normas de privacidade de dados novas ou aprimoradas. Deixar de se preparar adequadamente definitivamente não é uma opção viável para você.

Um ponto fraco significativo frequentemente observado em implementações típicas de gerenciamento de dados é a falta de visibilidade dos tipos precisos de dados mantidos em vários servidores locais, unidades de rede e, cada vez mais, locais de armazenamento em nuvem. Muitas empresas já sofreram violações, algumas passaram por situações de quase violação e outras estão migrando grandes cargas de trabalho para a nuvem sem entender completamente a natureza fundamental dos dados em si e os riscos de exposição envolvidos, situações que você deve evitar.

Antigamente, o conhecimento da equipe era suficiente e os métodos simples de criptografia “prontos para uso” de fornecedores de banco de dados satisfaziam as necessidades, mas isso não é mais suficiente com a vasta superfície de dados que está amplamente dispersa e cresce a cada segundo. É inevitável que você precise de assistência para assumir o controle e manter sua empresa segura.

A solução CipherTrust Data Discovery and Classification da Thales é...

Uma ferramenta que é significativamente mais eficaz e eficiente do que os métodos manuais para a descoberta de dados, pois examina todos os alvos e não apenas uma amostragem dos dados. Esta ferramenta ajuda a classificar todos os seus dados, ao mesmo tempo em que oferece suporte a todos os principais sistemas operacionais, tipos de armazenamento de dados e dados estruturados e não estruturados que você provavelmente possui. Os processos e as ferramentas existentes são complementados, e não substituídos, proporcionando altos níveis de automação em sua busca por dados confidenciais, onde quer que eles estejam. Por fim, ela pode ajudar você a se tornar mais ágil e ajuda a tomar melhores decisões de gerenciamento de dados.

Encontra dados confidenciais que você talvez não saiba que existem em sua empresa, ajudando a eliminar ameaças à continuidade dos seus negócios e reduzir a superfície de dados

Permite avaliar rapidamente os riscos da falta de conformidade e determinar medidas de proteção adequadas

Garante a proteção dos dados certos, como dados proprietários ou propriedade intelectual, em todos os locais de armazenamento de dados, incluindo na nuvem

O papel da CipherTrust Data Discovery and Classification (DDC)

A DDC oferece uma abordagem mais simplificada, precisa e autônoma (ou automatizada) em comparação com as pesquisas de dados confidenciais que usam métodos manuais. A DDC se destaca dos produtos da concorrência por abranger tipos adicionais de armazenamento de dados, ampliando a gama de dados estruturados e não estruturados que podem ser analisados e, ao mesmo tempo, oferecendo níveis mais altos de precisão ao encontrar dados confidenciais que outras ferramentas geralmente deixam passar.

Os elementos confidenciais encontrados pela DDC não se restringem apenas às leis e normas de privacidade de dados. A fina sintonia que usa infotipos personalizados (definidos por você) facilita a visibilidade de onde os dados confidenciais da sua organização estão presentes. Ao permitir que itens críticos (como dados financeiros internos, segredos comerciais, propriedade intelectual e planos de negócios confidenciais) sejam localizados, seus níveis atuais de proteção e os riscos associados de exposição não intencional podem ser mais bem compreendidos. A flexibilidade considerável vem da execução de várias varreduras simultaneamente, cada uma buscando diferentes tipos de informações (se desejado) para criar uma maneira mais rápida e eficiente de analisar o volume completo de dados em uma ampla variedade de locais de armazenamento. É a capacidade de criar vários perfis de classificação (personalizados quando necessário) que sustenta esses benefícios de desempenho e eficiência que nunca poderiam ser obtidos em um período de tempo comparável usando métodos manuais ou ferramentas menos capazes.

Descobrir dados é apenas uma parte da tarefa em questão, a classificação é igualmente importante, fornecendo uma compreensão aprofundada dos tipos de dados e sua pegada em sua empresa. A DDC não move nem modifica seus dados, apenas resume o que descobre durante as varreduras de maneira não intrusiva.

Você pode ver **exatamente como seus dados estão divididos** entre as categorias dados pessoais, financeiros, de saúde e de identificação nacional, e talvez se surpreenda com a existência de alguns deles. Pelo menos agora você terá uma visão exata de onde eles se encontram para gerenciar adequadamente o risco comercial.

Os insights disponíveis após a realização das varreduras fornecem **orientações importantes** sobre o que você precisa fazer, especialmente em relação à proteção. Você pode escolher quantas varreduras deseja incorporar em um determinado relatório. Cada relatório melhora a visibilidade dos dados, fornecendo informações detalhadas sobre:

Nomes dos infotipos encontrados com o número de correspondências de dados confidenciais

O risco associado a cada um dos objetos de dados analisados durante a varredura em questão

O status de proteção para poder ver o que está protegido e o que não está

A DDC oferece opções para executar varreduras a qualquer momento e repetidas vezes, se você quiser. A ferramenta deve ser usada regularmente para manter sua percepção atualizada, em vez de ser apenas uma atividade eventual. Como os dados estão sempre em um estado de fluxo, a DDC está pronta para transmitir a representação real mais recente do que você tem e do que pode ser necessário fazer para manter sua empresa segura.

A descoberta de segredos é um componente essencial da cibersegurança e da proteção de dados. Isso envolve a identificação de informações confidenciais, como chaves de API, senhas e números da previdência social, que podem ser expostas inadvertidamente em sistemas ou aplicativos.

É difícil ter visibilidade de segredos, pois eles estão em muitos lugares diferentes. Os desenvolvedores geralmente os espalham em repositórios de código, arquivos de configuração e dispositivos pessoais, o que torna a descoberta e o gerenciamento deles um desafio. Sistemas mais antigos, falsos positivos e o erro humano tornam a descoberta de segredos um desafio, especialmente porque os cibercriminosos estão sempre criando novas maneiras de explorar essas vulnerabilidades. Quando segredos como tokens, chaves de API, senhas ou nomes de usuário são descobertos por criminosos, eles podem ser usados para invadir os sistemas de TI. A CipherTrust Data Discovery and Classification utiliza IA para examinar proativamente o código em busca de padrões específicos, tornando os desenvolvedores cientes deles antes que se tornem ameaças à segurança. Secrets Discovery é um recurso da CipherTrust Data Discovery and Classification da Thales e é a ferramenta de descoberta de segredos mais abrangente e confiável do mercado atual. Ele ajuda a interromper proativamente agentes criminosos antes que eles obtenham acesso não autorizado aos seus dados. Embora existam outros provedores para a descoberta de segredos, eles não sabem contar a história completa da descoberta, proteção e controle como a Thales pode. A solução da Thales é abrangente e não requer soluções de envio de peças, como acontece com muitas soluções da concorrência.

Como tudo se encaixa

A DDC é configurada usando uma interface gráfica de usuário (iniciada a partir do console CipherTrust Manager) ou por meio da API REST. Esta solução oferece um fluxo de trabalho simples e intuitivo, permitindo que você defina locais de dados para questionamentos, especifique os tipos de dados que deseja descobrir e decida quando e com que frequência deseja repetir o processo de varredura. As visualizações avançadas fornecem uma visão aprofundada das correspondências de dados confidenciais, do status de proteção associado e da avaliação de risco dos locais dos dados em questão. Os principais recursos estão resumidos nas seções abaixo, fornecendo uma visão bem definida do poder, da flexibilidade e do controle disponíveis para você.

O fluxo de trabalho da DDC é fácil de seguir por meio da interface do usuário. **Três ingredientes principais** ajudam a definir seu ambiente: **armazenamentos de dados, perfis de classificação e infotipos**.

Normalmente, você pode adotar a seguinte sequência ao usar a DDC pela primeira vez:

Selecione e configure **armazéns de dados** de interesse – recomendamos primeiro se concentrar nos armazenamentos de dados mais frequentemente acessados e em um caminho selecionado em vez de todo o armazenamento.

Selecione um ou mais **perfis de classificação** – cria perfis de classificação personalizados, se necessário. Durante esse processo, seleciona um ou mais **infotipos** de interesse - utiliza a capacidade de infotipo personalizado se a lista criada for insuficiente.

Configure e inicie a **varredura** – considere a possibilidade de selecionar apenas um armazenamento de dados para sua primeira análise, a fim de testar sua configuração.

Armazenamentos de dados

Armazenamento local	Armazenamento local SharePoint sob demanda Servidor Exchange Windows e Linux locais	Armazenamento em rede - Windows Share (CIS/SMB) - Sistema de arquivos Unix (NFS)
Armazenamento em rede	Windows share (CIS/SMB)	
Banco de dados	BM DB2 Microsoft SQL MongoDS MySQL	Oracle DB PostgreSQL SAP HANA SQL
Big data	Hadoop clusters	Teradata
Nuvem	AWS S3 Buckets Azure Blobs e Table Google Workspace (Gmail e Gdrive)	Azure Table Office 365 (Exchange, SharePoint, & OneDrive) SalesForce

Tipos de arquivos suportados

Bancos de dados	Access Dbase	SQLite MSSQL MDF e LDF	Microsoft Office	v5 6 95 97 2000	XP 2003 em diante Arquivos Office: Word, Excel, PowerPoint. Access, Outlook, Other(.pub e .xps)
Imagens	BMP FAX GIF JPG	PDF (integrado) PNG TIF	Código aberto	Star Office /Open Office/Libre Office	
Compactados	Bzip2 Gzip (todos os tipos)	TAR ZIP (todos os tipos)	Padrões abertos	PDF RTF HTML	XML CSV TXT
Microsoft Backup Archive	Microsoft Binary/ KF				

Tipos de arquivos suportados

APA	Australia Privacy Amendment	HIPAA	Health Insurance Portability and Accountability Act
APPI	Act on Protection of Personal Information	KVKK	Lei turca de proteção de dados pessoais
CCPA	California Consumer Privacy Act	LGPD	Lei Geral de Proteção de Dados (Brasil)
GDPR	Finanças	NYDFS	New York State Department of Financial Services
GDPR	General Data Protection Regulation	PCI DSS	Payment Card Industry DataSecurity Standard
GDPR	Saúde	SHIELD	Privacy Shield Framework
GDPR	Identidade do sistema nacional de saúde	UK-GDPR	General Data Protection Regulation (UK)
GDPR	Dados pessoais		

A cobertura de dados estruturados e não estruturados fornecida pela DDC é atualizada frequentemente com novos recursos. Confira as especificações mais recentes aqui.

Os principais perfis de classificação estão integrados e alinhados com as principais leis e regulamentações de dados, tanto regionais quanto globais. É possível fazer alterações nesses perfis ou adicionar perfis totalmente novos, se necessário. Vários atalhos são fornecidos em termos de edição e cópia para que você possa criar e testar rapidamente seus próprios perfis. Há total flexibilidade na especificação de vários parâmetros, incluindo níveis de sensibilidade e infotipos.

Tipos de arquivos suportados

Nenhum	Público	Interno
Privado	Restrito	

Categorização de dados confidenciais

A DDC já vem com vários infotipos, mais de 250, abrangendo a grande maioria das leis e normas regionais e globais de privacidade de dados. Quando um modelo de perfil de classificação já existente é selecionado, o subconjunto apropriado de infotipos é adicionado automaticamente. Você pode modificar ou ampliar essa lista criando seus próprios infotipos personalizados, permitindo que sejam definidas regras que descrevam precisamente como o mecanismo de varredura deve procurar as cadeias de dados em questão. O acesso total aos grupos e categorias está disponível como parte da definição, de modo que as correspondências de dados possam ser exibidas nas seções apropriadas dos resultados da varredura.

Categorias de infotipos (já no produto)

Finanças	Cartões de crédito/débito	Informações de conta bancária
Dados pessoais	E-mails Credenciais de login Número do cartão Etnia Número da placa Número de registro Número do passaporte Data de nascimento Endereço MAC	Lista de endereços Número do telefone Sexo Religião Endereço IP Número do celular Nome Profanidade
Saúde	Informações de saúde do paciente	
Identidade do sistema nacional de saúde	Identificação pessoal	
Segredos	Descoberta de segredos	

Uso de agente para descoberta

A análise detalhada dos dados é realizada por agentes de descoberta que executam a varredura e informam os resultados ao DDC Connector para análise e processamento. Existem dois tipos de agentes: local e proxy. Normalmente, você instalaria agentes locais em locais de armazenamento de dados (para os quais você tem os direitos de acesso apropriados) para garantir que os dados nunca saiam do servidor por motivos de segurança ou desempenho. Por outro lado, os agentes proxy são usados para armazenamentos de dados em rede ou remotos, nos quais um servidor proxy separado hospeda o agente.

Tipo de agente	Prós	Contras
Local	Varredura mais rápida Os dados permanecem locais Não é preciso credencial	Tempo de implementação mais longo Gerenciamento mais complexo Suporta apenas armazenamentos de dados locais
Proxy	Implementação e dimensionamento mais rápidos Capacidade de fazer varredura de múltiplos armazenamentos de dados Suporte a vários tipos de armazenamentos de dados Nenhum recurso consumido no host de destino	Dados enviados pela rede para o agente antes da varredura Aumento da carga da rede e da superfície de dados O ideal é que estejam localizados na mesma LAN virtual (VLAN)

Benefícios comuns de ambos os tipos de agentes:

Um **número ilimitado** de agentes disponíveis para implementação sem custo extra, pois o licenciamento é baseado no volume de dados novos analisados

É possível executar várias subvarreduras para reduzir o tempo necessário para a varredura geral

A criptografia TLS está disponível para todas as comunicações entre armazenamentos de dados e agentes para proteger dados confidenciais contra escutas

Os dados de origem não são afetados, pois os agentes acessam apenas uma cópia temporária dos dados na memória interna durante a varredura

Os dados confidenciais não são armazenados durante o processo, pois é enviado apenas um resumo dos resultados da varredura para o DDC Connector

As varreduras **continuam** e registram resultados mesmo quando a conexão com o DDC Connector for cortada

Com seus agentes instalados, você pode começar a pensar sobre o que e como deseja fazer a varredura. Ofecemos uma grande flexibilidade na forma como as varreduras são configuradas, gerenciadas e operadas. Os parâmetros importantes configuráveis para cada varredura de forma independente incluem:

- Nome (até 64 caracteres)
- Descrição (até 250 caracteres)
- Um ou mais armazenamentos de dados (onde fazer a varredura)
- Um ou mais perfis de classificação (o que procurar)
- Operação manual ou programada (quando ativar)

Após a conclusão de uma determinada varredura, ela é adicionada a uma lista de todas as varreduras que foram realizadas. Após, utiliza-se a ferramenta de relatório para visualizar os resultados detalhados da varredura. Dependendo do que for encontrado, você poderá fazer alterações na configuração da varredura e executá-la novamente, o que é vantajoso ao trabalhar em diferentes armazenamentos de dados ou em novos tipos de normas de conformidade pela primeira vez.

Análise de resultados da varredura

Os resultados de varreduras anteriores e novas estão disponíveis para uso com a ferramenta de relatório integrada. São oferecidas três principais exibições para relatórios de varredura:

- **Varreduras**
- **Armazenamentos de dados**
- **Objeto de dados**

Antes que as informações detalhadas estejam disponíveis, é gerado um relatório que agrega os resultados de uma ou mais varreduras de sucesso. Muitas vezes, por motivos logísticos, de segurança ou de desempenho, você pode querer usar várias varreduras (cada uma procurando diferentes tipos de dados regulamentados) para analisar todo o seu espaço de dados. Com nossa abordagem flexível, você ainda pode fazer isso e ajustar cada varredura conforme necessário, usando várias iterações, antes de gerar um relatório final que possa representar o status atual de todos os seus dados. Também é fácil entender sua postura organizacional do ponto de vista de um único regulamento.

Cada guia do módulo de relatório oferece uma visão de aspectos ligeiramente diferentes dos seus dados - todas, porém, têm o objetivo comum de ajudar a identificar rapidamente quaisquer dados confidenciais em risco.

Visualização de varreduras

Fornece uma visão de varredura agregada de alto nível dos infotipos encontrados (divididos por porcentagem em cada categoria presente), juntamente com três outros gráficos que representam a presença de objetos de dados confidenciais em termos de distribuição de categorias, tipos de conteúdo e tipos de arquivo em questão.

Visualização dos armazenamentos de dados

Fornece uma lista dos armazenamentos de dados com detalhes que incluem risco, nível de confidencialidade, infotipos encontrados e número de objetos de dados confidenciais presentes em cada armazenamento de dados. Isso proporciona um meio rápido de avaliar em alto nível se os dados confidenciais estão ou não em risco e quais armazenamentos de dados estão envolvidos.

Visualização de objeto de dados

Fornece uma lista detalhada de todos os objetos de dados verificados que contêm dados confidenciais classificados em ordem decrescente de risco de exposição. Para cada objeto de dados confidenciais em questão, é possível ver onde ele está localizado, o armazenamento de dados no qual ele reside e os nomes individuais e as correspondências de dados para todos os infotipos associados encontrados. As informações sobre o status da correção também estão presentes, o que proporciona uma visão mais profunda dos seus dados confidenciais, confirmando se uma política de criptografia está ativa ou não. Nenhum dado confidencial é armazenado como parte do processo de relatório.

Exportação de dados

Além de visualizar objetos usando a ferramenta de relatório integrada, você também pode exportar dados em um formato NDJSON para análise por uma ferramenta de relatório externa, como a da Elastic usada nas demonstrações da Thales.

Motivos da nossa escolha de tipo de arquitetura

Plataforma única e integrada

Decidimos fazer da DDC uma parte integrante da Plataforma CipherTrust Data Security da Thales CipherTrust porque, em nossa experiência, a descoberta de dados é a base de qualquer estratégia eficaz de segurança de dados. Essa abordagem de plataforma integrada permite que o CipherTrust Manager atue como o console de gerenciamento central para vários conectores, incluindo descoberta de dados, criptografia transparente e tokenização. Se já estiver usando o CTE, você estará familiarizado com o console e se beneficiará da consistência na implementação de tarefas comuns de gerenciamento, como grupos de usuários, políticas de dados, controle de acesso e login.

Correspondência precisa de padrões

A Thales realizou uma extensa pesquisa para determinar a melhor tecnologia de descoberta de dados do mercado. Após muitas pesquisas e testes de bancada, a equipe percebeu uma diferença significativa ao usar a GLASS Technology™ em vez da Regex. A GLASS é uma tecnologia proprietária líder de Ground Labs (um parceiro tecnológico da Thales) para definir e combinar padrões simples e complexos de dados em escala, em oposição a uma linguagem de código de desenvolvedor não criada especificamente para esse fim. Ela foi projetada desde o início com o objetivo expresso de encontrar padrões de dados em conjuntos de dados modernos em cenários de armazenamentos de dados estruturados e não estruturados.

Descoberta de alto desempenho

Um objetivo importante era fornecer um mecanismo de descoberta altamente eficiente e preciso. A maioria das soluções de descoberta de dados disponíveis atualmente usa a linguagem de expressão regular (Regex) (originada na década de 1950) para pesquisar padrões dentro de sequências de texto. Essa abordagem requer amplo conhecimento do desenvolvedor para ser implementada e a sintaxe não se baseia na gramática inglesa. O maior inimigo do Regex é o desempenho, à medida que a simultaneidade e a complexidade dos padrões aumentam, mais lento é o desempenho obtido. O padrão Regex tem limites para os padrões que pode corresponder com precisão, o que o torna longe de ser ideal no mundo moderno, onde há centenas de regulamentações de privacidade diferentes e uma ampla gama de problemas de gerenciamento de dados a serem abordados.

Recursos fáceis de personalização

O suporte à personalização foi outro critério importante para complementar os modelos abrangentes incluídos. Para atender às necessidades proprietárias, os padrões de dados GLASS podem ser escritos por não desenvolvedores usando uma gramática no estilo inglês para expressar como um dado ou padrão existe. A análise detalhada mostra que ele superou todas as limitações importantes do Regex para técnicas de correspondência de padrões, especialmente sua capacidade de operar em várias plataformas e ambientes de nuvem, além de ser muito econômico em termos de sobrecarga da CPU. Isso fez do GLASS um componente central ideal para ser incorporado à DDC, funcionando de forma eficiente e transparente como parte da plataforma CipherTrust na identificação e proteção de dados críticos.

Modelo de licenciamento flexível

Um modelo de consumo baseado no total de dados analisados é usado para licenciar a DDC, proporcionando um alinhamento próximo com muitos modelos de assinatura de nuvem e oferecendo um número ilimitado de agentes de descoberta sem incorrer em taxas adicionais. Isso facilita muito o acesso de todas as suas equipes aos recursos de descoberta de dados, sendo que a única decisão real a ser tomada é a capacidade geral de descoberta de dados necessária para a sua empresa. Uma nova varredura de dados antigos não é subtraída da sua franquia de uso de dados restante, apenas os novos dados analisados são contabilizados.

Plataforma CipherTrust Data Security da Thales

Segurança em primeiro lugar

Como uma empresa de segurança líder de mercado, é óbvio que criamos e implementamos soluções seguras. A DDC não é exceção, com grande ênfase em garantir que nenhum dado confidencial seja armazenado ou fique vulnerável à exposição.

- Garante que todos os dados que fluem entre seus armazenamentos de dados e agentes sejam protegidos usando criptografia robusta
- Fornece controles de acesso granulares para que você possa adaptar a solução às suas necessidades exatas

Integração com outras soluções

Plataforma CipherTrust DataSecurity

A DDC foi otimizada para ser usada como parte da plataforma CipherTrust Data Security, um conjunto integrado de produtos e soluções de segurança centrados em dados que unificam a descoberta, proteção e controle de dados em uma única plataforma. Consequentemente, você pode atender a todas as necessidades de proteção de dados usando uma única plataforma de um único provedor, neste caso a Thales. Isso lhe oferece um conjunto completo de recursos de proteção de dados, incluindo gerenciamento de chaves, controle de acesso do usuário, criptografia no nível do arquivo, criptografia na camada de aplicativos, criptografia de banco de dados, criptografia com preservação de formato, tokenização e mascaramento de dados.

CipherTrust Manager

Todos os componentes utilizam o CipherTrust Manager como console de gerenciamento, oferecendo gerenciamento central de chaves de criptografia, controle de acesso granular e configuração de políticas de segurança. Uma das principais vantagens é que nossa solução foi projetada para proteger seus dados onde quer que eles residam, no local ou na nuvem, e qualquer que seja o mecanismo de armazenamento em uso, como arquivos, bancos de dados, big data ou containers. Por fim, você acabará exigindo menos recursos dedicados às operações de segurança de dados, cumprirá suas obrigações de conformidade com mais confiança e reduzirá o risco comercial para a sua empresa.

Também é possível implementar a DDC com outras ferramentas de proteção de dados de terceiros, como as que oferecem suporte à criptografia ou tokenização de dados. Nossa solução não é intrusiva e complementa as ferramentas que você já possui, em vez de substituí-las. No entanto, o CipherTrust Manager ainda é necessário, pois fornece o único método para iniciar o recurso de descoberta de dados e

gerenciar as licenças necessárias para sua operação, juntamente com as chaves necessárias para criptografar dados confidenciais.

Alguns dos principais motivos pelos quais os clientes da Thales têm usado a DDC junto com produtos de terceiros incluem:

Muitas vezes nos perguntam... **"Qual é a diferença entre a CipherTrust Data Discovery and Classification e outras soluções de prevenção contra perda de dados (DLP)?"**

Descoberta

Proteção

Controle

As soluções de DLP se concentram em impedir que dados confidenciais saiam do perímetro da empresa. A DDC se concentra na privacidade de dados, identificando dados confidenciais e obtendo uma compreensão clara dos dados e seus riscos. Isso permite as medidas adequadas para proteger seus dados e o cumprimento das normas de privacidade e segurança de dados.

- Nossa solução corrige erros na cobertura, já que a ferramenta de descoberta existente não pode fazer a varredura de todos os dados

Bloqueie o acesso desnecessário a dados para reduzir o risco de violações de dados

Mantenha-se atualizado com a evolução do panorama regulamentar para permanecer em

Aborda as preocupações com a transformação digital sobre segurança na nuvem para ajudar com objetivos empresariais e tecnológicos

estruturados e não estruturados

- Busca maior precisão nas correspondências de dados para eliminar as limitações que estão enfrentando com o padrão Regex
- Suporte a uma gama mais ampla de sistemas operacionais e plataformas para questionar mais a pegada de dados

Principais conclusões

Plataforma CipherTrust Data Security

Sua estratégia de gerenciamento e proteção de dados pode ser melhorada significativamente com a solução CipherTrust Data Discovery and Classification. Junto com o CipherTrust Manager e o CipherTrust Transparent Encryption, ela proporciona visibilidade e percepção consideráveis de seus dados confidenciais, oferecendo opções de proteção rápidas e eficazes. A solução permite:

***Experimente nossa avaliação gratuita de 90 dias para ver por si mesmo como nossa solução pode ajudar sua empresa agora.**

Abreviações

ACL	Lista de controles de acesso
CDSP	Plataforma CipherTrust Data Security
CIFS	Common Internet File System
CM	CipherTrust Manager
CTE	CipherTrust Transparent Encryption
DB	Banco de dados
DDC	CipherTrust Data Discovery and Classification
GUI	Interface gráfica do usuário
NAS	Armazenamento conectado à rede
REST API	Aplicativo de transferência de estado representacional Interface de programação
TDP	Plataforma de dados da Thales
NAS	Armazenamento conectado à rede

Glossário

Perfil de classificação	Um perfil de classificação usa uma lista de infotipos para definir o tipo de informação confidencial a ser pesquisada durante uma varredura
Conector	Um conector é um termo genérico relacionado aos diferentes produtos ou componentes licenciáveis (que incluem DDC e CTE) que são gerenciados usando o console CipherTrust Manager
Agente CTE	Um agente CTE é um componente de software usado para criptografar dados associados a GuardPoints definidos usando políticas CTE
Correspondência de dados	Uma correspondência de dados ocorre durante uma varredura quando é encontrada uma instância qualificada de um infotipo incluído no escopo da pesquisa
Objeto de dados	Um arquivo ou tabela de banco de dados localizado em um armazenamento de dados é conhecido como objeto de dados
Armazenamento de dados	Um armazenamento de dados é a entidade onde os dados são realmente armazenados, com a DDC oferecendo suporte a vários tipos: local, rede, banco de dados, big data e nuvem
Agente DDC	Um agente DDC é um componente de software usado para verificar um armazenamento de dados em busca de tipos específicos de dados definidos por meio de infotipos associados
Descoberta	perfil de classificação
Falsos negativos	A descoberta de dados é o processo de mapeamento dos ativos de dados de uma organização, incluindo seus locais, tipos e níveis de confidencialidade
Falsos positivos	Os falsos negativos ocorrem quando o processo de descoberta não consegue identificar uma ou mais instâncias válidas de dados confidenciais
GuardPoint	Um GuardPoint especifica a lista de pastas ou caminhos a serem protegidos, o acesso a arquivos e a criptografia de arquivos no GuardPoint são controlados por políticas de segurança
Infotipo	Um infotipo é usado para categorizar dados específicos (como números de passaporte ou e-mail) a serem procurados durante uma varredura de descoberta, formando um componente integral na definição de um perfil de classificação
Política	Uma política é um conjunto de regras que regem o acesso e a criptografia de dados
Remediação	Remediação se refere ao processo de proteção (ou segurança) dos dados que foram identificados como vulneráveis como resultado de uma varredura, os métodos típicos de correção incluem criptografia, tokenização, mascaramento de dados e controle de acesso.
Conjunto de recursos	Um conjunto de recursos se refere aos arquivos ou diretórios aos quais a política se aplicará, juntamente com as regras principais associadas
Risco	Um risco é a presença de um objeto de dados confidenciais em um armazenamento de dados e está diretamente relacionado às correspondências de dados encontradas no objeto de dados ou no armazenamento de dados
Varredura	Uma varredura faz parte do processo de descoberta usado para pesquisar dados confidenciais em armazenamentos de dados usando critérios definidos em perfis de classificação

Objeto de dados confidenciais	Um objeto de dados que contém qualquer correspondência de dados é conhecido como um objeto de dados confidenciais
Nível de confidencialidade	Nível de confidencialidade é um parâmetro obrigatório (ao definir armazenamentos de dados e perfis de classificação) relacionado ao grau de vulnerabilidade potencial de um determinado objeto de dados, se exposto
Dados estruturados	Os dados estruturados são altamente organizados e facilmente compreendidos pela linguagem de máquina, exemplos incluem nomes, datas, endereços, números de cartão de crédito, informações de estoque, geolocalização e muito mais
Tag	Uma tag ajuda a agrupar dados e pode ser especificada ao criar armazenamentos de dados e perfis de classificação
Plataforma de dados da Thales	A plataforma de dados da Thales (TDP) é uma plataforma de big data baseada na tecnologia Hadoop que é usada pela DDC para várias tarefas, incluindo o armazenamento de resultados de varreduras
Dados não estruturados	Dados não estruturados são informações que não têm um modelo de dados (ou esquema) predefinido ou não são organizados de maneira predefinida, o que os torna inadequados para armazenamento em um banco de dados relacionado

Thales CipherTrust Data Discovery and Classification

The crucial first step in privacy and data protection regulatory compliance is to understand what constitutes sensitive data, where it is stored, and how it is used. If you don't know what sensitive data you have, where it is, and why you have it, you cannot apply effective policies and controls to protect it.

Thales CipherTrust Data Discovery and Classification enables you to efficiently locate structured and unstructured regulated data across the cloud, big data, and traditional data stores in your enterprise. You get a complete understanding of your sensitive data and its risks, so you can make better decisions about closing your gaps, prioritizing remediation, securing your cloud transformation and third party data sharing.

Unlike alternative disjointed solutions that can leave data exposed or compromised, Thales CipherTrust Data Discovery and Classification provides a streamlined workflow all the way from policy configuration, discovery, and classification, to risk analysis and reporting. This eliminates security blind spots and complexities. As a result, you can easily uncover and mitigate your data privacy risks, enforce data sovereignty, and proactively respond to a growing number of data privacy and security regulations, including GDPR, CCPA, LGPD, PCI DSS and HIPAA.

Thales CipherTrust Data Discovery and Classification is available for sale to the U.S. Federal Government exclusively through Thales Trusted Cyber Technologies.

Effective for enterprise-wide data privacy

Thales CipherTrust Data Discovery and Classification is an enterprise-wide data privacy solution that is simple to deploy and scale. It provides a streamlined workflow to help you quickly discover your regulated data across traditional and cloud repositories.

Streamline data discovery and automate data protection

You can rely on Thales CipherTrust Intelligent Remediation to discovery, classify and use policy-based data encryption to automate data remediation and reduce business risk. It enables organizations to streamline processes, gain complete visibility to identify compliance gaps, automatically mitigate risks, and comply with data privacy and security regulations.

Quick start with built-in templates and flexibility for custom policies

Thales CipherTrust Data Discovery and Classification provides a comprehensive set of built-in classification templates for commonly requested data privacy and security regulations, such as GDPR, CCPA, etc., but is flexible enough to handle custom policies based on specific patterns, algorithms, and more.

Demonstrate compliance

Thales CipherTrust Data Discovery and Classification provides detailed reports that can help your auditors demonstrate compliance with various regulatory and business laws. Efficient scans enable you to build a strong foundation for overall data privacy and security.

Use Cases

- **Finding and classifying data:** Scans both structured and unstructured data using categorization techniques to find similar data more efficiently.
- **Enhancing security posture:** Delivers a detailed report of what sensitive data you have, where it resides and associated risk to help you make better decisions about what data needs protection.
- **Migrating data to the cloud:** Presents a detailed risk analysis prior to moving data to the cloud in order to qualify decisions based on solid facts.
- **Managing large data volume increases:** Maintains visibility of your data during rapid rises in storage and usage with a robust and scalable solution.
- **Ongoing compliance:** Keeps you up to date automatically with all major global and regional compliance requirements, while reducing the risk of failed audits or fines by proactively identifying compliance gaps.

Technical Specifications

Data Stores

- Local storage and local memory on the host
- Network storage
 - Windows Share (CIS/SMB)
 - Unix File System (NFS)
- Cloud
 - Office 365 Exchange Online
 - Office 365 SharePoint Online
 - Azure Blobs and Table
 - AWS S3
- Databases
 - IBM DB2
 - Oracle
 - SQL
 - PostgreSQL
 - SAP Hana
 - Teradata
 - MySQL
 - Mongo
- Big Data
 - Hadoop Clusters

Type of files supported

- Databases: Access, DBase, SQLite, MSSQL MDF & LDF
- Images: BMP, FAX, GIF, JPG, PDF (embedded), PNG, TIF
- Compressed: bzip2, Gzip (all types), TAR, Zip (all types)
- Microsoft Backup Archive: Microsoft Binary / BKF
- Microsoft Office: v5, 6, 95, 97, 2000, XP, 2003 onwards
- Open Source: Star Office / Open Office
- Open Standards: PDF, HTML, CSV, TXT

Type of data identified

- Health (US Health Insurance Claim number, etc.)
- Financial (American Express, Diners Club, Mastercard, VISA card numbers, bank account number, etc.)
- Personal (name, last name, address, DOB, email, etc.)
- National ID (social security number, etc.)
- Custom Information Types

Pre-built templates

The solution includes a wide range of ready-to-use templates that can help you meet common regulatory and business policy needs. For example:

- CCPA
- GDPR
- HIPAA
- PCI DSS
- LGPD
- NYDFS

Minimum RAM required

- 16GB.

Network Connection

- At least 1GB

CipherTrust Data Security Platform

CipherTrust Data Discovery and Classification is part of the CipherTrust Data Security Platform. The CipherTrust Platform unifies data discovery, classification, data protection, and provides unprecedented granular access controls, all with centralized key management. This simplifies data security operations, accelerates time to compliance, secures cloud migrations, and reduces risk across your business. You can rely on Thales CipherTrust Data Security Platform to help you discover, protect and control your organization's sensitive data, wherever it resides.

About Thales Trusted Cyber Technologies

Thales Trusted Cyber Technologies, a business area of Thales Defense & Security, Inc., protects the most vital data from the core to the cloud to the field. We serve as a trusted, U.S. based source for cyber security solutions for the U.S. Federal Government. Our solutions enable agencies to deploy a holistic data protection ecosystem where data and cryptographic keys are secured and managed, and access and distribution are controlled.

For more information, visit www.thalestct.com

Build a strong foundation for data privacy and security with CipherTrust Data Discovery and Classification

Data privacy in the spotlight

Today, the volume of enterprise data is exploding across industries. We talk about petabytes, and even exabytes, of data strewn across data centers, file shares, databases, cloud storage and backups. However, few organizations have the necessary visibility into their sensitive data to ensure its protection and to comply with regulatory requirements.

Most organizations simply do not know what sensitive data they have, where it is, how it flows, who can access it, and its risk of exposure. In organizations that are complex or have siloes of data, the lack of clear visibility into sensitive data can make it very difficult to apply effective policies and controls to protect this most critical asset.

Third-party risk is also a big concern. Vendors, partners, service providers, and others you share data with all add to your organization's risk not only for a data breach or a failed audit, but also for collateral damage to your customers' trust, your brand value, and your partner ecosystem.

Recently, high-profile data breaches have put data privacy in the spotlight. From lost business and reputational damage to devastating financial and legal consequences, the impact of a data breach can haunt companies for years.

However, that is just a part of the story. Stringent data privacy laws continue to be enacted around the world. This ever-evolving regulatory landscape leaves companies to interpret and comply with a growing patchwork of state, global, and industry-specific data privacy and security laws, creating significant risks for compliance. Clearly, companies need a simpler way to comply with regulatory requirements.

Data privacy versus data security

Data privacy and data security share a common goal to protect sensitive data, but they are not the same.

Data privacy focuses on the use and governance of personal data. It defines the policies to ensure that consumers' personal information is collected, shared, and processed in appropriate ways. It is about who has authorized access, and who can define or control it.

Data security focuses on protecting sensitive data from unauthorized access, malicious attacks, or misuse. A variety of tools, encryption techniques, and identity and access controls can be used to enforce policies and secure data.

For example, your organization may have deployed multiple layers of defense—encryption, key management, and access controls—to secure the sensitive data of your customers. But, if that data was collected, used, or shared with third parties without your customer's consent, you may be violating data privacy laws, even if the data is secured.

Thales CipherTrust Data Discovery and Classification

Thales CipherTrust Data Discovery and Classification enables your organization to get complete visibility of sensitive data with efficient data discovery, classification, and risk analysis across cloud, big data, and traditional environments. Thales Data Discovery and Classification is available for sale to the U.S. Federal Government exclusively through Thales Trusted Cyber Technologies.

The rich visualizations and insights provides a clear view of what sensitive data you have, where it resides, and its risk of exposure.

You can easily uncover and mitigate privacy risks, enforce data sovereignty, and comply with a growing number of data privacy and security regulations, including GDPR, CCPA, LGPD, PCI DSS and HIPAA.

Helps you uncover and mitigate data privacy risks

Thales CipherTrust Data Discovery and Classification streamlines the workflow from policy configuration, discovery, and classification, to risk analysis and reporting, enabling you to proactively mitigate risks and respond to evolving regulatory challenges.

1. Policies: Define your data privacy policies, data stores, classification profiles, and scans.
2. Discovery: Locate both structured and unstructured sensitive data across the entire enterprise in multi-cloud, big data, relational databases, or file storage systems.
3. Classification: Classify sensitive data, such as national IDs, financial data, and personal data, based on built-in templates or market-proven classification techniques.
4. Risk analysis: Understand your data and its risks with rich visualizations and risk scores.

5. Remediation: Remediate the risks with market leading data encryption and tokenization products and solutions available on the Thales CipherTrust Data Security Platform. CipherTrust Intelligent Remediation improves operational efficiency by applying the most appropriate protection immediately after sensitive data has been discovered.
6. Detailed reports Leverage charts and reports for risk analysis, status, and alerts throughout the data lifecycle.

Why Thales CipherTrust Data Discovery and Classification

Effective solution for enterprise-wide data privacy

- Efficiently locates structured and unstructured sensitive data across cloud, big data, and traditional data stores.
- Provides a comprehensive set of built-in templates for rapid discovery of your regulated or sensitive data.
- Available in agentless and/or agent-based deployment modes for reduced complexity and easy scalability.
- Offers a streamlined workflow that eliminates security blind spots and allows you to enforce unified policies.
- Supports a wide variety of datatypes, including custom Information Types.

Delivering complete visibility and control

- A centralized console with rich visualizations offers a clear view of sensitive data, allowing your organization to make informed decisions about cloud migration, data sharing, and risk remediation.
- Risk scores enable your security teams to uncover and close privacy gaps and prioritize remediation efforts.

Demonstrate compliance

- Detailed reports help your auditors demonstrate compliance to various regulations.
- Efficient scans enable you to build a strong foundation for your enterprise-wide data privacy and security.

Evaluation Guide : CipherTrust Data Discovery and Classification

Bringing agility and confidence to your data management

Thank you for agreeing to take part in an evaluation of the Thales [CipherTrust Data Discovery and Classification](#) (DDC) solution.

We are confident that it will help improve visibility on all the data in your organization, wherever it resides, enabling you to take the appropriate actions to protect sensitive or vulnerable assets with greater confidence.

About CipherTrust Data Discovery and Classification

Out of the box, CipherTrust Data Discovery and Classification (DDC) enables you to uncover the sensitive data you have (relating to all major privacy laws and regulations) and all the places it is stored, on-premises or in the cloud. Flexible customization capabilities enable you to discover and classify other sensitive assets, secrets and intellectual property, specific to you. Such comprehensive insight helps you make critical business decisions including precisely what data can be safely migrated to the cloud or shared with third parties for example.

The visual reports created as part of the discovery and classification analysis of the data locations you select are key to helping your team make better decisions about what specific data needs to be better protected – a strong factor in minimizing disruption in the event of a future data breach. Guidance is provided relating to data that can be eliminated, which if otherwise left to grow out of control could significantly increase both risk and liability for your organization.

Unlike the manual approach to searching for data, the use of our specialist solution eliminates the assumptions about what sensitive data may or may not exist – it provides a high degree of confidence that you are building a solid data management strategy with no critical data left unprotected.

Insights you can expect from your evaluation

The solution focuses on delivering rapid and insightful analysis of your data. You can configure scans to look for specific types of data in locations of your choice and then utilize the reporting module capabilities to establish what sensitive data you have, where it resides, its risk of exposure and any compliance gaps that may exist. You are then in prime position to take the necessary corrective actions.

The screen shots below provide a quick look at the main aspects you will be using.

Type of sensitive data stored (financial, national IDs, personal, medical)

Sensitive data location

Emergency-Response

Yes

A quick overview

As part of the CipherTrust Data Security Platform (CDSP), CipherTrust Data Discovery and Classification (DDC) allows you to search data repositories for sensitive data elements such as credit card numbers, tax IDs or personal information including names and email addresses. When the search is complete it can build reports that assess what data elements were present, their location within the data repositories and assign a risk assessment based upon the number and type of data elements found.

There are 3 main components of the solution.

- [CipherTrust Manager](#) (CM) – Management node where you use a browser interface to access this node to perform setup, define searches and view reports
- Thales Data Platform (TDP) – Thales-built Hadoop node which acts as the data repository of the solution for configuration and scan data
- Discovery Agent – The DDC agent which performs the data scan

The diagram below illustrates a typical DDC deployment. The agent component can be deployed directly on the server to be scanned or remotely on a proxy server. An agent deployed as a proxy can scan any supported databases or shared file systems. In contrast, a local agent must be deployed directly on servers to scan files that are only available on local file systems.

Typical DDC deployment

Steps to consider before deployment

There are some preparations you need to make before installing and using DDC. The table below provides guidance on ensuring you have the best possible environment in place to run your DDC evaluation.

Step	Action	Details
1.	Ensure you have suitable servers and network access	At certain stages of the installation you will need to install discovery agents – make sure you have details of the server names, their IP addresses to use and that the appropriate access rights are available to the team involved. The credentials required for all the locations to scan should have “read only” access rights.
2.	Decide which team members will participate in the evaluation	You may wish to check data belonging to different teams – make sure you have identified the critical people involved and secured their availability in advance.
3.	Clarify the locations and types of data stores to be part of your scans	Our recommendation would be to have clarity on the data store category, type and version in order to be able to properly select the agent for scanning. Specific information and supplementary guidance is provided in the online documentation. It is very important to select the correct agent and define the proper data store in order to be able to provide accurate scan results.
4.	Define the type(s) of data you wish to find	Ask the data owners well in advance, what types of data they wish to find during the evaluation – everything linked to data privacy laws are covered using pre-defined templates, but other data types proprietary to your organization will require extra preparation time (and subsequent use of the customization capabilities of the solution).
5.	Identify any data that is already encrypted (possibly using another vendor solution)	Will DDC be able to gain access to that data during the scan to perform some meaningful analysis? Please check with your Thales Account Manager or authorized reseller, if CipherTrust Manager is able to manage the keys for any third party product in question being used for the encryption.
6.	Decide when and how often you will activate the scans	Although the scanning process does not have any significant impact on the performance of your systems, you should start thinking about when you will run the scans and how many different types of scan you intend to perform during the evaluation period. Our recommendation is to start with simple scans over a small data footprint to gain experience of how long it takes in your environment - then you can add more complex search parameters and run more frequent scans. The targets, classification profiles, filters and frequency of the scan can be edited after a scan has been defined.
7.	Consider what action(s) you will take when you uncover sensitive data that is not protected	A main benefit of the evaluation is in qualifying whether or not you have sensitive data that is not currently protected. This may come as a surprise or you may have suspected such data would be found somewhere throughout your network of servers. If you are unfortunate enough to find regulated data that is not secure then you need to be prepared to take rapid corrective action to reduce your risk. Making use of other CipherTrust Data Security Platform connectors such as CipherTrust Transparent Encryption or CipherTrust Tokenization may prove to be an astute move.

Getting started

All of the documentation you need is available [online](#). To help you navigate through the important pieces, below you will find an outline of the minimal set of installation and configuration steps you need to complete before you can start defining the locations you wish to scan for sensitive data.

Pre-requisites:

- 1) Make sure you fulfill all the [requirements](#) for having DDC in place before you start with the installation steps

Installation steps:

- 1) If you are new to the CipherTrust platform or wish to install a separate version of CipherTrust Manager to use with your DDC evaluation, then you need to [install Virtual CipherTrust Manager](#)
- 2) If you are an existing CipherTrust Data Security Platform customer, then you will already have CipherTrust Manager installed and in use - **please note that currently DDC is designed to work with Virtual CipherTrust Manager rather than the physical appliance**
- 3) Once CipherTrust Manager is installed you can then install DDC in a specific sequence as follows:
 - a. [Install TDP](#)
 - b. [Configure TDP](#)
 - c. [Configure the DDC license in CipherTrust Manager](#)
- 4) [Install DDC agents](#)

When installation of CM, TDP and DDC is complete, you can then launch DDC from within the CM console and begin configuring the various items needed to create and run a scan.

Configurations steps:

- 1) [Configure branch locations](#) - a branch location specifies a site where the file servers, databases, and data centers that contain data to be scanned are physically located
- 2) [Configure data stores](#) - a data store is the entity where the data is actually stored, with DDC supporting various types - local, network, database, Big Data and cloud
- 3) [Configure classification profiles](#) using pre-defined infotypes where possible - an infotype is used to categorize specific data (such as passport numbers or email addresses) to look for during a discovery scan, forming an integral component in the definition of a classification profile
- 4) If necessary create one or more [custom infotypes](#) to meet your specific needs
- 5) [Configure scan](#) - a scan is part of the discovery process that is used to search for sensitive data within data stores using criteria defined in classification profiles

Suggested use case to explore – local storage protection

Following the steps below will help you plan your local storage protection. The links take you to the relevant section in our online documentation portal, Thales Docs.

- 1) [Set up your local data store in DDC](#)
- 2) [Configure a scan](#) defining what type of data you want to look for using one of the pre-defined classification profiles (GDPR, PCI DSS, CCPA, etc.)
- 3) [Run the scan](#)
- 4) [Generate the report](#) for the scan you have just run - the report will show locations and associated risk levels associated with data objects in the various data stores
- 5) [Analyze the results](#) locating the paths that contains sensitive data without protection and define your actions over those locations

Analyzing the results

The screen shots below provide an overview of how to interpret the results from the scans. We are using some examples from the Thales test environment to illustrate the power of the scanning and reporting capabilities of DDC.

In this first example, we are scanning a local storage called "Employee Repository Old" to search for CCPA data.

In this second example, we are grouping the information that we got after scanning a customer repository searching for GDPR data and a financial repository (Oracle DB) searching for PCI data.

In the following example, we are displaying a Data Object that we encrypted automatically using DDC after we discovered the file contained sensitive data (credit card numbers).

I can demonstrate the file is encrypted as it contains credit card numbers

Visibility into the different types of data stored in files without compromising the data security

If I have a breach, I can see if the file was encrypted before the incident

In the following example, we are showing a Data Object that contains sensitive data (email addresses, MC address, financial information, among others) and it cannot be protected as no CTE agent is available in that location.

Visibility into the riskiest file and its contents to assist with the security plan accordingly

The following report has been generated based on a NDJSON file created by DDC and using ELK for analysis and display.

Your feedback

Thank you for completing the evaluation of our CipherTrust Data Discovery and Classification solution. We trust you found it useful and look forward to hearing your feedback. We should be grateful if you would answer as many of the following questions as you can.

Question	Your response
How did DDC fit into your overall data security strategy?	
What is the main use case of interest for deployment of DDC?	
What were the highlights or benefits that you saw?	
What information was most useful in the dashboards (e.g. statistics, insights, incident report or something else)?	
What were the drawbacks of the solution for you?	
What, if anything, seemed confusing to you?	
What missing features would you like to see?	
How would that help you?	
Any other feedback you wish to share?	

You can use the following [link](#) to take the survey or scan the QR code below to launch the survey on a mobile device.

Thanks in advance.

The CipherTrust team at Thales.

About Thales

The people you rely on to protect your privacy rely on Thales to protect their data. When it comes to data security, organizations are faced with an increasing number of decisive moments. Whether the moment is building an encryption strategy, moving to the cloud, or meeting compliance mandates, you can rely on Thales to secure your digital transformation.

Decisive technology for decisive moments.

Thales CipherTrust Data Discovery and Classification

The crucial first step in privacy and data protection regulatory compliance is to understand what constitutes sensitive data, where it is stored, and how it is used. If you don't know what sensitive data you have, where it is, and why you have it, you cannot apply effective policies and controls to protect it.

Thales CipherTrust Data Discovery and Classification enables you to efficiently locate structured and unstructured regulated data across the cloud, big data, and traditional data stores in your enterprise. You get a complete understanding of your sensitive data and its risks, so you can make better decisions about closing your gaps, prioritizing remediation, securing your cloud transformation and third party data sharing.

Unlike alternative disjointed solutions that can leave data exposed or compromised, Thales CipherTrust Data Discovery and Classification provides a streamlined workflow all the way from policy configuration, discovery, and classification, to risk analysis and reporting. This eliminates security blind spots and complexities. As a result, you can easily uncover and mitigate your data privacy risks, enforce data sovereignty, and proactively respond to a growing number of data privacy and security regulations, including GDPR, CCPA, LGPD, PCI DSS and HIPAA.

Effective for enterprise-wide data privacy

Thales CipherTrust Data Discovery and Classification is an enterprise-wide data privacy solution that is simple to deploy and scale. It provides a streamlined workflow to help you quickly discover your regulated data across traditional and cloud repositories.

Streamline data discovery and automate data protection

Thales has created an automatic workflow that links CipherTrust Data Discovery and Classification with CipherTrust Transparent Encryption - we call this CipherTrust Intelligent Protection. This new solution discovers, classifies and uses policy-based data encryption to automate data remediation and reduce business risk. It enables organizations to streamline processes, gain complete visibility to identify compliance gaps, automatically mitigate risks, and comply with data privacy and security regulations.

Quick start with built-in templates and flexibility for custom policies

Thales CipherTrust Data Discovery and Classification provides a comprehensive set of built-in classification templates for commonly requested data privacy and security regulations, such as CCPA, HIPAA, PCI DSS, LGPD, NYDFS and UK GDPR, but is flexible enough to handle custom policies based on specific patterns, algorithms, and more.

Demonstrate compliance

Thales CipherTrust Data Discovery and Classification provides detailed reports that can help you demonstrate to auditors compliance with various regulatory and business laws. Efficient scans enable you to build a strong foundation for overall data privacy and security.

Use Cases

- **Finding and classifying data:** Scans both structured and unstructured data using categorization techniques to find similar data more efficiently.
- **Enhancing security posture:** Delivers a detailed report of what sensitive data you have, where it resides and associated risk to help you make better decisions about what data needs protection.
- **Migrating data to the cloud:** Presents a detailed risk analysis prior to moving data to the cloud in order to qualify decisions based on solid facts.
- **Managing large data volume increases:** Maintains visibility of your data during rapid rises in storage and usage with a robust and scalable solution.
- **Ongoing compliance:** Keeps you up to date automatically with all major global and regional compliance requirements, while reducing the risk of failed audits or fines by proactively identifying compliance gaps.

Technical Specifications

Data Stores

- Local storage and local memory on the host
- Network storage
 - Windows Share (CIFS/SMB)
 - Unix File System (NFS)
- Cloud
 - Office 365 Exchange Online
 - Office 365 SharePoint Online
 - Azure Blobs and Table
 - AWS S3
 - Google Mail
 - Google Drive
 - Salesforce
- Databases
 - IBM DB2
 - Oracle
 - SQL
 - PostgreSQL
 - SAP Hana
 - Teradata
 - MySQL
 - Mongo
- Big Data
 - Hadoop Clusters
 - SharePoint OnPremises

Type of files supported

- Databases: Access, DBase, SQLite, MSSQL MDF & LDF
- Images: BMP, FAX, GIF, JPG, PDF (embedded), PNG, TIF
- Compressed: bzip2, Gzip (all types), TAR, Zip (all types)
- Microsoft Backup Archive: Microsoft Binary / BKF
- Microsoft Office: v5, 6, 95, 97, 2000, XP, 2003 onwards
- Open Source: Star Office / Open Office
- Open Standards: PDF, HTML, CSV, TXT

Type of data identified

- Health (Australian Medicare Card, European EHIC, US Health Insurance Claim number, etc.)
- Financial (American Express, Diners Club, Mastercard, VISA card numbers, bank account number, etc.)
- Personal (name, last name, address, DOB, email, etc.)
- National ID (social security number, Spanish DNI, etc.)
- Custom Information Types

Pre-built templates

The solution includes a wide range of ready-to-use templates that can help you meet common regulatory and business policy needs. For example:

- CCPA
- GDPR
- HIPAA
- PCI DSS
- LGPD
- NYDFS
- UK GDPR

Minimum RAM required

- 16GB

Network Connection

- At least 1GB

CipherTrust Data Security Platform

CipherTrust Data Discovery and Classification is part of the CipherTrust Data Security Platform. The CipherTrust Platform unifies data discovery, classification, data protection, and provides unprecedented granular access controls, all with centralized key management. This simplifies data security operations, accelerates time to compliance, secures cloud migrations, and reduces risk across your business. You can rely on Thales CipherTrust Data Security Platform to help you discover, protect and control your organization's sensitive data, wherever it resides.

About Thales

The people you rely on to protect your privacy rely on Thales to protect their data. When it comes to data security, organizations are faced with an increasing number of decisive moments. Whether the moment is building an encryption strategy, moving to the cloud, or meeting compliance mandates, you can rely on Thales to secure your digital transformation.

Decisive technology for decisive moments.

Thales Data Platform

Version: v3.1.6 (latest)

4 February 2026

Thales Data Platform (On-prem) Deployment

Thales Data Platform (TDP) (on-prem) is a Big Data platform based on Hadoop technology. It can be used for POCs and production in conjunction with DDC.

Prior to deploying or upgrading your TDP cluster, please check the [Hardening Guidelines](#) and the [Compatibility Matrix between CM and TDP](#).

To deploy TDP 3.1.6, please follow the instructions belows depending on your current state.

Quick Setup Wizard

If you wish to try out TDP prior to installing it in production, you can use a quick setup script which simplifies the installation and reduces the number of manual configuration steps.

You can download the TDP IQ Wizard ZIP file corresponding to the CipherTrust Manager version from the [Thales Customer Support Portal](#).

Deployment Environments

How the Thales Data Platform is distributed and deployed is based on the environment. The supported environments are listed below along with the supported distribution method:

Public Cloud Images

We support Virtual Thales Data Platform in the following environments.

- Amazon Web Services: SafeNet Cloud Provisioning System

Refer to: [AWS Deployment](#)

- Microsoft Azure: Available as a BYOL image in the Microsoft Azure Marketplace

Refer to: [Azure Deployment](#)

Private Cloud Images

- VMware vSphere: OVA image file

Refer to: [Private Cloud Deployment](#)

Hardening Guidelines

The Thales Data Platform should be deployed into as secure an environment as possible. Every effort has been made to include Hadoop components without known security vulnerabilities, however, additional precautions should be taken especially when the Thales Data Platform is deployed into an untrusted environment.

Securing Hadoop

Here are some general guidelines on securing your TDP deployment. These recommendations are general and apply to any Hadoop cluster.

- The Hadoop cluster should only be deployed inside a corporate or trusted network. You must use a VPC network if deploying to a cloud.
- None of the Hadoop nodes should be exposed to the Internet.
- To access services from the Internet, it is recommended to use VPN access. If VPN is not available, it is recommended to use jump servers or bastion hosts. For example, to access SSH (port 22), do not expose it directly to the Internet. Instead, use a jump server or a bastion host.
- To access web services, such as DDC or Ambari, use a reverse proxy or some kind of a load balancer. These devices normally sit in a DMZ (demilitarized zone) and forwards only a specific TCP port to the Hadoop cluster.
- For Hadoop clusters configure the replication channels to use transport level encryption.
- Make sure that you configure a firewall to forbid external access to any IP/port other than those of Knox (by default it is listening on port 8443) unless the source machine is another TDP node. The SSH and Ambari ports should only be accessible to trusted source IPs.

Additionally for the DDC-TDP configuration, below you can find some guidelines that will help you set secure credentials and secure TLC configuration. For details and instructions, refer to your Hadoop documentation.

▪ Secure credentials

- Hadoop credentials must be rotated regularly.
- Credentials must be different for every installation.
- Password must meet the security requirements described below:
 - At least 10 characters in length.
 - Contains both uppercase (A-Z) and lowercase (a-z) alphabetic characters.
 - Has at least one numeric (0-9) character.
 - Has at least one special character (! @ # \$ % ^ & * () _ - + = , . / < > ? ; ' : \ " [] \ \ { } | ~ `).
 - Does not contain spaces or tabs.

▪ Secure TLS configuration

- Disable SSL and TLS 1.0 and 1.1.
- Use secure renegotiation or disable renegotiation.
- Disable TLS compression.

-
- Use Authenticated Encryption cipher suites.
 - Use cipher suites with strong key exchange.
 - Do not use cipher suites with known vulnerabilities.
 - Cipher suites order must be defined by the user.
 - Use Perfect Forward Secrecy (PFS).
 - Download the tool from <https://testssl.sh/> to check the configuration.

References

Thales strongly recommends appropriately configuring and securing your Hadoop environment according to industry best practices and your organization's security policies.

The following references are not comprehensive, but are intended to provide a starting point for background, tools, and best practices that may be applied to your Hadoop environment:

- [HDP Security Overview](#)
- [Introduction to Hadoop Security](#)
- [Securing Hadoop: Security Recommendations for Hadoop \(Paper\)](#)
- [Hadoop Security \(O'Reilly Book\)](#)

System Administrative Key

The SSH Private Key, used to access the System Administrative account `root`, is extremely sensitive and should be kept in a secure environment.

Configuring TDP nodes

While deploying a Thales Data Platform (TDP) instance, it is recommended to use a five-node cluster: **Two master nodes** and **three worker nodes**.

- **Two master nodes:** Using two master nodes eliminates single point of failure. If you use only one master node and it fails for some reason, TDP remains down until the administrator recovers the master node.
 - **Three worker nodes:** This is the default setting/replication factor (meaning each file is copied to three different nodes). Three worker nodes are recommended because:
 - HDFS clusters are not backed up frequently and using three nodes ensures data resilience.
 - All data stored in the service can withstand the failure of up to 'replication factor - 1' nodes. For example, in a system with three nodes, it can tolerate the failure of two nodes (*no data loss occurs when two nodes fail*).
 - If you use only two worker nodes, one node failure will necessitate an immediate action, as losing the
-

second node will lead to data loss. Three worker nodes provide sufficient time for the administrators to provision a new node and replicate the data, a process that can take several days. Using two worker nodes increases data loss risk during this time frame.

Note

You may choose to reduce the number of master/worker nodes if you can address the above mentioned risks or have a reliable backup system capable of quickly recovering any TDP node and its data to meet the required SLA.

Tip

If you are using TDP for proof of concept (PoC) or on a trial basis, you have the option to use the suggested five-node cluster or a one-node cluster to reduce costs and speed up the evaluation process.

1. Install Virtual Thales Data Platform

Virtual Thales Data Platform instances are available in select private and public cloud environments.

Virtual Deployment Environments

Public Cloud Images

We support Virtual Thales Data Platform in the following environments.

- Amazon Web Services: SafeNet Cloud Provisioning System

Refer to: [AWS Deployment](#)

- Microsoft Azure: Available as a BYOL image in the Microsoft Azure Marketplace

Refer to: [Azure Deployment](#)

Private Cloud Images

- VMware vSphere: OVA image file

Refer to: [Private Cloud Deployment](#)

Amazon Web Services Deployment

You can deploy a Thales Data Platform image within Amazon Web Services (AWS).

Minimum Requirements

To deploy a Thales Data Platform instance, the following minimum requirements apply:

The minimum requirements for each node are:

- System volume: minimum of 200 GB
- Memory: 32 GB
- vCPUs: 8

We recommend a five-node cluster:

- Two nodes as namenodes, Knox gateway,
- Three nodes as datanodes and Node Manager.

See [configuring TDP node](#) for more details.

The configuration recommended for each node when a five-node cluster is build is the following:

Instance	vCPU	Mem (GiB)	Storage	CPU Credits/ hour	Network Performance
t2.2xlarge	8	32	EBS-Only	81	Moderate

Note

These minimum system requirements are for a system with light to moderate load. For applications that heavily load the system, additional memory and CPU allocation are required. The system volume holds all data as well as backups.

Provisioning the AMI

AWS region-specific and confidential Virtual Thales Data Platform images (AMI) are obtained by provisioning. Provisioning places a Thales Data Platform AMI in your target AWS account in the target region(s).

Use the Thales Customer Support Portal to request provisioning for a Thales Data Platform AMI.

Note

Only authorized Customer Support Portal users can make provisioning requests.

1. Login to the [Thales Customer Support Portal](#).
2. Navigate to the [My Provisioning Requests](#) page, through the **Tools > Provisioning Requests** menu.

3. Click **Create Provisioning Request**.
4. Select **Thales Data Platform** from the **Product Name** dropdown.
5. Select the desired **Product Version** from the dropdown.

Note

We recommend deploying the most recent version for the latest security fixes and most current features.

6. Select the desired **AWS Region** from the dropdown.
7. Provide your **AWS Account Number**.
8. (Optional) If desired, type in the names of **Additional Regions** in the text field, to deploy AMIs in more than one region.
9. (Optional) If desired, adjust the **Priority**. The default priority is **3-Medium**.
10. Click **Submit**.

A Thales client services engineer will receive and work on the request.

When your provisioning request is completed, you will an email notification with the subject line **Cloud Provisioning Request Complete**. Alternatively, you can periodically check the provisioning request status directly on the **My Provisioning Requests** page.

11. Retrieve the AMI ID from the completed provisioning request.
 - a. Navigate to the [My Provisioning Requests](#) page, through the **Tools > Provisioning Requests** menu.
 - b. Click on the name of the completed provisioning request. The **Status** column indicates requests that are completed.
12. Proceed to [deploy](#) the Virtual Thales Data Platform image.

Deploying in AWS

This section provides the steps for deploying a Virtual Thales Data Platform instance in AWS.

Prerequisites

- A Virtual Thales Data Platform AMI provisioned using the **Thales Customer Support Portal**, as described above in [Provisioning the AMI](#).

- If using a Windows client use PuTTY or similar utility to SSH to your Thales Data Platform instance as root.

If needed, use PuTTYgen or similar utility to format the SSH Key Pair.

- If using a Linux client use SSH to login as root.

To launch a Thales Data Platform instance in AWS

1. Sign in to your AWS account at the AWS portal at: <https://aws.amazon.com>
2. In the **Compute** group, select **EC2** service.
3. On the AWS top bar and to the right, make sure you select the AWS Region you provisioned for your AMI.

4. In the left pane, under the **Images**, select **AMIs** and search for the AMI (e.g. ami-04d5de93aaa02ceef) that was provisioned for you by the **SafeNet Cloud Provisioning System**.

5. Select your image and then click on **Launch instance from image**.
6. In the **Choose an Instance Type** screen select the desired **Instance Type**:
 - a. Select "t2.2xlarge", if you're installing a node that will be part of a 5 node cluster.
 - b. Select **Next: Configure Instance Details**.
7. In the **Configure Instance Details** screen,
 - a. Key in the number of instances required for the **Number of instances**. For example, 5 for a 5-node cluster.
 - b. Select **Next: Add Storage**.
8. In the **Add Storage** screen, select the desired **Size (GiB)**.
Select **Next: Add Tags**.
9. In the **Add Tags** screen, select **Add Tag**
 - a. Enter Tag: Name

-
- b. Value: Something meaningful to the operator; for example "Thales Data Platform for lab use"
 - c. Select **Next: Configure Security Group**.

10. In the **Configure Security Group** screen:

- a. Create a new security group or re-use a previously created group.
- b. Refer to [Security Group Rules](#). Consider adding all of the recommended rules.

Note

To launch the Thales Data Platform, you need at a minimum Port 22 inbound/outbound for TDP SSH connection and Port 443 for an HTTPS connection to the GUI.

- c. Select the **Review and Launch** screen.

11. In the **Review Instance Launch** screen:

- a. Review your launch configuration settings.
- b. Make any changes by selecting the **Edit ...** at the right of each section.
- c. After your review, select **Launch**.

You are presented with this dialog box to select a key pair.

Select an existing key pair or create a new key pair ✕

A key pair consists of a **public key** that AWS stores, and a **private key file** that you store. Together, they allow you to connect to your instance securely. For Windows AMIs, the private key file is required to obtain the password used to log into your instance. For Linux AMIs, the private key file allows you to securely SSH into your instance.

Note: The selected key pair will be added to the set of keys authorized for this instance. Learn more about [removing existing key pairs from a public AMI](#).

Choose an existing key pair ▼

Select a key pair

-aws-key ▼

☒ I acknowledge that I have access to the selected private key file (mikes-aws-key.pem), and that without this file, I won't be able to log into my instance.

Cancel Launch Instances

- d. Select which **Key Pair** option to use. The key pair should be in Linux (PEM) format, not OpenSSH format. Valid options are:

- Choose an existing key pair from the drop-down list. If your key pair is not on this list, you can import it here:

Services > EC2 > Network and Security > Key Pairs

- Create a new key pair. (This option allows you to download your own key pair.)

- e. After selecting the **Key Pair**, check off the acknowledge statement at the bottom of the dialog box, confirming that you have access to the selected private key file.

Warning

It is important that you have access to the key pair you select, otherwise you will not have permissions to perform administrator operations like performing upgrades, advanced logging or an appliance reset.

12. Select **Launch Instances**.

The **Launch Status** screen appears. You can review the launch process on this screen.

Note

It can take a several minutes for your instance to launch.

13. Select **View Instances** to view the state of your instance as it is being launched. You may need to search for the name of your instance in the Instances table if it is among many others.
14. Select your instance in the table and then select **Connect**.

The **Connect To Your Instance** dialog box appears:

15. Copy the instance **Public DNS** string, for example: `ec2-54-89-148-184.compute-1.amazonaws.com`
16. If using PuTTY, begin a new session.
 - a. Paste the Public DNS in the **Host Name (or IP address)** field and preface this string with "root@".
 - b. Set the **Connection Type** to **SSH**.

17. In the **Category** pane:

- a. Select **Connection > SSH > Auth**.
- b. Select **Browse** and navigate to the folder with your Private Key.
- c. Select your Public Key file name. The file name and path is automatically places in the **Private key file for authentication** field.

- d. Select **Open**.

Note

If you are unable to connect to your instance using PuTTY, go to: <https://docs.aws.amazon.com/AWSEC2/latest/UserGuide/putty.html> for further assistance.

Please follow instructions in [Changing the Initial Password](#) and all its following steps: [Network Configuration](#), [Configuring Services After Deployment](#), and [Post Install](#) to continue configuring your Thales Data Platform cluster.

Microsoft Azure Deployment

You can deploy a Thales Data Platform within the Microsoft Azure Cloud Computing Platform, including in the Azure Government environment (Arizona, Iowa, Virginia, and Texas regions).

Minimum Requirements

To deploy a Thales Data Platform instance, the following minimum requirements apply:

On TDP version **MISSING VARIABLE: version** the minimum requirements for each node are:

- System volume: minimum of 200 GB
- Memory: 28 GB
- vCPUs: 8

We recommend a 5-node cluster:

- 2 nodes as namenodes, Knox gateway,
- 3 nodes as datanodes and Node Manager.

See [configuring TDP node](#) for more details.

The config recommended for each node when a 5-node cluster:

- Standard_DS4 - 8 vcpus, 28 GiB memory

Note

These minimum system requirements are for a system with light to moderate load. For applications that heavily load the system, additional memory and CPU allocation are required. The system volume holds all data as well as backups.

Deploying in Azure

This section provides the steps for deploying a Virtual Thales Data Platform instance in Microsoft Azure. Refer to the Azure documentation for general information on launching a VM in Microsoft Azure.

Prerequisites

- If using a Windows client, use PuTTY or similar utility to SSH to your Thales Data Platform instance, using the username that you create in the following Step 11, for example, tdpuser.

If needed, use PuTTYgen or similar utility to format the SSH Key Pair.

- If using a Linux client, use SSH to your Thales Data Platform instance, using the username that you create in the following Step 11, for example, tdpuser.

To launch a Virtual Thales Data Platform instance

1. Sign in to the Azure or Azure Government portal.
2. Search for **Thales Data Platform** on the Marketplace page.
3. Select the **Thales Data Platform** image from the Virtual Machines group.

Note

The following steps apply to the Azure recommended 'Resources Manager' deployment model.

4. Click **Create**. The first screen of the **Create virtual machine** page is displayed.

Create a virtual machine

Basics Disks Networking Management Advanced Tags Review + create

Create a virtual machine that runs Linux or Windows. Select an image from Azure marketplace or use your own customized image. Complete the Basics tab then Review + create to provision a virtual machine with default parameters or review each tab for full customization. [Learn more](#)

Select the subscription to manage deployed resources and costs. Use resource groups like folders to organize and manage all your resources.

Subscription *	Pay-As-You-Go
Resource group *	ddc-test
	Create new

Instance details

Virtual machine name *	tdp316n1
Region *	(US) West US
Availability options	No infrastructure redundancy required
Security type	Standard
Image *	Thales Data Platform 3.1.6 - Gen1
	See all images Configure VM generation
Azure Spot instance	☐
Size *	Standard_DS4 - 8 vcpus, 28 GiB memory (\$449.58/month)
	See all sizes

- Change the **Subscription** type if desired.
- Select an existing **Resource group** or enter the name for a new one.
- Specify the **Region** of an Azure Datacenter. For example, **West US**.

Note

For Azure government, this must be one of USGov Arizona, USGov Iowa, USGov Virginia, or USGov Texas.

- Enter a **Virtual machine name**, which is the hostname for the virtual machine your are creating, for example, "tdp316n1".

9. Select the **Size** for the VM that supports the [Minimum Requirements](#). **Standard_DS4** is recommended at this time.
10. Select the **SSH Public Key** for the **Authentication type**.

Note

SSH Public Key authentication must be used. **Password** authentication is not allowed when connecting as the initial user. We support OpenSSH format for the public key, and OpenSSH, PKCS1, or PKCS8 format for the private key.

Administrator account

Authentication type ☒ SSH public key ☐ Password

Azure now automatically generates an SSH key pair for you and allows you to store it for future use. It is a fast, simple, and secure way to connect to your virtual machine.

Username *

SSH public key source

Key pair name *

[Review + create](#) [Previous](#) [Next : Disks](#)

11. For the **Username**, enter any name but not 'root', for example, tdpuser.
12. For the **SSH public key source**, select one of "Generate new key pair", "Use existing public key", "Use existing public key stored in Azure". We support OpenSSH format for the public key, and OpenSSH, PKCS1, or PKCS8 format for the private key.

Warning

It is important that you have access to the key pair you select, otherwise you will not have permissions to perform administrator operations like performing upgrades, advanced logging or an appliance reset.

13. In the **SSH Public Key** field, provide the necessary information for the SSH public key source selected in the last step.

14. Select **Next: Disks** >. The **Disks** screen is displayed.

Create a virtual machine

Basics Disks Networking Management Advanced Tags Review + create

Azure VMs have one operating system disk and a temporary disk for short-term storage. You can attach additional data disks. The size of the VM determines the type of storage you can use and the number of data disks allowed. [Learn more](#) ⓘ

Disk options

OS disk type * ⓘ

Standard SSD (locally-redundant storage) ▼

The selected VM size supports premium disks. We recommend Premium SSD for high IOPS workloads. Virtual machines with Premium SSD disks qualify for the 99.9% connectivity SLA.

Next steps

- Setup auto-shutdown: Recommended
- Monitor VM health, performance and network dependencies: Recommended
- Run a script inside the virtual machine: Recommended

[Go to resource](#) [Create another VM](#)

- Click **Go to resource** then click **connect --> SSH**. Follow the same instructions as in [Connecting via SSH with client](#).

25. If using PuTTY, begin a new session.

- a. Paste the Public IP address and preface with '<username>@', in which <username> is the one created in step 11.
- b. Set the **Connection Type** to **SSH**.

- c. In the **Category** pane:
 - a. Select **Connection > SSH > Auth**.
 - b. Select **Browse** and navigate to the folder with your Private Key.
 - c. Select your Public Key file name. The file name and path is automatically places in the **Private key file for authentication** field.

d. Select **Open**.

Note

If you are unable to connect to your instance using PuTTY, go to [Connect with SSH by using PuTTY](#) for further assistance.

26. After the SSH session to your instance, run the following command, to switch to user 'root':

```
su -
```

Then follow the instructions in [Changing the Initial Password](#) and all its following steps: [Network Configuration](#), [Configuring Services After Deployment](#), and [Post Install](#) to continue configuring your Thales Data Platform cluster.

Connecting via SSH with client

1. Open the client of your choice, for example, PuTTY.
2. Ensure that you have read-only access to the private key.

```
chmod 400 tdpuser.pem
```

3. Provide a path to your SSH private key file.
Private key path:

```
~/.ssh/tdpuser
```

4. Run the example command below to connect to your VM.

```
ssh -i <private key path> tdpuser@52.225.38.222
```

Private Cloud Deployment

You can deploy a Thales Data Platform instance in a private cloud. Support is currently provided for VMware vSphere only.

Minimum Requirements

To deploy a Thales Data Platform instance, the following minimum requirements apply:

On TDP version **MISSING VARIABLE: version** the minimum requirements for each node are:

- System volume: minimum of 200 GB
- Memory: 32 GB
- vCPUs: 8

We recommend a 5-node cluster:

- 2 nodes as namenodes, Knox gateway,
- 3 nodes as datanodes and Node Manager.

See [configuring TDP nodes](#) for more details.

Note

These minimum system requirements are for a system with light to moderate load. For applications that heavily load the system, additional memory and CPU allocation are required. The system volume holds all data as well as backups.

Deploying on VMware vSphere

This section guides you through the steps needed to deploy a Virtual Thales Data Platform on VMware vSphere.

When installing the TDP OVA on ESXi 6.0 you may see an error regarding the vSphere Client not supporting the SHA256 hashing algorithm. If you see this error, please refer to the following KB article:

<https://kb.portsys.com/help/the-ovf-package-is-invalid-and-cannot-be-deployed-sha256-error>

On ESXi 6.0 you may see a warning that the configured guest (CentOS 4/5 or later) for this virtual machine does not match the guest that is currently running (CentOS 7). This is only a warning message. You may click the X button to dismiss it.

Prerequisite

- OVA file.

To launch the Virtual Thales Data Platform

Virtual Thales Data Platform supports VMware vSphere/ESXi v6.0 and higher versions.

1. In vSphere Client, select **Deploy OVF Template...**

Note

You will need sufficient privileges to access this selection.

2. In the **Deploy OVF Template** dialog box, enter the location of the OVA file in the **Source** field and launch the VM. After successful launch, the Virtual Thales Data Platform appears under the inventory folder in the left pane.

3. In the left pane, select the newly launched Virtual Thales Data Platform.
4. In the middle pane, select the **Summary** tab and click on the **Web console**.

The window opens in your browser.

Please follow instructions in [Changing the Initial Password](#) and all its following steps: [Network Configuration](#), [Configuring Services After Deployment](#), and [Post Install](#) to continue configuring your Thales Data Platform cluster.

2. Changing the Initial Password

The initial password must be changed before using the Thales Data Platform.

You should perform this step through ssh/putty because a private key will be generated and you will need to copy-and-paste it from the terminal to a file. You need the **public hostname** of the TDP instance (in VMware or AWS), to be able to ssh to it.

The initial `root` credentials for the image are:

Login: `root`

Password: `thales123`

The user will be prompted to change the root password after the initial login.

3. Network Configuration

Deploying on AWS

Change the Hostname

Set a hostname for your Ambari server and nodes of the Hadoop cluster. Change the hostname to the Private DNS. Run this command, for example, as root to set a new hostname:

```
hostnamectl set-hostname ip-172-31-3-54.ca-central-1.compute.internal
```

Repeat this on all hosts!

Deploying OVA on ESXi

Configure Network

The Hadoop VM is set to use DHCP by default. If a static IP is desired, you may choose **either** of these options:

- **Option 1** Use this utility:

```
/root/setup/network_setup.sh
```

- **Option 2** Manually update file `/etc/sysconfig/network-scripts/ifcfg-eth0`. Below, is an example of a static IP setting:

```
BOOTPROTO=static
IPADDR=10.3.16.227
NETMASK=255.255.0.0
GATEWAY=10.3.30.254
DNS1=10.3.110.224
DNS2=10.3.110.104
NM_CONTROLLED=no
```

Then restart the network service or reboot the server for the changes to take effect. Command to restart the network:

```
systemctl restart network
```

Set the Hostname

To set a hostname for your Ambari server, run the command:

```
hostnamectl set-hostname <hostname>
```

In the above command, substitute the `<hostname>` variable for the actual hostname of your Ambari server. For example: Set a hostname for your Ambari server and nodes of the Hadoop cluster. Change the hostname to the Private DNS. Run this command, for example, as root to set a new hostname:

```
hostnamectl set-hostname node1.hadoop-server.company.com
```

This hostname must be configured for both forward and reverse DNS. The Ambari and Hadoop applications must be able to translate the hostname to its IP address and back in order to work properly.

Update `/etc/hosts` file

Note

This step is optional if the hostname resolution is done by your DNS.

Update the `/etc/hosts` file by adding, for each node, one entry of IP address and hostname. You will need to repeat this procedure in every cluster node.

Warning

The `/etc/hosts` file on **ALL nodes** must have the hostname and IP of **ALL nodes** in the Hadoop cluster.

Example of how your `/etc/hosts` file should look like:

```
127.0.0.1    localhost localhost.localdomain localhost4 localhost4.localdomain4
::1         localhost localhost.localdomain localhost6 localhost6.localdomain6
10.1.1.1    node1.hadoop-server.company.com
10.1.1.2    node2.hadoop-server.company.com
10.1.1.3    node3.hadoop-server.company.com
10.1.1.4    node4.hadoop-server.company.com
10.1.1.5    node5.hadoop-server.company.com
```

Where `10.1.1.1` is the IP address of the `node1` with hostname `node1.hadoop-server.company.com`. The following line applies to a `node2` in the same fashion, and so forth. The `/etc/hosts` file in this example is identical in `node1`, `node2`, `node3`, `node4` and `node5`.

Tip

If you are using DHCP, the IP address can be obtained using the `ifconfig` command.

Caution

Do **NOT** set `127.0.0.1` to the hostname of the node VM. Hadoop host registration will fail.

Deploying on Azure

Change the Hostname

Set a hostname for your Ambari server and the nodes of the Hadoop cluster. Change the hostname so that it uses the name of the VM name with the Azure's default DNS suffix (`internal.cloudapp.net`).

Run this command, for example, as root to set a new hostname:

```
hostnamectl set-hostname tdp316-56-master.internal.cloudapp.net
```

Repeat this on all hosts!

4. Configuring Services After Deployment

Configure Ambari

Setting up a Multiple-Node Cluster

Use the same OVA image to create all nodes for a multiple-node cluster, for example 5-nodes. On each node, perform the step [Changing the Initial Password and Network Configuration](#).

Choose one node as Ambari Server. On this node, run the script:

```
/root/setup/ambari_setup.sh
```

This will prompt you to set the admin password. **This will be the password of the Ambari admin.** You can use these credentials to access the Ambari UI.

When this script finishes, it shows you the private key that has been set up for the node. **Please save the key.** You will need it for setting up the Ambari server private key.

```

```

On all other nodes, run the script:

```
/root/setup/node_setup.sh
```

This will prompt you for the public key of the Ambari server. Go to the Ambari server to retrieve the public key. This can be any of the two files:

- /root/.ssh/authorized_keys
- /root/.ssh/id_rsa.pub

Hadoop Services Installation Through Ambari

The Ambari server is configured to use TLS (https) at port 443 and using a self-signed certificate.

1. Navigate to Ambari GUI by using the hostname configured in the [Set the Hostname](#). Log in as **admin** with the password that you set in the step [Configure Ambari](#).

Tip

If you have troubles logging in, please refer to [Accessing Ambari](#) for further details.

- Click LAUNCH INSTALL WIZARD.

0. Name the Cluster

Choose a name that you consider more appropriate and descriptive for your cluster:

1. Select Version

At this point, you should see the UI in this state:

In the **Repositories** screen, make sure that you select the **Use Local Repository** option and fill in the **Base URL** fields per the screenshot above. The only needed OS in the Ambari configuration is Redhat 7, with the string `file:///var/repo/hdp` as value for the three paths. Those fields should be already filled in, if you can see any other OS, you can remove it.

- Click **NEXT**.

2. Install Options

In this screen the hosts are configured. Put the hostnames and private keys of all nodes that will be on your cluster. The private key is the one that you saved in the step **Configure Ambari**.

1. Click **REGISTER AND CONFIRM**.

3. Confirm Hosts

The installation will start for all nodes. This can take a few minutes.

Host	Progress	Status	Action
localhost		Registering	

Note

When this step finishes you may see the message "Some warnings were encountered while performing checks against the registered hosts above". This is a common behavior but usually there is no reason to worry so you can skip it.

1. Click **NEXT** → whenever the button gets enabled.

4. Choose Services

Here, we are going to select the services that will be available on our virtual machine. These are the required services for DDC:

- HDFS

- Yarn + MapReduce2
- HBase
- Spark
- Hive
- Tez
- Zookeeper
- Ambari Metrics
- Knox

Choose File System
Choose which file system you want to install on your cluster.

Service	Version	Description
☒ HDFS	3.1.1.0.1	Apache Hadoop Distributed File System

Choose Services
Choose which services you want to install on your cluster.

Service	Version	Description
☒ YARN + MapReduce2	3.1.1	Apache Hadoop Yarn/MapReduce (YARN)
☒ Tez	3.9.1	Tez is the next generation Hadoop Query Processing framework written on top of YARN
☒ Hive	3.1.2	Data warehouse system for ad-hoc queries & analysis of large datasets and table & storage management services
☒ HBase	2.1.8	Non-relational distributed database and centralized service for configuration management & synchronization
☒ ZooKeeper	3.4.14	Centralized service which provides highly reliable distributed coordination
☐ Infra-GUI	6.1.8	Core shared service used by Ambari managed components
☒ Ambari Metrics	6.1.8	A system for metrics collection that provides storage and retrieval capability for metrics collected from the cluster
☐ Kafka	2.8.0	A high-throughput distributed messaging system
☒ Knox	1.8.0	Provides a single point of authentication and access for Apache Hadoop services in a cluster
☐ Log Search	6.6.0	Log aggregation, analysis, and visualization for Ambari managed services. This service is Technical Preview
☒ Spark2	2.3.3	Apache Spark 2.3 is a fast and general engine for large-scale data processing

In the list shown in the GUI, we only need to select those. In the next step, we'll add PQS and Livy to the cluster.

Tip

To save resources please unselect the following not-mandatory services:

- Kafka

- Log Search
- Infra Solr

When prompted if you accept the *Limited Functionality Warning* confirm by clicking **PROCEED ANYWAY**.

1. Click **NEXT** →.

5. Assign Masters

All the services will be automatically distributed between all the nodes. You may keep all the default settings.

The screenshot displays the 'Assign Masters' configuration interface. On the left, a list of services is shown, each with a dropdown menu indicating the master node assignment. The services and their assigned masters are:

- MasterNode: hadoop-master (16.7 GB, 8 cores)
- SlaveNode: hadoop-slave (15.7 GB, 8 cores)
- Timeline Service V1.3: hadoop-master (16.7 GB, 8 cores)
- ResourceManager: hadoop-master (16.7 GB, 8 cores)
- Timeline Service V2.3 Reader: hadoop-master (16.7 GB, 8 cores)
- YARN Registry DNS: hadoop-master (16.7 GB, 8 cores)
- History Server: hadoop-master (16.7 GB, 8 cores)
- HBase Master: hadoop-master (16.7 GB, 8 cores)
- ZooKeeper Server: hadoop-master (15.7 GB, 8 cores)
- Metrics Collector: hadoop-master (16.7 GB, 8 cores)
- CephFS: hadoop-master (16.7 GB, 8 cores)
- Hive Gateway: hadoop-master (16.7 GB, 8 cores)
- Activity Explorer: hadoop-master (15.7 GB, 8 cores)
- HST Server: hadoop-master (16.7 GB, 8 cores)
- Activity Analyzer: hadoop-master (15.7 GB, 8 cores)

On the right, a preview of the 'hadoop-master' node configuration is shown, displaying a grid of service icons that will be installed on the master node.

Click **NEXT** →.

6. Assign Slaves and Clients

Select "Livy for Spark2 Server" and "Phoenix Query Server" in all nodes that you want these services running. You will need to remember which hosts you selected when you reach the "Update Livy configuration for Knox" step.

Caution

This step is really important. Make sure that you select "Livy for Spark2 Server" in at least one of your hosts because it is a hard requirement for DDC.

Click **NEXT** →.

7. Customize Services

Note

The services can be installed during the TDP installation or at any moment. If this is configured during the installation, you will not have to restart the installed services. It is possible to do so when a new service is installed, however in this case you will have to restart the services.

At this point, you only need to provide credentials for different services and review the installation.

CREDENTIALS sub-step

1. Create the Knox master secret password and store it somewhere.

Note

You will need the Knox master secret password when you get to the step [Updating and Exporting the Knox Server Certificate](#). It must have at least 6 characters.

In the **CREDENTIALS** section you will also be asked to set passwords for Grafana and Hive.

2. Click **NEXT** →.

DATABASES sub-step

Click **NEXT** →.

DIRECTORIES sub-step

Click **NEXT** →.

ACCOUNTS sub-step

Click **NEXT** →.

ALL CONFIGURATIONS sub-step

1. **HDFS** tab, **SETTINGS** sub-tab

- a. Set **NameNode directories** in **NameNode** section to:

`/hadoop/hdfs/namenode, /hadoop/hadoop/hdfs/namenode`

- b. Set **DataNode directories** in **DataNode** section to:

`/hadoop/hdfs/data, /hadoop/hadoop/hdfs/data`

2. **HDFS** tab, **ADVANCED** sub-tab

- a. If the **Advanced ssl-client** section is red please expand it and re-confirm `ssl.client.keystore.password` password

3. Click **NEXT** →.

8. Review

1. Review the configuration created
2. Click **DEPLOY** →.

9. Install, Start and Test

Note

If any of the required services fails to start automatically, you may need to start it manually. In case of repeated problems, please check out the service log for additional troubleshooting information. Refer to the article "[Viewing Service Logs](#)" on the Hortonworks documentation pages for details.

When the installation completes, click **NEXT**.

10. Summary

Click **COMPLETE**.

In the next step you will continue with the "Post Install" section.

For more detailed information about the above procedure, refer to the [Hortonworks official webpage](#).

Steps to Set up Additional Nodes in the Hadoop Cluster

Optionally, you may add an additional node (or nodes) to the cluster after the above steps.

Use the same OVA image to create all nodes for a multiple-node cluster, for example 5-nodes. On each node, perform the step [Changing the Initial Password and Network Configuration](#).

Then run the script:

```
/root/setup/node_setup.sh
```

This will prompt you for the public key of the Ambari server. Go to the Ambari server to retrieve the public key. This can be any of the two files:

- `/root/.ssh/authorized_keys`
- `/root/.ssh/id_rsa.pub`

Once the node is set up, log in to the Ambari server and add the node to the cluster with the following steps:

1. Go to the Ambari UI.
2. Click the **Hosts** button in the menu on the left. You should see the list of nodes already present on the cluster.
3. Click **Actions -> Add New Hosts**.

Note

- As in the host names field you can add more than one node, you can add more than one node at the same time. However, the previous steps are required on every node.
- The Ambari server must solve the hostname of each node and the node must be accessible from it.

4. On the ssh private key field you need to paste the private key of the Ambari Server node (typically, the first node of your cluster).
5. Click **Register and Confirm**.
6. Now, you just have to follow the instructions and add the desired services on the new node.

If you are setting up an additional node in the TDP cluster upgraded from a previous version, rename the repo path on the new node to match the repo path of the existing nodes in the cluster and recreate the repo.

For example to add a new node in cluster upgrade from 3.1.5.1 to 3.1.6:

1. Rename the repo:

```
mv /var/repo/hdp /var/repo/hdp-316
```

2. Re-create the repo:

```
createrepo /var/repo/hdp-316
```

Note

Perform these steps on a **new** node before running the `/root/setup/node_setup.sh` script.

5. Post Install

Updating and Exporting the Knox Server Certificate

When the Knox service is installed by Ambari, a self-signed certificate is created internally. However, the certificate created uses SHA1 and with a key size of 1024 bits. The **update_knox_cert.sh** script below will create and replace the certificate with a new one using SHA256 and a key size of 2048 bits.

1. Run this script in an SSH session on the TDP instance:

```
/root/setup/update_knox_cert.sh
```

2. When this script is run, it will prompt for the Knox master secret.

This secret is the one that you set in the step "7. Hadoop Services Installation Through Ambari > Customize Services" (**CREDENTIALS > Knox Master Secret**).

Finally, you need to export the SSL certificate of the Knox server and configure DDC to talk to Hadoop. You need to obtain the certificate where Knox is installed.

1. Put the Knox server certificate in a file, by using this command:

```
echo -n | openssl s_client -connect <IP_OF_KNOX_SERVER>:8443 | \
sed -ne '/-BEGIN CERTIFICATE-/,/-END CERTIFICATE-/p' > /tmp/hadoop.cert
```

2. Copy the certificate to the system where you will connect to the CipherTrust/DDC GUI.

Issue this command to display the certificate in the terminal window:

```
cat /tmp/hadoop.cert
```

Now, you can copy the certificate from the terminal window and paste it in its own file on your machine.

Tip

You will need to upload this file when configuring Data Discovery and Classification to talk to Thales Data Platform, be sure to save it locally. Refer to [Configuring TDP](#) section in the Data Discovery and Classification documentation to learn more.

You can find the comprehensive procedure at this [link](#) on the Hortonworks documentation pages.

Ambari additional configuration

To execute the instructions below you will need to access Ambari, please refer to [Accessing Ambari](#) for further information.

Enabling Namenode HA

Note

These steps are optional for multiple node cluster, but they are recommended.

1. In the Ambari toolbar on the left, expand **Services**, then click **HDFS**.
2. Go to the **ACTIONS** menu and click **Enable NameNode HA**.
3. Follow each step in the 'Enable NameNode HA Wizzard'.
 - a. In the **Get Started** step, input the Nameservice ID.
 - b. In **Select Hosts**, keep all the defaults and click **NEXT**.
 - c. In the **Review** step, click **NEXT**.
 - d. In **Create Checkpoint**, perform each step as listed. **NEXT** is only clickable after you complete all the steps.
 - e. In **Configure Components**, wait for the deployment of each component, then click **NEXT**.
 - f. In **Initialize JournalNodes**, perform each subsequent step. **NEXT** is only clickable after you complete all the steps.
 - g. In **Start Components**, wait for each process to complete. Then click **NEXT**.
 - h. In **Initialize Metadata**, perform each step, then click **NEXT**. Then click **OK** on the pop-up confirmation window that follows.
 - i. In **Finalize HA Setup**, wait for each process to complete, then click **DONE**.

Livy configuration

Update Livy configuration for Spark2

1. In the Ambari toolbar on the left, expand **Services**, then click **Spark2**.
2. Select the **CONFIGS** tab, then below it click **ADVANCED**.
3. Expand the **Custom spark2-defaults** section, then click the **Add Property...** link. In the **Add Property** popup, click the "multiple tags" icon to enable the **Bulk property add mode**. Then enter the following text, replacing `<zookeeper - node - hostname>` with the zookeeper node IP.

```
spark.yarn.appMasterEnv.ZK_URL_DDC = <zookeeper-node-hostname>:2181
```

Note

You can point to more than one Zookeeper node to ensure high availability on the DDC connection. To do that, use a semicolon (;) to separate the nodes. For example:

```
spark.yarn.appMasterEnv.ZK_URL_DDC = <zookeeper-node1-hostname>:2181;<zookeeper-node2-hostname>:2181
```

4. Expand the **Custom livy2-conf** section, then click **Add Property....** In the **Add Property** popup, click the "multiple tags" icon to enable the **Bulk property add mode**. Enter the following text.

```
livy.server.session.state-retain.sec = 24h
```

5. Expand the **Advanced livy2-conf** section. Update the following entry:

- livy.server.csrf_protection.enabled: `false`

6. Click **SAVE** and then restart **Spark2**.

At the top of the screen it will tell you that a restart is required and there is an orange **RESTART** button. Click that button and select **Restart All Affected**.

Update Livy configuration for Knox

1. In the Ambari toolbar on the left, expand **Services**, then click **Knox**.
2. Select the **CONFIGS** tab.
3. Expand the **Advanced topology** section.

4. For Spark/Livy configuration, add this entry one line before `</topology>`:

- For single node Spark2 Server:

```
<service>
  <role>LIVYSERVER</role>
  <url>http://<HOSTNAME_OF_SPARK2_SERVER>:8999</url>
</service>
```

- For multiple node Spark2 Servers:

```
<service>
  <role>LIVYSERVER</role>
  <url>http://<HOSTNAME_OF_SPARK2_SERVER1>:8999</url>
  <url>http://<HOSTNAME_OF_SPARK2_SERVER2>:8999</url>
  <url>http://<HOSTNAME_OF_SPARK2_SERVER3>:8999</url>
  ...
</service>
```

Tip

This topology will enable you to configure, in Data Discovery and Classification's **Hadoop Services**, **HDFS** with `/gateway/default/webhdfs/v1` as URI and **LIVY** with `/gateway/default/livy/v1` as URI. Refer to [Configuring TDP](#) section in the Data Discovery and Classification documentation to learn more.

5. Click **SAVE** then restart **Knox**.

At the top of the screen it will tell you that a restart is required and there is an orange **RESTART** button. Click that button and select **Restart All Affected**.

Update HDFS configuration for Knox

If your cluster has Namenode HA enabled, it is recommended to properly configure Knox to reach higher availability.

1. In the Ambari toolbar on the left, expand **Services**, then click **Knox**.
2. Select the **CONFIGS** tab.
3. Expand the **Advanced topology** section and add the following sections:

```
<provider>
<role>ha</role>
<name>HaProvider</name>
<enabled>true</enabled>
<param>
<name>WEBHDFS</name>
<value>maxFailoverAttempts=3;failoverSleep=1000;maxRetryAttempts=300;retrySleep=1000;enabled=true</value>
</param>
</provider>
```

4. Add an entry for the Phoenix Query Server.

```
//If the cluster has one PQS installed:
<service>
<role>AVATICA</role>
<url>http://<HOSTNAME_OF_PHOENIX_QUERY_SERVER>:8765</url>
</service>

//If the cluster has multiple PQS installed, you have to list all PQS nodes:
```

```
<service>
<role>AVATICA</role>
<url>http://<HOSTNAME_OF_PHOENIX_QUERY_SERVER1>:8765</url>
<url>http://<HOSTNAME_OF_PHOENIX_QUERY_SERVER2>:8765</url>
<url>http://<HOSTNAME_OF_PHOENIX_QUERY_SERVER3>:8765</url>
</service>
```

5. Click **SAVE** then restart **Knox**.

At the top of the screen it will tell you that a restart is required and there is an orange **RESTART** button. Click that button and select **Restart All Affected**.

HBase configuration

Update Zookeeper configuration for HBase

1. In the Ambari toolbar on the left, expand **Services**, then click **HBase**.
2. Select the **CONFIGS** tab, then below it click **ADVANCED**.
3. Expand the **Advanced hbase-site** section. Update the following entry:

- ZooKeeper Znode Parent: `/hbase`

Note

These properties will be added to the `hbase-site.xml` configuration file.

4. Click **SAVE** then restart all affected components.

At the top of the screen it will tell you that a restart is required and there is an orange **RESTART** button. Click that button and select **Restart All Affected**.

Update PQS configuration for HBase

Apache Phoenix requires additional modification. You need to enable namespace mapping and map the system tables to the namespace. For this procedure we are using the Ambari UI.

1. In the Ambari toolbar on the left, expand **Services**, then click **HBase**.
2. Expand the **Custom hbase-site** section. Click the **Add Property...** link. In the **Add Property** popup, click the "multiple tags" icon to enable the **Bulk property add mode**. Then enter the following text:

```
phoenix.schema.isNamespaceMappingEnabled=true
```

```
phoenix.schema.mapSystemTablesToNamespace=true
```

3. Click **SAVE** then restart all affected components.

Note

After you click **SAVE** you may see a few warnings, out of which this one pertains to the HBase configuration:

Values greater than 6.4GB are not recommended. Maximum ammount of memory each HBase RegionServer can use.

You can disregard this warning and just click **PROCEED ANYWAY** to continue.

At the top of the screen it will tell you that a restart is required and there is an orange **RESTART** button. Click that button and select **Restart All Affected**.

Updating HBase Site Configuration in Spark

To update the HBase site configuration copy the `hbase-site.xml` to Spark.

Run the following command on HBase Master node:

```
cp /etc/hbase/3.1.6-316/0/hbase-site.xml /etc/spark2/3.1.6-316/0/
```

Also run the following command on all nodes where HBase Master server and regionservers are:

```
cp /etc/hbase/conf/hbase-site.xml /etc/spark2/conf/
```

Knox Logging

Changing Knox Log Level

Warning

This is a highly recommended step.

Knox uses Log4j to keep track of its log messages. The default log level, which is INFO, may quickly cause the log file to use up the available space and DDC scans to fail.

Because of that you must change the log level to ERROR by editing the log configuration file. You can do this through Ambari, by following these steps:

1. In the Ambari toolbar on the left, click to expand **Services**, then click **Knox**.

2. Select the **CONFIGS** tab and scroll down to "Advanced gateway-log4j".
3. Open the "Advanced gateway-log4j" section and modify these parameters:
 - Change the log4j.logger.audit parameter to:

```
log4j.logger.audit=ERROR, auditfile
```

- Add these two additional parameters at the end:

```
log4j.appender.auditfile.MaxFileSize=10MB
log4j.appender.auditfile.MaxBackupIndex=10
```

4. Click **SAVE** and then restart Knox.

Purging the Knox Log Directory

If after applying these changes your Knox log grows too quickly, you may have to purge the log directory. First, however, you need to check if this is the case.

1. Check if Ambari is displaying a "NameNode Directory Status" error. This error indicates a failed directory (that is, one or more directories are reporting as not healthy.)
2. Check Ambari for a "Failed directory count" message to find out which directories are reporting problems. If the error message is showing "Failed directory count: 1" it may be the logs directory.
3. In the terminal, check the free disk space for `/var/log/` by issuing the command:

```
df -h
```

If the output of the command is showing no free disk space for the `/var/log/` directory, remove all the log files.

Start LDAP demo server

This step is applicable for demo purposes only.

Warning

It is your responsibility as the system owner to properly configure the authentication to secure the production environment. For demo purposes you can opt for the built-in LDAP server but for everything else you should configure your company's authentication/federation provider.

To set up the embedded LDAP for demo usage, follow these steps:

1. In the Ambari toolbar on the left, expand **Services**, then click **Knox**.

- Go to the **ACTIONS** menu and click **Start Demo LDAP**. Without starting the demo LDAP you cannot use the Knox logins.

Spark Tuning

Warning

This is a highly recommended step.

Spark can be configured by adjusting some properties via Ambari. There are plenty of properties that configure every aspect of the Spark behavior on the [Spark official documentation](#), but this section only just covers some of the most important properties.

Property Name	Default value	Purpose
spark.driver.cores	1	Number of cores to use for the driver process, only in cluster mode.
spark.driver.memory	1 GB	Amount of memory to use for the driver process.
spark.executor.memory	1 GB	Amount of memory to use per executor process, in MiB unless otherwise specified.
spark.executor.cores	1 in Yarn mode	The number of cores to use on each executor. In standalone and Mesos coarse-grained modes, for more detail, see this description .
spark.task.cpus	1	Number of cores to allocate for each task.
spark.executor.instances	2	The number of executors for static allocation. With <code>spark.dynamicAllocation.enabled</code> , the initial set of executors will be at least this large.

Caution

The following instructions are recommended if you have at least 8 CPU / 32GB RAM on board per cluster node.

To increase the resources dedicated to the Spark jobs, you will need to access Ambari, please refer to [Accessing Ambari](#) for further information.

1. In the Ambari toolbar on the left, expand **Services**, then click **Spark2**.
2. Select the **CONFIGS** tab, then below it click **ADVANCED**.
3. Expand **Custom spark2-defaults** and then click **Add Property...**
4. Add the following properties in the text box:

```
spark.driver.cores=3
spark.driver.memory=3g
spark.executor.cores=3
spark.executor.memory=3g
spark.executor.instances=3
```

5. Click **SAVE** then restart all affected components.

At the top of the screen it will tell you that a restart is required and there is an orange **RESTART** button. Click that button and select **Restart All Affected**.

Preparing HDFS for DDC

Warning

This procedure is only needed for a **new TDP cluster** and a **new CM**. You should omit it for any existing working environment (TDP + CM).

Creating HDFS User for DDC

By default, HDFS has permission checking enabled. Please follow the procedure below to properly configure DDC and have it ready to be used by DDC. For this example and throughout the following sections of this document, we will use user **bob** and group **hdfs**.

Tip

You can see if this permission checking is enabled by inspecting the property `dfs.permissions.enabled` in the `hdfs-site.xml` file.

1. SSH to the TDP instance and log in as `root`.
2. Create the user in Linux OS where HDFS is installed, and assign it to the desired group:

```
useradd -g hdfs bob
passwd bob
```

3. Next, you need to configure the new user in HDFS.

- a. Switch to the `hdfs` O.S. user:

```
su - hdfs
```

- b. Run the following commands to setup the user:

```
hdfs dfs -mkdir /user/bob
hdfs dfs -chown -R bob:hdfs /user/bob
hdfs dfs -ls /user
```

The result for the last command should include:

```
drwxr-xr-x - bob hdfs 0 2021-02-29 03:46 /user/bob
```

Tip

You can only use the following characters in the name of the HDFS folder: A to Z, a to z, 0 to 9, `'_'` and `'-'`.

- c. Still using the `hdfs` user, the last step is to refresh the namenode groups:

```
hdfs dfsadmin -refreshUserToGroupsMappings
```

From now on, DDC can use the `bob` user to run jobs that read and write files in the `/user/bob` directory.

- d. Optionally, you can assign a quota for the new user:

```
hdfs dfsadmin -setSpaceQuota 30g /user/bob
```

- e. Return to the `root` prompt

```
exit
```

4. Lastly, you need to configure the new user in LDAP.

Warning

It is your responsibility as the system owner to properly configure the authentication to secure the production environment. For demo purposes you can opt for the built-in LDAP server but for everything else you should configure your company's authentication/federation provider.

To set up the user `bob` in the embedded LDAP for demo usage, please follow those instructions. To execute the instructions below you will need to access Ambari, please refer to [Accessing Ambari](#) for further information.

- a. In the Ambari toolbar on the left, expand **Services**, then click **Knox**.
- b. Select the CONFIGS tab and expand the **Advanced users-Idif** section.

- c. Add this text at the bottom of the text box, replacing `<user-password>` for the desired user password:

```
dn: uid=bob,ou=people,dc=hadoop,dc=apache,dc=org
objectclass:top
objectclass:person
objectclass:organizationalPerson
objectclass:inetOrgPerson
cn: bob
sn: bob
uid: bob
userPassword:<user-password>
```

- d. Click **SAVE**.
- e. Click the **ACTIONS** button and then **Stop Demo LDAP** to stop it.
- f. Click the **ACTIONS** button and then **Start Demo LDAP** start it with the new configuration.

Note

This HDFS user must be configured on the Knox connection, inside the DDC Connection Manager (in the CM Connections Management page, select Access Management > Connections Management).

Creating a HDFS Directory for DDC

For DDC to utilize Hadoop Distributed File System (HDFS), you need to create a directory under HDFS. DDC will use this space for storing scan results and reports. You can create it through the command line. You need to do it only on the **primary node**. This directory can have any name, but for this example and throughout the following sections of this document, we will use `/ciphertrust_ddc`.

1. SSH to the TDP instance and log in as root.
2. Switch to the Linux user `hdfs`, who has permissions to create and destroy folders:

```
su - hdfs
```

3. You need to create the `/ciphertrust_ddc` directory in HDFS, by issuing this command:

```
hdfs dfs -mkdir /ciphertrust_ddc
```

4. Because the default permissions will not allow the scans to write over the Hadoop Database, you have to change the access permissions. By issuing this command you will grant full access rights for the DDC user configured in [Creating HDFS User](#), that is `bob`.

```
hdfs dfs -chown -R bob:hdfs /ciphertrust_ddc
```

By running `hdfs dfs -ls /` the result should include:

```
drwxr-xr-x - bob hdfs 0 2021-08-12 03:17 /ciphertrust_ddc
```

5. Return to the `root` prompt

```
exit
```

Tip

Those steps will enable you to configure **HDFS** in Data Discovery and Classification **Hadoop Services** with `/ciphertrust_ddc` as Folder. Refer to [Configuring TDP](#) section in the Data Discovery and Classification documentation to learn more.

Administration tasks

HDFS Administration

Once you have configured HDFS using the instructions above, you can use the user interface to browse through HDFS sub-directories. Please refer to [Browsing HDFS via User Interface](#)

Optionally you can configure HDFS to use an ACL. Please refer to [HDFS ACL's](#)

Configure LDAP Authentication

In production environments it is mandatory to delegate authentication to an external LDAP server. Please refer to [Configuring LDAP Authentication](#) to get instructions on how to configure Thales Data Platform with a LDAP server.

Your TDP is now ready to be used.

Setting Up the Ambari Server

Thales Data Platform 3.1.5 (TDP) is a Big Data platform based on Hadoop technology. It can be used for POCs and production in conjunction with DDC. TDP 3.1.5 is available as an OVA and AMI image.

NOTE

- > When installing the TDP OVA on ESXi 6.0 you may see an error regarding the vSphere Client not supporting the SHA256 hashing algorithm. If you see this error, please refer to the following KB article:
<https://kb.portsys.com/help/the-ovf-package-is-invalid-and-cannot-be-deployed-sha256-error>
- > On ESXi 6.0 you may see a warning that the configured guest (CentOS 4/5 or later) for this virtual machine does not match the guest that is currently running (CentOS 7). This is only a warning message. You may click the X button to dismiss it.

1. The Image

The virtual machine must have the following specifications:

- > 64-bit Intel/AMD.
- > OVA: VMware vSphere ESXi 6.0 or later. The OVA can be downloaded from the Thales portal.
- > AMI: You will need to instantiate the AMI in your AWS. For instructions on instantiating the AMI, refer to ["Launching the Amazon Instance" on page 29](#).
- > OS type: Linux, CentOS 7 (64-bit).
- > Minimum of 150 GB disk.
- > At least 4 CPUs.
- > At least 16 GB RAM. At least 64 GB RAM if deployed as a single node.

2. Initial Login Credentials

You should perform this step through ssh/putty because a private key will be generated and you will need to copy-and-paste it from the terminal to a file. You need the **public hostname** of the TDP instance (in VMware or AWS), to be able to ssh to it.

The initial root credentials for the image are:

- > **Login:** root
- > **Password:** thales123

NOTE The user will be prompted to change the root password after the initial login.

3. Set the Hostname

To set a hostname for your Ambari server, run the command:

```
hostnamectl set-hostname <hostname>
```

In the above command, substitute the <hostname> variable for the actual hostname of your Ambari server. For example:

```
hostnamectl set-hostname hadoop-server.company.com
```

NOTE This hostname must be configured for both forward and reverse DNS. The Ambari and Hadoop applications must be able to translate the hostname to its IP address and back in order to work properly.

3.1 Optional - Configure Networking

The Hadoop VM is set to use DHCP by default. If a static IP is desired, you may choose either of these options:

a. Use this utility:

```
/root/setup/network_setup.sh
```

b. Update this file:

```
/etc/sysconfig/network-scripts/ifcfg-eth0
```

Below, is an example of a static IP setting in ifcfg-eth0:

```
BOOTPROTO=static
IPADDR=10.3.16.227
NETMASK=255.255.0.0
GATEWAY=10.3.30.254
DNS1=10.3.110.224
DNS2=10.3.110.104
NM_CONTROLLED=no
```

Restart the network service or reboot the server for the changes to take effect. Command to restart the network:

```
$ sudo systemctl restart network
```

4. Configure Ambari

Run this script to configure the host as an Ambari Server:

```
# /root/setup/ambari_setup.sh
```

This will prompt you to set the admin password. **This will be the password of the Ambari admin.** You can use these credentials to access the Ambari UI.

When this script finishes, it shows you the private key that has been set up for the node. **Please save the key.** You will need it for setting up the Ambari server private key.

```

5. Steps to Set up Additional Nodes in the Hadoop Cluster

NOTE For a Demo installation this step is optional because a one node Hadoop deployment is sufficient for the demo purposes.

The OVA image can be used to create additional nodes for the cluster.

Perform the step ["2. Initial Login Credentials" on page 6](#) and ["3. Set the Hostname" on page 7](#).

Instead of running the `ambari_setup.sh` script in step 5, run the following script:

```
> /root/setup/node_setup.sh
```

This will prompt you for the public key of the Ambari server. Go to the Ambari server to retrieve the public key. This can be any of the two files:

```
> /root/.ssh/authorized_keys
```

```
> /root/.ssh/id_rsa.pub
```

Once the node is set up, log in to the Ambari server and add the node to the cluster with the following steps:

1. Go to the Ambari UI.
2. Click the **Hosts** button in the menu on the left. You should see the list of nodes already present on the cluster.
3. Click **Actions -> Add New Hosts**.

NOTE

- > As in the host names field you can add more than one node, you can add more than one node at the same time. However, the previous steps are required on every node.
- > The Ambari server must solve the hostname of each node and the node must be accessible from it.

4. On the ssh private key field you need to paste the private key of the Ambari Server node (typically, the first node of your cluster).
5. Click **Register and Confirm**.
6. Now, you just have to follow the instructions and add the desired services on the new node.

6. Browse the Ambari Server

The Ambari server is configured to use TLS (https) at port 443 and using a self-signed certificate.

1. Log in to the Ambari GUI by using the hostname configured in the step ["3. Set the Hostname" on page 7](#).
2. Log in as admin with the password that you set in the step ["4. Configure Ambari" on page 7](#).
3. Click LAUNCH INSTALL WIZARD.

TIP Ambari UI Not responding

If you cannot access the Ambari UI, try resetting the Ambari service. Open an SSH session on the machine and run the following command:

```
ambari-server restart
```

7. Hadoop Services Installation Through Ambari

Name the Cluster

Choose a name that you consider more appropriate and descriptive for your cluster:

Select Version

At this point, you should see the UI in this state:

Here, the repositories are pre-filled, so the user doesn't need to know them. The local repository will point to **file:///var/repohdp**.

The only needed OS in the Ambari configuration is Redhat 7, with the string **file:///var/repohdp** as value for the three paths. If you can see any other OS, you can remove it.

Install Options

In this screen the hosts are configured. Put the hostname and private key of all nodes that will be on your cluster. The private key is the one that you saved in the step ["4. Configure Ambari" on page 7](#).

Click **REGISTER AND CONFIRM**. After that, the installation will start for all nodes. This can take a few minutes.

NOTE When this step finishes you may see the message "Some warnings were encountered while performing checks against the registered hosts above". This is a common behavior but usually there is no reason to worry so you can skip it.

Choose Services

Here, we are going to select the services that will be available on our virtual machine. These are the required services for DDC:

- > HDFS
- > Yarn + MapReduce2
- > HBase
- > Zookeeper
- > Ambari_metrics
- > Knox

Choose File System
Choose which file system you want to add to your cluster.

Service	Version	Description
☒ HDFS	3.1.1	Apache Hadoop Distributed File System

Choose Services
Choose which services you want to add to your cluster.

Service	Version	Description
☒ MRJob + MapReduce	3.1.1	Apache Hadoop MapReduce (MR) and MapReduce (MR) + MapReduce (MR)
☐ Tez	0.8.4	Tez is the next generation Hadoop Query Processing framework written on top of MR/PC.
☐ Hive	2.1.1	Data warehouse system for storing, querying & analysis of large datasets and table & storage management service.
☒ HBase	2.1.1	Non-relational distributed database and centralized service for configuration management & synchronization.
☒ Zookeeper	3.4.6	Distributed service which provides highly reliable distributed coordination.
☐ Infra Job	0.1.0	Core shared service used by Ambari managed components.
☒ Ambari Metrics	0.1.0	A system for metrics collection that provides storage and retrieval capability for metrics collected from the cluster.
☐ Atlas	2.0.0	Atlas Metadata and Governance platform.
☐ Kafka	2.0.0	A high-throughput distributed messaging system.
☒ Hsqldb	1.0.0	Provides a single point of authentication and access for Apache Hadoop services in a cluster.
☐ Log Search	0.5.0	Log aggregation, analysis, and visualization for Ambari managed services. This service is Technical Preview.
☐ Sqoop	2.1.0	Apache Sqoop 2.1 is a fast and ground engine for large-scale data processing.

In the list shown in the GUI, we only need to select those. In the next step, we'll add PQS to the cluster.

TIP If any of the required services fails to start automatically, you may need to start it manually. In case of repeated problems, please check out the service log for additional troubleshooting information. Refer to the article ["Viewing Service Logs"](#) on the Hortonworks documentation pages for details.

Assign Masters

In our example, as we're only using one node, so this will be our master for all the services. In production environments, you can select other nodes as the service Master.

Assign Masters

Assign Master Components to the Ambari Server

NameNode	hadoop-test-server [16.7 GB, 8 cores]
SlaveNode	hadoop-test-server [16.7 GB, 8 cores]
Timeline Service V1.5	hadoop-test-server [16.7 GB, 8 cores]
ResourceManager	hadoop-test-server [16.7 GB, 8 cores]
Timeline Service V2.0 Reader	hadoop-test-server [16.7 GB, 8 cores]
YARN Registry DNS	hadoop-test-server [16.7 GB, 8 cores]
History Server	hadoop-test-server [16.7 GB, 8 cores]
HBase Master	hadoop-test-server [16.7 GB, 8 cores]
ZooKeeper Server	hadoop-test-server [16.7 GB, 8 cores]
Metrics Collector	hadoop-test-server [16.7 GB, 8 cores]
GlueJob	hadoop-test-server [16.7 GB, 8 cores]
Knox Gateway	hadoop-test-server [16.7 GB, 8 cores]
Activity Explorer	hadoop-test-server [16.7 GB, 8 cores]
HST Server	hadoop-test-server [16.7 GB, 8 cores]
Activity Analyzer	hadoop-test-server [16.7 GB, 8 cores]

hadoop-test-server [16.7 GB, 8 cores]

[NameNode](#)
[SlaveNode](#)
[Timeline Service V1.5](#)
[ResourceManager](#)
[Timeline Service V2.0 Reader](#)
[YARN Registry DNS](#)
[History Server](#)
[HBase Master](#)
[ZooKeeper Server](#)
[Metrics Collector](#)
[GlueJob](#)
[Knox Gateway](#)
[Activity Explorer](#)
[HST Server](#)
[Activity Analyzer](#)

Assign Slaves and Clients

NOTE This step is really important. Make sure that you select "Phoenix Query Server" because PQS is a hard requirement for DDC.

Assign Slaves and Clients

Assign Slave and Client Components to the Ambari Server

Assign Slave and Client Components to the Ambari Server

Host	all none	all none	all none	all none	all none	all none
hadoop-test-server	☒ Outgroups	☒ Metadata	☒ HadoopManager	☒ HadoopClient	☒ PhoenixQueryServer	☒ Client

Items per page: 25 | 1 | 10 | 20 | 50

Customize Services

At this point, you only need to provide credentials for different services and review the installation.

The screenshot shows the 'KNOX MASTER SECRET' field in the Ambari setup wizard. The field is labeled 'KNOX MASTER SECRET' and has a 'NEXT' button to its right. The field is currently empty, and a password icon is visible on the right side of the input box.

1. Create the Knox master secret password and store it somewhere. Then, keep clicking **NEXT** until the screen that shows **DEPLOY**. Click it.
2. When the installation completes, click **NEXT** and then click **COMPLETE**.

More detailed information about the steps: For further information, please refer to the [Hortonworks official webpage](#).

8. Namenode HA Configuration

This section is only required if you are deploying TDP in more than 1 node.

NOTE It is recommended to perform this step at setup, as any changes to the Namenode HA configuration will result in downtime.

1. Go to the Ambari UI and select the HDFS services (**Services > HDFS** in the Ambari menu on the left).
2. Click **ACTIONS** and then the **Enable NameNode HA** section.
3. Follow the wizard.

The screenshot shows the Ambari UI 'Services / HDFS / Summary' page. The left sidebar shows the 'Services' menu with 'HDFS' selected. The main content area displays the 'Summary' tab for HDFS services. The 'Summary' section shows the status of the services: 'NameNode' is 'Stopped', 'DataNode' is 'Started', and 'SecondaryNameNode' is 'Stopped'. The 'Actions' menu is open on the right, showing the 'Enable NameNode HA' option. The 'Service Metrics' section shows various metrics for the services, including 'NameNode' (1820, 95.91%), 'DataNode' (1820, 95.91%), and 'SecondaryNameNode' (1820, 95.91%).

9. Configuring Knox

The Apache Knox Gateway is a system that provides a single point of authentication and access for Hadoop services in a cluster. While Knox supports many authentication/federation providers this document will only describe configuring LDAP. Please check Apache Knox Gateway's online configuration for details on the other providers:

<http://knox.apache.org/books/knox-1-0-0/user-guide.html#Authentication>

****WARNING**** It is your responsibility as the system owner to properly configure the authentication to secure the production environment. For demo purposes you can opt for the built-in LDAP server but for everything else you should configure your company's authentication/federation provider.

A change in the Knox configuration is needed to provide access from the DDC client. There are two ways a user could configure Knox for DDC. One is to **modify the default topology** and the other is to **create a new topology**. If you want to create a new topology, refer to the Knox documentation.

Modifying Embedded LDAP

To set up the embedded LDAP for demo usage, follow these steps:

1. Go to Knox configuration in the Ambari server UI.
2. (applicable for demo purposes only) Go to the **ACTIONS** menu and click **Start Demo LDAP**. Without starting the demo LDAP you cannot use the Knox logins.

3. Expand the **Advanced topology** section.

4. Add an entry for the PQS server.

- Single node configuration:

```
<service>
  <role>AVATICA</role>
  <url>http://<HOSTNAME_OF_PHOENIX_QUERY_SERVER>:8765</url>
</service>
```

- (optional) If the cluster is Namenode HA enabled, you have to list all PQS nodes:

```
<service>
  <role>AVATICA</role>
  <url>http://<HOSTNAME_OF_PHOENIX_QUERY_SERVER1>:8765</url>
  <url>http://<HOSTNAME_OF_PHOENIX_QUERY_SERVER2>:8765</url>
  <url>http://<HOSTNAME_OF_PHOENIX_QUERY_SERVER3>:8765</url>
  ...
</service>
```

5. (optional for creating a cluster) If the cluster is Namenode HA enabled, add the following section:

```
<provider>
  <role>ha</role>
  <name>HaProvider</name>
  <enabled>true</enabled>
  <param>
    <name>WEBHDFS</name>
```

```
<value>maxFailoverAttempts=3;failoverSleep=1000;maxRetryAttempts=300;retrySleep=1000;enabled=true</value>
</param>
</provider>
```

6. (applicable for non-demo purposes) Example for LDAP:

```
<provider>
<role>authentication</role>
<name>ShiroProvider</name>
<enabled>true</enabled>
<param>
<name>main.ldapRealm</name>
<value>org.apache.shiro.realm.ldap.JndiLdapRealm</value>
</param>
<param>
<name>main.ldapRealm.userDnTemplate</name>
<value>uid= {0},ou=people,dc=hadoop,dc=apache,dc=org</value>
</param>
<param>
<name>main.ldapRealm.contextFactory.url</name>
<value>ldap://localhost:33389</value>
</param>
<param>
<name>main.ldapRealm.contextFactory.authenticationMechanism</name>
<value>simple</value>
</param>
<param>
<name>urls./**</name>
<value>authcBasic</value>
</param>
</provider>
```

7. Click **SAVE** then restart all the affected components.

At the top of the screen it will tell you that a restart is required and there is an orange **RESTART** button. Click that button and select **Restart All Affected**.

8. With this configuration, use '/gateway/default/avatica' for the PQS URI and '/gateway/default/webhdfs/v1' for the HDFS URI in "Configuring HDFS" and "Configuring HBase" in the "Thales CipherTrust Data Discovery and Classification Deployment Guide".

For instructions on configuring an external LDAP or Active Directory refer to the Apache Knox online documentation:

- > [LDAP Configuration](#)
- > [Active Directory Configuration](#)

Knox Authentication Information in Ambari

When you are using the demo LDAP embedded with Knox, there is a file with the users credentials. To view these default credentials, select:

Knox > CONFIGS > Advanced-users-Idif

Scroll down to the '#entry for sample user admin' to find the 'userPassword', which by default is 'admin-password'.

Advanced users-ldif

```

cn: Guest
sn: User
uid: guest
userPassword: guest-password

# entry for sample user admin
dn: uid=admin,ou=people,dc=hadoop,dc=apache,dc=org
objectclass: top
objectclass: person
objectclass: organizationalPerson
objectclass: inetOrgPerson
cn: Admin
sn: Admin
uid: admin
userPassword: admin-password

# entry for sample user sam
dn: uid=sam,ou=people,dc=hadoop,dc=apache,dc=org
objectclass: top
objectclass: person

```

Default admin user**NOTE**

In production environments, when you are using a real LDAP or Active Directory, you have to use a user with admin permissions on the service.

10. Configuring Phoenix Query Server (HBase)

Apache Phoenix requires additional modification before you can use it with DDC. You need to enable namespace mapping and map the system tables to the namespace. For this procedure we are using the Ambari UI.

1. In the advanced HBase configuration, scroll down to **Custom hbase-site (HBase > CONFIGS > ADVANCED > Custom hbase-site)**.

2. Use the **Add Property...** link to add these two additional properties (as illustrated in the image further below):

```
phoenix.schema.isNamespaceMappingEnabled=true
```

```
phoenix.schema.mapSystemTablesToNamespace=true
```

NOTE These properties will be added to the **hbase-site.xml** configuration file.

3. Click **SAVE** then restart all the affected components.

At the top of the screen it will tell you that a restart is required and there is an orange **RESTART** button. Click that button and select **Restart All Affected**.

11. Creating DDC Directory Under HDFS

For DDC to utilize Hadoop Distributed File System (HDFS), you need to create a directory under HDFS. DDC will use this space for storing scan results and reports. You can create it through the command line and using the Ambari UI. You need to do it only on the **primary node**. This directory can have any name, but for this example and throughout the following sections of this document, we will use **/ciphertrust_ddc**.

TIP You will need this path later to configure CipherTrust. See "Configuring HDFS" in the "Thales CipherTrust Data Discovery and Classification Deployment Guide".

Creating the DDC Directory Using the Command Line

1. SSH to the TDP instance and log in as root.
2. Switch to the "hdfs" user, who has permissions to create and destroy folders:

```
su - hdfs
```

3. Create the DDC directory in HDFS by issuing this command:

```
hdfs dfs -mkdir /ciphertrust_ddc
```

4. Because the default permissions will not allow the scans to write over the Hadoop Database, you have to change the access permissions.

Issue this command to grant full access rights to the directory for all users:

```
hdfs dfs -chmod 777 /ciphertrust_ddc
```

NOTE: After entering the third command, enter 'exit' to return to the root prompt.

Managing the DDC Directory Using the User Interface

NOTE This section is just for your information and optional. You do not have to perform the steps below.

Once you have created the HDFS directory using the CLI, you can use the user interface to create sub-directories, download the files, or simply check the HDFS status.

1. Open the Namenode UI:

2. Click to expand the **Utilities** menu and next click the **Browse the file system** link.

From here, you can see all the HDFS directories. In this particular case, you cannot create a directory on the root because the user used by the UI has no permissions to do it.

12. Creating the PQS Schema

DDC uses Hbase to store scan results and reports and uses Phoenix Query Server to store and access this data. To that end, you have to create a PQS schema in the cluster. We will use **ciphertrust_ddc** as the name of the schema.

TIP This is a known issue with the PQS library. It can cause an error when the user tries to configure the PQS service on DDC for the first time. It can be avoided by creating the PQS schema before configuring DDC.

1. Open an SSH session on a Hadoop node which has PQS installed.

If PQS is installed on multiple nodes, choose any one of them. If you don't remember which node has PQS installed, you can go to the **Hosts** tab and see the services installed on each node.

2. Run the **sqlline-thin.py** script to open the SQL interpreter. For example:

```
/usr/hdp/3.1.5.0-316/phoenix/bin/sqlline-thin.py http://localhost:8765
```

(Typically, you will find the script in `/usr/hdp/3.1.5.0-316/phoenix/bin/`).

3. Within the SQL interpreter, run the following command to create the DDC schema:

```
CREATE SCHEMA IF NOT EXISTS ciphertrust_ddc;
```

4. Use Ctrl-D to exit.

Use **ciphertrust_ddc** as the PQS schema in the CipherTrust configuration in the "Configuring HBase" section of the "Thales CipherTrust Data Discovery and Classification Deployment Guide".

You can find more details on creating the PQS schema in the [official Phoenix documentation](#) (section Usage => Client).

13. Updating and Exporting the Knox Server Certificate

When the Knox service is installed by Ambari, a self-signed certificate is created internally. However, the certificate created uses SHA1 and with a key size of 1024 bits. The **update_knox_cert.sh** script below will create and replace the certificate with a new one using SHA256 and a key size of 2048 bits.

1. Run this script in an SSH session on the TDP instance:

```
# /root/setup/update_knox_cert.sh
```

2. When this script is run, it will prompt for the Knox master secret.

This secret is the one that you set in the step "7. Hadoop Services Installation Through Ambari > Customize Services" (**CREDENTIALS > Knox Master Secret**).

Finally, you need to export the SSL certificate of the Knox server and configure DDC to talk to Hadoop. You need to obtain the certificate where Knox is installed.

1. Put the Knox server certificate in a file, by using this command:

```
$ echo -n | openssl s_client -connect <IP_OF_KNOX_SERVER>:8443 | sed -ne '/-BEGIN CERTIFICATE-/,/-END CERTIFICATE-/p' > /tmp/hadoop.cert
```

2. Copy the certificate to the system where you will connect to the CipherTrust/DDC GUI.

Issue this command to display the certificate in the terminal window:

```
# cat /tmp/knox.cert
```

Now, you can copy the certificate from the terminal window and paste it in its own file on your machine. You will need this file when configuring DDC to talk to Hadoop. Refer to "Configuring CipherTrust Manager" in the "Thales CipherTrust Data Discovery and Classification Deployment Guide".

You can find the comprehensive procedure at this [link](#) on the Hortonworks documentation pages.

14. Changing the Knox Log Level

Knox uses Log4j to keep track of its log messages. The default log level is INFO which may quickly cause the log file to use up the available space and DDC scans to fail. Unless you need this level of detail in the logs you should change it to ERROR by editing its configuration file.

1. SSH to the TDP instance and log in as root.

2. Stop Knox by issuing this command:

```
su -l knox -c '$gateway_home/bin/gateway.sh stop'
```

3. Switch to the "hdfs" user:

```
su - hdfs
```

4. Open the `/etc/knox/conf/gateway-log4j.properties` file for editing.

- Change the `log4j.logger.audit` parameter to:

```
log4j.logger.audit=ERROR, auditfile
```

- Add these two additional parameters at the end:

```
log4j.appender.auditfile.MaxFileSize=10MB
```

```
log4j.appender.auditfile.MaxBackupIndex=10
```

5. Start Knox:

```
su -l knox -c '$gateway_home/bin/gateway.sh start'
```

If after applying these changes your Knox log grows too quickly, you may have to purge the log directory. First, however, you need to check if this is the case.

1. Check if Ambari is displaying a "NameNode Directory Status" error. This error indicates a failed directory (that is, one or more directories are reporting as not healthy.)
2. Check Ambari for a "Failed directory count" message to find out which directories are reporting problems. If the error message is showing "Failed directory count: 1" it may be the logs directory.
3. In the terminal, check the free disk space for **/var/log** by issuing the command:

```
df -h
```

If the output of the command is showing no free disk space for the **/var/log** directory, remove all the log files.

15. Configuring CipherTrust Manager

Refer to the "DDC Deployment Guide" to complete the CipherTrust Manager configuration.

Upgrading the Thales Data Platform

This section describes how to upgrade TDP from version 3.1.4 to version 3.1.5.

Preparing for the Upgrade

The first stage is to download the upgrade script and the upgrade tarball and prepare the script for upgrade.

Please follow the steps below:

1. Download the TDP 3.1.5 upgrade script (`ambari_upgrade.sh`) from Thales support and copy it to every node in your TDP cluster.
2. Download the tar file (`rpms_315.tar.gz`) from Thales support. This can be placed on an internal server that is external to the TDP cluster nodes.
3. Place the downloaded tar file (`rpms_315.tar.gz`) into `/var/tmp/`. This way, the path for the tar file is `/var/tmp/rpms_315.tar.gz`.
4. Run the `ambari_upgrade.sh` script on each node in the cluster:
 - On the ambari-server select option 1 (ambari-server and ambari-agent)
 - On all other nodes select option 2 (ambari-agent)

NOTE After the above steps, some of the cluster's components might be in a stopped/stale status as indicated by red alert on the left panel or upper right of the page. It is strongly recommended to restart all services to prepare for the upgrade. This can be done using the Ambari server UI by clicking the 3 dots ("...") to the right of "**Services**" > "**Stop All**" then "**Start All**". As an alternative, for each service (HDFS, HBase, Zookeeper and Knox), go to "**Actions**" then click "**Restart All**".

Registering and Installing the Target Version on the Ambari-Server Node

The next step is to register and install the target version on the ambari-server node only. The steps are as follows:

1. Log in to the ambari-server UI.
2. Browse to **Cluster Admin > Stack and Versions**.
3. Click the **Versions** tab. You see the version currently running, marked as **Current**.

NOTE The full version depends on the HDP version you are actually running. For example, if you are currently running the HDP 3.1.4.0 release, you would see something like HDP-3.1.4.0-315 as the full version number.

4. Click "**Manage Versions**".
5. Proceed to register a new version by clicking "**Register Version**".
6. Put **5.0** in place of Version Number so the Name will look like HDP-3.1.5.0.
7. Check "**Use local repository**" and put the Base URL as `file:///var/repo/hdp-315` in all 3 fields. Click **Save**.

8. Click the **Dashboard**.
9. Browse from **“Cluster Admin”** > **“Stack and Versions”**.
10. Click the **“Versions”** tab.
11. On a registered target version, click **“Install Packages”** and click **OK** to confirm.

The Install version operation starts. This installs the target version on all hosts in the cluster. You can monitor the progress of the install by clicking the **“Installing link”**. When the installation completes, the **“Upgrade”** button will replace the **“Install Packages”** button.

Performing the Upgrade

At this point, you are ready to perform the upgrade, so follow all of the steps below on the ambari-server node only:

1. Log in to the ambari-server UI.
2. Before starting the upgrade you have to disable the Auto Start Settings in the Cluster:
Admin > Service Auto Start
3. Run **“Service Check”** on HDFS, HBASE and KNOX in **“Actions”** > **“Run Service Check”**.
4. Browse to **Cluster Admin > Stack and Versions**.
5. Click the **Versions** tab. The registered and installed target HDP version displays an **“Upgrade”** button.
6. Click **“Upgrade”** on the target version.

Based on your current HDP version and the target HDP version, Ambari performs a set of prerequisite checks to determine if you can perform a rolling or an express upgrade. Note that if any required checks pop up, you will need to perform the recommended actions until all checks pass. A dialog displays the options available.

7. Select **“Express Upgrade”** or **“Rolling Upgrade”** method.
 - A "Rolling Upgrade" orchestrates the TDP upgrade in an order that is meant to preserve cluster operation and minimize service impact during upgrade. This process has more stringent prerequisites (particularly regarding cluster high availability configuration) and can take longer to complete than an "Express Upgrade".
 - An "Express Upgrade" orchestrates the TDP upgrade in an order that will incur cluster downtime but with less stringent prerequisites.

TIP If there are mission critical applications running, a “Rolling Upgrade” is recommended.

8. Click **“Proceed”**.
9. There may be some manual steps needed at this point. Please follow the instructions given and check the box that says “I have performed the manual steps above” before proceeding.
10. When the upgrade stages complete, Click **“Finalize”** to complete the upgrade process.

TIP After the upgrade is completed, you can confirm the upgrade has succeeded by going to 'Stack and Versions' -> 'Versions'. You will see that the current version is HDP-3.1.5.0 (3.1.5.0-316). On the 'Stack and Versions' -> 'Upgrade History' tab, when you click 'Upgrade' and see the drop-down list, you will also see details of each service's versions before and after upgrade, together with other information about the upgrade.

Launching the Amazon Instance

NOTE Please contact Thales support to get the Amazon Machine Image (AMI) ID that you should use in your Amazon Web Services (AWS) region.

Installing the Instance

1. Select EC2 from you Amazon Management Console. Select a region, for example “Canada (Central) ca-central-1”.
2. Next, create the instance by clicking **Images > AMIs**.
3. Search for the AMI by “AMI Name” or “AMI ID”, then select the desired AMI.
4. Follow the wizard to launch the instance:
 - a. Choose AMI.

Select the desired AMI from the search list and click “**Launch Instance**”.
 - b. Choose Instance Type.
 - i. Select “t2.xlarge”, if you’re installing a node that will be part of a 5 node cluster, and for a single node select “m4.4xlarge”.
 - ii. Click **Next** [Next: Configure Instance Details].
 - c. Configure Instance.
 - i. Key in the number of instances required for the “**Number of instances**”. For example, 5 for a 5-node cluster and 1 for a single node.
 - ii. For the rest of the values go with the default options, if you are not customizing the instance, and click **Next** [Next: Add Storage].
 - d. Add Storage.

Go with the default values and click **Next** [Next: Add Tags].
 - e. Add Tags.
 - i. Click “**Add Tag**”.
 - ii. Add a “**Key**” and a “**Value**”. For example: “Owner demo-user”.
 - iii. Click **Next** [Next: Configure Security Group].
 - f. Configure Security Group.
 - i. Select “**Create a new security group**”.
 - ii. Change “**Type**” to “All traffic”.
 - iii. If a pre-configured group with all traffic is available, choose that by selecting the previous selection as “Select an existing security group”.
 - iv. Click [**Review and Launch**].
 - g. Review.
 - i. Review all the properties of the instance that you have selected in the wizard. If needed, you can edit them in this step.

- ii. When you are done, click **[Launch]**.
- h. Select an existing key pair or create a new key pair.
 - i. Create a new key by choosing “**Create a new key pair**” from the drop down menu, name the key pair and download the same for connecting to the instance.
 - ii. If the key pair was created prior to launching the AMI, use the same. In this case, select “**Choose an existing key pair**” and select the key by name.
 - iii. Click the acknowledge check box and click **[Launch Instance]**.
- 5. Once your instances are launched, on your EC2 Dashboard you will see the details as below. You can rename your instances - these here are examples, but they won't be the hostnames of your instances.

TIP Note down the Private DNS and Public IP of your instances as these will be required later.

Logging in to the Instance and Additional Configuration

The initial login for the image is:

- > **login:** root
- > **password:** thales123

You will be prompted to change the password after initial login.

1. Change the hostname.

Set a hostname for your Ambari server and nodes of the Hadoop cluster. Change the hostname to the Private DNS. Run this command, for example, as root to set a new hostname:

```
# hostnamectl set-hostname ip-172-31-3-54.ca-central-1.compute.internal
```

Repeat this on all hosts!

2. Continue with the configuration by following the steps in "Configure Ambari" under "Setting Up the Ambari Server" till step 13 . Then Configure CiperTrust Manager to complete the Installation.

Securing Hadoop Configuration

Thales strongly recommends appropriately configuring and securing your Hadoop environment according to industry best practices and your organization's security policies.

The following references are not comprehensive, but are intended to provide a starting point for background, tools, and best practices that may be applied to your Hadoop environment:

1. "HDP Security Overview":

https://docs.cloudera.com/HDPDocuments/HDP3/HDP-3.1.5/security-overview/content/hdp_security_overview.html

2. "Introduction to Hadoop Security":

<https://www.bmc.com/blogs/hadoop-security/>

3. "Securing Hadoop: Security Recommendations for Hadoop" (Paper):

<https://securosis.com/blog/securing-hadoop-security-recommendations-for-hadoop-new-paper>

4. "Hadoop Security" (O'Reilly Book):

<https://www.oreilly.com/library/view/hadoop-security/9781491900970/>

Hadoop Backup

At some point, you may want to make a backup of everything in Hadoop that is related to DDC. Such a backup will include the HBase tables and all the generated files (.tar) with the information of the scans (hdfs).

In order to save the DDC data and create a backup you have to perform these two steps (separately):

1. Back up HDFS
2. Back up HBase

Preparing for the Backup

- > Execute the `df -h` command in the hdfs directory to be copied and make sure that there is enough space in the destination location.

NOTE

- > It is not necessary to make the backup in each node, but it is good practice make the backup on the name node.
- > You need to have **root privileges** to make a backup and restore it.
- > To run Export/Import commands, you need to switch to the 'hdfs' user.

Backup Options

There are several options to make and restore a backup:

- > HBASE - Full Shutdown Backup (with stopping of the service)
- > HBASE - Make and restore a snapshot (recommended option)
- > HBASE - Export and Import a table. **WARNING:** This option is not a Clone of the table and inconsistencies could appear
- > HDFS - By using the `distcp` command

For more information about these options, refer to the official Cloudera documentation.

Create HDFS Backup

The best way to create a HDFS backup on a different cluster is to use DistCp. The most common use of DistCp is an inter-cluster copy:

```
hadoop distcp hdfs://nn1:8020/source hdfs://nn2:8020/destination
```

Where:

- > nn1 is the name node where your data is located
- > the source is folder where the .tar files are (that is, the folder indicated in the path field when HDFS is configured in DDC)
- > nn2 is the name node where you want to save your data (nn2 can be the same as nn1)

- > the destination is the folder to which the .tar files will be copied and saved

Example command:

```
hadoop distcp hdfs://sys146116.i.vormetric.com:8020/ddc_demo_83
hdfs://sys146116.i.vormetric.com:8020/ddc_backup/hdfs_dir/ddc_demo_83
```

You can find more information on using DistCp on the official webpage or on the Cloudera blog.

NOTE

- > The destination folder should be created before executing the discp command.
- > Note that DistCp requires absolute paths.
- > These actions are made on ACTIVE NameNode and as 'hdfs' user.

Restore HDFS Backup

To restore a backup you also have to use the DistCP command. Again, the most common use of DistCp is an inter-cluster copy:

```
hadoop distcp hdfs://nn2:8020/destination hdfs://nn1:8020/source
```

Where:

- > nn1 is the name node where your data is located
- > the source is the folder where the .tar files are (that is, the folder indicated in the path field when HDFS is configured in DDC)
- > nn2 is the name node where you want to save your data (nn2 can be the same as nn1)
- > the destination is the folder to which the .tar files will be copied and saved

Example command:

```
hadoop distcp hdfs://sys146116.i.vormetric.com:8020/ddc_backup/hdfs_dir/ddc_demo_83
hdfs://sys146116.i.vormetric.com:8020/ddc_demo_83
```

NOTE

- > If the file already exists, it will be skipped. New files (not yet backed up) will still be there, and deleted files will be restored.
- > If you want to completely restore the folder (and only keep the files that were there when the copy was made), you have to execute a command to delete the files. This action is left to your discretion.
- > These actions must be made on the NameNode and as 'hdfs' user.

Create and Restore HBase Backup

There are different approaches to how to create HBase backups. All of them are described at this link:

<https://blog.cloudera.com/approaches-to-backup-and-disaster-recovery-in-hbase/#export>

Here, we describe the most common scenario - a full backup.

NOTE It is possible to make a complete backup by stopping the services and using the `distcp` command. For more details on a full shutdown backup see the HBase documentation.

Snapshots

If you do not want to stop the services, you can use HBase snapshots by executing the steps as follows:

- > Take a snapshot for each table (hbase doc: Take a Snapshot)
- > Restore the snapshot for the tables that you want (hbase doc: Restore a snapshot)

How to use the HBase snapshot utility

To run these commands, please, open a SSH session on the HBase Master node. Let us start by listing all the tables of the original HBase. Please, note that "DDC_SCHEMA1" is the schema name defined on the PQS configuration (PQS Tab of Hadoop Services in Settings).

```
$ hbase shell
$ hbase(main):001:0> list
TABLE
DDC_SCHEMA1:DATASTORE_SUMMARY_REPORT
DDC_SCHEMA1:DATA_OBJECT_REPORT
DDC_SCHEMA1:SCAN_EXECUTION_REPORT
SYSTEM:CATALOG
SYSTEM:FUNCTION
SYSTEM:LOG
SYSTEM:MUTEX
SYSTEM:SEQUENCE
SYSTEM:STATS
TEST:DATASTORE_SUMMARY_REPORT
TEST:DATA_OBJECT_REPORT
TEST:SCAN_EXECUTION_REPORT
12 row(s)
```

Creating a Backup

Take the snapshot with the command

```
snapshot 'myTable', 'myTableSnapshot-122112'
```

and list the snapshots:

```
$ hbase(main):002:0> snapshot 'DDC_SCHEMA1:DATASTORE_SUMMARY_REPORT', 'myTableSnapshot-
datastore_summary_report'
$ hbase(main):003:0> snapshot 'DDC_SCHEMA1:DATA_OBJECT_REPORT', 'myTableSnapshot-data_object_
report'
$ hbase(main):004:0> snapshot 'DDC_SCHEMA1:SCAN_EXECUTION_REPORT', 'myTableSnapshot-scan_
execution_report'
$ hbase(main):005:0> list_snapshots
SNAPSHOT                                TABLE + CREATION TIME
myTableSnapshot-datastore_summary_report DDC_SCHEMA1:DATASTORE_SUMMARY_REPORT (2020-11-
24 06:36:13 -0800)
myTableSnapshot-data_object_report       DDC_SCHEMA1:DATA_OBJECT_REPORT (2020-11-24
06:37:05 -0800)
myTableSnapshot-scan_execution_report    DDC_SCHEMA1:SCAN_EXECUTION_REPORT (2020-11-24
06:37:12 -0800)
3 row(s)
```

Restoring the Backup

Restore the backup by executing the commands as follows:

```
$ hbase(main):006:0> disable 'DDC_SCHEMA1:DATASTORE_SUMMARY_REPORT'
$ hbase(main):007:0> restore_snapshot 'myTableSnapshot-datastore_summary_report'
$ hbase(main):008:0> enable 'DDC_SCHEMA1:DATASTORE_SUMMARY_REPORT'
$ hbase(main):009:0> disable 'DDC_SCHEMA1:DATA_OBJECT_REPORT'
$ hbase(main):010:0> restore_snapshot 'myTableSnapshot-data_object_report'
$ hbase(main):011:0> enable 'DDC_SCHEMA1:DATA_OBJECT_REPORT'
$ hbase(main):012:0> disable 'DDC_SCHEMA1:SCAN_EXECUTION_REPORT'
$ hbase(main):013:0> restore_snapshot 'myTableSnapshot-scan_execution_report'
$ hbase(main):014:0> enable 'DDC_SCHEMA1:SCAN_EXECUTION_REPORT'
```

Export/Import the Tables

The HBase tables can be exported to HDFS using "Export" Command. After that, we can use DistCP to store the data somewhere else.

To export the tables related to DDC, it's necessary to know the Schema that we are using in DDC. The tables are the same for each schema:

DATASTORE_SUMMARY_REPORT, DATA_OBJECT_REPORT and SCAN_EXECUTION_REPORT

How to use Export

First of all, let's list all the tables of our origin Hbase:

```
$ hbase shell
$ hbase(main):001:0> list
TABLE
DDC_SCHEMA1:DATASTORE_SUMMARY_REPORT
DDC_SCHEMA1:DATA_OBJECT_REPORT
DDC_SCHEMA1:SCAN_EXECUTION_REPORT
SYSTEM:CATALOG
SYSTEM:FUNCTION
SYSTEM:LOG
SYSTEM:MUTEX
SYSTEM:SEQUENCE
SYSTEM:STATS
TEST:DATASTORE_SUMMARY_REPORT
TEST:DATA_OBJECT_REPORT
TEST:SCAN_EXECUTION_REPORT
12 row(s)
$ hbase(main):001:0> quit
```

Export the tables on a HDFS directory executing hbase export command:

```
$ bin/hbase org.apache.hadoop.hbase.mapreduce.Export <tablename> <outputdir>

$ hbase org.apache.hadoop.hbase.mapreduce.Export DDC_SCHEMA1:DATASTORE_SUMMARY_REPORT
hdfs:///ddc_backup/hbase/ddc_schema1_datastore_summary_report
$ hbase org.apache.hadoop.hbase.mapreduce.Export DDC_SCHEMA1:DATA_OBJECT_REPORT hdfs:///ddc_
backup/hbase/ddc_schema1_data_object_report
$ hbase org.apache.hadoop.hbase.mapreduce.Export DDC_SCHEMA1:SCAN_EXECUTION_REPORT hdfs:///ddc_
backup/hbase/ddc_schema1_scan_exectuion_report
```

NOTE The output directory must not exist.

How to use Import

If you want to restore the same tables in the same schema, you can execute the hbase import command.

Import the tables from the HDFS directory where the previous export is. To do that, execute the hbase import command:

```
$ bin/hbase org.apache.hadoop.hbase.mapreduce.Import <tablename> <inputdir>

$ hbase org.apache.hadoop.hbase.mapreduce.Import DDC_SCHEMA1:DATASTORE_SUMMARY_REPORT
hdfs:///ddc_backup/hbase/ddc_schema1_datastore_summary_report
$ hbase org.apache.hadoop.hbase.mapreduce.Import DDC_SCHEMA1:DATA_OBJECT_REPORT hdfs:///ddc_
backup/hbase/ddc_schema1_data_object_report
$ hbase org.apache.hadoop.hbase.mapreduce.Import DDC_SCHEMA1:SCAN_EXECUTION_REPORT hdfs:///ddc_
backup/hbase/ddc_schema1_scan_exectuion_report
```

NOTE

- > The import utility replaces the existing rows, but it does not clone the table keeping the new rows after the export.
- > There may be inconsistencies in the data, especially in the latest reports.

Thales CipherTrust Data Discovery and Classification

DEPLOYMENT GUIDE

Document Information

Document Information

Product Version	2.2.0
Document Number	007-000727-002, Rev A
Release Date	17 February 2021

Trademarks

About this Document

This introductory section identifies the audience, provides a brief summary of the contents of this guide, and discusses the documentation conventions used. It contains the following sections:

- > ["Audience" below](#)
- > ["What's in This Guide" below](#)
- > ["Organization" below](#)
- > ["Document Conventions" on the next page](#)

Audience

This document is intended for Thales CipherTrust Data Discovery and Classification (DDC) users responsible for classification of data discovered on data stores. It is assumed that the users of this document are proficient with security and data discovery concepts.

All products manufactured and distributed by Thales are designed to be installed, operated, and maintained by personnel who have the knowledge, training, and qualifications required to safely perform the tasks assigned to them. The information, processes, and procedures contained in this document are intended for use by trained and qualified personnel only.

Thales designs data security products for use by file server administrators, network administrators, security engineers, database administrators, application developers, and other technology professionals responsible for daily operations in support of data security.

What's in This Guide

This guide provides information on deploying the Thales CipherTrust Data Discovery and Classification (Thales DDC) solution. The document describes the requirements that must be met before installing and configuring the DDC Agents on host machines. The document also provides list of compatible installers for different types of data stores. Finally, the document provides guidelines on enhancing the performance and security of the DDC solution. The DDC documentation does not include information that is already covered in the CipherTrust Manager documentation, available through the **Product Documentation** link on the CipherTrust Manager GUI login page.

Organization

The *Thales CipherTrust Data Discovery and Classification Deployment Guide* contains the following sections:

1. ["DDC Deployment Architecture" on page 10](#)
Contains a visual overview (a diagram) of a typical DDC deployment.
2. ["Software and Hardware Requirements" on page 12](#)
Software and hardware Requirements for the DDC Server and Agents.
3. ["Deployment Prerequisites" on page 15](#)
Lists requirements that must be fulfilled before you start the DDC deployment.

4. ["Running DDC in a Cluster" on page 17](#)

Information and considerations for deploying DDC in a CipherTrust Manager cluster.

5. ["Configuring CipherTrust Manager" on page 20](#)

Provides instructions to configure DDC so that it can use Hadoop for storing its data.

6. ["Agent Configurations" on page 24](#)

The section lists all supported installers for different types of data stores.

7. ["Installing Agents" on page 26](#)

Provides instructions to install DDC Agents on Windows and Linux hosts.

8. ["Hardening the Deployment" on page 31](#)

Provides guidelines to enhance the performance and security of your DDC deployment.

9. ["Uninstalling Agents" on page 29](#)

Provides instructions to uninstall DDC Agents from Windows and Linux hosts.

10. ["Upgrading Agents" on page 30](#)

Instructions for upgrading DDC Agents on supported platforms.

Document Conventions

This section describes the formatting conventions used in this user guide to indicate hyperlinks, special notes, important information, tips, and warnings.

Hyperlinks

Hyperlinked text will, by default, appear in the shade of purple.

For example: All technical document templates can be found on the [Technical Writing Community page](#).

Notifications

This user guide uses notes, tips, and warnings to alert you to important information that may help you to complete your task, or prevent personal injury, damage to the equipment, or data loss.

Notes

Notes are used to alert you to important or helpful information. These elements use the following format:

NOTE Take note. Notes contain important or helpful information that you want to make stand out to the user.

Cautions

Cautions are used to alert you to important information that may help prevent unexpected results or data loss. These elements use the following format:

CAUTION! Exercise caution. Caution alerts contain important information that may help prevent unexpected results or data loss.

Warnings

Warnings are used to alert you to the potential for catastrophic data loss or personal injury. These elements use the following format:

****WARNING**** Be extremely careful and obey all safety and security measures. In this situation you might do something that could result in catastrophic data loss or personal injury.

Command Syntax and Typeface Conventions

Convention	Description
bold	The bold attribute is used to indicate the following: > Button names (Click Save As.) > Check box and radio button names (Select the Print Duplex check box.) > Dialog box titles (On the Protect Document dialog box, click Yes.) > Field names (User Name: Enter the name of the user.) > Menu names (On the File menu, click Save.) (Click Menu > Go To > Folders.) > User input (In the Date box, type April 1.)
<i>italic</i>	The italic attribute is used for emphasis or to indicate a related document. (See the <i>Thales CipherTrust Data Discovery and Classification Customer Release Notes</i> for more information.)
Double quote marks	Double quote marks enclose references to other sections within the document. For example: Refer to "Disclaimer" on page 2.
<variable>	In command descriptions, angle brackets represent variables. You must substitute a value for command line arguments that are enclosed in angle brackets.
<pre>[optional] [<optional>]</pre>	Square brackets enclose optional keywords or <variables> in a command line description. Optionally enter the keyword or <variable> that is enclosed in square brackets, if it is necessary or desirable to complete the task.
<pre>[a b c] [<a> <c>]</pre>	Square brackets enclose optional alternate keywords or variables in a command line description. Choose one command line argument enclosed within the braces, if desired. Choices are separated by vertical (OR) bars.
<pre>{ a b c } { <a> <c> }</pre>	Braces enclose required alternate keywords or <variables> in a command line description. You must choose one command line argument enclosed within the braces. Choices are separated by vertical (OR) bars.

DDC Deployment Architecture

This section describes the main components of Thales CipherTrust Data Discovery and Classification (DDC) and how they operate together to provide the DDC solution. Before you go ahead with the actual deployment, review the graphic included in this section to get a feel for what a typical DDC deployment looks like. The concepts used in this diagram are introduced in the later sections of this document and explained at length in the "DDC Administration Guide".

* A Windows Proxy is needed to connect to databases.

At the heart of the DDC solution is CipherTrust Manager on which runs the DDC Server. It is from here that users interact with the DDC GUI or use the DDC APIs to create classification profiles, add data stores, launch scans and generate reports.

Supported Data Stores

DDC supports a number of different data stores:

- > NFS shares
- > CIFS shares
- > Databases
- > Hadoop storage
- > Local storage (Windows and Linux)

In order to access these data stores, the DDC Server communicates with one or more DDC Agents. The DDC Agent is a software component that is used to scan a data store for Infotypes (such as credit card numbers, email addresses and so on) that are part of a classification profile. All data that is collected is sent from the Agent to the DDC Server which stores the data, together with any user requested reports, on an external Hadoop cluster.

Where to Install the DDC Agents

Generally speaking, if you are scanning data stores that are local to Windows or Linux (no network shares), you should install the DDC Agent on the server where the data is located. For all other types of storage (top part of the figure), the DDC Agent should be installed on a proxy server.

As an example, let's assume that you wish to scan an NFS share. In this case, the NFS share should be mounted on the proxy server and the DDC Agent should be installed on the proxy server. To scan the share, specify the mount point of the NFS share when creating the scan. For DDC Agent requirements and the types of data stores supported, see ["Agent Configurations" on page 24](#). For information on securing the deployment, refer to ["Hardening the Deployment" on page 31](#).

How DDC Uses Hadoop

DDC uses Hadoop to generate reports from scans and to store their results (report data). Thales Data Platform (TDP) is the only Hadoop flavor currently supported for this purpose. This is different than the Hadoop cluster that DDC also supports as a data store, that is where the user stores the data.

DDC can directly query HDFS but it requires Phoenix Query Server (PQS) to interface with Hadoop's HBase to benefit from its multitenancy features.

The DDC server retrieves the results of the scan from the DDC Agent and stores this information in TDP together with any reports that are generated. It is imperative that your TDP cluster is highly available to avoid losing any data store scans or reports.

DDC also requires Apache Knox as a single point of access to the TDP cluster (both HBase and HDFS), to ensure all the communications get protected with TLS, and for authentication. Therefore, you only need to connect up DDC to Knox. For information on configuring DDC to use TDP, see ["Configuring CipherTrust Manager" on page 20](#).

Software and Hardware Requirements

Hardware Requirements

CipherTrust Manager requirements

DDC is only supported when running CipherTrust Manager as a Virtual Machine. The CipherTrust Manager VM has the following requirements:

- > **RAM:** 16 GB minimum
- > **CPU:** 4 cores. It is recommended to add extra cores if the average CPU usage is above 50% or CPU load is above 80% for extended periods of time.
- > **Disk space:** at least 256 GB

Agent requirements

Each concurrent DDC scan requires one core and typically less than 1 GB of RAM. Agents do not launch concurrent Local Storage scans. When running Local scans Linux agents require a minimum of 1 core and 1 GB of RAM and Windows agents require 2 cores and 4 GB of RAM.

The above requirements only take the DDC scanning agent requirements into account. The operating system requires additional resources, usually 1-2 cores and 2-4 GB of RAM, and consider the requirements of the other services.

Please note that an agent running in a server can behave as a Local proxy for scanning this server and as a Proxy agent to scan other Data Stores, so you should monitor the agent resource consumption while the scans are running if needed.

Software Requirements

DDC Agents for Debian require Debian kernel versions 3.x and higher.

Ports Used for Communication

This section provides a list of ports that should allow communication among agents, data stores, and CipherTrust Manager. Firewalls should be configured to allow this communication.

The following table lists the ports that are used by agents to connect to data stores:

Initiator	Receiver	Protocol	Port(s)	Connection Type	Description
Agents	CipherTrust Manager	TCP	11117	Persistent	Allow traffic between Agents and the CipherTrust Manager appliance. Agents initiate the communication and keep persistent connections.

Initiator	Receiver	Protocol	Port(s)	Connection Type	Description
Agents	IBM DB2	TCP	50000	Non-persistent	Allow traffic between Agents and the IBM DB2 database store. Agents initiate the communication and need the port during the current session.
Agents	Microsoft SQL	TCP	1433	Non-persistent	Allow traffic between Agents and the Microsoft SQL database store. Agents initiate the communication and need the port during the current session.
Agents	Oracle	TCP	1521	Non-persistent	Allow traffic between Agents and the Oracle database store. Agents initiate the communication and need the port during the current session.
Agents	CIFS/SMB server	TCP	445*	Non-persistent	Allows scanning of Windows remote CIFS file shares.
Agents	NFS server	TCP or UDP	2049**	Non-persistent	Allows scanning of NFS file shares.
Agents	Hadoop Scanning	TCP	8020, 50075 and 50010	Non-persistent	Allow traffic between Agents and Hadoop cluster nodes. Agents initiate the communication and need the ports during the current session.

Apart from Hadoop as data store, CipherTrust Manager uses Hadoop as an external database to store and process the scan results. CipherTrust Manager initiates the communication and needs these ports to be open during the current session:

Initiator	Receiver	Protocol	Port(s)	Connection Type	Description
CipherTrust Manager	Hadoop***	TCP	8443 and 8765	Non-persistent	Allow traffic between TDP cluster nodes and the CipherTrust Manager appliance. DDC supports Hadoop NameNodes and Apache Knox.

* Additional ports. For Windows 2000 and older:

- 137 (UDP)
- 138 (UDP)
- 139 (TCP)

** NFSv4 requires only port 2049 (TCP only). NFSv3 and older must allow connections on the following ports:

- 111 (TCP or UDP)
- Dynamic ports assigned by rpcbind.

*** Thales Data Platform (TDP) is the only Hadoop flavor currently supported.

Deployment Prerequisites

- > CipherTrust Manager must be installed, configured, and accessible through the GUI (also called the console).
- > Hadoop must be installed and configured with a Phoenix Query Server (PQS) mapped to HBase.
- > You must also have Apache Knox installed and configured for Hadoop.

Knox must also be **DNS addressable**, through a network DNS or by adding the DNS entry as described in the "CipherTrust Manager Administration Guide" ("Concepts" > "DNS Hosts" > "Configuring DNS Hosts" section).

Installing CipherTrust Manager

DDC is shipped as a module of CipherTrust Manager with a trial license already installed so no additional installation should be required in CipherTrust Manager. If you don't have CipherTrust Manager already installed, or you cannot find DDC in the list of installed licenses contact Thales Group or refer to the CipherTrust Manager product documentation for instructions.

Installing and Configuring Hadoop

Thales Data Platform 3.1.5 (TDP) is a Big Data platform based on Hadoop technology. We recommend running a **5 node** TDP 3.1.5 cluster that has the following services available:

- > HDFS
- > HBase
- > Phoenix Query Server (PQS) - available on at least one node
- > Knox

We recommend **2 name nodes** and **3 data nodes**. Each node should have the following minimum hardware configuration:

- > 8 CPUs / vCPUS
- > 16 GB RAM
- > 100 GB of disk

For installing TDP 3.1.5 refer to the "Thales Data Platform Installation Guide" and perform all the steps in there before continuing with the DDC installation.

For information about Hadoop, refer to the official HDP documentation page:

<http://docs.cloudera.com/HDPDocuments/HDP3/HDP-3.1.4/index.html>

Configuring DNS Connectivity

To ensure uninterrupted connectivity to the UI, it is recommended to create a DNS entry for the active CipherTrust Manager node and use this entry when configuring the Agents and accessing the CipherTrust Manager UI. This way the Agents will be able to reach CipherTrust Manager even if its IP address changes.

- > **Standalone CipherTrust Manager:** If the CipherTrust Manager appliance is standalone (not in a cluster), configure a DNS entry with its IP address.
- > **Clustered CipherTrust Manager:** In a CipherTrust Manager cluster, configure a DNS entry with the IP address of the cluster's "active" node. See ["Identifying the Active DDC Node" on page 18](#) for details.

Running DDC in a Cluster

Although running a DDC cluster is currently not supported, Agents can be deployed into a CipherTrust Manager cluster. In this configuration, one of the CipherTrust Manager nodes, has to be assigned the active DDC node, so all the Agents report to it. This DDC configuration does not support failover, so if the active node fails so will DDC. DDC will not work, as long as the active node is down, so the only way to retain the DDC operations without any data loss is to restore the original active node.

There are two possible scenarios for running DDC in a cluster:

- > **"Greenfield" deployment** - in this scenario DDC is deployed into a completely new environment. See ["Deploying DDC into a New Environment" below](#) for more information.
- > **"Brownfield" deployment** - in this scenario DDC is deployed into an existing CipherTrust Manager cluster. See ["Deploying DDC into an Existing Cluster" below](#) for more information.

In both these scenarios it is essential to identify the active DDC node as you need an active DDC node for DDC to function in a cluster. For information on assigning the active node and identifying the IP address/hostname of the active node, refer to ["Assigning the Active DDC Node" on the next page](#) and ["Identifying the Active DDC Node" on the next page](#).

Deploying DDC into a New Environment

If you are deploying DDC into an environment where there is no existing CipherTrust Manager server that you could connect the Agents to, you have to start by deploying CipherTrust Manager first as you need a running, active CipherTrust Manager server to complete Agents' installation and configuration. If you're considering having a CipherTrust Manager cluster at some point, and using the cluster with DDC, you need to plan your deployment ahead and think it out carefully.

It is strongly recommended to create any planned cluster of CipherTrust Manager nodes prior to deploying DDC into it. Creating a CipherTrust Manager cluster out of CipherTrust Manager servers already hosting DDC poses a risk of a **loss of data** collected by DDC prior to the cluster creation. This is because any new CipherTrust Manager node added to the cluster gets its DDC **database wiped out** and replaced with a copy of the database of the active node.

This scenario may prove destructive for cases, for example, when you initially planned to have a few independent DDC systems (for example, for monitoring different segments of the network) with unclustered CipherTrust Manager servers but then decided to form a cluster out of them. In such a case, all CipherTrust Manager servers that also act as DDC servers will lose all their DDC data and settings except for the active node.

Deploying DDC into an Existing Cluster

Deploying DDC into an existing CipherTrust Manager cluster is a relatively straightforward task and it should not pose huge problems. After the installation, you just have to make one of the CipherTrust Manager nodes the active DDC node. Next, you have to connect up all the Agents to that active DDC node to complete their configuration.

From then on, the active DDC node will store all the configuration settings in its database. The database of the active node gets replicated over all cluster nodes, so every cluster member has an identical copy of the database. All the copies get synchronized and updated every time new data is inserted into the copy on the active node.

Assigning the Active DDC Node

DDC always requires one active node regardless of the number of CipherTrust Manager nodes (whether it is a single CipherTrust Manager node or a cluster of two or more CipherTrust Manager nodes). It is this active node that the DDC Agents point to (via DNS) and it is only this node that will respond to GUI operations.

To create an active DDC node you have to " earmark" one of the CipherTrust Manager nodes as the active DDC node. This is a manual procedure, which can be performed either through the CipherTrust Manager UI or the command line. In both cases, you have to have the CipherTrust Manager admin rights. The assignment of the active DDC node does not affect the normal CipherTrust Manager cluster operation.

NOTE The assignment of a DDC active node cannot be undone!

- > To assign the active DDC node by using the CipherTrust Manager UI, follow this procedure:
 - a. Log in to the CipherTrust Manager node that you want to make the active DDC node.
 - b. Click the **Data Discovery and Classification** link to open the DDC app.
You should see the "The current node is inactive. The node must be activated to use DDC." message.
 - c. Click the **Activate** button below the message.
The CipherTrust Manager node becomes the active DDC node.
- > To assign the active DDC node by using the CipherTrust Manager command line, you need the **ksctl** tool installed and configured. For information on installing and configuring the tool, refer to the "Interfaces > CLI" section in the "DDC Administration Guide".

Connect to the CipherTrust Manager node that you want to make the active DDC node, and issue this command:

```
ksctl ddc active-node register
```

After you assign an active DDC node, you can perform all DDC related tasks through that node. The other nodes - non-active nodes - will not allow you to work with DDC. When you log in to a CipherTrust Manager node that is a non-active DDC node and enter the **Data Discovery and Classification** application, you will see this message displayed:

"You are currently connected to an inactive node. You must switch to the active node <**active DDC node IP address**> to run DDC."

Identifying the Active DDC Node

In this section, we show how to locate the active node. For this procedure you need the **ksctl** tool. The tool must be configured to access any of the cluster nodes. For detailed information on installing and configuring the **ksctl** tool, refer to the "Interfaces > CLI" section in the "DDC Administration Guide".

- > To find the IP address of the active CipherTrust Manager node, run this command:

```
ksctl ddc active-node info
```

The output shows the IP address of the cluster's active node. Use this IP address to configure a DNS entry for the active CipherTrust Manager. Use that DNS entry to configure the Agents and access the CipherTrust Manager UI.

```
{
  "public_address": "mycluster.thalesgroup.com",
  "host": "10.45.102.101"
}
```

If the CipherTrust Manager appliance is not in a cluster, the command returns the following error:

```
{
  "code": 15,
  "codeDesc": "NCERRBadRequest: Bad HTTP request",
  "message": "oleander is not in cluster mode"
}
```

In this case, just use the IP address (or DNS entry) of this single CipherTrust Manager node.

Configuring CipherTrust Manager

To configure DDC with Hadoop, perform the following steps:

1. Type the CipherTrust Manager URL in the browser and log on to the CipherTrust Manager console as the administrator.
2. Click the **Data Discovery** link to open the **Data Discovery** configuration screen.
3. In the sidebar on the left, click **Settings > Hadoop Services**. The **Hadoop Services** page is displayed. This page contains two tabs, **PQS** and **HDFS**. By default, **PQS** is the active tab.

NOTE Only the users with access to the **root domain** have access to and can modify the Hadoop Services configuration. For more information about domains, refer to the "Thales CipherTrust Manager Administrator Guide".

****WARNING**** Once configured, the Hadoop Services settings must not be modified or you will lose access to all data.

Hadoop Services

PQS **HDFS**

CONNECTION

Knox Gateway Hostname* Port*

URL*

Scheme*

Knox Gateway Server Certificate

No file selected

KNOX AUTHENTICATION

Username*

Password*

Click the lock icon to change the password

Once configured, the Services must not be modified or you will lose access to all your collected data. Make sure the node meets the system requirements for DDC.

Configuring HBase

1. To configure DDC for HBase, click the **PQS** tab and configure the PQS settings:
 - a. **Hostname** and **Port** - the connection details of the Knox server.

You must use the hostname of your Knox server not its IP address as the server certificate that you need to import later on is hostname based. The default port is **8443**.

Knox must also be **DNS addressable**, through a network DNS or by adding the DNS entry as described in the "CipherTrust Manager Administration Guide" ("Concepts" > "DNS Hosts" > "Configuring DNS Hosts" section).

- b. URI** - the PQS path as configured in Knox. The path consists of the Knox server bit and the PQS bit. Here is an example:

/gateway/default/avatica

where "gateway" is the Knox bit, "default" is the topology name, and "avatica" is the service name.

NOTE If you are not using the default topology, use your topology name instead of the "default" bit in the URI.

- c. Schema** - the PQS Schema as mapped to HBase namespace.

TIP To avoid potential issues, it is recommended to have this schema already created prior to performing this configuration step. Refer to the "Thales Data Platform Installation Guide", section "12. Creating the PQS Schema".

- d. Server Certificate** - Knox uses HTTPS for connection that is why DDC will only connect to the Hadoop Services if a valid and trusted certificate is used. If this certificate was signed by a public and recognized CA, DDC will trust it automatically, otherwise you should manually import it here.

Click the **Choose File** button in the **Select Server Certificate** section and import the server certificate.

IMPORTANT: Use the same certificate as you exported earlier in "13. Exporting the Knox Server Certificate" in the "Thales Data Platform Installation Guide".

TIP

- > If the certificate is self-signed, you have to export it first on the Knox server and then import on the machine where you are running the CipherTrust Manager console. The certificate is then permanently stored in DDC. You do not need to repeat this step on another DDC client machine.
- > Binary format certificates are not accepted. You can only import a plain-text certificate (such as for example, the Base-64 encoded X.509 standard).

- e.** In the **AUTHENTICATION** section fill in the **Username** and **Password** string for a Knox authorized user.

IMPORTANT: Use the same authentication details as you configured earlier in "9. Configuring Knox" in the "Thales Data Platform Installation Guide".

- 2.** Click **Save Changes** to save the configuration.

Configuring HDFS

1. To configure DDC for HDFS, click the **HDFS** tab, and configure the HDFS settings:

a. **Hostname** and **Port** - the connection details of the Knox server.

You must use the hostname of your Knox server not its IP address as the server certificate that you need to import later on is hostname based. The default port is **8443**.

Knox must also be **DNS addressable**, through a network DNS or by adding the DNS entry as described in the "CipherTrust Manager Administration Guide" ("Concepts" > "DNS Hosts" > "Configuring DNS Hosts" section).

b. **URI** - the path to HDFS as configured in Knox. The path consists of the Knox server bit and the HDFS bit. For example:

/gateway/default/webhdfs/v1

where "gateway" is the Knox bit, "default" is the topology name, and "webhdfs/v1" is the HDFS bit.

NOTE If you are not using the default topology, use your topology name instead of the "default" bit in the URI.

c. **Folder** - type in the DDC file system directory in HDFS that you created earlier (for example **/ciphertrust_ddc**).

IMPORTANT: Use the same directory name as you configured earlier in "11. Creating DDC Directory Under HDFS" in the "Thales Data Platform Installation Guide".

d. **Server Certificate** - as HTTPS is forced as the protocol for Knox you have to import the server certificate here.

Click the **Choose File** button in the **Select Server Certificate** section and import the server certificate.

IMPORTANT: Use the same certificate as you exported earlier in "13. Exporting the Knox Server Certificate" in the "Thales Data Platform Installation Guide".

NOTE

- > The certificate is typically self-signed so you have to export it first on the Knox server and then import on the machine where you are running the CipherTrust Manager console. The certificate is then permanently stored in DDC. You do not need to repeat this step on another DDC client machine.
- > Binary format certificates are not accepted. You can only import a plain-text certificate (such as for example, the Base-64 encoded X.509 standard).

- e. In the **AUTHENTICATION** section fill in the **Username** and **Password** string for a Knox authorized user.

IMPORTANT: Use the same authentication details as you configured earlier in "9. Configuring Knox" in the "Thales Data Platform Installation Guide".

2. Click **Save Changes** to save the configuration.

The connection was successful if no error is returned and this message is displayed:

"Success. HDFS settings have been updated"

Agent Configurations

DDC supports two types of Agent configurations:

- > **Local:** Agent is installed and configured directly on the machine that contains sensitive data.
- > **Proxy:** Agent is installed and configured on a proxy machine that is used to scan sensitive data on other machines.

The instructions to install and configure Agents in both types of configurations are the same.

Agent Compatibility and Installers

The following table lists supported Agent installers for different types of data stores for different platforms and databases to help you select an appropriate installer depending on your data store requirements.

Data Store Category	Data Store Type	Agent Configuration	Agent Installer Packages
Local Storage	RHEL, CentOS	Local	RHEL (.rpm) - 32 bit, 64 bit
	Debian based distros	Local	Debian (.deb) - 32 bit, 64 bit, 64 bit with database support (compatible with Debian 9 only)
	Windows	Local	Windows (.msi) - 32 bit, 64 bit, 32 bit with database support, 64 bit with database support
Database Storage	IBM DB2 11.1 and higher	Local, Proxy	Windows (.msi) - 32 bit with database support, 64 bit with database support
	Microsoft SQL 2005 and higher	Local, Proxy	Windows (.msi) - 32 bit with database support, 64 bit with database support
	Oracle 9 and higher	Local, Proxy	Windows (.msi) - 32 bit with database support, 64 bit with database support
Network Storage	Unix File Share (NFS)	Proxy	Debian (.deb) - 32 bit, 64 bit, 64 bit with database support (compatible with Debian 9 only) RHEL (.rpm) - 32 bit, 64 bit
	Windows Share (SMB, CIFS)	Proxy	Windows (.msi) - 32 bit, 64 bit, 32 bit with database support, 64 bit with database support
Big Data	Hadoop Cluster	Proxy	Debian (.deb) 64 bit with database support (compatible with Ubuntu 18 only)*

* Linux 3 64-bit "database runtime" version with additional packages for use with Hadoop Clusters only. For Hadoop as data store, Agents must have the following packages installed:

- libaio1

- libgsasl7
- libxml2
- libprotobuf10

Installing Agents

This section provides procedures for installing Agents for all supported operating systems.

1. Download the latest version of a compatible Agent installation file from the [Thales Customer Support Portal](#). The "[Agent Compatibility and Installers](#)" on page 24 lists all the data stores and their matching installer packages.
2. Save the downloaded installer on the host machine where you want to install the Agent.
3. Follow the appropriate installation procedure for your operating system.

TIP Before you begin the installation, make sure that CipherTrust Manager is reachable from the host where you are installing the Agent.

Installing Agents on RHEL

1. Navigate to the location where the Agent installation package (.rpm) is stored.
2. Log in as a user with root privileges (su) and Install the Agent by using the following command:

```
#rpm -ivh er2-2.x.xx-xxxx.rpm
```

For example:

```
#rpm -ivh er2-2.0.31-linux26-rh-x64.rpm
```

The package name that you use with the command may be different and depends on your system's architecture and Agent type.

3. Connect the Agent to the active CipherTrust Manager node:

```
#er2-config -i <hostname|ip_address>
```

where, <hostname|ip_address> represents the IP address or hostname of the CipherTrust Manager node.

4. Test the connection settings (on the data store that is using this host).

```
#er2-config -t
```

If the connection has been correctly configured, you should see the following message:

```
Testing connection setting...
Test SUCCESS. Saving settings
Configuration updated, please restart agent service
The configuration has been saved. Please restart the agent for the changes to take effect.
```

5. Restart the Agent:

- Option 1

```
#!/etc/init.d/er2-agent restart
```

- Option 2

```
#!/etc/init.d/er2-agent stop
#!/etc/init.d/er2-agent start
```

NOTE The installation script creates an **erecon** user in the **erecon** group. Please ensure that this user (or group) is able to read all the files to scan. For security reasons, the account has its password **locked** to ensure that the user is solely used by the DDC scanning agent.

Installing Agents on Debian

1. Navigate to the location where the Agent installation (.deb) package is stored.

2. Install the Agent by using the following command:

```
sudo dpkg -i er2_2.x.xx-xxxx.deb
```

For example:

```
sudo dpkg -i er2_2.0.31-linux26-x64.deb
```

The package name that you use with the command may be different and depends on your system's architecture and Agent type.

3. Connect the Agent to the active CipherTrust Manager node:

```
sudo er2-config -i <hostname|ip_address>
```

where, <hostname|ip_address> represents the IP address or hostname of the CipherTrust Manager node.

4. Test the connection settings (on the data store that is using this host).

```
sudo er2-config -t
```

If the connection has been correctly configured, you should see the following message:

```
Testing connection setting...
Test SUCCESS. Saving settings
Configuration updated, please restart agent service
The configuration has been saved. Please restart the agent for the changes to take effect.
```

5. Restart the Agent:

- Option 1

```
sudo /etc/init.d/er2-agent restart
```

- Option 2

```
sudo /etc/init.d/er2-agent stop
sudo /etc/init.d/er2-agent start
```

NOTE The installation script creates an **erecon** user in the **erecon** group. Please ensure that this user (or group) is able to read all the files to scan. For security reasons, the account has its password **locked** to ensure that the user is solely used by the DDC scanning agent.

Installing Agents on Windows

1. Log in to the host machine where you want to install the Agent as administrator.

2. Run the Agent installer.

3. In the **Welcome** screen of the setup wizard, click **Next** to continue.

4. The **End-User Licence Agreement** (EULA) screen is displayed.
 - a. Read the license agreement and select **I accept the terms in the Licence Agreement**.
 - b. Click **Next** to continue.
5. In the **Choose Setup Type** screen, select the **Install** option for the standard installation and click **Next** to continue.
6. The **Ready to Install** screen is displayed.
 - a. Click **Install** to install the product in the default location.
 - b. If the **User Access Control** dialog box appears, click **Yes** to confirm.

The installation begins and the progress is shown under the **Status** progress bar.
7. During the installation, in a separate **Node Configuration** window, you are asked for the connection details of the active CipherTrust Manager node.
 - a. **Master server IP address or host name** - specify the IP address or host name of the CipherTrust Manager node.
 - b. **Master server public key** and **Target Group** - skip this configuration part as it is optional and currently not used.
 - c. Click **Test Connection** to test the connection between the Agent and CipherTrust Manager.
 - If the connection is properly configured, a confirmation will appear stating "Connectivity test is successful". Click **OK** to close the prompt.
 - If the connectivity test fails, click **OK** to close the prompt, make sure that CipherTrust Manager is reachable from the Agent host, and retry the test.
 - d. Click **Finish** to complete the configuration.
8. After a successful Agent installation, click the **Finish** button to exit the wizard and complete the installation.

NOTE The installer creates a service called **Enterprise Recon 2 Agent** that runs under the Local System user account.

Uninstalling Agents

Uninstalling Agents from RHEL

To uninstall a DDC Agent:

1. Stop the DDC Agent.

```
/etc/init.d/er2-agent stop
```

2. Uninstall the DDC Agent.

```
rpm -e er2
```

Uninstalling Agents from Debian

To uninstall a DDC Agent:

1. Stop the DDC Agent.

```
sudo /etc/init.d/er2-agent -stop
```

2. Uninstall the DDC Agent.

```
sudo dpkg --remove er2
```

Uninstalling Agents from Windows

To uninstall a DDC Agent, you must be logged on as Administrator to the host where the Agent is running.

1. Navigate to the **Control Panel > Programs and Features**.
2. Locate the **Enterprise Recon 2 Agent** in the list of installed programs.
3. Right click the Agent and select **Uninstall**.
4. In the dialog box that is displayed, select to automatically close the **Enterprise Recon 2 Agent** application, and click **OK** to continue.
5. Walk through the wizard.

TIP Alternatively, to uninstall a DDC Agent from CLI, run the following commands as Administrator:

```
net stop "Enterprise Recon 2 Agent (<ARCH>)"  
wmic product where name="Enterprise Recon 2 Agent (<ARCH>)" uninstall
```

Upgrading Agents

Agents do not require an upgrade unless a feature available in an updated version of the Agent is needed. Older versions of the Agent are compatible with newer versions of the Server. To upgrade an Agent, simply re-install it. Prior to reinstalling, you have to uninstall the Agent.

- > For instructions on uninstalling Agents, see:
 - ["Uninstalling Agents" on page 29](#)
 - ["Uninstalling Agents" on page 29](#)
 - ["Uninstalling Agents from Windows" on page 29](#)
- > For instructions on installing Agents, see:
 - ["Installing Agents" on page 26](#)
 - ["Installing Agents" on page 26](#)
 - ["Installing Agents" on page 26](#)

Hardening the Deployment

CipherTrust Manager should be deployed into as secure an environment as possible. Every effort has been made to make CipherTrust Manager as secure as possible, however, additional precautions should be taken especially when CipherTrust Manager is deployed into an untrusted environment. Refer to "Hardening Guidelines" in the "CipherTrust Manager Deployment Guide" for details.

General Hardening Recommendations

When a scan is run, all the data is transferred from data stores to Agents so that they can read and discover info types. As a result, potentially sensitive data is transferred between data stores and Agents. Although we cannot provide the comprehensive list of actions to secure the data being transferred, for security and performance reasons, we offer at least the following recommendations:

- > As a general rule, take all necessary actions to eliminate or minimize the transfer of data between data stores and Agents.
- > It is recommended to install a different Agent in each subnet with sensitive data, and to configure the firewalls to block any connection to the sensitive data stores from Agents in different subnets. This ensures that sensitive data does not leave the subnet and company policies are respected.
- > Agents should not be in a different network security zone. This ensures that data does not cross the network security zone boundaries.
- > Agents should be used in the same subnet as the data stores for Big Data stores. This can prevent firewalls from collapsing.
- > Local Agents should be used, when possible, in data stores with huge amount of data. This ensures that the data never leaves the server.
- > Contact your corporate security teams if data stores reside in different network security zones to determine where to locate the CipherTrust Manager appliance.
- > Agents should be hardened to comply with the company security policies for the sensitivity of the data located in the data stores they will scan, as all the scanned data will be transferred to the Agents.
- > DDC should be configured with secure protocols (for example, using TLS) to connect to data stores whenever possible, to ensure that the data travels protected with channel encryption.
- > Use firewalls to restrict the access to data stores, so only the allowed computers can connect to their endpoints.

Certificate Security Recommendations

- > **Certificate generation**
 - Certificate private keys must not be generated or transformed on public web services.
 - The certificate format must not be transformed on public web services.
 - Cryptographic algorithms and key length must satisfy a minimum security strength of 112 bits.
 - For the symmetric key, we recommend to use at least AES128.

- For the asymmetric key: use DSA-2048, RSA-2048, and ECDSA224-255.
- Certificate validity and Key usage period should not exceed 2 years.
- Digital signatures must use a strong hash function. We recommend using at least SHA256.
- > **Certificate usage**
 - User must keep secret his private key and related activation data.
 - Receivers of a certificate must verify the certificate.
 - Users must respect the PKI Certificate Policy requirements when using a certificate.
 - Do not share Wildcard Certificates for Different Security Contexts or Security Levels.
- > **Certificate revocation**
 - Subscribers must revoke their certificates when necessary (for example, when it's compromised).
- > **Certificate renewal**
 - Subscribers must renew their certificate before it expires.

Securing the Hadoop Configuration

Here are some general guidelines on securing your Hadoop deployment. These recommendations are general and apply to any Hadoop cluster.

- > The Hadoop cluster should only be deployed inside a corporate or trusted network. You must use a VPC network if deploying to a cloud.
- > None of the Hadoop nodes should be exposed to the Internet.
- > To access services from the Internet, it is recommended to use VPN access. If VPN is not available, it is recommended to use jump servers or bastion hosts. For example, to access SSH (port 22), do not expose it directly to the Internet. Instead, use a jump server or a bastion host.
- > To access web services, such as DDC or Ambari, use a reverse proxy or some kind of a load balancer. These devices normally sit in a DMZ (demilitarized zone) and forwards only a specific TCP port to the Hadoop cluster.
- > For Hadoop clusters configure the replication channels to use transport level encryption.

Additionally for the DDC-Hadoop configuration (PQS/HDFS), below you can find some guidelines that will help you set secure credentials and secure TLC configuration. For details and instructions, refer to your Hadoop documentation.

- > **Secure credentials**
 - Hadoop credentials must be rotated regularly.
 - Credentials must be different for every installation.
 - Password must meet the security requirements described below:
 - At least 10 characters in length.
 - Contains both uppercase (A-Z) and lowercase (a-z) alphabetic characters.
 - Has at least one numeric (0-9) character.
 - Has at least one special character (! @ # \$ % ^ & * () _ - + = , . / < > ? ; ' : \ " [] \ \ { } | ~ `).

- Does not contain spaces or tabs.

> **Secure TLS configuration**

- Disable SSL and TLS 1.0 and 1.1.
- Use secure renegotiation or disable renegotiation.
- Disable TLS compression.
- Use Authenticated Encryption cipher suites.
- Use cipher suites with strong key exchange.
- Do not use cipher suites with known vulnerabilities.
- Cipher suites order must be defined by the user.
- Use Perfect Forward Secrecy (PFS).
- Download the tool from <https://testssl.sh/> to check the configuration.

Thales CipherTrust Data Discovery and Classification

ADMINISTRATOR GUIDE

Document Information

PREFACE: About this Document

This introductory section identifies the audience, provides a brief summary of the contents of this guide, and discusses the documentation conventions used. It contains the following sections:

- > ["Audience" below](#)
- > ["What's in This Guide" below](#)
- > ["Organization" below](#)
- > ["Document Conventions" on the next page](#)

Audience

This document is intended for Thales CipherTrust Data Discovery and Classification (DDC) users responsible for classification of data discovered on data stores. It is assumed that the users of this document are proficient with security and data discovery concepts.

All products manufactured and distributed by Thales are designed to be installed, operated, and maintained by personnel who have the knowledge, training, and qualifications required to safely perform the tasks assigned to them. The information, processes, and procedures contained in this document are intended for use by trained and qualified personnel only.

Thales designs data security products for use by file server administrators, network administrators, security engineers, database administrators, application developers, and other technology professionals responsible for daily operations in support of data security.

What's in This Guide

This guide explains data discovery concepts such as data stores, branch locations, classification profiles, and data discovery scans. The document also explains how to generate scan-based reports on the discovered data. Finally, the document describes how to read generated reports.

Organization

The *Thales CipherTrust Data Discovery and Classification Administrator Guide* contains the following chapters:

1. ["Solution Overview" on page 11](#)

Describes data discovery concepts such as branch locations, classification profiles, sensitivity levels, tags, data stores, data discovery scans, and user roles and permissions.

2. ["Licensing" on page 18](#)

Describes different types of DDC licenses.

3. ["DDC User Groups" on page 22](#)

Describes all predefined groups of DDC users with their rights to use various product features.

4. ["Accessing and Interacting With DDC" on page 24](#)

This section introduces the primary channel to interact with DDC , the console.

5. ["Managing Branch Locations" on page 25](#)

Describes how to add and view branch locations.

6. ["Managing Classification Profiles" on page 27](#)

Describes how to add, view, and duplicate classification profiles.

7. ["Managing Data Stores" on page 32](#)

Describes how to add and edit different types of data stores. The types of data stores are local, network, database, and big data.

8. ["Managing Scans" on page 44](#)

Describes how to add, run, and view scans.

9. ["Managing Reports" on page 50](#)

Describes how to configure and run aggregated reports on the discovered data.

10. ["APPENDICES" on page 57](#)

Additional useful information and tools related to system administration, such as system error messages, handy commands, and additional interfaces for interacting with the product.

Document Conventions

This section describes the formatting conventions used in this user guide to indicate hyperlinks, special notes, important information, tips, and warnings.

Hyperlinks

Hyperlinked text will, by default, appear in the shade of purple.

For example: All technical document templates can be found on the [Technical Writing Community page](#).

Notifications

This user guide uses notes, tips, and warnings to alert you to important information that may help you to complete your task, or prevent personal injury, damage to the equipment, or data loss.

Notes

Notes are used to alert you to important or helpful information. These elements use the following format:

NOTE Take note. Notes contain important or helpful information that you want to make stand out to the user.

Cautions

Cautions are used to alert you to important information that may help prevent unexpected results or data loss. These elements use the following format:

CAUTION! Exercise caution. Caution alerts contain important information that may help prevent unexpected results or data loss.

Warnings

Warnings are used to alert you to the potential for catastrophic data loss or personal injury. These elements use the following format:

****WARNING**** Be extremely careful and obey all safety and security measures. In this situation you might do something that could result in catastrophic data loss or personal injury.

Command Syntax and Typeface Conventions

Convention	Description
bold	The bold attribute is used to indicate the following: > Button names (Click Save As.) > Check box and radio button names (Select the Print Duplex check box.) > Dialog box titles (On the Protect Document dialog box, click Yes.) > Field names (User Name: Enter the name of the user.) > Menu names (On the File menu, click Save.) (Click Menu > Go To > Folders.) > User input (In the Date box, type April 1.)
<i>italic</i>	The italic attribute is used for emphasis or to indicate a related document. (See the <i>Thales CipherTrust Data Discovery and Classification Customer Release Notes</i> for more information.)
Double quote marks	Double quote marks enclose references to other sections within the document. For example: Refer to "Disclaimer" on page 2.
<variable>	In command descriptions, angle brackets represent variables. You must substitute a value for command line arguments that are enclosed in angle brackets.
[optional] [<optional>] [a b c] [<a> <c>]	Square brackets enclose optional keywords or <variables> in a command line description. Optionally enter the keyword or <variable> that is enclosed in square brackets, if it is necessary or desirable to complete the task. Square brackets enclose optional alternate keywords or variables in a command line description. Choose one command line argument enclosed within the braces, if desired. Choices are separated by vertical (OR) bars.

Convention	Description
<code>{ a b c }</code> <code>{ <a> <c> }</code>	Braces enclose required alternate keywords or <variables> in a command line description. You must choose one command line argument enclosed within the braces. Choices are separated by vertical (OR) bars.

Solution Overview

This section describes the main components of the Thales CipherTrust Data Discovery and Classification (DDC) solution. The concepts used in this diagram are briefly discussed in this section and explained at length in the later sections of this document.

> KeySecure, DDC Server

At the heart of the DDC solution is CipherTrust Manager on which runs the DDC Server. It is from here that users interact with the DDC GUI or use the DDC APIs to create classification profiles, add data stores, launch scans and generate reports.

> REST APIs, GUI

Various types of interfaces used to interact with DDC.

> Hadoop, PQS, HDFS

DDC uses Hadoop to generate reports from scans and to store their results (report data). DDC can directly query HDFS but it requires Phoenix Query Server (PQS) to interface with Hadoop's HBase.

> DDC Agent, Proxy Agent, Local Agent

DDC Agents perform the actual scanning jobs and report the results back to the DDC Server for analysis and processing. DDC supports two types of Agent configurations: **Local Agents** are installed and configured directly on the machine that contains sensitive data; **Proxy Agents** are installed and configured on a proxy machine that is used to scan sensitive data on other machines.

> Data Store

A data store is where the data actually resides. It can be a file server, a database, or a Hadoop cluster. For more information see ["Managing Data Stores" on page 32](#).

> Local storage

A type of a data store, a file system (Windows or Linux) that is localized to the same machine where the Agent scanning it is installed.

> NFS, CIFS

A type of data store, a network share (Windows or Linux) that resides on a different machine than that where the Agent scanning it is installed.

> Branch Locations

A branch location specifies a site where the file servers, databases, and data centers that contain data to scan are located. Branch locations are used to indicate where different data stores are physically located. For more information see ["Managing Branch Locations" on page 25](#).

> Sensitivity Levels

A sensitivity level defines how sensitive the data is. Sensitivity levels are required in creating classification profiles and data stores. For more information see ["Sensitivity Levels" on the next page](#).

> Information Types

An information type (or infotype) categorizes data to look for during a scan. A large number of predefined information types are available to better categorize the data. For more information see ["Information Types" on the next page](#).

> Tags

A tag helps group data together. Tags are used to filter data for generating reports. They can be specified when creating data stores and classification profiles.

DDC includes a number of predefined tags. The predefined tags are APA, APPI, CCPA, FINANCIAL, GDPR, HEALTH, HIPAA, KVKK, LEGAL, PCI, PERSONAL, PHI, PII, and SHIELD.

DDC also provides the ability to create custom tags when creating data stores and classification profiles.

> Classification Profiles

A classification profile defines what kind of sensitive information to search for during a scan. It includes information such as a sensitivity level, information types, and tags. Classification profiles can be created based on predefined templates or custom templates. For more information see ["Managing Classification Profiles" on page 27](#).

> Data Objects

A file or a database table stored in a data store is called a Data Object.

> Sensitive Data Objects

A data object that contains any data match is called a Sensitive Data Object.

> Data Matches

A concrete instance of any of the infotypes is called a Data Match.

> Risks

A risk is the presence of a sensitive data object in an unprotected data store.

> Scans

A scan is an entity that helps in scanning data stores. Each scan specifies the location to scan and what to look for during scanning. Findings of scans can be used to generate reports for different purposes. Scans can be either run manually (any time) or scheduled to run and stop at a specified time. For more information ["Managing Scans" on page 44](#).

Sensitivity Levels

A sensitivity level defines how sensitive the data is. Sensitivity levels are required in creating classification profiles and data stores. Prebuilt sensitivity levels are:

- > **None:** The sensitivity level for such data has not yet been specified.
- > **Public:** Specifies the least sensitive data with no specific need for data security. Such data can be shared with anybody.
- > **Internal:** Specifies the data with low sensitivity. Exposure of such data may not affect an organization, but is not meant for public disclosure.
- > **Private:** Specifies that the data is personal. Such data should be protected from public viewing.
- > **Restricted:** Specifies highly sensitive data, for example, customer's personal data and trade secrets etc. This type of data requires the best possible data security. Disclosure of such data can lead to severe financial and legal consequences for an organization. Businesses must prioritize remediation efforts related to this type of data.

Information Types

An information type (infotype) categorizes data to look for during a scan. A large number of prebuilt information types are available to better categorize the data.

Different regions and countries can have different regulatory requirements, so these information types are categorized based on geographical regions. These regions are Global, Africa, Americas, Asia, Europe, and Oceania. The information types can be further categorized into:

- > **Financial:** Financial data such as credit card numbers and bank account details.
- > **Personal Data:** Personal data such as age, gender, race, and religion.
- > **Medical:** Medical data such as history of medical problems and disabilities.
- > **National ID:** National identity documents such as Social Security Number (SSN).

For a list of all available predefined information types, refer to the appendix ["Information Types" on page 77](#).

DDC also allows you to create custom information types. For more information, see ["Creating Custom Infotypes" below](#).

Creating Custom Infotypes

You can create a custom information type, if you require one. This can be achieved from the **Infotypes** screen. To access it, click **Settings** and then **Infotypes** in the sidebar on the left.

1. Click the **+Add Infotype** button in the top right corner of the **Infotypes** screen. The **Add Infotype** wizard is displayed.
 - a. In the **General Info** step of the wizard, provide the following information for your new infotype:
 - **Name:** Choose a name for your infotype.
 - **Category:** Select a category to which your infotype belongs (Financial, Personal Data, Medical, or National ID).

- **Family:** Select a family for your infotype. A family is a subcategory inside the **Category** and the choice of options depends on what you selected in the **Category** menu. The following families are available inside their corresponding categories:

Financial: Credit/Debit Cards; Bank Account Info

Medical: Patient Health Data

National ID: Personal Identification

Personal Data: Email addresses; Login credentials; Card Number; Ethnicity; License Number; Roll Number; Passport Number; Date Of Birth; MAC Address; Mailing Address; Telephone Number; Gender; Religion; IP Address; Phone Number; Name

- **Region:** Select the region for your infotype (Global, Africa, Americas, Asia, Europe, and Oceania).

Click **Next** to go to the next step of the wizard.

- In the **Infotype Definition** step of the wizard, you configure the rules for your new information type. You configure the rules in the **Simple View** tab, and then you can view these rules as translated into an expression of the internal language of the DDC engine in the **Expert View** tab (the expression in the Expert View is **read-only**).

To configure the rules for your new information type, click to expand the **Add Rules** menu in the **Simple View** tab and select one of the following types:

- **Character:** Search for one or more specific characters as specified in the **Select Rule** menu. If the character is found, the location will be returned as a match. For a list of available character type rules, refer to ["Character Type Rules Explained" on the next page](#).

Use the **From** and **To** controls to set the number of consecutive occurrences of the selected character.

- **Phrase:** Search for a specific pattern as defined in the **Phrase** textbox (in layman terms, it is used to look for specific words). Searching for phrases is **case insensitive**.
- **Built-In:** Pre-defined infotypes can be used in combination with other types (Character or Phrase). The complete list of built-in information types is available in the appendix ["Information Types" on page 77](#).

Use the **Apply** button to complete your selection. The selection is displayed in the list of defined infotype rules. You can remove it from the list of rules by clicking the **Remove** link on its right.

You can use each of these types on their own, or combine them to form a more complex rule, involving multiple types in various configurations. See ["Examples of Custom Infotypes" on page 16](#) for some examples.

NOTE

- > Due to a known limitation, it is currently not possible to have two built-in infotypes, one after the other. They must be separated by something, such as another type infotype, or even a plain space. For example:
"american express" " " "english name"
- > Due to a known limitation, when adding a range of characters, all the possible combinations inside the range will appear as matches. For example, for a range of numbers from 1 to 4, when in a document you have a sequence "1234", the search will yield the following matches:
"1", "12", "123" and "1234"
- > When you introduce spaces at the beginning or the end of the phrase, the spaces are removed. Also, when you introduce more than one space between words, only one space is considered.

2. Click **Save** to save your new infotype. Your new information type has been added and is now listed in the **Infotypes** screen, and marked 'Custom' in the **Type** column.

Character Type Rules Explained

Specific predefined characters are used to create custom infotypes using character based rules. They are explained below:

Rule	Expert View Keyword	Usage
Space	SPACE	Matches any ASCII whitespace character such as blank space, horizontal tab, new line, vertical tab, form feed and carriage return.
Horizontal space	HSPACE	Matches an ASCII horizontal space only.
Vertical space	VSPACE	Matches an ASCII vertical space only.
Any	BYTE	Matches any byte within the ASCII 0x00 to 0xFF range.
Alphanumeric	ALNUM	Matches any ASCII alphanumeric character.
Alphabet	LETTER	Matches any ASCII alphabet character.
Digit	DIGIT	Matches any ASCII numeral.
Printable	PRINTABLE	Any printable ASCII character including horizontal and vertical whitespace.
Printable ASCII only	PRINTABLEASCII	Matches a printable ASCII only.

Rule	Expert View Keyword	Usage
Printable non-alphabet	PRINTABLENONALPHA	Matches any printable ASCII characters excluding alphabet characters and including horizontal and vertical whitespace.
Printable non-alphanumeric	PRINTABLENONALNUM	Matches any printable ASCII characters excluding alphanumeric characters and including horizontal and vertical whitespace.
Graphic	GRAPHIC	Matches any ASCII character that is not whitespace or a control character.
Same line	SAMELINE	Matches any printable ASCII character including horizontal whitespace but excluding vertical whitespace.
Non-alphanumeric	NONALNUM	Matches any character that is not an ASCII alphanumeric character.
Non-alphabet	NONALPHA	Matches any character that is not an ASCII alphabet.
Non-digit	NONDIGIT	Matches any character that is not an ASCII numeral.

Examples of Custom Infotypes

Example 1. You want to search for a "Driver License Number" from Illinois, whose format is "M532-4218-1341". You would then create the following rule:

Character Alphabet From 1 to 1 Times

Character Digit From 3 to 3 Times

Phrase -

Character Digit From 4 to 4 Times

Phrase -

Character Digit From 4 to 4 Times

The above example will have the following syntax in the **Expert View**:

```
RANGE LETTER TIMES 1-1
THEN RANGE DIGIT TIMES 3-3
THEN WORD NOCASE '-'
THEN RANGE DIGIT TIMES 4-4
THEN WORD NOCASE '-'
THEN RANGE DIGIT TIMES 4-4
```

In this rule, the expression "**Character Alphabet From 1 to 1 Times**" means that you only expect one alphabetic character, the expression "**Character Digit From 3 to 3 Times**" means that you expect exactly three digits, and the expression "**Phrase -**" means that you expect to find a hyphen (-) in the sequence.

Example 2. You want to search for a name and last name separated by a number of spaces between 1 and 3. To that end you would create the following rule:

Phrase John

Character Space **From** 1 **to** 3

Phrase Gordon

The above example will have the following syntax in the **Expert View**:

```
WORD NOCASE 'John'
THEN RANGE SPACE TIMES 1-3
THEN WORD NOCASE 'Gordon'
```

This rule will allow you to search for a combination of "John" and "Gordon" with one through three spaces between them. By comparison, using the rule **Phrase** John Gordon will only allow you to search for a combination "John Gordon", with only one space. Any additional spaces in the phrase will be truncated.

Example 3. You want to search for the Spanish NIE (foreigners identity number) preceded by the phrase "NIE:" and a number of spaces between 0 and 5. For example, "NIE: X8691474Q".

Phrase NIE

Character Space **From** 0 **to** 5

Built-in Spanish NIE

The above example will have the following syntax in the **Expert View**:

```
INCLUDE 'DEFINE_NID'
WORD NOCASE 'NIE'
THEN RANGE SPACE TIMES 0-5
THEN REFER 'NID_SPAIN_NIE'
```

This rule will find both "NIE: X8691474Q" and "nie: x8691474q" since searching (regardless of the type - Character, Phrase, or Built-in) is case insensitive.

Licensing

Trial License

Thales CipherTrust Data Discovery and Classification (DDC) is deployed with a trial license already installed and activated "out of the box". This allows you to enjoy a fully-functional product for **90 days** and up to the **2 TB** of data allowance.

After the trial license expires, the DDC configuration in CipherTrust Manager becomes read-only. While you still have access to your old reports you are not able to generate new ones, add new targets, or create new scans. You have to contact Thales Group to request a full license and install it in CipherTrust Manager. For more information on obtaining and installing licenses, refer to the "Licensing" section in the "Thales CipherTrust Manager Administrator Guide".

CAUTION! Data allowances of the trial license and full license do not add up! After installing a new full license your data allowance will be that of the new license only (for example, if your trial license has 2 TB data allowance and your full license 50 TB, after installing the full license your data allowance will be 50 TB not 52 TB).

Full License Options

Under the full license you get a fully-functional product with a specified data allowance and for a specific period of time. The license model offers you enough flexibility to choose an option that best suits your needs in terms of the license duration and prospective data allowance. You can choose from among these values:

> Expiration period

- 1 year
- 2 years
- 3 years

> Data allowance

- 15 TB
- 50 TB
- 100 TB
- 150 TB
- 250 TB
- 500 TB
- 1 PB
- 1.5 PB
- 3 PB
- Unlimited

Viewing the License Status

To view the status of your DDC license:

1. Log in to CipherTrust Manager and navigate to the licenses screen (**Admin Settings > Licensing**).
2. Search for **DDC_Data_Allowance** in the list of installed features.

TIP Use the **Search** box if the list is too long and you cannot quickly find the DDC_Data_Allowance entry.

3. Having found the DDC license, you have a few options available:
 - You can quickly check its status by looking at the **State** column in the DDC_Data_Allowance entry. It can be either **Active** or **Expired**.
 - You can check the license expiration date, in the **Expiration** column.
 - If the license is still active, you can view additional details about it. To do that, click the black arrow on the left of DDC_Data_Allowance to expand the whole entry. This displays the **Client Usage** card, with the information about the total data allowance that you have (**Total**), the amount of data allowance that you have already used up (**Used**), and the amount of data allowance that you still have available (**Available**).

NOTE If the **Available** figure has a negative value, it means that you have used up and exceeded your available data allowance. However, you can still run scans and the data from the scans is stored by DDC. The amount of this extra data stored is reflected by the negative value. You can access this data after you install a new license.

NOTE After installing or removing a license you have to wait some time for that action to be reflected in the licenses screen (usually, about one minute).

What If My License Stopped Working?

A license - trial or full - can stop working in one of the following cases:

- > **A trial license expires:** you cannot run new scans. However, the data collected so far is not deleted, so you can still generate reports based on it, and you can access it again when you install a new license.
- > **The data allowance of a trial license is used up:** you can continue scanning but you cannot generate reports. However, the data from scans is stored so after you install a new license you are able to access the data and generate reports.
- > **A license is deleted:** DDC stops working but the data is not deleted so you just have to reinstall the license or install a new one.
- > **You overwrite a trial license with a full one:** the new license takes over the data stored under the trial license.
- > **A full license expires:** it is the same case as the expired trial license above.

- > **The data allowance of a full license is used up:** it is the same case as the trial license with data allowance used up above.

Encryption Keys Used by DDC

DDC uses AES256 encryption to protect sensitive data. For that purpose, DDC creates a number of encryption keys that are stored in CipherTrust Manager. You can find these DDC keys in the **Keys & Access Management** application in CipherTrust Manager:

- > Four encryption keys to protect the Hadoop configuration before storing it inside the DDC Database. Each key is used to protect one configuration parameter (PQS Server, PQS credentials, HDFS Server, and HDFS credentials). These keys have the following format: **citrus-<UUID>** (for example, citrus-6e0cb668-3a3d-4f2c-8687-17092b83b41b).
- > As many encryption keys as there are data stores, and each key is used to encrypt the data store credentials before storing them inside the DDC Database, and to encrypt the results of the scans completed in that data store, before storing them in HDFS. These keys have the following format: **d<UUID>** (for example, d8b2d8404-c9ae-4a34-800a-01258dfaa383).
- > As many encryption keys as there are scans, and each key is used to encrypt the scan data before storing it in HDFS. These keys have the following format: **s<UUID>** (for example, s14912791-bed5-4e73-b733-6a36ecfe338f).

****WARNING**** These keys must never be deleted, or DDC will not be able to process the related scans or data stores properly.

DDC User Groups

System Predefined Groups

DDC has different kinds of users with different responsibilities in administering and using the system. A number of predefined groups are included to ensure that users are granted minimal permissions needed to perform their tasks while ensuring flexibility to meet security requirements across industries.

The table below lists all DDC predefined groups with their rights to use various DDC features. **R/W** in a cell means that the user has **view** and **edit** rights to this aspect of the product. **R** means that the user has only **view** rights.

	DataStores	Scans	Profiles	Reports	SensitivityLevels	BranchLocations	Custom Infotypes ⁷	Hadoop Configuration
Admin ¹	R/W	R/W	R/W	R/W	R/W	R/W		R/W
DDC Admins ²	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
DDC Store Viewers	R				R	R		
DDC Store Admins	R/W				R	R/W		
DDC Scan Viewers ⁶		R					R	
DDC Scan Admins	R	R/W	R			R	R	
DDC Profile Viewers			R				R	
DDC Profile Admins		R	R/W		R		R	
DDC Report Admins ^{3, 5}	R	R	R	R/W	R	R	R	
DDC Full Report Admins ^{4, 5}	R	R	R	R/W	R	R	R	
DDC Infotype Viewers							R	
DDC Infotype Admins							R/W	
DDC L3 Support								R/W

1. **Admins** can see their own and other users' reports. Admins can also decrypt scan packages from the Hadoop database.
2. **DDC Admins** can only see their own reports.
3. **DDC Report Admins** can only see their own reports.

4. **DDC Full Report Admins** can only see their own reports.
5. The difference between **Report Admins** and **Full Report Admins** is that **Full Report Admins** do not need access to specific user defined groups to be able to view or generate reports that use data stores restricted to user defined groups. For more information, see "[User Defined Groups](#)" below.
6. Scan Viewers are allowed to run scans.
7. **DDC Store Viewers**, **DDC Store Admins**, and **DDC L3 Support** do not have access to custom infotypes.

The users belonging to the "L3 Support" group are DDC Support Administrators. These users can help identify and troubleshoot issues you may encounter when using DDC. They can also can also decrypt scan packages from the Hadoop database.

User Defined Groups

Apart from system predefined groups, DDC also allows you to create **user defined groups**. User defined groups are used to prevent certain users from viewing sensitive information in reports. These groups are defined by the CipherTrust Manager Admin in Keys & Access Management -> Groups in CipherTrust Manager. In DDC, they are applicable when creating a Data Store, in the Data Store creation wizard when you are granting access to selected groups. See "[Managing Data Stores](#)" on page 32 for details (the **ACCESS: Selected group/s** setting in "Configuring a Data Store – Tags and Access").

In other words, a data store that is restricted to a specific user defined group is visible to all the groups with permissions to see data stores, the same goes for scans. However, a user without a permission to see a data store which is restricted to a group, but with a permission to create and generate reports, will not be able to generate reports for those data stores. For this user, the scan executions will not be visible in the New Report wizard.

NOTE The only users that do not have to belong to a specific user defined group to be able to see reports for all the data stores are **Full Report Admins** and **Admins**.

For example, if a user created a report that has Data Store "DS1" but the data store is restricted to a specific group, that user will see the report template, but when he tries to access the report he will get an "insufficient permissions" error.

Accessing and Interacting With DDC

The primary channel to interact with Thales CipherTrust Data Discovery and Classification (DDC) is through the CipherTrust Manager's GUI, also called the **console**. The console allows you to perform the management operations, such as managing data stores and scans.

You can also interact with DDC by using the CLI tool or REST API.

- > **CLI tool** - The CipherTrust Manager includes a CLI tool, named **ksctl**, that can be downloaded and run locally to control a remote CipherTrust Manager appliance. For more information, refer to ["CLI" on page 76](#).
- > **REST API** - You can use the REST interface from the *API playground*, or via any REST client such as curl. For more information, refer to ["REST API" on page 75](#).

In this guide we provide instructions to perform all management functions such as creating branch locations and data stores only through the CipherTrust Manager console (GUI).

Accessing DDC in the Console

Use this procedure to get access to the DDC features in the GUI.

1. Open the CipherTrust Manager URL in a browser. The log in page is displayed.
2. Enter **Username** and **Password**.
3. Click **Log In**. The GUI of the CipherTrust Manager is displayed.
By default, the **Applications** page is displayed with links to various applications.
4. Click the **Data Discovery** link to open the Data Discovery application.

Managing Branch Locations

You manage branch locations through the **Branch Locations** page, which is accessed by clicking the **Settings > Branch Locations** link in the **Data Discovery** sidebar on the left.

From the **Branch Locations** page you can:

- > View all currently available branch locations. See "[Viewing Branch Locations](#)" below.
- > Create a new branch location. See "[Adding Branch Locations](#)" below.

Viewing Branch Locations

The **Branch Locations** page lists available branch locations. This view also shows the total number of existing branch locations. The **Branch Locations** page shows the following details:

Item	Description
Site Name	Name of the branch location.
Country	Name of the country.
State/Province	Name of the state/province. This field is applicable to the United States. For other countries, the field is unavailable, indicated by N/A.
City	Name of the city.

TIP Use the **Search** text box to filter branch locations. Search results display branch locations that contain the specified text in their names.

Adding Branch Locations

Adding a branch location requires specifying the country and city where the branch is located. To add a branch location:

1. Click **+ Add Location** on the right of the **Branch Locations** page.
2. In the **Add Branch Location** dialog box, enter the following details:

Item	Description
Site Name	Specify a unique name for the branch location. The name must be longer than two characters and up to 64 characters. This field is mandatory.
Country	Select the country from the drop-down list. This field is mandatory.
State/Province	Select the state/province from the drop-down list. This field is applicable to the United States. For other countries, the field is unavailable.

Item	Description
City	Specify name of the city. This field is mandatory.
Description	Describe the branch location (up to 250 characters).

3. Click **Save.**

The newly created location appears on the Branch Locations page. By default, branch locations are displayed in alphabetic order by name. Depending on the number of entries per page, you might need to navigate to other pages to view the newly created branch location.

Managing Classification Profiles

You manage classification profiles through the **Classification Profiles** page, which is accessed by clicking the **Classification Profiles** link in the **Data Discovery** sidebar on the left.

From the **Classification Profiles** page you can:

- > View all the available classification profiles. See ["Viewing Classification Profiles" below](#).
- > Create a new classification profile. See ["Adding Classification Profiles" on the next page](#).
- > View details of a selected classification profile. See ["Viewing Details of Classification Profiles" on page 30](#).
- > Modify an existing classification profile. See ["Editing Classification Profiles" on page 30](#).
- > Create a new classification profile from an existing one. See ["Duplicating Classification Profiles" on page 31](#).

Viewing Classification Profiles

The **Classification Profiles** page lists available classification profiles. Initially, the page shows prebuilt classification profile templates only. Newly created and duplicate classification profiles are also shown on this page. Duplicating classification profiles is the process of creating copies of existing profiles with identical properties. Additionally, the page shows the total number of available profiles.

The list view of the **Classification Profiles** page shows the following details:

Item	Description
Name	Name of the classification profile.
Infotypes	Number of infotypes linked with the profile.
Sens. Level	Sensitivity level applied to the profile.
Modified	Time when the profile is modified.
Tags	Number of applied tags.

TIP

- > Use the **Search** text box to filter classification profiles. Search results display classification profiles that contain specified text in their names.
- > By default, classification profiles are listed in ascending alphabetic order of their names. Classification profiles can be sorted by their names and percentage of sensitivity levels.
- > Classification profiles can be filtered using the **Sens. Level** filter.

Classification Profile Templates

Classification profiles can be created based on predefined templates or custom templates. You can use the following predefined templates:

- > **Blank:** Provides the ability to specify custom sensitivity level, information types, and tags for the profile. The Blank template does not contain preselected infotypes.
- > **CCPA (California Consumer Privacy Act):** Affects organizations that process the personal data of a California resident, regardless of where the organization is headquartered.
- > **GDPR (General Data Protection Regulation):** Affects organizations that process the personal data of EU citizens, regardless of where the organization is headquartered.
- > **HIPAA (Health Insurance Portability and Accountability Act):** Covers the healthcare information in the US. HIPAA relates to protection, encryption, and key management.
- > **PCI (Payment Card Industry):** Affects organizations that play a role in processing credit and debit card payments. These organizations must comply with the strict PCI DSS (Data Security Standard) compliance requirements for the processing, storage, and transmission of data.
- > **Privacy Shield:** Regulates transatlantic exchanges of personal data for commercial purposes between the European Union and United States.

Adding Classification Profiles

Use the Add Classification Profile wizard to add a classification profile. Adding a classification profile involves the following steps:

Select Profile Template

1. In the **Classification Profiles** page, click the **+ Add Profile** button on the right. The **Add Classification Profile** wizard is displayed.
2. In the **Select Profile Template** step, select the required profile template from these options:
 - **Blank**
 - **CCPA**
 - **GDPR**
 - **HIPAA**
 - **PCI**
 - **Privacy Shield**

See "[Classification Profile Templates](#)" above for more information about these classification profile templates.

3. Click **Next** to go on to the **Name and Describe** screen.

General Info

1. Specify a **Profile Name**. The name must be longer than two characters and up to 64 characters.

2. Provide a **Description** for the profile (up to 250 characters).
3. Select a **Sensitivity Level** from the drop-down list. A sensitivity level suggests DDC what level of sensitivity is OK to find in this data store. For details, see ["Sensitivity Levels" on page 13](#).
4. Click **Next** to go on to the **Select Infotypes** screen.

Select Infotypes

1. The **Select Infotypes** screen is displayed. The screen shows the list of available information types. The screen shows details such as Infotype Name, Category, and Region.

NOTE Based on the selected profile template, certain information types may already be applied/selected. The applied information types can be viewed by turning on the **Selected only** toggle switch.

2. Search for the required infotypes. You can use the following options:
 - **Search** text box: Enter text to filter information types. Search results display information types that contain specified text in their names.
 - **Category** filter: Click the filter icon, select or clear categories, and click **OK**.
 - **Region** filter: Click the filter icon, select or clear categories, and click **OK**.
3. Click **Next** to go on to the **Apply Tags** screen.

Apply Tags

1. The **Apply Tags** screen is displayed.

NOTE Based on the selected profile template, certain tags may appear already applied. You can select existing tags, enter new tags, and remove existing tags, as appropriate.

2. Select a tag from the **Add Tags (optional)** drop-down list. The prebuilt tags are APA, APPI, CCPA, FINANCIAL, GDPR, HEALTH, HIPAA, KVKK, LEGAL, PCI, PERSONAL, PHI, PII, and SHIELD.

TIP

- > New tags can also be added. Start typing a new tag, and click the **New: <new_tag>** link that appears below the drop-down list.
- > Add as many tags as needed.
- > To remove a tag, click the close icon in the tag name.

3. Click **Save**.

The newly created classification profile appears on the Classification Profiles page. By default, profiles are displayed in alphabetic order by name. Depending on the number of entries per page, you might need to navigate to other pages to view the newly created profile.

Viewing Details of Classification Profiles

The default view of the Classification Profiles page lists prebuilt profile templates, created profiles, and duplicate profiles. Names of profiles and their modification times are also shown. Additionally, the view shows infotypes, sensitivity levels, and tags applied to available classification profiles.

The edit view of the page shows additional details of each classification profile. The details include the number of linked scans, profile name, profile description, applied sensitivity level, list of linked infotypes, and applied tags.

To view details of a classification profile:

1. In the left pane of the **Data Discovery** application, click **Classification Profiles**. The **Classification Profiles** page is displayed. This page lists available classification profiles.
2. Click the overflow icon () corresponding to the desired profile. A shortcut menu appears.
3. Click **View**. The **Classification Profiles** page shows additional details of the profile.

NOTE

- > For new and duplicate classification profiles, the button name is **View/Edit**. Clicking this button shows the edit view of the **Classification Profiles** page. The details can be viewed and edited on this page. Refer to ["Editing Classification Profiles" below](#) for details.
- > Only the users with appropriate rights can see the **View/Edit** button. For all other users, only the **View** button is visible.

Editing Classification Profiles

Newly created and duplicate classification profiles can be modified to suit your requirements. Use the edit view of the page to modify individual classification profiles. You can edit the profile name, profile description, applied sensitivity level, linked infotypes, and applied tags.

NOTE Prebuilt classification profiles cannot be edited. However, you can duplicate them and edit the copy to suit your requirements.

To edit a new or a duplicate classification profile:

1. In the left pane of the **Data Discovery** application, click **Classification Profiles**. The **Classification Profiles** page is displayed. This page lists available classification profiles.
2. Click the overflow icon () corresponding to the desired profile. A shortcut menu appears.
3. Click **View/Edit**. The edit view of the **Classification Profiles** page appears.

NOTE

- > For new and duplicate classification profiles, the button name is **View/Edit**. Clicking this button shows the edit view of the **Classification Profiles** page. The details can be viewed and edited on this page.
- > Only the users with appropriate rights can see the **View/Edit** button. For all other users, only the **View** button is visible.

4. Expand **GENERAL**. General details are displayed.
5. Modify the required details.
6. Expand **INFOTYPES**. The list of infotypes is displayed.
7. Select or clear infotypes, as required.
8. Expand **TAGS**. The applied tags, if any, are displayed.
9. Add new tags or modify existing tags, as required.
10. Click **Save Changes**.

The list view of the Classification Profiles page shows updated information.

Duplicating Classification Profiles

Duplicating classification profiles is the process of creating copies of existing profiles with identical properties. This process simplifies the creation of new profiles. Duplicate profiles can be modified later to suit your requirements, if needed.

To duplicate a classification profile:

1. In the left pane of the **Data Discovery** application, click **Classification Profiles**. The **Classification Profiles** page is displayed. This page lists available classification profiles.
2. Click the overflow icon () corresponding to the desired profile. A shortcut menu appears.
3. Click **Duplicate**.

A message appears stating that the profile has been duplicated successfully. The duplicate profile with the name **<original_profile_name> - Copy** appears on the Classification Profiles page. For example, if the profile **APA - Australia Privacy Amendment** is duplicated, a profile named **APA - Australia Privacy Amendment - Copy** is created.

Managing Data Stores

You manage data stores through the **Data Stores** page, which is accessed by clicking the **Data Stores** link in the **Data Discovery** sidebar on the left.

From the **Data Stores** page you can:

- > View all the available data stores. See ["Viewing Data Stores" below](#).
- > Create a new local type data store. See ["Adding Local Stores" on the next page](#).
- > Create a new network type data store. See ["Adding Network Stores" on page 35](#).
- > Create a new database type data store. See ["Adding Database Stores" on page 37](#).
- > Create a new Big Data type data store. See ["Adding Big Data Stores" on page 40](#).
- > Edit an existing data store. See ["Editing Data Stores" on page 41](#).
- > Select an Agent for a data store. See ["Automatic Agent Selection" on page 43](#).

Viewing Data Stores

The list view of the Data Stores page shows the number of:

- > Existing data stores with the number of scanned and unscanned data stores.
- > Supported data types with the number of configured data stores of each type.
- > Scanned data stores with the number of data stores containing sensitive and nonsensitive data.

Click the refresh button to refresh the displayed information.

The list view of the **Data Stores** page shows the following details:

Item	Description
Name	Name of the data store.
Type	Type of the data store.
Sens Level	Sensitivity level applied to the data store.
Location	Location of the data store.
Tags	Number of applied tags.
%Sens. Info	Percentage of data objects in the data store that are considered as sensitive data objects. A hyphen "-" indicates that a data store is not yet scanned.
Status	Status of the data store - enabled or disabled. During a scan, DDC searches for agents in enabled data stores. Click the toggle switch to change the status. The status of a data store could be disabled while it waits for an Agent or if it fails to select an Agent. Disabled data stores are skipped during the scan.

TIP

- > Use the **Search** text box to filter data stores. Search results display data stores that contain specified text in their names.
- > By default, data stores are listed in ascending alphabetic order of their names.
- > Data stores can be sorted by their names, types, sensitivity levels, locations, and percentage of sensitive information.

Adding Local Stores

Use the Add Data Store wizard to add a local data store. Adding a data store involves the following steps:

Select Store Type

1. In the left pane of the **Data Discovery** application, click **Data Stores**. The **Data Stores** page is displayed. This page lists available data stores.

2. On the right, click **+ Add Data Store**. The **Add Data Store** wizard is displayed.

The **Select Data Store** screen displays options to filter data store types:

- **Filter by Data Store category:** Shows categories of data stores. Click a category to filter available options under the **Select Type** drop-down list.
- **Select Type:** Shows types of data storage. By default, the drop-down list shows all types of data stores. When a category is selected under **Filter by Data Store category**, the label **Select Type** is changed to reflect the selection. For example, for **Local Storage**, the label becomes **Select Local Storage Type**.

NOTE This document uses **Filter by Data Store category** to filter data stores.

3. Under **Filter by Data Store category**, click **Local Storage**.
4. From the **Select Local Storage Type** drop-down list, select **Local Storage**.
5. Click **Next** to go on to the **Configure Connection** screen.

Configure Connection

1. The **Configure Connection** screen is displayed.
2. Specify **Hostname/IP** of the machine where the local data store resides. Specify a valid hostname, IP address, or Uniform Resource Identifier (URI). The hostname must be longer than two characters. This is a mandatory field.

NOTE Local data stores need a DDC Agent installed on the same host.

3. Click **Next** to go to the **General Info** screen.

General Info

1. The **General Info** screen is displayed.
2. Specify a unique **Name** for the data store. The name must be longer than two characters and up to 64 characters.
3. Provide a **Description** for the data store (up to 250 characters).
4. Select a **Branch Location** from the drop-down list.
5. Select a **Sensitivity Level** from the drop-down list. A sensitivity level suggests to DDC what level of sensitivity is OK to find in this data store. For details, see ["Sensitivity Levels" on page 13](#).

NOTE The **Enable Data Store** check box is selected by default. This means that this data store is available for scans. If the check box is cleared, the data store is disabled (not available) for scans.

6. Click **Next** to go on to the **Add Tags & Access Control** screen.

Add Tags & Access Control

1. The **Add Tags & Access Control** screen is displayed.
2. Under **ACCESS**, select user groups that can access the data store. Access to a data store provides ability to see reports that include scans of that data store.

The available options are:

- **All groups:** All groups of users can access the data store through reports. This is the default setting.
- **Selected group/s:** Specified user defined groups can access the data store through reports. When this option is selected, select a group from the drop-down list. This list shows existing user defined groups. The user defined groups must already exist on CipherTrust Manager. If no user defined groups exist, ask the administrator to create a group.

If needed, you can select multiple groups. Start typing the name of the desired group and select from the suggested groups.

3. Under **TAGS**, select a tag from the **Add Tag** drop-down list. The prebuilt tags are APA, APPI, CCPA, FINANCIAL, GDPR, HEALTH, HIPAA, KVKK, LEGAL, PCI, PERSONAL, PHI, PII, and SHIELD.

TIP

- > New tags can also be added. Start typing a new tag, and click the **New: <new_tag>** link that appears below the drop-down list.
- > Add as many tags as needed.
- > To remove a tag, click the close icon in the tag name.

4. Click **Save**.

The newly created data store appears on the Data Stores page. By default, data stores are displayed in alphabetic order by name. Depending on the number of entries per page, you might need to navigate to other pages to view the newly created data store.

Adding Network Stores

DDC supports two types of Network Storage types as data stores: Linux Network File Share (**NFS**) and Windows share (**SMB/CIFS**).

NOTE SMB/CIFS is supported for Windows only. Currently, the SMB implementation on Linux (Samba) is not supported. Also, we cannot guarantee that NFS type data stores on MAC will work properly.

Prerequisites for Network Storage Data Stores

To create a **Windows Network Storage** data store:

- > Use a Windows Proxy Agent.
- > Ensure that the target storage is accessible from the Proxy agent host.

To create a **Linux Network Storage** data store:

- > Use a Linux Proxy Agent.
- > The target storage path must be mounted on the Proxy agent host.

For both types of these data stores, the credentials to access the target storage must have the minimum permissions required to scan it. Bear in mind that data discovery or scanning of data requires **read access**.

Creating a Data Store

To create a new data store, navigate to the **Data Stores** screen (**Data Discovery > Data Stores**). Click the **+Add Data Store** button to open the **Add Data Store** wizard.

In the wizard, you have to go over four configuration steps for each data store that you create:

1. **Select Store Type** - Select a data store type that you want to create. Refer to individual procedures for each data store type for details.
2. **Configure Connection** - provide the connection details for the data store that you selected in the previous step. This step is different for every data store type. Refer to individual procedures for each data store type for configuration details.
3. **General Info** - specify the name, description, branch location, and sensitivity level for your data store. These settings are shared by all data store types. See ["Configuring a Data Store - General Information" on page 37](#) for details.
4. **Add Tags & Access Control** - grant access rights to your data store and add tags. These settings are shared by all data store types. See ["Configuring a Data Store – Tags and Access Control" on page 37](#) for details.

Creating a Windows Data Store

1. To create a Windows Data Store, click **Network Storage > SMB/CIFS Share** in the **Select Store Type** screen in the **Add Data Store** wizard. For details, refer to ["Configuring a Data Store – Tags and Access Control" on page 37](#).

2. In the **Configure Connection** screen of the wizard, provide the following configuration details for your data store:
 - > **Hostname/IP** - a valid hostname, IP address, or URI of the data store.
 - > **Share Name** - a valid Windows share name. These characters are not allowed in the Share Name: = * ? , < > | ; : + [] " / \

CAUTION! Do not confuse the **Share Name** with the **Network Path**. In Windows, the **Share Name** is typically set in the **Advanced Sharing** settings in the folder sharing properties.

- > **Credentials** - provide a valid username and password. Use the appropriate user name format for the target Windows hosts credentials:
 - `<domain\username>` - target host resides in the same Active Directory domain as the Windows proxy agent.
 - `<target_hostname\username>` - target host does not reside in the same Active Directory domain as the Windows proxy agent.
3. In the **General Info** screen of the wizard, specify the name, description, branch location, and sensitivity level for your data store. See ["Configuring a Data Store - General Information" on the next page](#) for details.
 4. In the **Add Tags & Access Control** screen of the wizard, grant access rights to your data store and add metadata. See ["Configuring a Data Store – Tags and Access Control" on the next page](#) for details.
 5. Click **Save** to create the data store. At any time during the configuration you can click **Back** to go to any of the previous wizard screens to update the configuration.

Creating a Linux Data Store

1. To create a Linux Data Store, click **Network Storage > NFS Share** in the **Select Store Type** screen in the **Add Data Store** wizard. For details, refer to ["Configuring a Data Store – Tags and Access Control" on the next page](#).
2. In the **Configure Connection** screen of the wizard, provide the following configuration details for your data store:
 - > **Hostname/IP** - a valid hostname, IP address, or URI of the data store.
 - > **Share Path** - a valid NFS path, it must begin with a slash ("/"). The path must be set to the mount path on the Proxy host.
 - > **Agent Hostname/IP** - a valid hostname, IP address, or URI of the host where the DDC agent resides.
 - > **Mount Point (On Proxy Agent)** - the mount path on the Proxy host (for the **Share Path** above). See also ["Mounting an NFS Share" on page 74](#).
3. In the **General Info** screen of the wizard, specify the name, description, branch location, and sensitivity level for your data store. See ["Configuring a Data Store - General Information" on the next page](#) for details.
4. In the **Add Tags & Access Control** screen of the wizard, grant access rights to your data store and add metadata. See ["Configuring a Data Store – Tags and Access Control" on the next page](#) for details.
5. Click **Save** to create the data store. At any time during the configuration you can click **Back** to go to any of the previous wizard screens to update the configuration.

Configuring a Data Store - General Information

The **General Info** screen in the **Add Data Store** wizard allows you to specify the name, description, branch location, and sensitivity level of your data store. More details below:

- > **Name** - the name of your data store. The name must be longer than two characters and up to 64 characters.
- > **Description** - the description for the data store (up to 250 characters).
- > **Branch Location** - select a branch location from the drop-down list. If no branch location is available, you have to create it. See ["Managing Branch Locations" on page 25](#) for details.
- > **Sensitivity Level** - select a sensitivity level from the drop-down list. A sensitivity level suggests to DDC what level of sensitivity is acceptable to find in this data store. For details, see ["Sensitivity Levels" on page 13](#).
- > **Enable Data Store** - when selected it means that this data store is available for scans. The **Enable Data Store** check box is selected by default. If the check box is cleared, the data store is disabled (not available) for scans.

Configuring a Data Store – Tags and Access Control

The **Add Tags & Access Control** screen in the **Add Data Store** wizard allows you to grant access rights to your data store and add tags. More details below:

- > **ACCESS** - select user groups that can access the data store. Access to a data store provides ability to see reports that include scans of that data store. The available options are:
 - **All groups**: All groups of users can access the data store through reports. This is the default setting.
 - **Selected group/s**: Specified user defined groups can access the data store through reports. When this option is selected, select a group from the drop-down list. This list shows existing user defined groups. The user defined groups must already exist on CipherTrust Manager. If no user defined groups exist, ask the administrator to create a group. If needed, you can select multiple groups. Start typing the name of the desired group and select from the suggested groups.
- > **TAGS** - select a tag from the **Add Tag** drop-down list. The predefined tags are: APA, APPI, CCPA, FINANCIAL, GDPR, HEALTH, HIPAA, KVKK, LEGAL, PCI, PERSONAL, PHI, PII, and SHIELD.

TIP New tags can also be added. Start typing a new tag, and click the **New: <new_tag>** link that appears below the drop-down list. Add as many tags as needed. To remove a tag, click the close icon in the tag name.

Adding Database Stores

Use the **Add Data Store** wizard to add a database type data store. Adding a data store involves the following steps:

Select Store Type

1. In the left pane of the **Data Discovery** application, click **Data Stores**. The **Data Stores** page is displayed. This page lists available data stores.

2. On the right, click **+ Add Data Store**. The **Add Data Store** wizard is displayed.

The **Select Data Store** screen displays the following options to filter data store types:

- **Filter by Data Store category**: Shows categories of data stores. Click a category to filter available options under the **Select Type** drop-down list.
- **Select Type**: Shows types of data storage. By default, the drop-down list shows all types of data stores. The label **Select Type** changes to reflect the category selected under **Filter by Data Store category**. For example, for **Database**, the label becomes **Select Database Type**.

NOTE This document uses **Filter by Data Store category** to filter data stores.

3. Under **Filter by Data Store category**, click **Database**.
4. From the **Select Database Type** drop-down list, select a database. The available options are:
 - **IBM DB2**: Select to add an IBM DB2 database.
 - **Oracle**: Select to add an Oracle database
 - **Microsoft SQL**: Select to add a Microsoft SQL database.
5. Click **Next** to go on to the **Configure Connection** screen.

Configure Connection

1. The **Configure Connection** screen is displayed.
2. Specify **Hostname/IP** of the database server. Specify a valid hostname, IP address, or Uniform Resource Identifier (URI). The hostname must be longer than two characters. This is a mandatory field.
3. Specify **Port** of the database server. The port must be a number between 1 and 65535. The default ports are 50000 for IBM DB2, 1521 for Oracle, and 1433 for Microsoft SQL. This is a mandatory field.
4. Specify name of the **Database** service. This is a mandatory field. For an Oracle database, specify **Database or SID**.

NOTE If you are using **Oracle 12x**, or if the Oracle database displays a “**TNS: protocol adapter error**”, you must specify a **SERVICE_NAME** in the **Database or SID** field. For example: HR(SERVICE_NAME=XE)

5. Select an authentication method to connect to the database. The available options are:
 - **Credentials**: Select for password-based authentication. This is the default setting. Specify valid user credentials (**User** and **Password**) to access the network storage. For password-based authentication, valid user credentials are mandatory.
 - **Certificate**: Select for certificate-based authentication. Click **Choose File** to upload a valid certificate file. For certificate-based authentication, uploading a valid certificate is mandatory.

NOTE

- > The certificate must be in either **PEM** or **.p12** format.
- > The certificate size must be less than **30 KB**.

6. Click **Next** to go on to the **General Info** screen.

General Info

1. The **General Info** screen is displayed.
2. Specify a unique **Name** for the data store. The name must be longer than two characters and up to 64 characters.
3. Provide a **Description** for the data store (up to 250 characters).
4. Select a **Branch Location** from the drop-down list.
5. Select a **Sensitivity Level** from the drop-down list. A sensitivity level suggests to DDC what level of sensitivity is OK to find in this data store. For details, see ["Sensitivity Levels" on page 13](#).
6. Click **Next** to go on to the **Add Tags & Access Control** screen.

Add Tags & Access Control

1. The **Add Tags & Access Control** screen is displayed.
2. Under **ACCESS**, select user groups that can access the data store. Access to a data store provides ability to see reports that include scans of that data store.

The available options are:

- **All groups:** All groups of users can access the data store through reports. This is the default setting.
- **Selected group/s:** Specified user defined groups can access the data store through reports. When this option is selected, select a group from the drop-down list. This list shows existing user defined groups. The user defined groups must already exist on CipherTrust Manager. If no user defined groups exist, ask the administrator to create a group.

If needed, you can select multiple groups. Start typing the name of the desired group and select from the suggested groups.

3. Under **TAGS**, select a tag from the **Add Tag** drop-down list. The prebuilt tags are APA, APPI, CCPA, FINANCIAL, GDPR, HEALTH, HIPAA, KVKK, LEGAL, PCI, PERSONAL, PHI, PII, and SHIELD.

TIP

- > New tags can also be added. Start typing a new tag, and click the **New: <new_tag>** link that appears below the drop-down list.
- > Add as many tags as needed.
- > To remove a tag, click the close icon in the tag name.

4. Click **Save**.

The newly created data store appears on the Data Stores page. By default, data stores are displayed in alphabetic order by name. Depending on the number of entries per page, you might need to navigate to other pages to view the newly created data store.

Adding Big Data Stores

Use the Add Data Store wizard to add a big data type data store. Adding a data store involves the following steps:

NOTE In a Hadoop cluster:

- > Nodes where data blocks distributed by HDFS are stored are called DataNodes. DataNodes are treated as “slaves” in a Hadoop cluster.
- > A node that maintains the index of directories and files and manages data blocks stored on DataNodes is called a NameNode. A NameNode is treated as “master” in a Hadoop cluster.

Select Store Type

1. In the left pane of the **Data Discovery** application, click **Data Stores**. The **Data Stores** page is displayed. This page lists available data stores.
2. On the right, click **+ Add Data Store**. The **Select Data Store** screen of the **Add Data Store** wizard is displayed.

The **Select Data Store** screen displays the following options to filter data store types:

- **Filter by Data Store category**: Shows categories of data stores. Click a category to filter available options under the **Select Type** drop-down list.
- **Select Type**: Shows types of data storage. By default, the drop-down list shows all types of data stores. The label **Select Type** changes to reflect the category selected under **Filter by Data Store category**. For example, for **Big Data**, the label becomes **Select Big Data Type**.

NOTE This document uses **Filter by Data Store category** to filter data stores.

3. Under **Filter by Data Store category**, click **Big Data**.
4. From the **Select Big Data Type** drop-down list, select **Hadoop Cluster**.
5. Click **Next** to go on to the **Configure Connection** screen.

Configure Connection

1. The **Configure Connection** screen is displayed.
2. Specify **Hostname/IP** of the Hadoop cluster's active NameNode. Specify a valid hostname, IP address, or Uniform Resource Identifier (URI). The hostname must be longer than two characters. This is a mandatory field.
1. Click **Next** to go on to the **General Info** screen.

General Info

1. The **General Info** screen is displayed.

2. Specify a unique **Name** for the data store. The name must be longer than two characters and up to 64 characters.
3. Provide a **Description** for the data store (up to 250 characters).
4. Select a **Branch Location** from the drop-down list.
5. Select a **Sensitivity Level** from the drop-down list. A sensitivity level suggests to DDC what level of sensitivity is OK to find in this data store. For details, see ["Sensitivity Levels" on page 13](#).
6. Click **Next** to go on to the **Add Tags & Access Control** screen.

Add Tags & Access Control

1. The **Add Tags & Access Control** screen is displayed.
2. Under **ACCESS**, select user groups that can access the data store. Access to a data store provides ability to see reports that include scans of that data store.

The available options are:

- **All groups:** All groups of users can access the data store through reports. This is the default setting.
- **Selected group/s:** Specified user defined groups can access the data store through reports. When this option is selected, select a group from the drop-down list. This list shows existing user defined groups. The user defined groups must already exist on CipherTrust Manager. If no user defined groups exist, ask the administrator to create a group.

If needed, you can select multiple groups. Start typing the name of the desired group and select from the suggested groups.

3. Under **TAGS**, select a tag from the **Add Tag** drop-down list. The prebuilt tags are APA, APPI, CCPA, FINANCIAL, GDPR, HEALTH, HIPAA, KVKK, LEGAL, PCI, PERSONAL, PHI, PII, and SHIELD.

TIP

- > New tags can also be added. Start typing a new tag, and click the **New: <new_tag>** link that appears below the drop-down list.
- > Add as many tags as needed.
- > To remove a tag, click the close icon in the tag name.

4. Click **Save**.

The newly created data store appears on the Data Stores page. By default, data stores are displayed in alphabetic order by name. Depending on the number of entries per page, you might need to navigate to other pages to view the newly created data store.

Editing Data Stores

Existing data stores can be modified to suit your requirements. Use the edit view of the page to modify properties of data stores. You can edit the data store name, description, linked branch location, and applied sensitivity level. Additionally, connection settings, access rights, and tags can be modified.

To edit a data store:

1. In the left pane of the **Data Discovery** application, click **Data Stores**. The **Data Stores** page is displayed. This page lists available data stores.
2. Click the overflow icon () corresponding to the desired data store. A shortcut menu appears.

TIP Alternatively, to open the edit view a data store, click the **Name** link of the desired data store. Only the users with appropriate rights can see edit data store settings. All other users can only the settings.

3. Click **View/Edit**. The edit view of the **Data Stores** page appears.

NOTE Only the users with appropriate rights can see the **View/Edit** button. For all other users, only the **View** button is visible.

4. Expand **GENERAL**. General details are displayed.
5. Modify the required information.

NOTE The current data store type, which is displayed under **Select Type**, cannot be changed.

6. Expand **CONNECTION**. Connection settings are displayed. Based on the storage type, the displayed fields can be different.
7. Modify the required information.

NOTE When using the **Authentication** method, specify valid credentials in **User** and **Password**. To change the existing password, unlock the **Password** field by clicking the lock icon and enter the new password.

8. Click **Test Connection** to test the modified connection settings. If any error occurs, correct the connection settings and retry.

NOTE The **Test Connection** button is available only if a compatible Agent is found.

9. Expand **ACCESS**. The granted access rights are displayed.
10. Modify access rights under **Grant Access to**, if required.
11. Expand **TAGS**. The applied tags, if any, are displayed.
12. Add new tags or modify existing tags, as required.
13. Click **Save Changes**.

The list view of the Data Stores page shows updated information.

Automatic Agent Selection

Data stores that do not have a DDC Agent installed on the same host require using a DDC Agent as a proxy to get from the CipherTrust Manager appliance to the data store endpoint. To achieve this, data stores select agents automatically.

When a data store is added, the following situations can occur:

- > **DDC searches for a compatible agent:** When DDC searches for a compatible Agent, a rotating spinner next to the data store's name is displayed. If you hover the mouse over the spinner, "Waiting for Agent" is shown.
- > **DDC finds a compatible agent:** When a compatible agent is found, no spinner is seen next to the name. You can now test its connectivity with the Agent by clicking the "Test Connection" button inside the data store's settings. Refer to ["Editing Data Stores" on page 41](#) for details.
- > **DDC does not find a compatible agent:** DDC retries the agent selection for seven days. If cannot find a compatible agent in seven days, an error icon is displayed. If you hover the mouse over the icon, it states "Agent not available". The "Find Agent" button to relaunch the Agent selection is visible on clicking the overflow icon () next to the data store.

To relaunch automatic agent selection for a data store:

1. In the **Data Discovery** application, click the overflow icon () corresponding to the desired data store. A shortcut menu appears.
2. Click **Find Agent**.

NOTE

- > Instructions to install and configure DDC Agents can be found in the Thales CipherTrust Data Discovery and Classification Deployment Guide.
- > Port 11117 on the CipherTrust Manager appliance must be accessible from DDC Agent hosts.
- > Data store endpoint needs to be accessible from DDC Agent hosts.
- > To proxy requests to database stores, a Windows-based DDC Agent is required.
- > To proxy requests to Hadoop data stores, a Linux-based DDC Agent is required.
- > When the DDC Agent is properly identified, the data store status changes to ready. At this point, it is now possible to run scans against this data store.

Managing Scans

You manage scans through the **Scans** page, which is accessed by clicking the **Scans** link in the **Data Discovery** sidebar on the left.

From the **Scans** page you can:

- > View all currently available scans. See ["Viewing Scans" below](#).
- > Create a new scan. See ["Adding Scans" on the next page](#).
- > Execute a scan. See ["Running Scans" on page 48](#).
- > Delete a scan. See ["Removing Scans" on page 49](#).

Viewing Scans

The list view of the **Scans** page shows the number of:

- > Scans with the number of executed and unexecuted scans.
- > Executed scans with the number of scans containing sensitive and non-sensitive data.
- > Scanned data objects with the number of sensitive and other data objects.

Click the refresh button to refresh the displayed information.

The list view of the **Scans** page shows the following details:

Item	Description
Name	Name of the scan.
Profile	Number of classification profiles.
Schedule	Schedule of the scan.
Last Scan	Time when the scan last ran.
Duration	Time taken to complete the run.
Status	Status of the scan. The status could be Completed, In progress, Failed, Disabled, Stopped, Unscanned, Validating, or Pending.

TIP

- > Use the **Search** text box to filter scans. Search results display scans that contain specified text in their names.
- > By default, scans are listed in ascending alphabetic order of their names.
- > Scans can be sorted by their name, last scan time, duration, and status.

Adding Scans

To add a scan, navigate to the **Scans** screen (**Data Discovery > Scans**). Click the **+Add Scan** button to open the **Add Scan** wizard.

In the wizard, you have to go over these configuration steps for each scan that you add:

1. **"General Info" below** - Name the scan and give a short description.
2. **"Select Data Stores" below** - Select which data stores will be scanned.
3. **"Add Targets" on the next page** - Narrow down the scan scope by selecting specific scan targets.
4. **"Select Profiles" on the next page** - Choose which Classification Profile you want to scan for.
5. **"Schedule Scan" on page 47** - Configure when you want your scan to run.

General Info

1. In the **General Info** screen, the wizard asks you to specify a unique name for the scan and to give it a short description:
 - **Name** - The name must be longer than two characters and up to 64 characters.
 - **Description** - optional description of up to 250 characters.
2. Click **Next** to move on to the **Select Data Stores** screen.

Select Data Stores

The **Select Data Stores** screen lists all data stores in tabular form. By default, no data stores are selected. The table has three columns:

- **Data Store Name**: Lists available data stores (with their number).
- **Type**: The type of the data store, such as Local Storage, Network Share, etc.
- **Agent**: Displays the Agent that is connected to that data store. In this column, you can also see if the Agent is ready (that is, if the data store is ready).

To select a data store to scan:

1. Search for the desired data stores by specifying the search criteria in the search box. The search results will be displayed in the table under it.
2. Select a data store for the scan by selecting the corresponding check box. Similarly, select multiple data stores, if needed.

TIP Use the **Selected only** toggle switch to display only the selected data stores or all data stores (if the switch is 'off' all data sources are displayed).

3. Click **Next** to move on to the **Add Targets** screen .

Add Targets

In the **Add Targets** screen you can review a list of the data stores that you selected for the scan. By default, the scan will scan the entire data store, and this wizard step allows you to narrow down the scan scope by selecting specific targets for your selected data stores. The **Add Targets** screen is divided into three columns:

- **Data Store:** The list of selected data stores.
- **Targets:** Any selected specific target for the listed data store. "Full DS" indicates that no specific target has been selected, that is, the entire data store will be scanned. If you have added a scan target for the data store, it will be listed after you expand the data store row (by clicking the arrow button next to the data store name, on the left).
- **Add Target:** In this field you can type in a specific target and add it to the scan parameters. Scanning of this data store will be limited to the added target only.

NOTE

Any scan target that you add must be **valid**, otherwise the scan will fail. What is a valid scan target depends on the data store type, but here are a few tips to have in mind:

- > When adding scan targets for database data sources (IBM DB, Oracle, and MS-SQL):
 - Note that table names are case sensitive but schema names are not case sensitive.
 - Oracle data stores accept only tables as scan targets.
 - IBM DB and MS-SQL data stores accept schemas or tables as scan targets.
- > For Hadoop type data stores, you can configure a scan to use a specific Hadoop **file** as a scan target.

- > To add a scan target for a selected data store:
 - Type your scan target in the **Add Target** field.
 - Click the Apply button on the right of **Add Target** to add the target.
- > To remove a scan target for a selected data store:
 - Click the arrow button next to the data store name for which you want to remove a scan target.
 - Click the **Remove** link next to the scan target to remove it.
- > To move on to the **Select Profiles** screen, click **Next**.

Select Profiles

The **Select Profiles** screen lists all classification profiles in tabular form. By default, no profiles are selected. The table has three columns:

- **Classification Profile Name:** Lists available profiles.
- **Infotypes:** Displays the number of information types associated with the profile.
- **Sensitivity:** Displays the sensitivity level assigned to this classification profile. See "[Sensitivity Levels](#)" on page 13 for more information.

To select a classification profile for the scan:

1. Search for the desired profiles by specifying the search criteria in the search box. The search results are displayed in the table under it.

2. Select profiles for the scan by selecting the check boxes corresponding to desired profiles.

TIP Use the **Selected only** toggle switch to display only the selected classification profiles or all classification profiles (if the switch is 'off' all classification profiles are displayed).

3. Click **Next** to move on to the **Schedule Scan** screen.

Schedule Scan

1. In the **Schedule Scan** screen select the frequency with which you want the scan to run. The options are:

- **Manual:** Select to run the scan manually. This is the default setting.

NOTE If you select **Run Now**, the scan will be run just once after the scan is added successfully.

- **Scheduled:** Select to specify a schedule for the run. The scan will be run automatically on the specified schedule. When **Scheduled** is selected, the following fields appear on the screen:
 - **Increment:** Select the increment pattern of the run. This is a mandatory field. The options are **Daily**, **Weekly**, and **Monthly**. By default, **Daily** is selected.
 - **Every:** Specify when the run should repeat. This is a mandatory field.
For example, if Daily is selected as Increment, enter 2 to run the scan once every two days. If Weekly is selected as Increment, enter 2 to run the scan once every two weeks. Similarly, if Monthly is selected as Increment, enter 2 to run the scan once every two months.
 - **Time:** Specify the time when the run should start. This is a mandatory field. Specify the time in 12-hour format.
 - **Time Zone:** Select a time zone from the drop-down list.
 - **Starting:** Specify the day when the schedule should start. This is a mandatory field. By default, **Today** is selected. To specify a particular start date, select **On this date**, click the calendar icon, and select the date.
 - **Ending:** Specify the day when the schedule should end. This is a mandatory field. By default, **No End** is selected. To specify a particular end date, select **On this date**, click the calendar icon, and select the date.

NOTE A scan cannot run unless there is an identified Agent for every data store included in the scan. If it fails to run, check the status of different data stores included in the scan.

2. Click **Save** to complete adding the scan.

As a result, the newly created scan appears on the **Scans** page. By default, scans are displayed in alphabetic order by name. Depending on the number of entries per page, you might need to navigate to other pages to view the newly created scan. By default, the Status of a newly created scan is Unscanned.

NOTE If your CipherTrust Manager system clock does not match the Agent's system clock, your scans will not run as scheduled, so it is highly recommended to set up a NTP server to synchronize the clocks. This can be achieved in CipherTrust Manager through the **Admin Settings -> System -> NTP**. For details, refer to the "Thales CipherTrust Manager Administrator Guide".

Running Scans

To run a scan, navigate to the **Scans** screen (**Data Discovery > Scans**). Scans can be run either manually or automatically at a scheduled time.

- > To run a scan manually:
 - a. Search for the scan to run.

TIP

- > Use the **Search** text box to filter scans. Search results display scans that contain specified text in their names.
- > By default, scans are listed in ascending alphabetic order of their names.
- > Scans can be sorted by their name, last scan time, duration, and status.

- b. Move the mouse pointer to the row that contains the scan. The **Run Now** button appears. This button disappears as soon as the mouse pointer is moved out of the row.
- c. Click **Run Now**.

As soon as the scan is initiated, its status becomes **Pending**.

- > To configure a scan to run automatically, refer to the information in ["Schedule Scan" on the previous page](#).

Scan Statuses

The status of the scan changes in the sequence: Validating > Pending > Running now / Paused / Stopped > Processing > Completed / Failed.

Status	Description
Validating	Checking if all the data stores are ready.
Pending	Scan is pending and the linked data stores are being contacted. Depending on factors such as the network connectivity, this stage may: • Complete in a flash. You may not see it on the Scans page. • Remain for some time in this state.
Running now / Paused / Stopped	Scan is running, or is paused or stopped.
Processing	Scan is processing the collected data.

Status	Description
Completed / Failed	Scan run is successful or has failed.

Potential Problems When Running Scans

- > **Ready/Not Ready data store:** A scan cannot run unless there is an identified Agent for every data store included in the scan. Such a data store has the status **Ready**. A scan that has at least one data store that is **Not Ready** will fail to run, and display an error. If more than one data stores associated with a scan are **Not Ready** the system will fail on the first scanned data store that is **Not Ready** and will not check the remaining data stores.
- > **Disabled/Enabled data store:** You can manually deactivate a data store. Such a data store has a status **Disabled** and it will not be scanned. A scan that has several data stores associated will still run (without an error) even if one or more data stores are **Disabled** as long as at least one data store is enabled, but it will only scan the enabled data stores. A scan with all data stores **Disabled** will not run at all.
- > **Hadoop file access rights:** You get a **"data store path not accessible"** error when scanning a Hadoop data store that has a Hadoop file configured as its scan target, if you do not have access rights to that file.
- > **IBM, Oracle and MS-SQL - empty table or schema:** You get a **"table or schema not accessible"** error when scanning an empty table or schema.
- > **IBM, Oracle y MS-SQL - case sensitive table name:** In these data stores database schema names are not case sensitive, but table names are case sensitive.

Removing Scans

1. In the **Scans** screen, use the **Search** text box to filter scans and search for the scan that you want to remove.
2. Click the overflow icon () corresponding to the desired scan. An overflow menu is displayed, with a **View** and **Remove** options available.

NOTE The **Remove** option is not always available in the menu, only if a scan is **Failed**, **Completed**, **Stopped**, or **Disabled**.

3. Click **Remove** in the menu. As a result, a warning message **"Remove Scan? Are you sure you want to remove this scan?"** is displayed.
4. Click the **Remove** button in the warning message window to confirm the removal of the selected scan.

Managing Reports

You manage reports through the **Reports** page, which is accessed by clicking the **Reports** link in the **Data Discovery** sidebar on the left.

From the **Reports** page you can:

- > View all existing reports. See ["Viewing Reports" below](#).
- > Create a new report. See ["Creating Reports" on the next page](#).
- > Generate a report. See ["Generating Reports" on page 53](#).
- > View details of a selected report. See ["Report Details" on page 53](#).

Viewing Reports

The **Reports** page displayed lists available reports. Initially, the page shows no reports. Newly configured reports are shown on this page. Additionally, the page shows the total number of available reports.

By default, reports are listed in ascending alphabetic order of their names. The list view of the **Reports** page shows the following details:

Item	Description
Name	Name of reports.
Type	Type of reports.
Analysis	Analysis type is Aggregated.
Last Run	Time when the report was run.
Schedule	Schedule of the report run is Manual.
Status	Status of the report. The status could be Pending, Running now, Stopped, Processing, Completed, or Failed.

- > Use the **Search** text box to filter reports. Search results display reports that contain specified text in their names.
- > Reports can be sorted by their name, type (Scans), analysis (Aggregated), the last time that the scan was run, schedule, and status.
- > Click the link embedded in the report name to display the details of that report. For more information, see ["Report Details" on page 53](#).

Report Types

There are two different types of reports:

- **Static report:** This report is based on a scan run on a specific date.

- The report is 'frozen' with the last successful scan that has been executed up to now.
- In the case of multiple executions of the scan for the selected day, the report will include the information for the latest execution on that day.
- **Dynamic report:** This report is always showing the information found on the latest scan execution, so the results will change if the underlying data in the Data Store or the Classification Profile is modified. In other words, such a report is dynamic, it will be regularly updated whenever:
 - There are changes in the machine, such as the quantity of data has changed (increased or decreased).
 - There are changes in any aspect of the DDC configuration in DDC, such as when the classification profiles have been modified.

NOTE

- > For one report, it is possible to select scans in a dynamic and static manner. This would result in one report that is 'frozen' and another that is not 'frozen'.
- > In order to see an updated report you must run the scan since the report reflects the scan information.

Creating Reports

To create a report you aggregate data from multiple sources. When a report is generated it contains the results of executed scans.

To create a report use the **New Report** wizard described in the following sections. To launch the wizard, click the **+ Add Report** button in the **Reports** page on the right.

General Info

Provide the following information in the **General Info** screen of the **New Report** wizard:

- > A unique **Name** for the report. The name must be longer than two characters and up to 64 characters. This field is mandatory.
- > An optional **Description** for the report (up to 250 characters).

Click **Next** to go on to the **Configure Content** step of the wizard.

Configure Content

This **Configure Content** screen shows available scans with their number and the number of selected scans.

1. Use the **Search** text box to filter available scans. Search results display scans that contain specified text in their names.
2. Select the **Scan Name** check boxes corresponding to desired scans.
3. You can create two different types of reports:
 - A **static report** is based on a scan run on a specific date. For a static report, click "Latest Execution" and select the date of the scan that you wish to use.

- A **dynamic report** can change if the underlying data store or protection profile is modified and a scan is run again. For a dynamic report leave "Scan Execution" as "Latest Execution".

See ["Report Types" on page 50](#) for more information on these reports.

4. Click **Save** and a message will appear stating that the report has been created successfully.

The content identified in this step will be merged in a single report. This is called an **aggregated report**.

To create a report use the New Report wizard described in the following sections.

Name and Describe

1. In the **Reports** page on the right, click **New Report**. The **Name and Describe** screen of the **New Report** wizard is displayed.
2. Specify a unique **Name** for the report. The name must be longer than two characters and up to 64 characters. This field is mandatory.
3. Provide a **Description** for the report (up to 250 characters).

Configure Content

NOTE Content identified in this step will be merged in a single report. This is called an aggregated report.

1. Click **Next**. The **Configure Content** screen is displayed. This screen shows available scans with their number and the number of selected scans.
2. Use the **Search** text box to filter available scans. Search results display scans that contain specified text in their names.
3. Select the **Scan Name** check boxes corresponding to desired scans.
4. Create a static report or dynamic report:
 - For a static report - click **Latest Execution** and select the date of the scan that you wish to use.
 - For a dynamic report - leave **Scan Execution** as **Latest Execution**.

For information on these report types, see ["Report Types" on page 50](#).

5. Click **Save** and a message will appear stating that the report has been created successfully.

As soon as a new scan-based report is created, it is automatically run and results are visible. For information on the details of the report, see ["Report Details" on the next page](#).

NOTE

- > Scan-based reports are for personal use only. Users can only access the scan-based reports that they create. No user can access the scan-based reports created by others.
- > Selecting a scan forces DDC to retrieve the results discovered during the last execution of the given scan. As different scans may be taken into account, different runs of the same scan-based report may provide different results.

Generating Reports

After you have configured a report, it can be generated at anytime. Configured reports can be generated any number of times.

To generate a report:

1. In the **Reports** page, search for the report that you want to generate.

TIP

- > Use the **Search** text box to filter reports. Search results display reports that contain specified text in their names.
- > By default, reports are listed in ascending alphabetic order of their names.
- > Reports can be sorted by their name, type (Scans), analysis (Aggregated), last run time, schedule, and status.

2. Click the overflow icon () corresponding to the desired report. A shortcut menu appears.

3. Click **Run report**.

As soon as the report starts to run, its status becomes **Pending**. The status of the report changes in the sequence: Pending > Running now / Stopped > Processing > Completed / Failed.

NOTE Permissions to access the data stores accessed by the scans included in a scan-based report are checked every time the report is run. If the current user no longer has the correct permission for any of them, an error is displayed.

Report Details

The report details page displays such information about the report as the report name, the number of scans, data stores, and data objects. The page also shows the total data objects scanned, sensitive data objects found, sensitive data matches, and selected infotypes found.

NOTE There may be a mismatch between the number of objects scanned as shown in the **Total Data Objects Scanned** info card, top left of the **Data Objects** page and the number of objects listed in the table at the bottom ("**Showing _ of _**"). This is because the table also lists all so called "inaccessible" items that have been found in the scan.

Inaccessible items are data objects that could not be scanned because the Agent could not access their contents. The main reasons for this is a lack of permissions at the OS level (that is, the Agent is not able to read the file) and/or issues encountered when extracting the text data, such as file contents protected with a password, corrupted files, and the like.

The table in the report details lists the following findings distributed among these columns:

- **Object Name** - The name of the data object scanned and listed in the report details.
- **Risk** - The number of risks founds by the report in the given scanned data object. A risk is the presence of a sensitive item of data.

- **Type** - The type of the scanned data object listed in the report details, such as "File" or "Folder".
- **Path** - The path to the object that is listed in the report details.
- **Store** - The name of the data store where the object listed in the report details was found.
- **Owner** - The owner of the listed object.
- **Modified** - The date of the last modification of the scanned and reported data object.
- **Infotypes** - The number of information types found in the data object that is listed in the report.

NOTE Due to a known limitation of the processing engine, the information on the **Owner** and **Modified** is usually not listed in the report details.

To return to the **Reports** page, click **All Reports** at the top of the report details page.

Logging

DDC prints out its log messages to the CipherTrust Manager logs. CipherTrust Manager logs are located in the **/opt/keysecure/logs** directory. The CipherTrust Manager System Administrator (ksadmin) can log in using ssh to retrieve CipherTrust Manager logs. Also the DDC Application Administrators have access to the logs.

For more details on collecting DDC logs, see "Troubleshooting Issues in Conjunction with Customer Support" in the "Thales CipherTrust Manager Administrator Guide".

Default Logging Level

By default, log level setting for DDC is INFO. With this log level set DDC prints out the INFO and ERROR level messages to the log. Among the various messages that DDC prints to the logs, the error messages and security audit messages are the most useful for troubleshooting DDC issues and securing the deployment.

Identifying DDC Log Messages

The microservices behind DDC are **Oleander** and **Sundew** and the messages coming to the CipherTrust Manager log from DDC can be identified by those names.

Additionally, Oleander has these three modules:

- > Clustering
- > Agent_Selection
- > Scan_watcher

Each of these modules will generate its own error messages, each in its separate log.[] log file.

The logging service responsible for collecting and processing these messages is FLUENTD. It is capable of displaying those messages to the terminal through the log command. Here's an example of such a command:

```
> log | grep oleander | grep "clustering"
```

This command would display all messages coming from the Oleander's Clustering module.

For a complete list of error messages that DDC sends to the CipherTrust Manager log, see the appendix ["Error Log Messages" on page 63](#).

Security Audit Log Messages

The DDC security audit messages can be identified by the **Oleander | INFO [security]** bit that they contain. The full format of such a log message (or log line) is:

```
<date> | Oleander | INFO [security] <event> <error (if any)> <details (if any)>
```

For example:

```
2020-06-29 | Oleander | INFO | [security] DDCScanClientUnexpectedErrorProbe "error: error  
probing scan client" "details: [scan_id:5432-5432-543254-2-5432]"
```

Usually, only the event type is printed out to the log (in the example above, it would be DDCScanClientUnexpectedErrorProbe). You can find the full list of events with explanations in the appendix ["Security Audit Log Event Messages" on page 90](#).

Enabling Syslog Logging

Audit records are logged to a local database by default. This is suitable for production systems and clusters with a limited load. However, for clusters that support a large number of transactions, it is recommended to configure the CipherTrust Manager Manager to disable logging to a local database and enable logging using a remote Syslog server. This significantly reduces cluster traffic and disk usage. For more information, refer to the following sections in the “Thales CipherTrust Manager Administrator Guide”:

- > “Disabling local database audit logging”
- > “Configuring remote Syslog server”
- > “Configuring Connection to a Syslog Server”

APPENDICES

Error Messages

This section lists the various error messages that the system can display, with explanations and solutions (if available).

Error Message	Explanation
Branch Locations	
"Branch Location name already exists" (message on toast)	You tried to create a branch location with a name that is already taken by another branch location. SOLUTION: Choose another name.
Data Stores	
"Data Store name already exists" (message on toast)	You tried to create a data store with a name that is already taken by another data store. SOLUTION: Choose another name.
"A valid agent could not be found" (Agent selection - on mouse-over on the data store)	There is no active agent for this data store that the automatic agent selection process has been able to detect. SOLUTION: This requires additional research, such as checking if the agent is installed on the data store, if it has the right type (local/proxy), if it is of the right OS "flavor" (Linux, Windows), or of the right type (e.g. database). Refer to the "Deployment Guide" for more information on troubleshooting this issue.
Scans	
"Scan name already exists" (message on toast)	You tried to create a scan with a name that is already taken by another scan. SOLUTION: Choose another name.
"All Data Stores are disabled" (message on toast)	You attempted to run a scan that has all data stores disabled. SOLUTION: Enable at least one data store for the scan. Refer to the "Managing Scans" on page 44 chapter for instructions.

Error Message	Explanation
"The following Data Stores are not accessible: <xyz>" (message on toast)	You tried to scan a data store that is not accessible. The scan is marked as Failed, and includes a warning icon with the message "The data store <xyz> included in the scan is not accessible" on mouse-over. SOLUTION: Verify the connectivity from the agent to the data store. Verify the data store configuration.
"One or more Data Stores are not accessible." (On mouse-over on the scan fail icon)	The scan failed because the data store that is configured is inaccessible. The data store failed after the scan was launched. SOLUTION: There may be a number of reasons for this. To troubleshoot a failed data store refer to "Managing Data Stores" on page 32.
"The following Data Stores have no agent available: <xyz>" (On mouse-over on the scan fail icon)	You tried to scan a data store that had no agent available when the scan was executed. There is a problem with the agent. The data stores that failed are listed. SOLUTION: This requires additional research, such as checking if the agent is installed on the data store, if it has the right type (local/proxy), if it is of the right OS "flavor" (Linux, Windows), or of the right type (e.g. database). Refer to the "Deployment Guide" for more information on troubleshooting this issue.
"Data Store has incorrect credentials" (on mouse-over on the scan fail icon)	Data store credentials provided are incorrect so the scan cannot be executed. These data stores are listed. SOLUTION: Update the server credentials for the data store.
"One or more Data Stores have incorrect credentials" (message on toast)	The credentials for one or more data stores are no longer valid (credentials modified, user deleted, and so on) preventing the scan from completing. SOLUTION: Reconfigure the data store and re-launch the scan.
"The scanner service is not available" (message on toast)	You tried to run a scan with the scan engine unavailable. SOLUTION: Check the status of the scan engine (the KeySecure server).

Error Message	Explanation
"The following Data Stores have missing agents: <xyz>" (message on toast)	This happens when an agent was assigned to the listed data store(s) and then when a scan was launched, for some reason the assigned agent could not be found on the server. SOLUTION: Try to re-assign the agent in the data stores screen. If this does not work, check the agent assigned to the <xyz> data store.
"The following Data Stores have agent errors: <xyz>" (message on toast)	This happens when a management request for an agent fails (for example, at verification or when setting it as a proxy) during the scan execution. SOLUTION: It is usually a transient issue. Wait a few minutes and run the scan again. If it still fails, check the agent status.
"Error processing scan" (message on toast)	This happens when the scan fails in the processing stage, that is when the scan results are being processed by DDC. SOLUTION: Run the scan again. If the error persists, contact Thales support.
"Error connecting to HDFS" (message on toast)	This happens when the scan fails because there is no HDFS connectivity. SOLUTION: Check the HDFS configuration in DDC (Hadoop Services). Refer to the "Deployment Guide" for information on configuring the DDC-HDFS connection.
"Error connecting to PQS" (message on toast)	This happens when the scan fails because there is no PQS connectivity. SOLUTION: Check the HDFS configuration in DDC (Hadoop Services) or PQS/Hadoop configuration in your Hadoop deployment. Refer to the "Deployment Guide" for information on configuring the DDC-PQS connection.
"Error checking the data allowance" (message on toast)	This happens when DDC is not licensed. DDC sends a request for data allowance to the license server and the server responds that there is no license. SOLUTION: Obtain and install a valid DDC license.

Reports

Error Message	Explanation
"Report name already exists" (message on toast)	You tried to create a report with a name that is already used in another report. SOLUTION: Choose another name.
Classification Profiles	
"Classification Profile name already exists" (message on toast)	You tried to create a classification profile with a name that is already taken by another classification profile. SOLUTION: Choose another name.
Licensing	
"DDC License not found - try again in a few minutes if you recently inserted one" (message on toast)	Any action performed in the UI results in this message, because there is no valid DDC license installed. SOLUTION: Obtain and install a valid license.
"DDC License expired" (message on toast)	Any action performed in the UI results in this message, because your DDC license has expired. SOLUTION: Obtain and install a valid license.
Hadoop Configuration	
"Hadoop is not active. Please go to DDC Settings --> Hadoop" (message on toast)	Problem communicating with Hadoop or DDC has not been configured with Hadoop. SOLUTION: Assuming that you have Hadoop deployed in your environment, configure DDC to use it (DDC Settings --> Hadoop in the KeySecure UI). For a detailed procedure, refer to the "Deployment Guide".
"Error connecting to the PQS database" (message on toast)	Problem communicating with the Phoenix Query Server database (i.e. HBase). SOLUTION: Check the PQS configuration in DDC (Hadoop Services) or PQS/Hadoop configuration in your Hadoop deployment. Refer to the "Deployment Guide" for information on configuring the DDC-PQS connection.

Error Message	Explanation
"Error creating the PQS database schema" (message on toast)	Problem communicating with the Phoenix Query Server database. SOLUTION: Check the PQS configuration in DDC (Hadoop Services) or PQS/Hadoop configuration in your Hadoop deployment. Refer to the "Deployment Guide" for information on configuring the DDC-PQS connection.
"Error using the PQS database schema" (message on toast)	Problem communicating with the Phoenix Query Server database. SOLUTION: Check the PQS configuration in DDC (Hadoop Services) or PQS/Hadoop configuration in your Hadoop deployment. Refer to the "Deployment Guide" for information on configuring the DDC-PQS connection.
"Error connecting to HDFS" (message on toast)	SOLUTION: Check the HDFS configuration in DDC (Hadoop Services). Refer to the "Deployment Guide" for information on configuring the DDC-HDFS connection.
"Invalid HDFS directory path: Not a directory" (message on toast)	SOLUTION: Check the HDFS configuration in DDC (Hadoop Services). Refer to the "Deployment Guide" for information on configuring the DDC-HDFS connection.
"Incorrect credentials in the HDFS connection" (message on toast)	SOLUTION: 1. Check the HDFS configuration in DDC (Hadoop Services). Refer to the "Deployment Guide" for information on configuring the DDC-HDFS connection. 2. Check that the authentication service is up and running.
"Incorrect HDFS URI" (message on toast)	SOLUTION: Check the HDFS configuration in DDC (Hadoop Services). Refer to the "Deployment Guide" for information on configuring the DDC-HDFS connection.
"Invalid HDFS folder: the path to the folder does not exist" (message on toast)	SOLUTION: Check the HDFS configuration in DDC (Hadoop Services). Refer to the "Deployment Guide" for information on configuring the DDC-HDFS connection.
"Invalid server certificate in the HDFS request" (message on toast)	SOLUTION: Check the HDFS configuration in DDC (Hadoop Services). Refer to the "Deployment Guide" for information on configuring the DDC-HDFS connection.

Error Message	Explanation
"Incorrect credentials in the PQS connection" (message on toast)	SOLUTION: 1. Check the PQS configuration in DDC (Hadoop Services) or PQS/Hadoop configuration in your Hadoop deployment. Refer to the "Deployment Guide" for information on configuring the DDC-PQS connection. 2. Check that the authentication service is up and running.
"Invalid server certificate in the PQS request" (message on toast)	SOLUTION: Check the PQS configuration in DDC (Hadoop Services) or PQS/Hadoop configuration in your Hadoop deployment. Refer to the "Deployment Guide" for information on configuring the DDC-PQS connection.
"Your system does not meet the 16GB RAM minimum" (message displayed across the bottom of all DDC screens)	DDC requires at least 16GB of RAM to be able to run properly. SOLUTION: Increase the RAM memory on board to at least the required minimum of 16GB.

Error Log Messages

This section lists the various error messages that DDC sends to the KeySecure log.

Error Message	Comment/Explanation
OLEANDER ERRORS	
2020-02-20 19:53:08 oleander Error connecting to the scan service	This error means a connectivity issue between the oleander and the sundew/ER2 .
2020-02-13 08:50:17 oleander DDC Error creating the database schema.: error executing http request. Code: 500 - Body:<html>	To check the connectivity with Hadoop external data base a schema is created. So this means that there is no connectivity with Hadoop. (also, possibly related to "Error creating the PQS database schema" in the UI)
"CLIENT_CREDENTIAL_PARTITION is not set"	CLIENT_CREDENTIAL_PARTITION variable is not set in the config object.
"[Background-Processes] Error retrieving license from DMV", "error", err	Oleander GetLicenses request against DMV has failed. This error could have been caused by DMV being down.
"[Background-Processes] Error killing all agents selections"	When the oleander instance loses its license or the current license expires, all ongoing agent selections will stop. This error is caused by an internal Oleander issue while this agent selections are being shut down.
"[Background-Processes] Error killing all scan watchers"	When the oleander instance loses its license or the current license expires, all ongoing scan tracking will stop. This error is caused by an internal Oleander issue during this scan tracking shut down.
"[Background-Processes] Error removing all scan schedules due to DDC not licensed"	When the oleander instance loses its license or the current license expires, all scheduled scans will be stopped. This error is caused by an internal Oleander issue during this scheduled scans stopping.
"[Background-Processes] Error starting agent selection for datastores"	The listed Data Stores have no agent available.
"[Background-Processes] Error starting scans watchers"	When the oleander instance receives a valid license from DMV, all stopped agent selections must be resumed. This error is caused by an internal Oleander issue during this agent selections resuming.

Error Message	Comment/Explanation
"[Background-Processes] Error starting cron schedules"	When the oleander instance receives a valid license from DMV, all stopped scheduled scans must be resumed. This error is caused by an internal Oleander issue during this scheduled scans resuming.
"[Background-Processes] Error trying to migrate the PQS database"	During the PQS configuration, an error occurred trying to apply the changesets to update the Database, create the tables, etc...
"[Background-Processes] Error creating cron", "error", err	Background_processes service constantly creates crons for license status checking against DMV, this error is caused by an internal Oleander issue during the creation of one of this crons.
"[Background-Processes] Error with unmarshal."	Any "unmarshal/unmarshalling" error is caused by an internal Oleander issue converting a golang object to JSON format or vice versa.
"[Background-Processes] Error while trying to update status to FAILED for datastore.", "name", ds.Name, "error", err	When background_process services gets an invalid or expired license from DMV all running scans must be stopped and set as FAILED, this message indicates an internal Oleander error changing the scan status for some scan.
"[Background-Processes] Error while trying to retrieve scans from background processes table"	When the oleander instance receives a valid license from DMV, all stopped normal scans must be resumed. This error is caused by an internal Oleander issue accessing the background processes table, which contains all the information for the scans resuming.
"[Background-Processes] Watcher has failed updating scan status for scan", "name", sc.Scan.Name, "error", err	background_processes service has the responsibility to track the running scans and update their Oleander status, this error message indicates an internal Oleander issue updating the scan_process table.
"Cannot retrieve the HDFS settings", "error", err	Connectivity or internal Oleander error trying to retrieve HDFS settings from Citrus.
"Cannot retrieve the PQS settings", "error", err	Connectivity or internal Oleander error trying to retrieve PQS settings from Citrus.
"Cannot find the country", "error", err	When a user creates a BranchLocation and he sets a country that is not registered in our DB.
"Cannot find the state", "error", err	When a user creates a BranchLocation and he sets a state ID that is not registered in our DB.

Error Message	Comment/Explanation
"Trying to verify if the country has states", "error", err	When a user creates a BranchLocation and he sets a state "Name" that is not registered in our DB.
"Missing tag %s for the default classification profiles", r	When inserting default classification profiles, there is no tag that matches the correct Regulation
"[Datastores] Error encrypting connection for datastore: ", "Name", d.Name	Error when calling Scrim Helper for the encryption of the Connection field for a datastore.
"[Datastores] Error while trying to create background process resource for datastore: ", "Name", d.Name	When a datastore is created, a new row is inserted into the Background Processes table for further tracking, this error message indicates an internal Oleander issue inserting that row.
"[Datastores] Error selecting agent for datastore ", "Name", dsAAS.Name, "error", err	No suitable agent has been found for this datastore.
"[Datastores] Error while trying to retrieve datastore for background process, agent selection might fail: ", "error", err	Error retrieving a datastore from DB for background processes purposes in a datastore.update operation.
"[Datastores] Error running automatic agent selection", "error", errAgentUpdate	An internal Oleander error has occurred while trying to update the status of a datastore during the automatic agent selection.
"[Datastores] Error while trying to unmarshal datastore from background processes"	An internal Oleander error has occurred while trying to translate a JSON object to a goLang object while recovering the automatic agent selections.
"Error closing the json file", "error", err	Oleander failed trying to close a JSON file.
"Error trying to close the families json file"	Oleander reads a families JSON file for startup DB population. This error message indicates an internal Oleander error while closing this file.
"Error initializing the account", "error", *errPtr	Oleander failed trying to set the initialization status to the accounts map.
"Error closing oleander", "error", err	Oleander service could not be closed.
"Error starting background processes", "error", err	Some error has occurred trying to execute all background processes.
"Error connecting to HDFS", "error", err	This happens when the scan fails because there is no HDFS connectivity.

Error Message	Comment/Explanation
"Error trying to close the info types json file"	Oleander reads an infotypes JSON file for startup DB population. This error message indicates an internal Oleander error while closing this file.
"Error connecting to PQS", "error", err	This happens when the scan fails because there is no PQS connectivity.
"Error closing the temporary file", "FileName", f.Name(), "error", err	Oleander failed closing the temporary file used for decrypting the raw data file.
"Error deleting the temporary file", "FileName", f.Name(), "error", err	Oleander failed deleting the temporary file used for decrypting the raw data file.
"Error trying to close the zip file", "error", merry.Wrap(err).WithHTTPCode(http.StatusBadRequest)	Oleander failed closing the zip file used for decrypting the raw data file.
"Error changing the scan status", "error", err	Internal Oleander error while trying to update the scan status in the Scan Process table.
"[Scan-Launcher] Error while trying to create background process resource for datastore", "name", rsc.Name	Oleander inserts a row in the Background Processes table for further scan tracking - this message indicates an internal Oleander error while performing this insert.
"[Scan-Launcher] The scan watcher returned an error", "error", err	Generic error message for any issue during the scan watcher process.
"[Scan-Launcher] Agent not found for datastore", "DS name", s.ScanDatastores[i].Datastore.Name, "error", err	The listed Data Stores have no agent available.
"[Scan-Launcher] Error getting absolute paths", "DS name", s.ScanDatastores[i].Datastore.Name, "error", err	Oleander was unable to retrieve the absolute paths of the mentioned datastore for further scan execution.
"[Scan-Launcher] Error getting connection path", "DS name", s.ScanDatastores[i].Datastore.Name, "error", err	Oleander was unable to retrieve the connection paths of the mentioned datastore for further scan execution.
"[Scan-Launcher] Error retrieving the oleander context"	Error while generating the Oleander service user. (this is the context for executing actions on behalf of the itself, instead of a specific user).
"[Scan-Launcher] Error while validating the scan"	This is a generic error, one of the steps of the validation has failed. (could be that some datastores are not ready, a probe has failed, etc)

Error Message	Comment/Explanation
"[Scan-Launcher] Error while retrieving extensions"	The extensions necessary for the scan execution could not be retrieved from the DB.
"[Scan-Launcher] Unable to initialize background process"	The background process object could not be initialized so the scan watcher cannot start.
"[Scan-Actions] Error found while trying to delete background process resource"	When Oleander has finished tracking a scan it removes the corresponding row from background processes table - this error message indicates an internal Oleander issue removing that row.
"[Scan-Actions] Error trying to execute the Scan scheduled run", "error", err	Oleander failed trying to add a scan schedule for a scan.
"Error changing the scan status", "error", err	Generic error message for an issue during the update of the scan status.
"[Scan-Watchers] Watcher has failed getting scan status from scanned service", "scan", sc.Scan.Name, "error", err	This indicates an underlying connectivity issue with Sundew.
"[Scan-Watchers] Watcher has failed updating scan status", "scan", sc.Scan.Name, "error", err	Error updating the scan status in the scan process table.
"[Scan-Watchers] Error processing the report: ", "error", err	Oleander scan collector has failed trying to create the scan collector background process for the mentioned scan.
"[Scan-Watchers] Scan aborted, maximum wait for scan results exceeded", "MaxTimeInterruptedState (minutes)", o.Config.Er2MaxInterruptedTime/60, "scan", sc.Scan.Name, "current status", sc.Scan.ScanProcess.Status, "scan service status", er2MappedStatus	The scan has been in INTERRUPTED er2 state for too long, when it exceeds the timeout the status is changed to FAILED in DDC.
"Error trying to parse er2 polling frequency from env"	Oleander failed trying to read the ER2 POLLING FREQUENCY env variable from the config object.
"Error while trying to retrieve scans from background processes table", "error", err	Oleander tried to retrieve all SCAN rows in the background processes table but it failed.
"Error trying to recover the scan watchers", "error", err	One of the scan watchers instantiated by the recovery system has returned an error and stopped working.
"Wrong datastore credentials"	Oleander was unable to reach a datastore due to credentials failure.

Error Message	Comment/Explanation
"Wrong target path defined"	A scan has failed because the target path defined was not valid.
"Wrong db schema in target path"	A scan has failed because the db schema defined was not valid.
"Wrong db table in target path"	A scan has failed because the DB defined was not valid.
"Wrong defined file extension in target path"	A scan has failed because a file was specified without an extension.
"Error connecting to the scan service"	Oleander is unable to connect with ER2.
"Error processing the scan reports"	Generic error while trying to process a scan report.
"No Data Allowance Licensing detected"	Oleander does not have a Data Allowance record.
"Error reading the scan report"	Generic error while trying to read a scan report.
"Probing path can be launched only on folders. Files are not supported"	Scan failed because a file was specified as target instead of a folder.
"Probing a File or Directory that does not exist"	Scan failed because the specified directory does not exist.

OLEANDER INFO

"[Background-Processes] This node was NOT selected as active node. Turning off background processes"	Related to clustering, self-explanatory error.
"[Background-Processes] This node was selected as active node. Turning on background processes"	Related to clustering, self-explanatory error.
"[Background-Processes] Recovering collectors"	Oleander has received a valid license and recovers the collector processes that were stopped.
"[Background-Processes] Updating license from DMV"	Oleander is requesting from DMV the licenses available for DDC.
"[Background-Processes] Global license status set to nil"	Oleander is unlicensed.
"[Background-Processes] Global license status set to ", "newLicenseStatus", *newLicenseStatus"	Oleander license status is whatever <i>newLicenseStatus</i> is.

Error Message	Comment/Explanation
"[Background-Processes] Checking HDFS connectivity"	Oleander is sending a ping to HDFS to check the connectivity.
"[Background-Processes] Cannot connect with HDFS", "error", err	Oleander's ping against HDFS has failed. Oleander has no connectivity with HDFS.
"[Background-Processes] HDFS connectivity successful"	Oleander has successfully performed a ping against HDFS. Oleander has connectivity with HDFS.
"[Background-Processes] Checking PQS connectivity"	Oleander is sending a ping to PQS to check the connectivity.
"[Background-Processes] Cannot connect with PQS", "error", err	Oleander's ping against PQS has failed. Oleander has no connectivity with PQS.
"[Background-Processes] PQS connectivity successful"	Oleander has successfully performed a ping against PQS. Oleander has connectivity with PQS.
"[Background-Processes] License status has changed"	Oleander license status has changed since the last license cron execution.
"[Background-Processes] Initializing fast cron: Oleander unlicensed", "UnlicensedCronFrequency", o.Config.UnlicensedCronFrequency	Oleander is unlicensed so the license cron (which asks DMV for a DDC license) increments its frequency. The frequency is defined in the docker-compose file.
"[Background-Processes] Initializing fast cron: waiting for Hadoop connectivity", "HadoopConnectivityCronFrequency", o.Config.HadoopConnectivityCronFrequency	Oleander has a valid license but does not have connectivity with Hadoop.
"[Background-Processes] Initializing slow cron: Oleander licensed and Hadoop connectivity successful", "RunningCronFrequency", o.Config.RunningCronFrequency	Oleander has a valid license and has connectivity with Hadoop, the license cron decrements its frequency. The frequency is defined in the docker-compose file.
"[Background-Processes] About to run NO LICENSE scenario"	Oleander has no valid license so it will stop all running scan watchers, automatic agent selections and scan schedules.
"[Background-Processes] About to run VALID LICENSE scenario"	Oleander didn't have a valid license but now it has one so all scan watchers, automatic agent selections and scan schedules that were stopped are being resumed.
"[Background-Processes] Recovering automatic agent selection"	Part of the VALID LICENSE scenario above.

Error Message	Comment/Explanation
"[Background-Processes] Starting automatic agent selection for pending datastores", "pending datastores", strings.Join(ds, ", ")	Part of the VALID LICENSE scenario above.
"[Background-Processes] Recovering watchers"	Part of the VALID LICENSE scenario above.
"[Background-Processes] Starting watchers for ongoing scans", "ongoing scans", strings.Join(ss, ", ")	Part of the VALID LICENSE scenario above.
"[Background-Processes] Recovering scan schedules"	Part of the VALID LICENSE scenario above.
"[Background-Processes] Migrating PQS database"	Self-explanatory message.
"[Background-Processes] Deleting background process for scan", "name", sc.Scan.Name	Oleander has no valid license so all scans are being stopped as well as their corresponding background processes.
"[Background-Processes] Updating status to FAILED for scan", "name", sc.Scan.Name	Oleander has no valid license so all scans are being stopped (with status FAILED).
"Cannot connect to HDFS", "settings", hdfsSettings, "error", err	Oleander's ping against HDFS has failed. Oleander has no connectivity with HDFS.
"Cannot connect to PQS", "Settings", pqsSettings, "error", err	Oleander's ping against PQS has failed. Oleander has no connectivity with PQS.
"[Datastores] Agent selected: ", "Name", a.Name	Oleander has found and assigned a suitable agent for the mentioned datastore.
"Unable to connect with datastore", "datastore name", d.Name, "error", err	A probe against the mentioned datastore has failed during a test connectivity check.
"Instantiating new scrim helper"	Oleander is instantiating a new ScrimHelper object which is used for communication with Scrim, Minerva, Sallyport and DMV.
"Instantiating new hdfs scan collector"	Oleander is instantiating a new HDFSCollector object which is used for communication and processing with HDFS.
"Instantiating scheduler cron"	Oleander is instantiating a new SchedulerCron and starting the background processes.
"[WARNING] PQS connector can not be closed in GetSummaryReport service"	Oleander was unable to close the PQS connector while executing a GetSummaryReport operation.

Error Message	Comment/Explanation
"[WARNING] PQS connector can not be closed in GetDatastoresDetailsReport service"	Oleander was unable to close the PQS connector while executing a GetDatastoresDetailsReport operation.
"[WARNING] PQS connector can not be closed in GetReportTemplate service"	Oleander was unable to close the PQS connector while executing a GetReportTemplate operation.
"[Scan-Actions] [WARNING] PQS connector can not be closed in GetScanExecutions service"	Oleander was unable to close the PQS connector while executing a GetScanExecutions operation.
"[Scan-Watchers] Stop watcher signal received", "scan", sc.Scan.Name	A running scan watcher has received a STOP signal and the current execution is cancelled.
"[Scan-Watchers] Watcher has failed stopping scan from scanned service"	The scan has been in an INTERRUPTED status for too long so Oleander has tried to stop the scan in ER2 but the request was unsuccessful.
"[Scan-Watchers] Watcher has detected different status", "scan", sc.Scan.Name, "current status", sc.Scan.ScanProcess.Status, "scan service status", er2MappedStatus	The scan watcher has detected a change in the scan status, scan status will be updated in DDC.
"[Scan-Watchers] Interrupted status received", "MaxTimeInterruptedState", o.Config.Er2MaxInterruptedTime, "scan", sc.Scan.Name, "current status", sc.Scan.ScanProcess.Status, "scan service Mapped status", er2MappedStatus, "scan service status", er2Status, "InterruptedTimestamp", sc.InterruptedTimestamp	The scan watcher has received an INTERRUPTED status for the scan, the scan watcher will continue asking until the status changes or the timeout is exceeded.
"[Scan-Watchers] Scan has finished... collector starting", "scan", sc.Scan.Name	The scan watcher has received a COMPLETED status for the scan, the scan status is set to PROCESSING in DDC and the scan collector starts.

SUNDEW INFO

"Asking for license status"	Sundew is requesting from Oleander the DDC license status.
"Active license information received", "http ret code", c	Sundew has received a valid license status from Oleander.
"Starting scan service..."	Sundew is launching ER2.
"Connectivity test successful, scan service is up"	Sundew confirms that ER2 is up-and-running.

Error Message	Comment/Explanation
"Generating scan service license...", "ID", s.er2Status.lastIssuedLicenseID	Sundew is generating a license for ER2.
"Injecting license into scan service"	Sundew is injecting the generated license into ER2.
"License won't be generated/refreshed in this iteration", "ID", s.er2Status.lastIssuedLicenseID, "checks (intervals)", s.Config.GeneratingLicenseInterval-s.er2Status.lastIssuedLicense	No action is required from Sundew for this iteration regarding licensing.
"Not active license or product not licensed response received", "http ret code", c	Sundew has received an invalid license status from Oleander.
"Scan service stopped"	Sundew is stopping ER2.
"Unexpected error code in response for /license/status", "http ret code", c	Sundew asked Oleander for the license status but got an unexpected response.

SUNDEW ERROR

"CLIENT_CREDENTIAL_PARTITION is not set."	CLIENT_CREDENTIAL_PARTITION variable is not set in the config object.
"Error trying to ask for license status", "error", err	Sundew failed trying to request DDC status from Oleander.
"Error trying to start the scan service", "error", err	Sundew failed trying to start ER2.
"Connectivity test to the scan service failed", "error", conErr	Sundew failed trying to ping ER2. ER2 is down.
"Error during validation of received license", "error", err	Sundew failed trying to validate the DDC license retrieved from Oleander.
"Error parsing the license ID", "error", err	Sundew failed trying to parse the DDC license ID received from Oleander.
"Error while injecting license inside scan service", "error", err	Sundew failed trying to inject the generated license into ER2.
"Error stopping scan service", "error", err	Sundew failed trying to stop ER2.
"Error closing the response body", "error", err	Sundew failed trying to close the HTTP response body from a request.
"Error closing sundew", "error", err	Error when trying to close the Sundew service.

Reconfiguring Agents

In some situations, for example, if the hostname or IP address of the CipherTrust Manager appliance changes, Agents' connection with DDC must be reconfigured with the new hostname or IP address.

Reconfiguring DDC Agents on Windows

To reconfigure a DDC Agent:

1. Log on to the host machine as administrator.
2. Open Enterprise Recon Configuration Tool (**er2_config_cmd.exe**).
By default, the tool is available at C:\Program Files (x86)\Ground Labs\Enterprise Recon 2\.
3. In the **Master server IP address or host name** field, specify the new hostname or IP address of the CipherTrust Manager.
4. Click **Test Connection**. A message stating "Connectivity test is successful" confirms successful reconfiguration.
5. Click **Finish**.

Reconfiguring DDC Agents on Debian

To reconfigure a DDC Agent:

1. Log on to the host machine as a user with root privileges.
2. Reconfigure connection with DDC on the CipherTrust Manager appliance.

```
sudo er2-config -i <hostname|ip_address>
```

Here, <hostname|ip_address> represents the new IP address or hostname of the CipherTrust Manager appliance.
3. Restart the Agent service. Configuration settings will be effective after the Agent restarts.

```
sudo /etc/init.d/er2-agent -restart
```

Reconfiguring DDC Agents on RHEL

To reconfigure a DDC Agent:

1. Log on to the host machine as a user with root privileges.
2. Reconfigure connection with DDC on the CipherTrust Manager appliance.

```
er2-config -i <hostname|ip_address>
```

Here, <hostname|ip_address> represents the new IP address or hostname of the CipherTrust Manager appliance.
3. Restart the Agent service. Configuration settings will be effective after the Agent restarts.

```
/etc/init.d/er2-agent restart
```

Restarting DDC Agents

Restarting Agents on Windows

To restart a DDC Agent, run the following commands:

```
net stop "Enterprise Recon 2 Agent (<ARCH>)"
net start "Enterprise Recon 2 Agent (<ARCH>)"
```

Here, <ARCH> represents the Windows architecture - x32 or x64.

Restarting Agents on Debian

To restart a DDC Agent, run: `sudo /etc/init.d/er2-agent restart`

TIP Alternatively, restart the Agent service by stopping it and again starting it manually. Run the following commands:

```
sudo /etc/init.d/er2-agent stop
sudo /etc/init.d/er2-agent start
```

Restarting Agents on RHEL

To restart a DDC Agent, run: `#!/etc/init.d/er2-agent restart`

TIP Alternatively, restart the Agent service by stopping it and again starting it manually. Run the following commands:

```
#!/etc/init.d/er2-agent stop
#!/etc/init.d/er2-agent start
```

Mounting an NFS Share

To mount an NFS share on a Proxy agent, run this command as root:

```
# mount <nfs-server-hostname|nfs-server-ipaddress>:</target/directory/share-name>
```

REST API

You can use the REST interface from the *API playground*, or via any REST client such as curl. To use the REST interface from the API playground, acquire an authorization token and use it when making API calls.

Acquiring an Authorization Token

To acquire a token:

1. Open the CipherTrust Manager URL in a browser. The login page is displayed.
2. Click the **API & CLI Documentation** link. The API playground is displayed.
3. At the top right, click **Authenticate**.
4. Enter **username** and **password**.
5. Click **POST**.

NOTE This acquires an API token and prefills it in the playground examples. The token expires in 300 seconds (5 minutes). When it expires, use this process again to acquire a new token.

On successful token generation, the remaining token expiry time in seconds is displayed. Two new buttons, **Clear Credentials** and **Re Authenticate**, are also displayed at the top right.

Using the Token

The authorization token acquired above is used in examples in the API playground. The token expires in 5 minutes; if expired, generate a new token, as described in ["Acquiring an Authorization Token" above](#).

Making an API Call

To make an API call, in the left pane, find the API and click it. In the right pane, specify the values of the required parameters, and click appropriate button (for example, **POST**, **GET**, **DELETE**, and **Curl**, as appropriate) in the playground. For example, to create a branch location on the CipherTrust Manager:

1. In the left pane of the API playground, click **DDC**.
2. Under **ddc/system-settings/branch-locations**, click **Create**. The **Create** section of the API playground is displayed in the right pane.
3. In the **body** field, specify the parameters with their values, as shown below.

```
{
  "name": "mybranch",
  "city": "Paris",
  "countryId": "18faaf74-c511-4086-a5fb-8062ecf2d8f4",
  "stateId": ""
}
```

Expand **schema** under the **body** field for names and types of fields. Mouse over each field to view its description. The parameter names and casing in the **body** field must match with those shown in the schema. Also, ensure that parameters and their values are specified in double quotes.

4. Click **POST**.

Alternatively, to get an equivalent `curl` command, click the **Curl** button. The `curl` equivalent will be shown in the text field below. Use the `curl` tool to run the command to make the REST API call.

Similarly, all API calls can be made by referring to the schema shown in the playground.

CLI

The CipherTrust Manager includes a CLI tool, named **ksctl**, that can be downloaded and run locally to control a remote CipherTrust Manager appliance. **ksctl** exclusively uses the REST API to communicate with the CipherTrust Manager, so anything that you can do with the tool, you can also do directly with the REST API. Conversely, **ksctl** exposes most of the functionality of the REST API. It can perform management functions, such as managing registration tokens and clients. **ksctl** is designed to be run from a **remote system**, not on CipherTrust Manager itself.

To use the CLI:

1. Open the CipherTrust Manager URL in a browser.
2. Click the **API & CLI Documentation** link. The API playground is displayed.
3. At the top left, click **CLI Guide**. The CLI documentation is displayed.
4. At the top right, click the **CLI** download button. This downloads the **ksctl_images.zip** file.
5. Unzip the **ksctl_images.zip** file.
6. Set up the **ksctl-os** file for your system.
7. Run **ksctl ddc** to run Thales CipherTrust Data Discovery and Classification specific commands.

Refer to the CipherTrust Manager documentation for details. For details on commands related to Thales CipherTrust Data Discovery and Classification, refer to the online documentation of **ksctl ddc**.

Supported Formats

Files

Type	Format
Compressed	bzip2, Gzip (all types), TAR, Zip (all types)
Databases	Access, DBase, SQLite, MSSQL MDF & LDF
Images	BMP, FAX, GIF, JPG, PDF (embedded), PNG, TIF
Microsoft Backup Archive	Microsoft Binary / BKF
Microsoft Office	v5, 6, 95, 97, 2000, XP, 2003 onwards
Open Source	Star Office / Open Office / Libre Office
Open Standards	PDF, RTF, HTML, XML, CSV, TXT

Office files

WORD

- > **Legacy:** Legacy filename extensions denote binary Microsoft Word formatting that became outdated with the release of Microsoft Office 2007. Although the latest version of Microsoft Word can still open them, they are no longer developed. Legacy filename extensions include:
 - .doc – Legacy Word document; Microsoft Office refers to them as "Microsoft Word 97 – 2003 Document"
 - .dot – Legacy Word templates; officially designated "Microsoft Word 97 – 2003 Template"
 - .wbk – Legacy Word document backup; referred as "Microsoft Word Backup Document"
- > **OOXML:** Office Open XML (OOXML) format was introduced with Microsoft Office 2007 and became the default format of Microsoft Word ever since. Pertaining file extensions include:
 - .docx – Word document
 - .docm – Word macro-enabled document; same as docx, but may contain macros and scripts
 - .dotx – Word template
 - .dotm – Word macro-enabled template; same as dotx, but may contain macros and scripts
 - .docb – Word binary document introduced in Microsoft Office 2007

EXCEL

- > **Legacy:** Legacy filename extensions denote binary Microsoft Excel formats that became outdated with the release of Microsoft Office 2007. Although the latest version of Microsoft Excel can still open them, they are no longer developed. Legacy filename extensions include:

-
- .xls – Legacy Excel worksheets; officially designated "Microsoft Excel 97-2003 Worksheet"
 - .xlt – Legacy Excel templates; officially designated "Microsoft Excel 97-2003 Template"
 - .xlm – Legacy Excel macro
- > **OOXML:** Office Open XML (OOXML) format was introduced with Microsoft Office 2007 and became the default format of Microsoft Excel ever since. Excel-related file extensions of this format include:
- .xlsx – Excel workbook
 - .xlsm – Excel macro-enabled workbook; same as xlsx but may contain macros and scripts
 - .xltx – Excel template
 - .xltn – Excel macro-enabled template; same as xltx but may contain macros and scripts

POWERPOINT

> Legacy:

- .ppt – Legacy PowerPoint presentation
- .pot – Legacy PowerPoint template
- .pps – Legacy PowerPoint slideshow

> OOXML:

- .pptx – PowerPoint presentation
- .pptm – PowerPoint macro-enabled presentation
- .potx – PowerPoint template
- .potm – PowerPoint macro-enabled template
- .ppam – PowerPoint add-in
- .ppsx – PowerPoint slideshow
- .ppsm – PowerPoint macro-enabled slideshow
- .sldx – PowerPoint slide
- .sldm – PowerPoint macro-enabled slide

ACCESS

> Legacy:

- .ade – Protected Access Data Project (not supported in 2013)
- .adp - Access Data Project (not supported in 2013)
- .mdb - Access Database (2003 and earlier)
- .cdb - Access Database (Pocket Access for Windows CE)
- .mda - Access Database, used for addins (Access 2, 95, 97), previously used for workgroups (Access 2)
- .mdt - Access Add-in Data (2003 and earlier)
- .mdf - Access (SQL Server) detached database (2000)
- .mde - Protected Access Database, with compiled VBA and macros (2003 and earlier)

-
- .ldb - Access lock files (associated with .mdb)

> **Available formats since Access 2007:**

- .accdb – The file extension for the new Office Access 2007 file format. This takes the place of the MDB file extension
- .accde – The file extension for Office Access 2007 files that are in "execute only" mode. ACCDE files have all Visual Basic for Applications (VBA) source code hidden. A user of an ACCDE file can only execute VBA code, but not view or modify it. ACCDE takes the place of the MDE file extension
- .accdt – The file extension for Access Database Templates
- .accdr – is a new file extension that enables you to open a database in runtime mode. By simply changing a database's file extension from .accdb to .accdr, you can create a "locked-down" version of your Office Access database. You can change the file extension back to .accdb to restore full functionality

OTHER

- .pub – a Microsoft Publisher publication
- .xps – a XML-based document format used for printing (on Windows Vista and later) and preserving documents

Security Audit Log Event Messages

The following table contains a complete list of security audit log event messages that DDC prints in the log file.

Message	Explanation
DDCScanClientInvalidCredentialsProbe	A probe with invalid credentials.
DDCScanClientUnexpectedErrorProbe	An unknown probe error.
DDCPhoenixBackgroundProcessAuthenticationError	A failed authentication against PQS in background processes.
DDCPhoenixUpdatePQSSettingsAuthenticationError	A failed authentication against PQS updating PQS settings.
DDCHDFSUpdateHDFSSettingsAuthenticationError	A failed authentication against HDFS updating HDFS settings.
DDCHDFSBackgroundProcessAuthenticationError	A failed authentication against HDFS in background processes.
DDCUnauthorizedCloneRequest	An unauthorized CLONE request.
DDCUnauthorizedGetRequest	An unauthorized GET request.
DDCUnauthorizedListRequest	An unauthorized LIST request.
DDCUnauthorizedListPaginatedRequestWithContext	An unauthorized LIST PAGINATED request with context.
DDCUnauthorizedCreateRequest	An unauthorized CREATE request.
DDCUnauthorizedUpdateRequest	An unauthorized UPDATE request.
DDCUnauthorizedListProvisionedRequest	An unauthorized LIST PROVISIONED request.
DDCUnauthorizedGetProvisionedRequest	An unauthorized GET PROVISIONED request.
DDCUnauthorizedGetActiveNodeRequest	An unauthorized GET ACTIVE NODE request.
DDCUnauthorizedTestConnectivityRequest	An unauthorized TEST CONNECTIVITY request.
DDCUnauthorizedGetLicenseRequest	An unauthorized GET LICENSE request.
DDCUnauthorizedDecryptRawDataFileRequest	An unauthorized DECRYPT RAW DATA FILE request.

Message	Explanation
DDCUnauthorizedGetDatastoreReportRequest	An unauthorized GET DATASTORE REPORT request.
DDCUnauthorizedFindScanRequest	An unauthorized FIND SCAN request.
DDCUnauthorizedScanActionRequest	An unauthorized SCAN ACTION request.
DDCPQSUnaccessibleGetSummaryReportError	An inaccessible PQS in GET SUMMARY REPORT request.
DDCPQSUnaccessibleGetDatastoreDetailReportError	An inaccessible PQS in GET DATASTORE DETAIL REPORT request.
DDCPQSUnaccessibleGetDataObjectsDetailsReportError	An inaccessible PQS in GET DATAOBJECTS DETAIL REPORT request.
DDCPQSUnaccessibleGetInfotypesSummaryReportError	An inaccessible PQS in GET INFOTYPES SUMMARY REPORT request.
DDCPQSUnaccessibleGetDataObjectsSummaryReportError	An inaccessible PQS in GET DATAOBJECTS SUMMARY REPORT request.
DDCPQSUnaccessibleGetScanDetailsReportError	An inaccessible PQS in GET SCAN DETAILS REPORT request.
DDCPQSUnaccessibleCreateReportTemplateError	An inaccessible PQS in CREATE REPORT TEMPLATE request.
DDCPQSUnaccessibleGetReportTemplateError	An inaccessible PQS in GET REPORT TEMPLATE request.
DDCPQSUnaccessibleFindReportTemplatesError	An inaccessible PQS in FIND REPORT TEMPLATE request.
DDCPQSUnaccessibleUpdateReportTemplateError	An inaccessible PQS in UPDATE REPORT TEMPLATE request.
DDCPQSUnaccessibleGetScanExecutionsError	An inaccessible PQS in GET SCAN EXECUTIONS request.
DDCResourceRetrievalGenericCloneError	A GENERIC CLONE request.
DDCResourceRetrievalGenericGetError	A GENERIC GET request.
DDCResourceRetrievalGenericListError	A GENERIC GET request.

Message	Explanation
DDCResourceRetrievalGenericListPaginatedRequestError	A GENERIC LIST PAGINATED request.
DDCResourceRetrievalGenericCreateError	A GENERIC CREATE request.
DDCResourceRetrievalGenericUpdateError	A GENERIC UPDATE request.
DDCResourceRetrievalGenericListProvisionError	A GENERIC LIST PROVISION request.
DDCDatastoreDecryptDataEncryptionKeyNotFoundError	A GET KEY request.
DDCDatastoreEncryptDataError	An ENCRYPT DATA request.
DDCSaveWatcherInterruptedTimeout	An INTERRUPTED TIMEOUT request.
DDCSaveClientRetrieveScanTimeout	A RETRIEVE SCAN TIMEOUT request.
DDCSaveActionRequest	A SCAN ACTION request.
DDCDatastoreUpdateRequest	A DATASTORE UPDATE request.
DDCDatastoreCreateRequest	A DATASTORE CREATE request.
DDCSaveDeleteRequest	A SCAN DELETE request.
DDCSummaryReportGetRequest	A GET SUMMARY REPORT request.
DDCDatastoreDetailReportGetRequest	A GET DATASTORE DETAILS REPORT request.
DDCDataObjectsDetailReportGetRequest	A GET DATASTORE DETAILS REPORT request.
DDCInfotypesSummaryReportGetRequest	A GET INFOTYPES SUMMARY REPORT request.
DDCDataObjectsSummaryReportGetRequest	A GET DATAOBJECTS SUMMARY REPORT request.
DDCSaveDetailsReportGetRequest	A GET SCAN DETAILS REPORT request.

A man and a woman are in a server room. The man, wearing a green jacket and a lanyard, is holding a laptop and looking at the woman. The woman, with long blonde hair, is looking at the laptop. The background shows server racks and a blue-tinted overlay.

confidence to your data
management**

Executive summary

The rapid, often exponential, growth of data year-on-year in organizations like yours makes effective data management an extremely challenging proposition. An increasing switch to remote working raises the bar even higher with many data storage areas or volumes coming into play which are outside your IT team's direct control.

As part of the broader group within your organization responsible for data privacy and security compliance, ensuring no vulnerable areas are overlooked when implementing your data protection strategy is of paramount importance. After all, a data breach will inevitably cause severe business disruption in addition to large fines incurred for non-compliance with the seemingly endless stream of new or enhanced data privacy laws and regulations. Failing to prepare properly is definitely not a viable option for you.

A significant weakness often seen in typical data management implementations is the lack of visibility into the precise types of data being held across various local servers, network drives and increasingly cloud storage locations. Many organizations have been breached already, some have encountered near misses and others are migrating large workloads to the cloud without fully understanding the fundamental nature of the data itself and the exposure risks involved – situations for you to avoid.

Historically staff knowledge was sufficient and simple 'off-the-shelf' encryption methods from database vendors would satisfy needs – no longer with the vast data footprint that is widely dispersed and growing by the second. You inevitably need assistance to take control and keep your organization safe.

Thales CipherTrust Data Discovery and Classification is...

A tool that is significantly more effective and efficient than manual methods for data discovery. It helps classify all your data, while supporting every mainstream operating system, data storage type, structured and unstructured data you are likely to possess. Existing processes and tools are supplemented, rather than replaced, providing high levels of automation in your search for sensitive data, wherever it resides. Ultimately, it can help you become more agile and support better data management decisions:

It finds sensitive data that you may not realize even exists in your organization, helping you eliminate threats to your business continuity and reduce your data footprint

It enables you quickly to assess your risks of non-compliance and determine the appropriate protection actions to take

It provides confidence that you are protecting the right assets, including proprietary data or intellectual property, across all your data storage locations including the cloud

The role of CipherTrust Data Discovery and Classification (DDC)

DDC offers a more streamlined, accurate and unattended (or automated) approach in comparison to sensitive data searches using manual methods. If you are using a data discovery tool from another vendor you should still take a closer look at DDC - it likely covers additional data storage types, extending the range of structured and unstructured data that can be analyzed while offering higher levels of accuracy by finding sensitive data other tools often miss.

Sensitive items found by DDC are not just restricted to data privacy laws and regulations. Fine tuning using custom infotypes (which you define) facilitates visibility on where data sensitive to your organization is present. By enabling critical assets (such as internal financial data, trade secrets, intellectual property and confidential business plans for example) to be located, their current levels of protection and associated risks of unintended exposure can be better understood. Considerable flexibility comes from running multiple scans simultaneously, each looking for different types of information (if desired) to create a faster and more efficient way to analyze your complete data footprint across a diverse range of storage locations. It is the ability to create multiple classification profiles (customized where needed) that underpins such performance and efficiency benefits that never could be achieved in a comparable timeframe using manual methods or less capable tools.

Discovering the data is only part of the task in hand – **classification is equally important**, providing deeper understanding of the types of data and their footprint in your organization. DDC does not move or modify your data, merely summarizing what it uncovers during scans in a non-intrusive manner.

You can **see exactly how your data is split** between the personal, financial, medical and national ID categories – you may be surprised that some of this even exists. At least now you will have insight into precisely where it resides to manage the business risk appropriately.

The insights available after scans have been performed provide **important guidance** on what you may need to do next, especially related to protection. You can choose how many scans you wish to incorporate in any given report. Each report improves data visibility, providing detailed insight into:

The names of the infotypes found together with the number of sensitive data matches

The risk associated with each of the data objects analyzed during the scan in question

The protection status so that you can see what it protected and what is not

DDC provides options to run scans at any time, over and over again if desired. The tool is intended to be used regularly to keep your insight up to date rather than just being a one-off activity. Since data is always in a state of flux, DDC is ready to convey the latest true representation of what you have and what you might need to do to keep your business safe.

How it all fits together

DDC is configured using a graphical user interface (launched from within the CipherTrust Manager console) or via the REST API. It offers a simple and intuitive workflow, enabling you to define data locations for interrogation, specify the types of data you wish to discover and decide when and how often you wish to repeat the scanning process. Ultimately the rich views provide a deep dive into the sensitive data matches, the associated protection status and risk assessment of the data locations in question. The main features are summarized in the sections below, providing a high level insight into the power, flexibility and control available to you.

The workflow for DDC is easy to follow via the user interface. **Three main ingredients** help define your environment – **data stores**, **classification profiles** and **infotypes**.

Typically, you might adopt the following sequence when using DDC for the first time:

Select and configure **data stores** of interest – we recommend concentrating on the most frequently accessed data stores first and a selected path rather than the whole store.

Choose one or more **classification profiles** – create custom classification profiles if necessary. During this process, select one or more **infotypes** of interest – use the custom infotype capability if the prebuilt list is insufficient.

Configure and start the **scan** – consider just selecting one data store for your first scan to test your configuration.

Data stores

Local storage	Local storage	
Network Storage	Windows share (CIS/SMB)	Unix file system (NFS)
Database	IBM DB2 Microsoft SQL MongoDB MySQL	Oracle DB PostgreSQL SAP HANA
Big Data	Hadoop clusters	Teradata
Cloud	AWS S3 Buckets Azure Blob Azure Table	Google (Gmail & Gdrive) Office 365 (Exchange, OneDrive & SharePoint) Salesforce
Server	Sharepoint Server	

Types of file supported

Databases	Access	SQLite	Microsoft Office	v5	XP
	Dbase	MSSQL MDF & LDF		6	2003 onwards
				95	Office Files: Word, Excel, PowerPoint.
				97	Access, Outlook, Other
				2000	(.pub & .xps)
Images	BMP FAX GIF JPG	PDF (embedded) PNG TIF	Open Source	Star Office / Open Office / Libre Office	
Compressed	Bzip2 Gzip (all types)	TAR ZIP (all types)	Open Standards	PDF RTF HTML	XML CSV TXT
Microsoft Backup Archive	Microsoft Binary / BKF				

Classification profile templates (prebuilt)

APA	Australia Privacy Amendment	HIPAA	Health Insurance Portability and Accountability Act
APPI	Act on Protection of Personal Information	KVKK	Turkish Personal Data Protection Law
CCPA	California Consumer Privacy Act	LGPD	General Data Protection Law (Brazil)
GDPR	Financial	NYDFS	New York State Department of Financial Services
GDPR	General Data Protection Regulation	PCI DSS	Payment Card Industry Data Security Standard
GDPR	Healthcare	PDP	Personal Data Protection Bill
GDPR	National ID	SHIELD	Privacy Shield Framework
GDPR	Personal Details	UK-GDPR	General Data Protection Regulation (UK)

The structured and unstructured data coverage provided by DDC is frequently being updated with new capabilities – check out the latest specifications [here](#).

Core classification profiles are prebuilt and aligned with major data laws and regulations, both regional and global. You can make changes to these or add totally new profiles if required. Various shortcuts are provided in terms of editing and copying so that you can quickly create and test your own profiles. There is full flexibility in specifying various parameters including sensitivity levels and infotypes.

Sensitivity levels

None

Public

Internal

Private

Restricted

Categorizing sensitive data

DDC is prebuilt with various infotypes, over 200 and counting, covering the vast majority of regional and global data privacy laws and regulations. When a prebuilt classification profile template is selected, the appropriate subset of infotypes is added automatically. You can modify or extend this list by creating your own custom infotypes, allowing rules to be defined which describe precisely how the scanning engine should look for the data strings in question. Full access to the groups and categories is available as part of the definition so that data matches can be displayed in the appropriate sections of the scan results.

Infotype categories (prebuilt)

Financial	Credit/ debit cards	Bank account info
Personal data	Email addresses Login credentials Card number Ethnicity License number Roll number Passport number Date of birth MAC address	Mailing address Telephone number Gender Religion IP address Phone number Name Profanity
Medical	Patient health data	
National ID	Personal identification	

Using agents for **discovery**

Detailed data analysis is carried out by discovery agents which perform the scanning and report the results back to the DDC Connector for analysis and processing. Two types of agents exist – local and proxy. You would normally install local agents on data store locations (for which you have the appropriate access rights) to ensure the data never leaves the server for security or performance reasons. In contrast, proxy agents are used for network or remote data stores where a separate proxy server hosts the agent.

Type of agent	Pros	Cons
Local	Faster scan Data remains local No need for credentials	Longer deployment time More complex management Only supports local data stores
Proxy	Faster to deploy and scale Ability to scan multiple data stores Supports multiple data store types No resources consumed on target host	Data sent over network to agent prior to scanning Increased network load and data footprint Ideally should be located on same virtual LAN (VLAN)

Common benefits apply to both types of agent:

An **unlimited number** of agents is available for deployment at no additional cost since licensing is based on the volume of new data scanned

Multiple simultaneous sub-scans can be launched to reduce the time required for the overall scan

TLS encryption is available for all communications between data stores and agents to protect sensitive data from eavesdropping

Source data is untouched as agents only access a temporary data copy in internal memory during the scan

No sensitive data is stored during the process as only a summary of the scan results is sent to the DDC Connector

Scans can **still proceed** and record results even when connection to the DDC Connector is lost

With your agents installed, you can then start to think about what and how you wish to scan. We provide a great deal of flexibility in how scans are configured, managed and operated. Important parameters configurable for each scan independently include:

Name (up to 64 characters)

Description (up to 250 characters)

One or more data stores
(where to scan)

One or more classification
profiles (what to look for)

Manual or scheduled operation
(when to activate)

On completion of any given scan, it is added to a list of all scans that have been performed. Next, you would use the reporting tool to view detailed results from the scan. Depending on what is found you may make changes to the scan configuration and rerun the scan which is beneficial when working on different data stores or new types of compliance regulations for the first time.

Analyzing scan results

The results from historical and new scans are available for use with the built-in reporting tool. Three main views for scan reports are offered:

Scans

Data stores

Data objects

Before detailed information is available, a report is generated which aggregates the results from one or more successful scans. Often for logistical, security or performance reasons you may wish to use multiple scans (each looking for different types of regulated data) to analyze your entire data footprint. With our flexible approach you can still do this and fine-tune each scan as required using multiple iterations, before generating a final report which can represent the current status of all your data. It is also easy to understand your organizational posture from a single regulation point of view.

Each tab within the report module offers an insight into slightly different aspects of your data – all however have a common goal in helping you identify quickly any sensitive data at risk.

Scans view

Provides a high level, aggregated scan view of the infotypes found (broken down by percentage in each category present) together with three other charts representing the presence of sensitive data objects in terms of category distribution, content types and file types in question.

Data stores view

Provides a list of the data stores with details including the risk, sensitivity level, infotypes found and the number of sensitive data objects present for each data store – this provides a rapid means of assessing at a high level whether or not sensitive data is at risk and which data stores are involved.

Data objects view

Provides a detailed list of all data objects scanned containing sensitive data, sorted in descending order of risk of exposure. For each sensitive data object in question, you can see where it is located, the data store in which it resides and the individual names and data matches for all of the associated infotypes found. Remediation status information is also present which provides a deeper insight into your sensitive data, confirming whether or not an encryption policy is active. No sensitive data is stored as part of the reporting process.

Exporting data

In addition to viewing objects using the built-in reporting tool, you can also export data in a NDJSON format for analysis by an external reporting tool such as one from [Elastic](#) used in Thales demonstrations.

Getting answers to **key** questions quickly

We make it easy to get up and running, so you can experience the wealth of insight obtainable from DDC

What types of regulated data exist in my organization?

Create a series of scans to search for different types of regulated data

Use one classification profile per scan for optimum performance

Narrow initial scanning to paths within data stores you use the most

Use the reporting tool to collate the scan results

The extent and categories of sensitive data found are presented clearly

Have I any sensitive data that is not protected?

Run one or more scans involving the data stores, classification profiles and infotypes of interest

Select the appropriate sensitivity levels

Consider using custom infotypes to help find data proprietary to you

Generate a report incorporating results from one or more previous scans

Use the subsequent report view to determine if you have any vulnerabilities

What are the priority items to address?

Use the 'Data Stores' tab view to sort data stores in descending order of risk

Click on the first data store to retrieve the next level of detail

The breakdown of the sensitive infotypes split by family is displayed, sorted by descending order of occurrence

Alternatively look at sensitive content by data object by using the 'Data Object' tab where the data object list is sorted by descending risk of exposure

Where is the vulnerable data located?

The 'Data Stores' tab provides information on the precise location of any target paths (if applicable) within the data store in question where sensitive data has been found

It always provides the name of the location where the data store is present

How can I use encryption to protect sensitive data?

Use the CipherTrust Intelligent Protection option to perform discovery and protection in a single step with no manual intervention

An alternative manual approach is to use DDC to find your sensitive data, then use CipherTrust Transparent Encryption (CTE) as a separate manual step to encrypt the data

You may also consider other CipherTrust platform protection solutions such as tokenization, data masking or ACLs as an alternative to encryption

What happens if some of my data is already encrypted?

Data with no encryption applied can be scanned and analyzed providing the discovery agent has been granted access to the location or path in question

Data encrypted using CTE can be scanned and analyzed providing the discovery agent has been granted access to the location or path in question within the data store

Data that has been encrypted using a third party tool can be scanned and analyzed properly only if DDC has access to the decrypted data – otherwise DDC will scan the encrypted data and not find any match

Discovery and protection in a **single** step

This feature creates an automatic workflow stage that links CipherTrust Data Discovery and Classification (DDC) with CipherTrust Transparent Encryption (CTE) – we call this CipherTrust Intelligent Protection. This is an optional feature that you can switch on or off as required for any given data store or file location which is linked to a GuardPoint accessible to both CTE and DDC.

- 1** CTE Admin creates a policy (using a classification-based resource set) on the CTE Connector and configures the GuardPoint on the CTE Agent
- 2** CTE Agent scans the GuardPoint and uploads the list of files to the Thales Data Platform
- 3** DDC User adds a data store located on the server where the CTE Agent resides and configures the classification profile
- 4** DDC User creates and initiates a scan on the data store linked to the GuardPoint path and enables protection
- 5** DDC Agent stores the scan results in the Thales Data Platform on completion of the scan, including the classification for each of the files linked to the GuardPoint
- 6** DDC Connector notifies the CTE Connector that new scan results are ready
- 7** CTE Connector notifies the CTE Agent that new classifications are ready
- 8** CTE Agent downloads the classification information from the Thales Data Platform
- 9** CTE Agent applies the security rules, to enforce access control, based on policy and classifications
- 10** CTE Agent encrypts each file according to the policy key rule, updating the file status information in the Thales Data Platform at the same time

Reasons for our choice of architecture

Single integrated platform

We decided to make DDC an integral part of the Thales CipherTrust Data Security Platform because, in our experience, data discovery is the foundation of any effective data security strategy. This integrated platform approach enables CipherTrust Manager to act as the central management console for various connectors including data discovery, transparent encryption and tokenization. If you are using CTE already, you will be familiar with the console and will benefit from consistency in how common management tasks such as user groups, data policies, access control and logging are implemented.

Accurate pattern matching

Thales performed an extensive investigation to determine the best data discovery technology in the market. After much research and bench testing, the team experienced a significant difference using GLASS Technology™ over regex. GLASS is a proprietary market-leading technology from [Ground Labs](#) (a Thales Technology Partner) for defining and matching simple and complex patterns of data at scale as opposed to a developer code language not built specifically for purpose. It was designed from the ground up with the express purpose of finding patterns of data in modern data sets across both structured and unstructured data storage scenarios.

High performance discovery

An important goal was to provide a highly efficient and accurate discovery engine. Most data discovery solutions available today use the regular expression (regex) language (originating from the 1950's) to search for patterns inside text strings. This approach requires extensive developer knowledge to implement and the syntax is not based on English grammar. The biggest enemy of regex is performance – as pattern concurrency and complexity increases, the slower the performance achieved. Regex has limits to the patterns it can match accurately, making it far from ideal in the modern world where there are hundreds of different privacy regulations and a broad range of data management issues to address.

Easy customization capabilities

Customization support was another important criteria to supplement the comprehensive prebuilt templates. To address proprietary needs, GLASS data patterns can be written by non-developers using English-style grammar to express how a piece of data or pattern exists. Detailed analysis shows it has overcome all important regex limitations for pattern matching techniques, especially its ability to operate across multiple platform and cloud environments, while being very frugal in terms of CPU overhead. This made GLASS an ideal core component for embedding inside DDC, working efficiently and transparently as part of the CipherTrust platform in identifying and securing critical data.

Flexible licensing model

A consumption model based on total data scanned is used to license DDC, providing close alignment with many cloud subscription models and offering an unlimited number of discovery agents without incurring any additional fees. This makes it much easier for all your teams to have access to the data discovery capabilities, with the only real decision to make is how much overall data discovery capacity is required for your organization. Re-scanning existing data does not subtract from your remaining allowance, only new data scanned is counted.

Security first

Naturally as a market leading security company we design and implement secure solutions. DDC is no exception with strong emphasis on ensuring no sensitive data is stored or vulnerable to exposure:

Ensuring that all data flowing between your data stores and the agents is protected using strong encryption

Providing granular access controls so that you can tailor the solution to your exact needs

Enabling you to secure any sensitive data discovered quickly using the automated workflow associated with CipherTrust Intelligent Protection

Cloud Key Management

CipherTrust Data Security Platform

DDC is optimized for use as part of the CipherTrust Data Security Platform, an integrated suite of data-centric security products and solutions that unify data discovery, protection and control in one platform. Consequently you can cover all data protection needs using a single platform from one vendor, in this case Thales. This provides you with a full suite of data protection capabilities including key management, user access control, file-level encryption, application-layer encryption, database encryption, format-preserving encryption, tokenization and data masking.

CipherTrust Manager

All components utilize CipherTrust Manager as their management console, delivering central management of encryption keys, granular access control and security policy configuration. One key advantage is that our solution is designed to protect your data wherever it resides, on-premises or in the cloud and whatever storage mechanism is in use, such as files, databases, big data or containers. Ultimately you will end up requiring fewer resources dedicated to data security operations, meet your compliance obligations with greater confidence and reduce the business risk to your organization.

It is also possible to deploy DDC alongside other third party data protection tools, such as those supporting data encryption or tokenization for example. It is non-intrusive, complementing tools you have already, rather than replacing them. However, CipherTrust Manager is still necessary since it provides the sole method to launch the data discovery capability and to manage the licenses required for its operation together with keys required for encrypting sensitive data.

Unlike deploying CipherTrust Intelligent Protection, if DDC is used to find the sensitive data and another non-CipherTrust tool from a third party is used to encrypt the data, two distinct steps would be necessary (potentially with a long lapse in-between).

Some of the main reasons Thales customers have been using DDC in conjunction with third party products include:

Trying to fill gaps in coverage since their existing discovery tool cannot scan all their structured and unstructured data

Seeking higher accuracy with data matches to eliminate the limitations they are experiencing with regex technology

Supporting a wider range of operating systems and platforms to interrogate more of their data footprint

We often get asked...

‘What is the difference between CipherTrust Data Discovery and Classification and other Data Loss Prevention (DLP) solutions?’

The DLP solutions focus on preventing sensitive data from leaving the organization's perimeter. DDC focuses on data privacy - identifying sensitive data, and getting a clear understanding of data and its risk. This enables appropriate steps to be taken to protect data and comply with data privacy and data security regulations.

Key takeaways

CipherTrust Data Security Platform

Your data management and protection strategy can ultimately be improved significantly using CipherTrust Data Discovery and Classification. In conjunction with CipherTrust Manager and CipherTrust Transparent Encryption it provides considerable visibility and insight into your sensitive data while offering quick and effective protection options. It enables you to:

Block unnecessary data access to reduce risk of data breaches

Keep up to date with the evolving regulatory landscape to remain in compliance

Address digital transformation concerns relating to cloud security to support business and technology goals

Abbreviations

1/3

ACL	Access Control List
CDSP	CipherTrust Data Security Platform
CIFS	Common Internet File System
CIP	CipherTrust Intelligent Protection
CM	CipherTrust Manager
CTE	CipherTrust Transparent Encryption
DB	Database
DDC	CipherTrust Data Discovery and Classification
GUI	Graphical User Interface
NAS	Network-attached Storage
REST API	Representational State Transfer Application Programming Interface
TDP	Thales Data Platform
NAS	Network-attached Storage

Classification profile	A classification profile uses a list of infotypes to define what kind of sensitive information to search for during a scan
Connector	A connector is a generic term which relates to the different licensable products or components (which includes DDC and CTE) that are managed using the CipherTrust Manager console
CTE agent	A CTE agent is a software component that is used to encrypt data associated with GuardPoints defined using CTE policies
Data match	A data match occurs during a scan when a qualified instance of an infotype actively included in the scope of the search is found
Data object	A file or database table located inside a data store is known as a data object
Data store	A data store is the entity where the data is actually stored, with DDC supporting various types - local, network, database, Big Data and cloud
DDC agent	A DDC agent is a software component that is used to scan a data store for specific types of data defined using infotypes in the associated classification profile
Discovery	Data discovery is the process of mapping an organization's data assets including their locations, types and sensitivity levels
False negatives	False negatives are where the discovery process fails to identify one or more valid instances of sensitive data
False positives	False positives are where the discovery process wrongly identifies sensitive data matches where none exist
GuardPoint	A GuardPoint specifies the list of folders or paths to be protected – access to files and encryption of files under the GuardPoint is controlled by security policies
Infotype	An infotype is used to categorize specific data (such as passport numbers or email addresses) to look for during a discovery scan, forming an integral component in the definition of a classification profile
Policy	A policy is a collection of rules that govern data access and encryption
Remediation	Remediation refers to the process of protecting (or securing) data that has been identified as vulnerable as the result of a scan – typical remediation methods include encryption, tokenization, data masking and access control
Resource set	A resource set refers to the files or directories to which the policy will apply together with the associated governing key rules

Risk	A risk is the presence of a sensitive data object in a data store and is directly related to the data matches found in the data object or data store
Scan	A scan is part of the discovery process that is used to search for sensitive data within data stores using criteria defined in classification profiles
Sensitive data object	A data object that contains any data match is known as a sensitive data object
Sensitivity level	The sensitivity level is a mandatory parameter (when defining data stores and classification profiles) relating to the degree of potential vulnerability of any given data object if exposed
Structured data	Structured data is highly organized and easily understood by machine language – examples include names, dates, addresses, credit card numbers, stock information, geolocation and more
Tag	A tag helps group data together and can be specified when creating data stores and classification profiles
Thales Data Platform	The Thales Data Platform (TDP) is a Big Data platform based on Hadoop technology which is used by DDC for various tasks including storage of scan results
Unstructured data	Unstructured data is information that either does not have a pre-defined data model (or schema) or is not organized in a pre-defined manner, making it unsuitable for storage in a relational database

CipherTrust Transparent Encryption for Kubernetes

Challenge: Securing Applications for Kubernetes Environments

Modern applications are increasingly built using containers, which are microservices packaged with their configurations and dependencies. Kubernetes is an open-source software for deploying and managing these containers. Containerized applications can be delivered, deployed and managed faster with Kubernetes to provide improved efficiency through re-usable modular components, cost savings through optimized resource utilization and reduced licensing expenses. However, there are several risks:

- **Privileged user abuse.** By default, Docker processes run with root privileges, administrators have full access to all tenant secrets. This level of untethered access poses multiple risks. Organizations could be subject to privilege escalation attacks, if administrators have unchecked access to container images and the data stored within them.
- **Cross container access.** Poor configuration of permissions can result in multiple containers having access to information that should remain private. Further, when containers are hosted in shared virtualized or cloud environments, critical information can be exposed to third parties.
- **Compliance risks.** Many compliance mandates require stringent access controls and auditing data access. However, many security teams have limited controls available to manage and track access to data held within containers and images. As a result, these teams find it difficult to comply with relevant security policies and regulatory mandates.

Solution: CipherTrust Transparent Encryption for Kubernetes

CipherTrust Transparent Encryption for Kubernetes delivers in-container capabilities for encryption, access controls, and data access logging, that enables organizations to establish strong safeguards around data in Kubernetes environments. With this extension for CipherTrust Transparent Encryption, data protection can be applied on a per-container basis, both to secure data inside of containers and in external storage accessible from containers, all centrally managed from the CipherTrust Manager..

Benefits

CipherTrust Transparent Encryption for Kubernetes provides:

- **Compliance.** This extension of CipherTrust Transparent Encryption addresses compliance requirements and regulatory mandates for protecting sensitive data such as— payment cards, healthcare records or other sensitive assets.
- **Protection from Privileged-User Threats.** This solution offers encryption with data access controls, enabling privileged users, such as Docker or OpenShift cluster administrators, to operate as regular users, without gaining unauthorized access to sensitive data.
- **Achieve Robust Security.** CipherTrust Transparent Encryption for Kubernetes enforces data security policies wherever the container is stored or used – data centers, virtualized environments, even in cloud implementations. Deploy and use containers where needed for cost effectiveness, control, or performance without having to make any changes to applications, containers, or infrastructure sets.

Features

- **Comprehensive Data Security Safeguards.** CipherTrust Transparent Encryption for Kubernetes extends CipherTrust Transparent Encryption, enabling security teams to establish data security controls inside of containers. With this extension, you can apply encryption, access controls, and data access logging on a per-container basis. Encryption can be applied to data generated and stored locally within the container and to data mounted in the container by network file systems.
- **Scalable Transparent Encryption.** Provides data security controls without having to make any changes to applications, containers or infrastructure sets. It enables a single policy to be applied to all containers within a Kubernetes cluster, or distinct policies applied to each container within a cluster. This solution can scale up or shrink down a Kubernetes environments as business needs change.
- **Granular Access Controls and Visibility.** CipherTrust Transparent Encryption for Kubernetes offers the detailed visibility and control you need to comply with the most stringent policies and mandates. With this Kubernetes security solution, enterprises can establish granular access policies based on specific users, processes, and resource sets within containers. Finally, this solution can establish isolation between containers, so only authorized containers can access sensitive information.

CipherTrust Manager

The CipherTrust Manager centralizes key, policy, and log management for the CipherTrust Data Security Platform including CipherTrust Transparent Encryption. It is available in both virtual and physical form-factors for securely storing master keys with an elevated root of trust. These appliances can be deployed on-premises as well as in private or public cloud infrastructures.

About Thales Cloud Protection & Licensing

The people you rely on to protect your privacy rely on Thales to protect their data. When it comes to data security, organizations are faced with an increasing number of decisive moments. Whether the moment is building an encryption strategy, moving to the cloud, or meeting compliance mandates, you can rely on Thales to secure your digital transformation.

Decisive technology for decisive moments.

Introduction to CipherTrust Transparent Encryption for Kubernetes

Kubernetes is an open-source container-orchestration system that aims to provide a "platform for automating deployment, scaling, and operations of container workloads".

CTE for Kubernetes is an implementation of CipherTrust Transparent Encryption with native support for Kubernetes through the implementation of a CSI (Container Storage Interface) driver. Unlike traditional CTE, product installation and Guard Policy management is done through Kubernetes. This means that as the cluster scales up with more nodes, CTE for Kubernetes scales with it. CTE for Kubernetes is designed to protect Kubernetes Persistent Storage Claims that are backed by storage with filesystem semantics.

In order to support customers with diverse workloads, registration to CipherTrust Manager has been decentralized from the cluster nodes/ hosts operating system. Registration now happens through the use of Storage Classes which allows for a single cluster, and even a single node, to register different CTE for Kubernetes groups, each with a different set of policies and keys.

CTE Agent and CSI driver are deployed as container images. CTE devices are exposed as Persistent Storage volumes and Customer application containers do not need to be modified.

This document shows some examples on how a customer can protect their pod's persistent storage data through the use of CTE for Kubernetes.

Prerequisites

The CTE for Kubernetes solution requires the following:

- Kubernetes v1.22 or subsequent versions [Kubernetes IO releases](#)
- Available Persistent Storage for protecting with CTE for Kubernetes
- CipherTrust Manager v2.8 and subsequent versions
- Kubernetes nodes with access to the Internet to fetch CTE for Kubernetes images from Docker Hub
- Public Docker Hub credentials for pulling the images
- Working Kubernetes Cluster that can communicate with the cluster using `kubectl`

Required Privileges

Administrators can use security context constraints (SCCs) to control permissions for pods with an OpenShift Cluster. These permissions include actions that a pod can perform and what resources it can access. You can use SCCs to define a set of conditions that a pod must run with to be accepted into the system. You can also use the Security Context Constraints to provide additional privileges to the Service Accounts that are used by the CTE for Kubernetes driver in an OpenShift Cluster. A subset of these permissions are specified in the Pod specification for use in Kubernetes where SCC is not available.

For a container to exploit the System Administrator permissions, the container must run as a privileged container.

System Administrator Permissions	Value	Definition	Resources Used
<code>allowedCapabilities</code>	<code>SYS_ADMIN</code>	The CSI Controller component performs tasks like create, publish, unpublish, delete, snapshot, and restore volumes, on any node in the Kubernetes cluster. Without the <code>SYS_ADMIN</code> capability, the driver does not work and CTE functionality is lost.	
<code>allowPrivilegedContainer</code>	<code>true</code>	For a container to have <code>SYS_ADMIN</code> capability, the container must run as a privileged container.	
<code>allowHostDirVolumePlugin</code> <code>volumes</code>	<code>true</code> <code>emptyDir</code> <code>hostPath</code> <code>projected</code>	The CTE for Kubernetes driver mounts the directories from the host node into the containers. These two permissions allow for the CTE driver to mount these directories as volumes inside the container.	Directory examples: <code>/etc/kubernetes/</code> <code>/var/lib/kubelet/</code> <code>plugins_registry/</code> <code>/var/lib/kubelet/</code> <code>pods</code> It also mounts one of the following directories, depending on which CRI is configured: <code>/run/crio/</code> <code>crio.sock</code> <code>/run/cri-dockerd.sock</code> <code>/run/containerd/</code> <code>containerd.sock</code>
<code>allowHostPID</code>	<code>True</code>	The CTE for Kubernetes driver requires the process PID to track and authorize application processes accessing protected data.	
<code>runAsUser</code>	<code>type: RunAsAny</code>	Controls which user ID containers can use.	

System Administrator Permissions	Value	Definition	Resources Used
		RunAsAny allows processes inside the container to run with any user ID, including root, in that container's context.	
seLinuxContext	type: RunAsAny	Controls which SeLinux context the container can use. RunAsAny allows changes to the SELinux Context assigned to the namespace in which the container is running.	
fsGroup	type: RunAsAny	Controls which fsGroup owns the volumes created by the container. RunAsAny allows users to own any files/directories created by the container.	

Minimum System Requirements

Pod Type	Memory (RAM)	CPU
CTE CSI Controller	512Mb	1
CTE CSI Node Server	512Mb + 100Mb per Guard Policy	2
CTE CSI Staging pod	5Mb	0.1

Note

- Encryption CPU requirements on the node server are highly dependent on the workload that is accessing the CTE for Kubernetes encrypted volume. Additional CPU resources may be required depending on the expected number of IOPS for the application
- Applying hard memory limits on the CTE for Kubernetes node server pods can result in the pod being evicted. This will cause a service interruption to the CTE for Kubernetes volume. Hard memory limits are not recommended for the CTE node server.
- Staging pods do not consume any CPU resources after starting and very minimal memory resources after starting.

Audience

This document is intended for personnel responsible for maintaining your organization's security infrastructure. This includes security officers, key manager administrators, and network administrators.

All products manufactured and distributed by Thales Group are designed to be installed, operated, and maintained by personnel who have the knowledge, training, and qualifications required to safely perform the tasks assigned to them. The information, processes, and procedures contained in this document are intended for use by trained and qualified personnel only.

Thales expects that the users of this product are proficient with security concepts and knowledgeable in all aspects of Kubernetes cluster administration and management.

Users must be able to:

- Install the CTE for Kubernetes CSI driver
- Create RBAC (role-based access control) rules
- Add Persistent Storage Claims to a namespace within the Kubernetes cluster

Limitations

- Killing CTE CSI pods can leave a pod with protected volumes in an unusable state. You should terminate all pods using a CTE protected volume before attempting to stop the CTE for Kubernetes service pods.

Support for Managed Clouds

CTE for Kubernetes can be deployed in the following Cloud environments:

- Amazon Elastic Kubernetes Service (AWS)
- Azure Kubernetes Service (Azure)
- Google Kubernetes Engine (GKE)
- Red Hat OpenShift

Kubernetes Terminology

For relevant Kubernetes definitions, see [CTE for Kubernetes Terminology](#) for more information.

Kubernetes Configuration Concepts

For explanations and examples of the configuration concepts for CTE for Kubernetes, see [Kubernetes Configuration Concepts](#) for more information.

Configuration Concepts

The following concepts are important to understand for success with CTE for Kubernetes.

For more information on Kubernetes, consult the [Kubernetes documentation](#).

CipherTrust Manager CTE for Kubernetes Storage Groups

CTE for Kubernetes configuration is accomplished with CipherTrust Managers(CM) through **K8s Storage Groups**. Security administrators define which combination of Kubernetes Storage Classes and Namespaces are allowed to register to CM. Once a K8s Storage Group is defined, the user can create a **GuardPolicy** that can be used by the CTE-CSI volume to create, view, edit, and delete Kubernetes (K8s) storage groups on the K8s Storage Groups page of the CipherTrust Manager GUI.

Note

A single node in a Kubernetes cluster can register itself multiple times to different K8s Storage Groups based on different Storage Class and Namespace usage patterns. This allows for separation of security context based on the security needs of the Kubernetes namespace that the application pod will be running in.

- See [Managing Kubernetes Storage Groups and Clients](#) for more information about creating storage groups in CipherTrust Manager.

Using CipherTrust Manager with CTE for Kubernetes

On the CipherTrust Manager, to setup your Kubernetes environment:

1. Create a [Kubernetes Client](#).
2. Create a Kubernetes storage group, which includes a client profile which contains a Guard Policy. The Guard Policy must contain:
 - Supported access controls
 - Resource sets
 - Process sets
 - Signature sets
 - User sets with UIDs
3. Register the Kubernetes Client

Registration is the process of configuring a Kubernetes (Kubernetes) client with CipherTrust Manager. This process creates SSL certificates for further communication between the CipherTrust Manager and the Kubernetes client.

After registration, the Kubernetes client can communicate with the CipherTrust Manager. All of the Guard Policies applied to the Kubernetes storage group are automatically added to the Kubernetes client. The client configuration is then built for the Kubernetes client (exactly like a CTE client) and sent to the CipherTrust Manager.

After successful registration, the Kubernetes client appears on the Kubernetes Clients page of the CipherTrust Manager GUI. The client status becomes Healthy.

CTE for Kubernetes CSI driver

Protecting Persistent volumes in a Kubernetes Cluster

Unlike traditional CSI drivers, the CTE for Kubernetes CSI driver (CTE-CSI) does not store persistent data. CTE-CSI relies on other Persistent Volumes(PV) in the cluster for actual data storage. The CTE-CSI driver provides a layer on top of those PVs that adds encryption and data protection. This encryption is transparent to the Pod that wants to use a CTE-CSI volume. Each CTE Persistent Volume Claim (PVC) must be backed by a filesystem-capable PV that is claimed by a PVC in the same namespace.

Each CTE PVC must be configured to use a GuardPolicy, configured in CM, that will provide the required access control and key rules.

When protecting a PV, you must:

1. Choose a PVC in the cluster to protect and to act as your data source.
2. Create a CTE-CSI Storage Class with a parameter to connect to CM.
3. Create a CTE-CSI PVC with a GuardPolicy and a data source for PVC parameters.
4. Add the CTE-CSI PVC to a Pod as a regular volume.

Supported Persistent volumes

CTE Kubernetes is expected to work well with most persistent volumes types with file system semantics. Raw volumes with no filesystem are not supported at this time.

For more information, see [Types of Persistent Volumes](#)

The following table lists the **unsupported** PVC volumes:

Storage Type	Supported	Full Name
configMap	No	ConfigMap
downwardAPI	No	Downward API
emptyDir	No	EmptyDir
fc	No	Fibre Channel (FC) storage
flocker	No	Flocker storage
gitRepo	No	Git repository
hostPath	No	HostPath volume
projected	No	Projected volume
quobyte	No	Quobyte volume
secret	No	Secrets

Storage Type	Supported	Full Name
storageOS	No	StorageOS volume
subPath	No	Subpath volume

CTE service pods

CTE for Kubernetes is implemented as a Kubernetes CSI driver. A typical CTE-CSI driver deployment will contain one **cte-csi-node-xxxx** for every worker node in the cluster. These pods are the main workers for CTE for Kubernetes and perform tasks such as volume attachment, CTE agent registration and volume encryption within the cluster node. The cluster will also contain at least one **cte-csi-controller-xxxx** which is in charge of dynamic provisioning of CTE-CSI volumes. These two types of service pods run in the **kube-system** namespace and are able to serve volumes across different namespaces in the cluster.

Warning

It is important to *never* restart a node's **cte-csi-node-xxx** pod if this node still has CTE-CSI volumes attached to it from other application pods. Killing a busy CTE-CSI pod will result in application Pods losing their connection to the encryption service. This will render the volume on those pods inaccessible, and can result in data loss. When this happens, the application Pod must be restarted to restore proper functionality.

CTE for Kubernetes registration

CTE for Kubernetes dynamically registers the agent when a CTE-CSI volume attachment request is performed on a node. CTE will use the configuration parameters of the StorageClass, as well as the Namespace of the Pod, requesting the volume to attempt registration. Registration only succeeds if the Storage Class name and the Pod's Namespace matches that of the Storage Group defined in CipherTrust Manager. The CTE-CSI driver will automatically deregister itself for a given StorageClass/Namespace combination once all Pods that were consuming a particular registration in the node have been evicted from the node. The amount of time that the CTE-CSI driver waits from last eviction to deregistration can be configured through the StorageClass **registration_period** parameter

Note

Registration and deregistration to CM is dynamic, based on pod usage within the nodes in the cluster. This can quickly exhaust registration token client capacity. Therefore, it is recommended that the user define a CipherTrust Manager registration token with a large client capacity.

Warning

Kubernetes will always retry and mount a Pod's volume in the event of a failure. If that failure is due to a registration failure (for example, non-matching StorageClass/Namespace parameters in the K8s Storage Group), retry attempts by Kubernetes will quickly exhaust registration token client capacity.

CTE-CSI Storage Class

For CTE for K8s, as soon as you create a pod to protect a cte-csi volume, cte-csi is using a storage class. Once this storage class is created, it automatically creates a K8s client and registers it with CipherTrust Manager.

When first creating Storage Class objects, Administrators set the name and other parameters for a class in a yaml file. Note that objects cannot be updated once they are created.

Important standard Kubernetes specification definitions

The following list defines the parts of the yaml file:

- **metadata.name:** Name of the StorageClass. This name **MUST** match the StorageClass name specified in the CM K8s Storage Group.
- **provisioner:** Determines what volume plugin is used for provisioning Persistent Volumes. This field must be specified. For CTE for Kubernetes, it is always defined as **csi.cte.cpl.thalesgroup.com**
- **reclaimPolicy:** Determines what to do with the PersistentVolume once its claim has been deleted. CTE PVs do not hold any data. They act solely as configuration placeholders for real PVs. The policy **MUST** be set to **Delete** as they are not usable outside of the context of its PVC that created it.
- **allowVolumeExpansion:** CTE for Kubernetes does not store data so these volumes are not expandable. This does not prevent the source unprotected volume from being expandable. This **MUST** be set to **false**

CTE-CSI Storage Class parameters

- **key_manager_addr:** Domain name or IP address of the CipherTrust Manager. This is a required field.
- **k8_storage_group:** Name of the CipherTrust Manager K8s Storage Group. This is a required field.
- **registration_token_secret:** Kubernetes Secret with CM registration token. The CM registration token must be saved into the Kubernetes secret with as a base64 encoded string. This is a required field.
- **registration_period:** Time in minutes to wait before deregistering from the CipherTrust Manager once all volumes on a node have been unguarded. Parameter must be added as a string integer value. Default "10" minute. This field is optional.

Example

```
apiVersion: storage.k8s.io/v1
kind: StorageClass
metadata:
  name: <CHANGE ME to K8s Storage Class>
provisioner: csi.cte.cpl.thalesgroup.com
reclaimPolicy: Delete
volumeBindingMode: Immediate
allowVolumeExpansion: false
parameters:
```

```
#Domain name or IP address of the CipherTrust Manager (Required)
key_manager_addr: <CHANGEME to your CM ADDR>

#Name of the CipherTrust Manager K8s Storage Group. (Required)
k8_storage_group: <CHANGEME to your K8s Storage Group name>

#Kubernetes Secret with CM registration token (Required)
registration_token_secret: <CHANGEME to K8s secret>

#Time in minutes to wait before unregistering from the CipherTrust Manager
#once all volumes have been unguarded. Parameter must be added as a string
#integer value. Default "10" minute. (Optional)
registration_period: "10"
```

CTE Persistent Volume Claim

CTE-PVC is the protected Persistent Volume Claim. You can use it to configure CTE-K8s features and functionalities.

CTE-PVC is used by the protected pods. Configuration information like CipherTrust Manager Guard Policy information, and underlying source PVC information can be provided with this CTE-PVC.

You can configure many features with a CTE-PVC, such as:

- Dataxform
- Taints & Tolerations
- Guard Policy Tuning
- Volume management (volume cloning, volume snapshot, etc)

Important standard Kubernetes spec definitions

The following list defines the parts of the yaml file:

- **metadata.name:** Name of the CTE-CSI PVC. Use this PVC name in your Pod definition instead of the unprotected source PVC.
- **metadata.annotations.csi.cte.cpl.thalesgroup.com/policy:** CTE for Kubernetes GuardPolicy name. This GuardPolicy is located on the CipherTrust Manager and should match a policy name available on the storage class for this PVC. This parameter is required.
- **metadata.annotations.csi.cte.cpl.thalesgroup.com/source_pvc:** Name of the unprotected source PVC that will be protected by this CTE-PVC. This parameter is required.
- **spec.storageClassName:** CTE-CSI StorageClass name. This parameter is required
- **spec.resources.requests.storage:** Kubernetes PV capacity request. This parameter is required by Kubernetes but ignored by CTE-CSI as capacity is dictated by the source PVC.

Example

```

apiVersion: v1
kind: PersistentVolumeClaim
metadata:
  name: cte-claim
  annotations:
    # CTE for Kubernetes GuardPolicy name. This GuardPolicy is located on the
    # CipherTrust Manager and should match a policy name available on the
    # storage class for this PVC. (Required)
    csi.cte.cpl.thalesgroup.com/policy: <CHANGEME CTE for Kubernetes policy>

    # Name of the unprotected source PVC that will be protected by this CTE-P
VC.
    # (Required)
    csi.cte.cpl.thalesgroup.com/source_pvc: <CHANGEME to a regular PVC to pro
tect>
spec:
  storageClassName: <CHANGEME to the CTE-CSI StorageClass>
  accessModes:
    - ReadWriteMany
  resources:
  requests:
    # This parameter is required by Kubernetes but ignored by CTE-CSI.
    storage: 1Ki

```

CTE for Kubernetes Terminology

The following Kubernetes terms are important to understand when working with CTE for Kubernetes containers.

Container Storage Interface

Container Storage Interface (CSI) is a plugin for Kubernetes that allows the implementation of third-party persistent storage solutions. This provides Kubernetes users more options for storage. CTE for Kubernetes is implemented as a CSI plugin which allows Thales to provide encryption and data protection while using Kubernetes volume configuration semantics.

Persistent Volumes

A PersistentVolume (PV) is a piece of storage in the cluster that has been provisioned by an administrator, or dynamically provisioned using [Storage Classes](#). It is a resource in the cluster. PVs are volume plugins like volumes, but have a lifecycle independent of any individual Pod that uses the PV. This API object captures the details of the implementation of the storage.

Unlike other storage plugins, CTE PVs are virtual in nature and do not hold store actual data. They functions as an overlay on top of other Kubernetes PVs. It then encrypts the contents of that PV.

Persistent Volume Claims

A Persistent Volume Claim (PVC) is a request to bind a PV to a namespace. Once claimed, a PV can be attached to any Pod within the same namespace. A PV that has not been claimed is not used by any Pod.

Storage Class

Provides a method for administrators to describe the classes of storage they offer. They are the foundation for defining parameters for dynamic provisioning.

Namespaces

In Kubernetes, namespaces provide a mechanism for isolating groups of resources within a single cluster. Namespaces are a way to divide cluster resources between multiple users.

Note

- Namespaces **cannot** be nested inside one another. Each Kubernetes resource can only reside in one namespace.
- Avoid creating namespaces with the prefix `kube-`. It is reserved for Kubernetes system namespaces.
- Names of the resources need to be unique within a namespace, but not across namespaces.

Pods

A Pod is a group of one or more containers, with shared storage and network resources, and a specification for how to run the containers. A Pod's contents are always co-located and co-scheduled, and run in a shared context. A Pod models an application-specific "logical host": it contains one or more application containers which are relatively tightly coupled. A pod consumes the nodes resources. In non-cloud contexts, applications executed on the same physical or virtual machine are analogous to cloud applications executed on the same logical host. Pods are the smallest deployable units of computing that you can create and manage in Kubernetes.

CTE Staging Pod

A CTE staging pod is a special pod that mounts on a Persistent Volume available to a Kubernetes cluster, so that CTE can attach the protection layer on top of the PV. CTE for Kubernetes automatically generates a staging pod on the same node where a Pod with a CTE PVC volume is deployed.

Storage Group

Similar, conceptually, to a Client Group. A Kubernetes Storage Group is created in CipherTrust Manager and consists of Kubernetes clients, similar to how a Client group consists of CTE Clients.

Installation Methods

CTE for Kubernetes supports two installation methods: Helm Charts and Operator. Beginning with version 1.5.0, the Operator is the default installation method. The desired installation method can be specified using command-line arguments in the `deploy.sh` script.

Operator Installation

The Operator-based installation deploys a dedicated operator pod that monitors the usage of CTE PVCs across the cluster. It automates the upgrade of CTE for Kubernetes by detecting when nodes are no longer using CTE and proceeds with the upgrade process accordingly.

- [Install Operator](#)

Helm Charts Installation

Helm offers a manual method to deploy CTE for Kubernetes. It places the responsibility on the user to manage node upgrades. Before upgrading, users must ensure that no applications on the node are actively using a CTE Persistent Volume Claim (PVC). Manual draining of the node is required to complete the upgrade process.

- [Installing with Helm](#)

Using Operator

- [Introduction to the Kubernetes Operator Resource](#)
- [Installation, Deployment and Configuration for CTE for Kubernetes](#)
- [Installing and Managing CTE for Kubernetes in an Operator Environment](#)
- [Kubernetes Operator Maintenance](#)

Introduction to the Kubernetes Operator Resource

The CTE for Kubernetes Operator is an OpenShift operator that Thales created for CTE for Kubernetes. The Kubernetes Operator can deploy, monitor, upgrade and delete CTE for Kubernetes. When the Operator is deployed, its controller deploys the CTE for Kubernetes driver in the OpenShift cluster. The manifests required to deploy the CTE-K8s driver are bundled with the operator.

Kubernetes has various default resources like Pod, Deployment, DaemonSet, etc. When you define a manifest for instantiating one of those resources, you must specify the **Kind** as Pod/Deployment/DaemonSet etc. Kubernetes provides a default set of controllers that understand the resource definitions and know how to manage their life cycle. For instance, the Deployment Controller manages the Create/Update/Delete of the Deployment resource.

Kubernetes architecture allows users to extend the API server in a way that users can create their own custom resource (CR) and write their own controller to manage the custom resource. An operator bundles a CR and the Controller that manages the CR. An operator can watch resources across the cluster and take actions when required. The operator contains a CR, an API for managing a CR, and a custom controller that manages this resource. When you install the CTE for Kubernetes Operator on an OpenShift cluster, the operator registers the new CR and the controller with the Kubernetes API server. Whenever the API server receives a request to create a resource, where `Kind=CTEK8sOperator`, it passes on the request to CTE for Kubernetes Operator's Custom Controller. The controller contains all of the logic needed to complete tasks before, during or after the deployment of the driver.

For more information on how to use operators to manage other applications, refer to the [Kubernetes Operator pattern](#).

Note

- The CTE for Kubernetes feature is supported with CTE for Kubernetes v1.2.0 and subsequent versions.
- For CTE for Kubernetes v1.5.0 and subsequent versions, Operator is the default deployment method.
- CTE-Kubernetes Operator version v1.5.9 has been certified with Redhat and published on the Redhat portal: [RedHat Portal](#).
- For Kubernetes cluster, including managed Kubernetes clusters in the cloud, namely Google GKE

cluster, Amazon EKS cluster and Microsoft's AKS cluster, the operator is also certified and available at: [Kubernetes Catalog](#).

- CTE for Kubernetes Operator supports both x86_64 and arm64 deployment

Installation, Deployment and Configuration

Getting CTE for Kubernetes deployment files

Obtain CTE for Kubernetes through the `yaml` files available in the `cte-csi-deploy` Git repository at:

```
git clone https://github.com/thalescpl-io/ciphertrust-transparent-encryption-kubernetes.git
```

Prerequisites

Installation Dependencies for Kubernetes Operator

CTE for Kubernetes v1.5.0 and subsequent versions install with the CTE for Kubernetes Operator by default. Therefore, you must install the Operator Lifecycle Manager (OLM) if you choose to use Kubernetes Operator. If OLM is not properly installed, the operator installation fails.

OLM is a framework for managing the lifecycle of Kubernetes Operators. It simplifies the process of installing, managing, and upgrading operators and their associated applications within a Kubernetes cluster.

When installing CTE for Kubernetes, it requires the following dependencies:

Dependency	Deployment Method
kubectl	Helm / Kubernetes Operator
Operator LifeCycle Manager (OLM)	Kubernetes Operator

Creating the Required Kubernetes Secret

For CTE for Kubernetes Operator v1.5.9, the Operator Controller Manager has a change that requires an additional step to be carried out by the cluster administrator before deployment. **This prerequisite is mandatory.**

There has been a change in how the Kubernetes Operator Controller Manager downloads images. The `kube-rbac-proxy` used by the `operator-controller-manager` pod performs RBAC authorizations with the Kubernetes API Server. The CTE for Kubernetes Operator previously pulled this image from `gcr.io`. However, this image has been deprecated and will be removed from GCR. The CTE for Kubernetes Operator has shifted to pulling the image hosted by `registry.redhat.io`. While `gcr.io` is a public registry and does not require authentication for pulling images, `registry.redhat.io` requires authentication.

Due to this change, it is now a requirement to create a specific Kubernetes secret named `rh-kube-proxy-secret`. The cluster administrator must create this secret in the namespace in which they are deploying the operator. Without this secret, attempts to create new pods will result in errors due to the authentication

requirement of `registry.redhat.io`.

OpenShift Environment

1. Use a login account created on redhat to create the secret using the following command:

```
oc create secret docker-registry rh-kube-proxy-secret --docker-username="<username on Redhat portal>" --docker-password="<Redhat portal password>" --docker-server="registry.redhat.io" --namespace="<namespace in which CTE-K8s Operator is to be deployed>"
```

If you miss this step, you will encounter the following in an `ErrImagePull/ImagePullBackOff` in the Events section of the `cte-k8s-operator-controller-manager-XXXXXXXXXX-YYYYYY` pod:

```
Events:
Type      Reason      Age          From          Message
----      -
Normal    Pulling      18m (x3 over 19m)    kubelet        Pulling image "registry.redhat.io/openshift4/ose-kube-rbac-proxy-rhel9:v4.17.0-202503121206.p0.g7718265.assembly.stream.el9"
Warning   Failed       18m (x3 over 19m)    kubelet        Failed to pull image "registry.redhat.io/openshift4/ose-kube-rbac-proxy-rhel9:v4.17.0-202503121206.p0.g7718265.assembly.stream.el9": failed to pull and unpack image "registry.redhat.io/openshift4/ose-kube-rbac-proxy-rhel9:v4.17.0-202503121206.p0.g7718265.assembly.stream.el9": failed to resolve reference "registry.redhat.io/openshift4/ose-kube-rbac-proxy-rhel9:v4.17.0-202503121206.p0.g7718265.assembly.stream.el9": failed to authorize: failed to fetch anonymous token: unexpected status from GET request to https://registry.redhat.io/auth/realms/rhcc/protocol/redhat-docker-v2/auth?scope=repository%3Aopenshift4%2Fose-kube-rbac-proxy-rhel9%3Apull&service=docker-registry: 401 Unauthorized
```

2. If you experience this error:
 - a. Create a secret, `rh-kube-proxy-secret`, in the `kube-system` namespace in which the operator is being installed:

```
kubectl create secret docker-registry rh-kube-proxy-secret --docker-username="<your userid on Redhat portal>" --docker-password="<your redhat portal password>" --docker-server="registry.redhat.io" -n <namespace of operator deploy>
```

- b. Verify the secret has been created successfully:

```
kubectl get secret rh-kube-proxy-secret -n <namespace>
```

c. Once the secret is created, delete the pod that is showing `ImagePullErr`: `kubectl delete pod -n cte-k8s-operator-controller-manager-c6997c9fd-lc9mq`

This will cause the pod to restart, pick up the secret that you just created, and pull the image successfully.

Note

The previous steps do not have any effect on the CTE-K8s pods that have already been deployed by an earlier version of the Operator.

Standard Kubernetes Environment

- In a standard Kubernetes environment, create the secret using the following command:

```
kubectl create secret docker-registry rh-kube-proxy-secret \
--docker-server=registry.redhat.io \
--docker-username=<your_redhat_username> \
--docker-password=<your_redhat_password> \
--docker-email=<your_email> \
-n <your_namespace>
```

Installing the CTE for Kubernetes Operator

Warning

- Do not uninstall CTE for Kubernetes and the operator from the CLI, if they were installed using the GUI.
- Similarly, do not uninstall CTE for Kubernetes and the operator from the GUI, if it was installed using the CLI.

Note

You can install CTE for Kubernetes and the Operator **only** in the OpenShift-operators namespace. If you want to install in other namespaces, use the CLI option.

The CTE for Kubernetes Operator can be installed using one of two methods:

- CLI
- Cluster Console GUI

CLI Method Prerequisites

1. Install the [Operator Lifecycle Manager \(OLM\)](#) on the cluster. Refer to [Installing OLM](#) for instructions on how to install OLM on the cluster.

Note

The latest version of OpenShift is installed by default.

2. Install `oc` (OpenShift CLI command for OpenShift cluster) on the cluster.

Note

The user installing the Operator must have Cluster Admin permissions.

3. Download the [Deploy Scripts](#).
4. Execute the `deploy.sh` script from the deploy directory, type:

```
./deploy.sh --operator --operator-ns=<namespace-in-which-to-deploy-the-operator> --cte-ns=<namespace-in-which-to-deploy-cte-4-k8s>
```

Example

```
./deploy.sh --operator-ns=my-ns1 --cte-ns=my-ns2
```

If either of the namespace options is not specified, the script sets `kube-system` as the default namespace for deployment.

Installing a specific image

1. Change to the CTE for Kubernetes directory, type:

```
cd ciphertrust-transparent-encryption-kubernetes
```

2. Deploy the specific image:

```
./deploy.sh -t 1.6.0.31
```

Namespace Deployments

Ensure that the namespace passed to the deployment script exists before initiating deployment. This prevents the script from prompting for creation of namespace during deployment. For example, if the deployment script is invoked as:

```
./deploy.sh --operator --operator-ns=my-ns1 --cte-ns=my-ns2
```

where both namespaces `my-ns1` and `my-ns2`, do not exist, the script would prompt with the following response:

```
Starting the cte-csi containers
NAMESPACE my-ns1 not found!!!!!!
Namespace my-ns1 not found. Do you want to create it now [N/y]
```

Once the namespace information is available, the script proceeds to create the objects required and installs the operator. After installing the operator, the script deploys `ctek8soperator` CRD. This deploys CTE for Kubernetes on the cluster in the namespace specified.

Using the Cluster Console Web GUI

The CTE for Kubernetes Operator is certified with Red Hat for the OpenShift platform. It is integrated with OperatorHub. The operator can be discovered on the OperatorHub page.

1. Open a browser and navigate to the **Operators > OperatorHub** link, in the left navigation panel on the console GUI. Type `CTE` in the search field under **All Items** to find the CTE for Kubernetes Operator.
2. Click on the tile to access the install option.
3. Ensure that all prerequisites are met before installing the operator.
4. Click **Install** to install the operator. Do not change the default values on the install page.

Installing and Managing CTE for Kubernetes in an Operator Environment

Installing CTE for Kubernetes

To install CTE for Kubernetes (when CTE for Kubernetes Operator is already installed):

1. Navigate to the deploy directory that was downloaded for operator install.
2. Ensure the file `ctek8soperator-crd.yaml` has correct values.
3. Type:

```
oc apply -f <path to>/ctek8soperator-crd.yaml
```

Updating CTE for Kubernetes

To update CTE for Kubernetes:

1. Stop any application that is using CTE for Kubernetes volumes.
2. Navigate to the deploy directory that was downloaded for operator install.
3. Edit the `ctek8soperator-crd.yaml` file.
4. Update the `version` field in the spec section to the latest version of [CTE for Kubernetes](#).
5. Apply the change with the command:

```
oc apply -f <path to>/ctek8soperator-crd.yaml
```

Using user-defined Configuration Parameters with RedHat OpenShift

You can use user-defined configuration parameters for CTE-K8s daemonset so user can control on which nodes CTE-K8s is deployed as an operator

cte-csi-node manifest

```
apiVersion: apps/v1

Using ConfigMaps to customize deployment of CTE for Kubernetes

If you are deploying CTE for Kubernetes using Helm, you can customize this deployment by modifying parameters in *values.yaml* file or manifest files (*cte-csi-controller.yaml*, *cte-csi-driver*, and *cte-csi-nodeserver.yaml*) directly.

However, if you are deploying CTE for Kubernetes using operator, you can customize the deployment by modifying only small subset of parameters that are available in the *ctek8soperator-crd.yaml* CRD. The operator uses these values to update the values in the bundled CTE for Kubernetes manifest files before deploying it. To modify other parameters (such as, parameters in the manifest files), you require a new build of the operator, which supports that parameter in its CRD. This is because the manifest files required for deploying CTE for Kubernetes are bundled into an operator image at the time operator is built.

From version 1.5.0 and subsequent versions, this limitation has been addressed. Now, you can either use the CRD to customize small set of parameters, or modify the manifest files and upload them as a ConfigMap. The Kubernetes cluster administrator can customize the deployment by modifying the manifest files (*cte-csi-controller.yaml* and *cte-csi-nodeserver.yaml*) and uploading them as a ConfigMap.

Note

If ConfigMap is available then changes in *ctek8soperator-crd.yaml* CRD are ignored.

Once the operator finds the ConfigMap, it extracts the manifests from this ConfigMap and uses them to deploy CTE for Kubernetes. If the ConfigMap is not found or the operator is not able to successfully extract the manifests, then it falls back to the manifests packaged at the time of build.

To create a custom ConfigMap follow the steps below.

1. On the cluster where you want to deploy CTE for Kubernetes, clone the `ciphertrust-transparent-encryption-kubernetes.git` repository and navigate to this directory.

```

git clone https://github.com/thalescpl-io/ciphertrust-transparent-encryption-kubernetes.git

```

```
cd ciphertrust-transparent-encryption-kubernetes
```

2. Execute the `detemplatize_manifest.sh` command. To execute this command Helm must be installed.

```
./detemplatize_manifest.sh
```

This script creates a `custom_manifests/<CTE-K8s version>` directory tree.

3. Edit the manifest files in the `custom_manifests` directory corresponding to the version of CTE for Kubernetes being deployed. For instance, if you are deploying version 1.6.0 (1.6.0-latest), then edit the files in the `custom_manifests/1.6.0` directory.
4. Execute the `kubectl` command to create the ConfigMap.

Note

It is mandatory to name the ConfigMap as `ctecustomconfig` and create it in the same namespace where the CTE for Kubernetes operator is being deployed.

Example: To create `ctecustomconfig` in the `kube-system` namespace for deployment of version 1.6.0, execute the below command:

```
kubectl create configmap ctecustomconfig -n kube-system --from-file=./custom_manifests/1.6.0/
```

5. Verify that the manifest was created.

```
kubectl get configmap ctecustomconfig -n kube-system
```

After completing above steps, deploy the operator and CTE for Kubernetes using either GUI or the deployment scripts.

Upgrading CTE for Kubernetes

1. Check the [Docker site](#) for a new version of CTE for Kubernetes:
2. Stop any application that is using CTE for Kubernetes volumes.
3. Expand **Operators** section and click **Installed Operators** page from the left hand bar on the page.
4. Click on the Name of the operator installed.

5. On the next page, select the **YAML** tab. This displays the manifest of CTE for Kubernetes instances installed on the cluster.
6. Update the version parameter in the CRD spec with the updated CTE-K8s version.
7. Click **Save**.

The upgrade process terminates all of the CTE for Kubernetes pods running the previous version, while activating new pods running the new version. Once the `cte-csi-node-XXXX` pods are running on all of the nodes of the cluster, the application that uses the CTE for Kubernetes volume can be re-deployed.

8. If any of the other parameters in `CTE-K8s-Operator.yaml`, like `logLevel`, `apiburst`, `apqps`, etc. need to be updated, follow the same process as above to update the relevant parameter.

Deleting CTE for Kubernetes

To delete CTE for Kubernetes:

1. Stop any application that is using CTE for Kubernetes volumes.
2. Navigate to the deploy directory that was downloaded for operator install.
3. Type:

```
oc delete -f <path to>/ctek8soperator-crd.yaml
```

Kubernetes Operator Maintenance

Upgrading CTE for Kubernetes Operator

The operator is designed to upgrade to a newer version automatically as soon as a new version is published by Thales. The Operator Lifecycle Manager, or OLM, constantly polls for updates and upgrades the operator whenever an update is available.

Uninstalling CTE for Kubernetes Operator

To uninstall CTE for Kubernetes Operator from the User Interface:

1. Stop any application that is using CTE for Kubernetes volumes.
2. Expand “Operators” section and click **Installed Operators** page from the left hand bar on the page.
3. Click on the Name of the operator installed.
4. On the next page, select the **Actions** tab.
5. Click **Uninstall Operator** in the list of actions displayed.

6. Click **Uninstall** on the confirmation pop-up to uninstall CTE for Kubernetes.

To uninstall the CTE for Kubernetes Operator using the CLI:

1. Stop any application that is using CTE for Kubernetes volumes.
2. Navigate to the deploy directory that was downloaded for operator install, type:

```
./deploy.sh --operator --operator-ns=<namespace-in-which-ctek8soperator-is-dep
loyed> --cte-ns=<namespace-in-which-ctek8s-is-deployed> --remove
```

This removes both CTE for Kubernetes and the operator.

Using Helm with CTE for Kubernetes

- Installing and Deploying with Helm
- Deploying in an Air-Gapped Kubernetes Cluster Environment using HELM
- Migrating a CTE install from Helm to Operator deployment
- Upgrading CTE for Kubernetes with a Helm-based Installation

Installing and Deploying with Helm

How to Deploy pods/services in Kubernetes Cluster

The CTE for Kubernetes images are distributed through the [Thales Docker Hub](#).

- All of the pods/services are deployed using `yaml` files. The `yaml` files are executed using the provided `deploy.sh` scripts.
- CTE for Kubernetes **only** supports homogeneous Kubernetes clusters, i.e. all nodes of the Kubernetes clusters must be x86_64 or all nodes must be arm64.

Options for Deploy Scripts

Deploy all of the pods by using the following command and needed arguments from the following table:

Option	Function	Description
-r	remove	Remove all the running pods, services and secrets.
-t	tag	Tag of the image on the server. Default is the latest.
	--helm	Deploy CTE for Kubernetes using Helm.

Option	Function	Description
	--operator-ns=	The namespace in which to deploy the Operator.
	--cte-ns=	The namespace in which to deploy the CSI driver.
	--cri-sock=	Container Runtime Interface socket path.

For CTE for Kubernetes v1.3.0 and subsequent versions, the deployment script uses the repository image index as the image name, instead of the individual platform image names. The manifest (`cte_csi : <tag>`) points to an image.

Note

The **default** image name is: `cte_csi`. You do not need to specify the image name if you use the default name.

Install Helm

Helm is a package manager for Kubernetes.

1. Download Helm CLI, type:

```
curl https://raw.githubusercontent.com/helm/helm/master/scripts/get-helm-3 \ |
bash
```

2. Check for the version, type:

```
helm version --client
```

3. Validate the connection, type:

```
helm ls --all-namespaces
```

Installing using Helm

1. Change to the CTE for Kubernetes directory, type:

```
cd ciphertrust-transparent-encryption-kubernetes
```

2. Deploy with Helm:

```
./deploy.sh --helm
```

Terminating Pods

To terminate all of the pods and delete all of the services and secrets:

1. Change to the CTE for Kubernetes directory, type:

```
cd ciphertrust-transparent-encryption-kubernetes
```

2. For Helm deployment, type:

```
./deploy.sh --remove --helm
```

Verify CTE for Kubernetes

Verify that CTE for Kubernetes is running, type:

```
kubect1 get pods --namespace=kube-system -o wide | grep cte-csi
```

Helm Charts Deployment

Helm offers a straightforward method for deploying CTE for Kubernetes. However, it places the responsibility on the user to manage node upgrades. Before upgrading, users must ensure that no applications on the node are actively using a CTE Persistent Volume Claim (PVC). Manual draining of the node is required to complete the upgrade process.

Specify the desired installation method using command-line arguments in the `deploy.sh` script. When using the Operator method, you must install the Operator Lifecycle Manager (OLM) prior to deployment.

- See [Deploying CTE for Kubernetes in an Air-Gapped Kubernetes Cluster Environment using HELM](#)

Migrating Helm to Operator

You can migrate Helm to Operator if you choose to move from manual to automatic management:

- [Migrating a CTE for Kubernetes install from Helm to Operator deployment](#)

Upgrading Helm

Helm must be upgraded manually by the administrator:

- [Upgrading CTE for Kubernetes with HELM](#)

Migrating a CTE install from Helm to Operator deployment

For CTE for Kubernetes v1.5.0 and subsequent versions, CTE for Kubernetes Operator is automatically installed by default.

Prior to v1.5.0, users had to manually migrate from a Helm-based deployment to Operator-based deployment. This is an optional feature for prior versions.

Upgrading to v1.5.0 from a prior version

If you are using a version prior to v1.5.0, for example, CTE for Kubernetes v1.3.0 deployed using Helm, then if you attempt to install CTE for Kubernetes v1.5.0, CTE for Kubernetes displays an error message stating that the existing deployment was completed using Helm. For that scenario, you have the following two options:

- Pass the `--helm` parameter to the `deploy.sh` script to upgrade to CTE for Kubernetes v1.5.0 using Helm charts. See [\[Upgrading\]](#)
- Migrate to operator based deployment using the following section:

Manually migrating to CTE for Kubernetes Operator

To switch to a Kubernetes operator deployment, you can manually migrate from Helm to Operator so that you can upgrade to CTE for Kubernetes v1.5.0 and subsequent versions:

1. Stop all of your applications that use CTE Volumes. Ensure that you stop all application pods using CTE-K8s and those actively accessing CTE volumes.
2. Revert the CTE for Kubernetes deployment, type:

For CTE for Kubernetes v1.5 and subsequent versions

```
./deploy.sh --helm --remove
```

For CTE for Kubernetes v1.4 and previous versions

```
./deploy.sh --remove
```

3. Deploy Kubernetes operator, type:

```
./deploy.sh --operator -t <image tag>
```

4. Redeploy the application pods that use CTE volumes.

Deploying in an Air-Gapped Kubernetes Cluster using HELM

Prerequisites

On a system that has access to the internet and to an internal container registry:

1. **Install skopeo.** Skopeo is a command-line utility (CLI) used to interact with local and remote container images and container image registries.
2. **Install jq.** JQ is a lightweight and flexible command-line JSON processor.
3. If the internal registry is private, and requires authorization to add/list images, then, **before** executing the script, create an authorization file to allow **skopeo** access to the internal registry:

```
skopeo login <url-for-internal-registry[:port number]> --authfile ./docker_auth -u <username>
```

Example

```
skopeo login <k8s.gcr.io[:22]> --authfile ./docker_auth -u penderyn
```

Note

The name of the authfile **must** be `docker_auth`. If this is changed, then the name must be updated in the following script.

4. Enter the password for the user when prompted.
5. Copy and paste the following into a script and execute the script:

```
#!/bin/bash

DOCKER_AUTH_JSON=./docker_auth
SRC_REGISTRY="docker.io/thalesciphertrust"
SRC_CTEK8S_NAME="${SRC_REGISTRY}/ciphertrust-transparent-encryption-kubernetes"
DEST_REGISTRY=<path to your registry such as example.com[:port]/my-internal-re
```

```

gistry>

skopeo login ${DEST_REGISTRY} --authfile ${DOCKER_AUTH_JSON} -u <username>

DEST_REGISTRY=`echo ${ DEST_REGISTRY} | sed -e "s/\//g"`
for VER in `skopeo list-tags docker://${SRC_CTEK8S_NAME} | jq '.Tags' | grep
-vE "[\\|]" | sed -e s/[\\",,]/g`
do

skopeo copy --all docker://${SRC_CTEK8S_NAME}:${VER} \
                docker://${DEST_CTEK8S_NAME}:${VER} --authfil
e ${DOCKER_AUTH_JSON}
done

skopeo copy --all docker://k8s.gcr.io/sig-storage/csi-node-driver-registrar:v
2.0.1 \
                docker://${DEST_REGISTRY}/csi-node-driver-registrar:v2.0.1 --authf
ile ${DOCKER_AUTH_JSON}

skopeo copy --all docker://k8s.gcr.io/sig-storage/csi-attacher:v3.3.0 \
                docker://${DEST_REGISTRY}/csi-attacher:v3.3.0 --authfile ${DOCKE
R_AUTH_JSON}

skopeo copy --all docker://k8s.gcr.io/sig-storage/csi-provisioner:v4.0.0 \
                docker://${DEST_REGISTRY}/csi-provisioner:v4.0.0 --authfile ${DOCK
ER_AUTH_JSON}

skopeo copy --all docker://k8s.gcr.io/pause:3.9 \
                docker://${DEST_REGISTRY}/pause:3.9 --authfile ${DOCKER_AUTH_JSON}

```

Deploying in an Air-Gapped Kubernetes Cluster

1. Download CTE for Kubernetes deployment files, type:

```
git clone https://github.com/thalescpl-io/ciphertrust-transparent-encryption-k
ubernetes.git
```

2. Change to the CTE for Kubernetes directory, type:

```
cd ciphertrust-transparent-encryption-kubernetes
```

3. Edit the script variables to reflect your setup, type:

```
vi deploy/kubernetes/1.6.0/values.yaml
```

a. Replace `docker.io/thalesciphertrust/ciphertrust-transparent-encryption-kubernetes` with appropriate values for your environment: `<example.com/my-internal-registry>/ciphertrust-transparent-encryption-kubernetes`

b. Replace `registry.k8s.io/pause:3.9` with appropriate values for your environment: `<example.com/my-internal-registry>/pause:3.9`

c. Replace `registry.k8s.io/sig-storage/csi-provisioner:v4.0.0` with appropriate values for your environment: `<example.com/my-internal-registry>/csi-provisioner:v4.0.0`

d. Replace `k8s.gcr.io/sig-storage/csi-attacher:v3.3.0` with appropriate values for your environment: `<example.com/my-internal-registry>/csi-attacher:v3.3.0`

e. Replace `k8s.gcr.io/sig-storage/csi-node-driver-registrar:v2.0.1` with appropriate values for your environment: `<example.com/my-internal-registry>/csi-node-driver-registrar:v2.0.1`

4. Deploy the script, type:

```
./deploy.sh -t 1.6.0-latest --helm
```

Upgrading CTE for Kubernetes with a Helm-based Installation

Introduction

Upgrading CTE for Kubernetes to the latest release is accomplished by invoking the `deploy.sh` script with the desired release tag. The CTE for Kubernetes node server cannot be automatically upgraded. Doing this will result in application failures for existing pods using CTE volumes on the nodes. You must use a manual procedure to stop the pods running on the nodes and delete the CTE for Kubernetes node server pods on that node.

Redeploy CTE for Kubernetes

To redeploy CTE for Kubernetes, type:

```
./deploy.sh -t <version#>.<build#>
```

For example:

```
./deploy.sh -t 1.6.0.31
```

Drain and update a node

To upgrade the nodes:

1. Get a list of nodes currently running CTE for Kubernetes, type:

```
kubectl get pods -n kube-system -o wide -l app=cte-csi-node --no-headers -o custom-columns=":spec.nodeName"
```

Response Example:

```
control.example.com  
node1.example.com
```

2. Drain a node from the list, type:

```
kubectl drain --delete-emptydir-data --ignore-daemonsets <nodeName>
```

Response example:

```
node/node1.example.com cordoned  
node/node1.example.com drained
```

Note

The drain command pauses while it waits for the node to be drained.

3. Use a compound kubectl command to delete the CTE for Kubernetes node server on this node:

```
kubectl delete -n kube-system pod $(kubectl get pods -n kube-system --field-selector spec.nodeName=<nodeName> -l app=cte-csi-node --no-headers -o custom-columns=":metadata.name")
```

- The `kubectl get pods` needs to be bounded to only output the CTE for Kubernetes-node label for this node
- Use `--field-selector spec.nodeName=<nodeName>` to specify the CTE for Kubernetes node to drain.
- Use `-l app=cte-csi-node` to select only the CTE for Kubernetes node server from that node.
- Use `--no-headers -o custom-columns=":metadata.name"` to tell kubectl to only output the pod names.
- Pass the output of that command to the `kubectl delete pod` which triggers a new CTE for Kubernetes

node server pod to be created with the desired image.

4. Verify that the pod has started successfully, type:

```
kubectl get pods -n kube-system --field-selector spec.nodeName=<nodeName> -l app=cte-csi-node -o wide
```

Response example:

NAME	READY	STATUS	RESTARTS	AGE	IP	NODE
NOMINATED NODE	READINESS GATES					
cte-csi-node-kgwkj	4/4	Running	0	14m	192.168.77.163	node1.example.com
	<none>	<none>				

5. Return node to working status, type:

```
kubectl uncordon <nodeName>
```

Response example:

```
node/node1.example.com uncordoned
```

Deployment Methods

Deployment Methods for Clusters Connected to the Internet

CTE for Kubernetes supports two deployment methods: Kubernetes Operator and Helm Charts. Beginning with version 1.5.0, the Operator is the default deployment method.

Operator Deployment

The Operator-based installation deploys a dedicated operator pod that monitors the usage of CTE PVCs across the cluster. It automates the upgrade of CTE for Kubernetes by detecting when nodes are no longer using CTE and proceeding with the upgrade process accordingly.

- See [Using the CTE for Kubernetes Operator Resource](#) for more information

Once the operator is installed, the Kubernetes API servers becomes aware of the Kubernetes customer resource (CR).

- See [Deploying with a Custom Resource Definition](#) for more information

Helm Deployment

Helm is a package manager for Kubernetes.

- Deploy a CTE for Kubernetes Volume with [HELM](#).

Deployment Methods for Clusters NOT Connected to the Internet

Operator Deployment

- Deploying CTE for Kubernetes in an Air-Gapped OpenShift Container Platform Cluster using CTE for Kubernetes Operator

Helm Deployment

- Deploying CTE for Kubernetes in an Air-Gapped Kubernetes Cluster Environment using HELM

Deploying with a Custom Resource Definition

Once the operator is installed, the Kubernetes API servers becomes aware of the Kubernetes customer resource (CR). The installation process registers the:

- CR
- API for managing the CR
- Controller that handles the requests, for the CR, from the API Server

To instantiate the CR:

1. Click **View Operator** on the page displayed immediately after the operator is installed.
2. Alternatively:
 - a. Expand “Operators” section and click **Installed Operators** page from the left hand bar on the page.
 - b. Click on the Name of the operator installed.
 - c. Click **Create Instance** link on the page displayed.
 - d. Click **Create** to deploy CTE for Kubernetes.

Deploying with a Custom Resource Definition

You can deploy CTE for Kubernetes using a Custom Resource Definition (CRD). The following displays a sample CRD used to create an instance of the CTE for Kubernetes:

CTE-K8S-Operator-crd.yaml

```
apiVersion: cte-k8s-operator.csi.cte.cpl.thalesgroup.com/v1
kind: CteK8sOperator
metadata:
  labels:
```

```

    app.kubernetes.io/name: ctek8soperator
    app.kubernetes.io/instance: ctek8soperator
    app.kubernetes.io/part-of: cte-k8s-operator
    app.kubernetes.io/managed-by: kustomize
    app.kubernetes.io/created-by: cte-k8s-operator
  name: ctek8soperator
  spec:
    replicas: 1
    image: "docker.io/thalesciphertrust/ciphertrust-transparent-encryption-kubernetes"
    version: "1.2.0-latest"
    imagePullPolicy: Always
    logLevel: 5
    apiBurst: 300
    apiQPS: 200
    imagePullSecrets:
      - name: cte-csi-secret
    registrationCleanupInterval: 10
    pauseImage: "k8s.gcr.io/pause:latest"
    volumes:
      - name: cri-sock
        hostPath:
          path: "/run/crio/crio.sock"
    # The following parameters are optional. If values are not specified, CT
    E-K8s uses the default values
    csiProvisionerImage: registry.k8s.io/sig-storage/csi-provisioner:v4.0.0
    csiNodeDriverRegistrarImage: k8s.gcr.io/sig-storage/csi-node-driver-registrar:v2.0.1
    csiAttacherImage: k8s.gcr.io/sig-storage/csi-attacher:v3.3.0
    csiSnapshotterImage: registry.k8s.io/sig-storage/csi-snapshotter:v6.3.3
    snapImagePullPolicy: IfNotPresent

```

Applying a CRD

To apply the CRD, type:

```
kubectl apply -f <path to\cte-k8s-operator.yaml>
```

Deploying CTE for Kubernetes in an Air-Gapped OpenShift Container Platform Cluster using CTE for Kubernetes Operator

Overview

This section documents the mandatory steps to deploy CTE for Kubernetes Operator and CTE for Kubernetes on an OCP cluster that is not connected to the internet. Once your OCP cluster is setup and configured properly, you can then mirror the CTE for Kubernetes Operator Catalog, CTE for Kubernetes images, and other images on which CTE for Kubernetes is dependent.

Note

The following information is valid for CTE for Kubernetes Operator v1.5.9 and subsequent versions. It is **not valid** with any previous version.

Prerequisites

You must have a docker-v2 compliant image registry that is set up properly, running, and is accessible from the internal network used by your OCP cluster. The illustrative commands in this document use the registry setup internally at `ocp-discon.lab.ocp.lan:5000`. This registry is accessible on the OCP private network.

Assumptions for this Document

The Bastion/Service/Helper node of the OCP cluster has access to the internet and the OCP cluster.

If this is not true, then you must manually mirror the CTE for Kubernetes Operator Catalog onto a system that has access to internet. The catalog may include other related images in the form of a file archive from docker.io (or their respective locations). This archive must then be copied to the Bastion/Service/Helper node.

Mirror the CTE for Kubernetes Catalog

"

1. Configure `imageset-configuration-ctek8soperator.yaml`. Refer to [Appendix: Sample Script](#) for a sample `ImageSetConfiguration` file for CTE for Kubernetes Operator and related images.
2. Mirror the CTE for Kubernetes Operator Catalog, and other related images, to a file on a disk.
3. Run the `oc-mirror` command, type:

```
oc-mirror --config imageset-configs/imageset-config-ctek8soperator.yaml file:///root/ocp-mirror/ocp-release/ctek8soperator-images 2>&1 | tee ctek8soperator-mirror.log
```

Expected output:

```
---> info: Mirroring completed in 3m58.31s (11.52MB/s)
---> Creating archive /root/ocp-mirror/ocp-release/ctek8soperator-images/mirror_seq1_000000.tar
```

4. Disable internet access

Note

Not applicable if creating the mirror archive through another server. If so, manually copy the archive.

5. Upload the images, that were just mirrored to the file archive, to your internal docker-v2 compliant registry:

```
oc-mirror --from=/root/ocp-mirror/ocp-release/ctek8soperator-images/mirror_seq
1_000000.tar docker://ocp-discon.lab.ocp.lan:5000
```

Expected output:

```
---> Rendering catalog image "ocp-discon.lab.ocp.lan:5000/shetland/ciphertrus
t-transparent-encryption-kubernetes-operator-catalog:v1.2.5" with file-based c
atalog
---> Writing image mapping to oc-mirror-workspace/results-1737970204/mapping.t
xt
---> Writing CatalogSource manifests to oc-mirror-workspace/results-1737970204
---> Writing ICSP manifests to oc-mirror-workspace/results-1737970204
```

Edit the deploy scripts -- Mandatory

1. Edit the file `oc-mirror-workspace/results-1737970204/imageContentSourcePolicy.yaml` and change the `Spec.Metadata.Name`:

```
metadata:
  name: cte-operator-generic-0
  :
  :
metadata:
  labels:
    operators.openshift.org/catalog: "true"
  name: cte-operator-0
```

2. Apply `imageContentSourcePolicy.yaml`.

```
cat oc-mirror-workspace/results-1737970204/imageContentSourcePolicy.yaml
```

Response:

```
imagecontentsourcepolicy.operator.openshift.io/cte-operator-generic-0 created
imagecontentsourcepolicy.operator.openshift.io/cte-operator-0 created
```

3. Open the following file for editing:

```
oc-mirror-workspace/results-1737970204/catalogSource-cs-ciphertrust-transparent-encryption-kubernetes-operator-catal.yaml
```

4. Append the following 5 lines to the file:

```
displayName: CTE-K8s Operator Catalog
publisher: Thales Group
updateStrategy:
  registryPoll:
    interval: 24h
```

Response:

```
apiVersion: operators.coreos.com/v1alpha1
kind: CatalogSource
metadata:
  name: ctek8soperator-catalog
  namespace: openshift-marketplace
spec:
  image: ocp-discon.lab.ocp.lan:5000/public-repos/ciphertrust-transparent-encryption-kubernetes-operator-catalog:v1.2.5
  sourceType: grpc
  displayName: CTE-K8s Operator Catalog
  publisher: Thales Group
  updateStrategy:
    registryPoll:
      interval: 24h
```

5. Apply the CatalogSource manifest:

```
oc apply -f oc-mirror-workspace/results-1741799472/catalogSource-cs-ciphertrust-transparent-encryption-kubernetes-operator-catal.yaml
```

Response:

```
catalogsource.operators.coreos.com/ctek8soperator-catalog created
```

6. Verify the catalog resource:

```
oc get catsrc -n openshift-marketplace
```

Response:

NAME	DISPLAY	TYPE	PUBLISHER	AGE
ctek8soperator-catalog	CTE-K8s Operator Catalog	grpc	Thales Group	5s

7. Verify the pods:

```
oc get pods -n openshift-marketplace
```

Response:

NAME	READY	STATUS	RESTARTS	AGE
ctek8soperator-catalog-9wv58	1/1	Running	0	27s

Download and configure deploy scripts -- Mandatory

Before Deployment, you must follow the steps in this section. It is mandatory.

1. Clone the deploy scripts from <https://github.com/thalescpl-io/ciphertrust-transparent-encryption-kubernetes.git>
2. Edit this file:

```
vi deploy/kubernetes/x.y.z/values.yaml
```

3. Replace the registry name for each of the images with the corresponding URL in the file `oc-mirror-workspace/results-nnnnnnnn/mapping.txt`.
4. Execute the `detemplatize_manifest.sh` script to create a set of files for use in creating a configMap.
Type:

```
./detemplatize_manifest.sh
```

This script:

- Picks up manifest files from `deploy/kubernetes/*/templates`
- Uses the `values.yaml` file from the respective chart version to get values for fields templated in the manifests.

- Creates a set of detemplatized manifest files for creating a custom ConfigMap for CTE-K8s deployment

In case further changes are required, beyond what can be customized via `values.yaml` (`logLevel`, `Image URL`, `APIServerThrottle.burst`, `APIServerThrottle.qps`), like change tolerations, change nodeAffinity, for controller pod or nodeserver pod, do it now directly on the custom manifest files generated.

5. Create a ConfigMap with the customized manifests, type:

```
oc create configmap ctecustomconfig -n <operator namespace> --from-file=./custom_manifests/X.Y.Z/
```

6. Verify that the ConfigMap was created, type:

```
oc get configmap ctecustomconfig -n <operator namespace>
```

7. Edit this file:

```
vi deploy/kubernetes/x.y.z/operator-deploy/ctek8soperator-subscription.yaml
```

Change the `Spec.source` and `Spec.sourceNamespace` to match the values in `oc-mirror-workspace/results-1741799472/catalogSources-ciphertrust-transparent-encryption-kubernetes-operatorcatal.yaml` that you changed in the section above.

8. Edit the `deploy/kubernetes/X.Y.Z/operator-deploy/deploy.sh`
9. Comment out the line containing `certified-operators`. The difference should look like the following:

```
diff --git a/deploy/kubernetes/1.6.0/operator-deploy/deploy.sh b/deploy/kubernetes/1.6.0/operator-deploy/deploy.sh
```

Response:

```
diff --git a/deploy/kubernetes/1.6.0/operator-deploy/deploy.sh b/deploy/kubernetes/1.6.0/operator-deploy/deploy.sh
index b556bc3..3462943 100755

Preparing a CTE for Kubernetes Volume for Deployment

The following sections must be completed in order to ensure success with deploying CTE for Kubernetes.

1. [Preparing CipherTrust Manager](#)
2. [Create a CTE Policy for Kubernetes](#)
3. [Using Kubernetes service accounts](#)
4. [Prepare a file system persistent volume](#)
5. [Deploying Pods/Services in a Kubernetes Cluster](#)
6. [Deploying CTE for Kubernetes Storage Classes](#)
7. [Using Dynamic PVCs with CTE for Kubernetes](#)
8. [Creating a CTE for Kubernetes Claim Against the PVC](#)
9. [Individual Guard Policy Tuning](#)
10. [Create a CTE-CSI protected Persistent Storage Claim by deploying an application/staging pod](#)
11. [Using Taints and Tolerations](#)
12. [Allow only Trusted Pods to mount to CTE for Kubernetes volumes](#)

Preparing CipherTrust Manager

Note

Make sure that all of the names are written in lower case letters or else the yaml file will generate errors.

Managing Kubernetes Storage Groups and Clients

For information on how to create and manage Kubernetes (K8s) storage groups, K8s clients, apply GuardPolicies to storage groups, and protect K8s clients, see the CipherTrust Manager K8s documentation:

- [Managing Kubernetes Storage Groups](#)
- [Managing Kubernetes Clients](#)
- [Protecting Kubernetes Clients](#)

Create a CTE Policy for Kubernetes

For the generic instructions on how to create a CTE for Kubernetes policy, see [Protecting Kubernetes Clients](#).

Specifically, when creating a policy for protecting Persistent Volumes in CTE for Kubernetes: CTE for Kubernetes

1. Create a policy with type : **CTE for Kubernetes**
2. For the CTE CSI policy name, use the name listed for the policy parameter:
`csi.cte.cpl.thalesgroup.com/policy` in the `cte-csi-claim.yaml` file.
3. Make the GuardPolicy name the same name as the CSI policy.
4. Attach this GuardPolicy to the K8s Storage Group.

Note

CTE for Kubernetes only supports **User Sets** with a UID and GID. User names and Group names are **not** supported.

Using Kubernetes service accounts

A service account is a type of Kubernetes account that provides a distinct identity, in a Kubernetes cluster, so that you can allow or restrict access based on this service account. Application Pods, system components, and entities inside and outside the cluster can use a specific Service Account's credentials to identify as that Service Account. This is needed because the UID inside a K8s pod is not persistent, and changes frequently in OpenShift deployments. Therefore, access control based on user IDs is not feasible for such workloads.

Some service accounts may have administrator privileges to use any Kubernetes API resource on the cluster, while others may only have the privilege to start pods without any other access to the Kubernetes API.

Each service account is bound to a Kubernetes namespace. Every namespace gets a default ServiceAccount upon creation.

Configuring on CipherTrust Manager

Configure this feature on CipherTrust Manager. The feature uses the existing User Set. It leverages the unused `UNAME` value from the User Set, remapping it for use as a Service Account name. In your policy, you can add rules that allow or deny access to a CTE volume-based on the service account pod status.

- See [Creating User Sets](#) for more information.

Creating Namespace & ServiceAccounts in Kubernetes

1. Create a namespace, type:

```
NS=<service-account-name>
kubectl create ns "$NS"
```

Example

```
NS=<demo-sa>
kubectl create ns "$NS"
```

2. Create service accounts, type:

```
kubectl -n "$NS" create serviceaccount <service-account-role>
```

Example

```
kubectl -n "$NS" create serviceaccount sa-restricted
kubectl -n "$NS" create serviceaccount sa-admin
```

Note

An `sa-restricted` service account **cannot execute** pods. Only an `sa-admin` service account **can execute** pods.

Restricted Role

The restricted role allows only the following functions on pods:

- get
- list
- watch
- create

Role-Based Access Control (RBAC) Examples

The following simple examples are provided so that you can use them to evaluate the feature. Use the service account feature in the appropriate method for solving your use case. Refer to the following Kubernetes documentation: [Service Accounts](#), for more information.

Role: Restricted

```
apiVersion: rbac.authorization.k8s.io/v1
kind: Role
metadata:
  name: restricted
  namespace: demo-sa
rules:
- apiGroups: [""]
  resources: ["pods"]
  verbs: ["get", "list", "watch", "create"]
```

Role: Administrator

```
apiVersion: rbac.authorization.k8s.io/v1
kind: Role
metadata:
  name: admin-lite
  namespace: demo-sa
rules:
- apiGroups: [""]
  resources: ["pods", "pods/exec", "configmaps"]
  verbs: ["*"]
- apiGroups: ["apps"]
  resources: ["deployments"]
  verbs: ["*"]
```

Role: K8s Restricted --> Service account restricted

```
apiVersion: rbac.authorization.k8s.io/v1
kind: RoleBinding
metadata:
```

```

name: restricted-to-sa-restricted
namespace: demo-sa
subjects:
- kind: ServiceAccount
  name: sa-restricted
  namespace: demo-sa
roleRef:
kind: Role
name: restricted
apiGroup: rbac.authorization.k8s.io

```

K8s Administrator --> Service Account Administrator

```

apiVersion: rbac.authorization.k8s.io/v1
kind: RoleBinding
metadata:
name: admin-lite-to-sa-admin
namespace: demo-sa
subjects:
- kind: ServiceAccount
  name: sa-admin
  namespace: demo-sa
roleRef:
kind: Role
name: admin-lite
apiGroup: rbac.authorization.k8s.io

```

- To apply it, type:

```
kubectl apply -f rbac.yaml
```

Pod manifests

Demo of Service Account restricted yaml file

```

apiVersion: v1
kind: Pod
metadata:
name: demo
namespace: demo-sa
spec:
serviceAccountName: sa-restricted
volumes:
- name: data
  persistentVolumeClaim:
    claimName: cte-clain
containers:
- name: app
  image: busybox:1.36
  command: ["sh", "-c", "sleep 365d"]
  volumeMounts:

```

```
- name: data
  mountPath: /data
```

- To apply it, type:

```
kubectl apply -f demo-pod-sa-restricted.yaml
```

Demo as Service Account Administrator yaml file

```
apiVersion: v1
kind: Pod
metadata:
  name: demo
  namespace: demo-sa
spec:
  serviceAccountName: sa-admin
  volumes:
    - name: data
      persistentVolumeClaim:
        claimName: cte-clain
  containers:
    - name: app
      image: busybox:1.36
      command: ["sh", "-c", "sleep 365d"]
      volumeMounts:
        - name: data
          mountPath: /data
```

- To apply it, type:

```
kubectl apply -f demo-pod-sa-admin.yaml
```

Prepare a file system persistent volume

Prerequisite

1. Create an NFS Server.
2. Export the path.
3. In the example below, the `yaml` file uses the NFS server `10.10.10.10` and the exported path is: `/my/nfs/volume/path`.

Limitation

CTE for Kubernetes **does not support** mounting conventionally-protected PVCs and CTE-protected PVCs simultaneously. This could lead to unexpected behavior.

Create a Persistent Storage (PV) YAML file description

The following example explains how to create a persistent storage for CTE for Kubernetes to guard. Find more information on creating Persistent Volumes at:

- [Persistent Volumes](#)

Note

Replace the dummy entries for path and server with your own working NFS configuration.

nfs-pv.yaml

```
apiVersion: v1
kind: PersistentVolume
metadata:
  name: nfs-test-pv
spec:
  capacity:
    storage: 1Gi
  accessModes:
    - ReadWriteMany
  storageClassName: nfs
  persistentVolumeReclaimPolicy: Retain
  mountOptions:
    - hard
  nfs:
    path: /my/nfs/volume/path
    server: 10.10.10.10
```

Create a Persistent Storage Claim (PVC) YAML file description

nfs-claim.yaml

```
apiVersion: v1
kind: PersistentVolumeClaim
metadata:
  name: nfs-test-claim
spec:
  storageClassName: nfs
  accessModes:
    - ReadWriteMany
  resources:
    requests:
      storage: 1Gi
```

Note

The PV name is not referenced in the PVC. This particular claim will claim any PV that matches the requirements.

Apply Persistent Storage YAML files

Type:

```
kubectl apply -f nfs-pv.yaml
kubectl apply -f nfs-claim.yaml
```

Deploying Pods/Services in a Kubernetes Cluster

The CTE for Kubernetes images are distributed through the [Thales Docker Hub](#).

- All of the pods/services are deployed using `yaml` files. The `yaml` files are executed using the provided `deploy.sh` scripts.
- CTE for Kubernetes **only** supports homogeneous Kubernetes clusters, i.e., all nodes of the Kubernetes clusters must be x86_64, or all nodes must be arm64.

Pod Types Created

The installation of CTE for Kubernetes creates two types of pods:

- `cte-csi-controller-XXXXXXXXXX-XXXXX`
 - Kind: **Pod Deployment Type**

A Deployment manages a set of Pods to run an application workload. After you describe a desired state in a Deployment, and the Deployment Controller changes to that actual state at a controlled rate, you can define Deployments to create new ReplicaSets, or to remove existing Deployments, and adopt all of their resources with new Deployments. See [Kubernetes Deployments](#) for more information.

- One Pod, started by default, may be scaled up post installation
- `cte-csi-node-XXXXX`
 - Kind: **Pod DaemonSet Type**

A DaemonSet defines Pods that provide node-local facilities. It ensures that all, or a subset of, nodes run a copy of a specified Pod. As nodes are added to the cluster, Pods are added to them. As nodes are removed from the cluster, those Pods are garbage collected. Deleting a DaemonSet will clean up the Pods it created. See [DaemonSet](#) for more information.

- One Pod for each Kubernetes node in the cluster

Options for Deploy Scripts for Pods

Deploy all of the pods by using the following command and needed arguments from the following table:

Short Option	Long Option	Description
-r	--remove	Remove all the running pods, services and secrets.
-t	--tag	Tag of the image on the server. Default is the latest.
-o	--operator	Deploy the CTE for Kubernetes Operator and CSI driver.
	--operator-ns=	The namespace in which to deploy the Operator.
	--cte-ns=	The namespace in which to deploy the CSI driver.
	--cri-sock=	Container Runtime Interface socket path.

For CTE for Kubernetes v1.3.0 and subsequent versions, the deployment script uses the repository image index as the image name, instead of the individual platform image names. The manifest (`cte_csi : <tag>`) points to an image.

Note

The **default** image name is: `cte_csi`. You do not need to specify the image name if you use the default name.

Terminating Pods

To terminate all of the pods and delete all of the services and secrets:

1. Change to the CTE for Kubernetes directory, type:

```
cd ciphertrust-transparent-encryption-kubernetes
```

2. For Operator deployment, type:

```
./deploy.sh --remove --operator-ns=my-ns1 --cte-ns=my-ns2
```

3. For Helm deployment, type:

```
./deploy.sh --remove --helm
```

Verify CTE for Kubernetes

Verify that CTE for Kubernetes is running, type:

```
kubect1 get pods --namespace=kube-system -o wide | grep cte-csi
```

RESPONSE

NAME	READY	STATUS	RESTART
S AGE IP Node			
kube-system cte-csi-controller-5db888d6cb-tn6lr	4/4	Running	0
6m59s 10.244.1.5 ubuntu20-02-kubcluster-worker	<none>	<none>	
kube-system cte-csi-node-lz7t9	4/4	Running	0
6m59s 10.244.0.26 ubuntu20-02-kubcluster-master	<none>	<none>	
kube-system cte-csi-node-pzvwb	4/4	Running	0
6m59s 10.244.2.2 ubuntu20-02-kubcluster-worker2	<none>	<none>	
kube-system cte-csi-node-wmhh1	4/4	Running	0
6m59s 10.244.1.4 ubuntu20-02-kubcluster-worker	<none>	<none>	

Deploying CTE for Kubernetes Storage Classes

For information on K8 storage classes, see [Storage Classes](#) for more information.

Note

All of the Kubernetes clients that you want to attach to a storage group must have the same Kubernetes Namespace and Kubernetes structureless pods.

To deploy a storage class for CTE for Kubernetes:

1. Create and save a registration token in CipherTrust Manager. See [Tokens](#) for more information.

Note

Select **Base64** format for the registration token, if using CipherTrust Manager v2.10 and subsequent versions.

2. Create a K8s Storage Group in CipherTrust Manager. See [Creating a K8s Storage Group](#) for more information.
3. If using CipherTrust Manager v2.9 or previous versions, encode the token in base64 format, type:

```
echo -n <CM REGISTRATION TOKEN STRING> | base64 -w 0
```

4. Copy the base64 encoding to create a Kubernetes secret YAML file, **cte-csi-cmtoken.yaml**:

```
apiVersion: v1
kind: Secret
metadata:
  name: <CHANGE to name of the K8s secret. For example: cm-reg-token>
type: Opaque
data:
  # This is a base64 encoded registration token. To generate:
  # echo <CM REGISTRATION TOKEN STRING> | base64 -w 0
  registration_token: bWlEaUJlZ08xNkNsbnRqZmc4a1dvcU1SUG9uaVpnNkVtUjVYSGFLUV
  ZVTHRhbGRrb0M5T1ZwTEpvTXp4UldmSQ==
```

5. The name of the K8s secret must be embedded in the `registration_token_secret` parameter in the storage class YAML file. Use the YAML file, **cte-storageclass.yaml** and fill in the appropriate values.

```
apiVersion: storage.k8s.io/v1
kind: StorageClass
metadata:
  name: <CHANGE to name of the Kubernetes Storage Class. For example: csi-test-sc>
provisioner: csi.cte.cpl.thalesgroup.com
reclaimPolicy: Delete
volumeBindingMode: Immediate
allowVolumeExpansion: true
parameters:

  # Domain name or IP address of the CipherTrust Manager (Required)
  key_manager_addr: <CHANGE_ME to your CM IP ADDR>

  # Name of the CipherTrust Manager K8s Storage Group. (Required)
  k8_storage_group: <CHANGE to the name of the Kubernetes Storage Group. For example: test-group>

  # Kubernetes Secret with CM registration token (Required)
  registration_token_secret: <CHANGE to the K8s secret. For example: cm-reg-token>

  # Time in minutes to wait before unregistering from the CipherTrust Manager
  # once all of the volumes have been unguarded. Parameter must be added as a string
```

```
# integer value. Default is 10 minutes. (Required)
registration_period: "10"
```

- Record the storage class name, for further use. Deploy by typing:

```
kubectl apply -f cte-csi-cmtoken.yaml
kubectl apply -f cte-storageclass.yaml
```

Registering to Multiple CipherTrust Manager Servers for failover in an HA Cluster

For a cluster for CipherTrust Manager servers, you can configure multiple IP addresses with `cte-storageclass.yaml` to allow for seamless failover to the next available CipherTrust Manager if a CipherTrust Manager server fails.

- CipherTrust Manager IP addresses must be comma separated. For example:

```
key_manager_addr: <CM_1_IP_ADDR>, <CM_2_IP_ADDR>, <CM_3_IP_ADDR>
```

- You can provide one CM IP address, or multiple CM IP addresses. Thales recommends using more than one IP address.

Note

When providing multiple IP addresses, the IP addresses **must** be part of same CipherTrust Manager cluster.

Using Dynamic PVCs with CTE for Kubernetes

Static provisioning for Persistent Volumes (PV) requires the administrator to make assumptions, in order to create PVs that applications may need. As your Kubernetes environment expands, this can become a bottleneck.

Dynamic provisioning solves this issue. Instead of the Kubernetes administrator creating specific PVs, the administrator defines Storage Classes. Each Storage Class has a specific storage pool from which PVs can be provisioned automatically to meet an application's requirements.

Kubernetes provides a variety of internal provisioners. With dynamic provisioning, a developer can use a PVC to request a specific storage type and have a new PV provisioned automatically. The PVC must request a StorageClass that has already been created and configured on the target cluster, by an administrator, for dynamic provisioning to work.

CTE for Kubernetes now allows you to deploy HELM charts that use a StorageClass as input for creating volumes. Helm Charts help you define, install, and upgrade Kubernetes applications, thereby helping you manage Kubernetes clusters.

Specifying a Storage Class on a HELM chart means that the cluster will select volumes from the pool of volumes for that storage class. If no volumes exist, but the CTE-CSI driver has the capabilities for automatic provisioning, a new volume will be created and added to the cluster. Traditional CTE for Kubernetes PVCs must be specified with a source PVC in the definition, which makes it incompatible with this type of deployment. By using HELM charts, this will allow CTE for Kubernetes volumes to pass enough information to a source Storage Class so that dynamic provisioning in a CTE for Kubernetes PVC can dynamically provision and attach a data source PVC based on the PVC specifications.

Specifically, with dynamic PVCs now being supported, it changes the creation method for PVs. The CTE-K8s StorageClass is created with the new parameters and the CTE-K8s PVC is created without sourcePVC annotations, (policy annotation is optional). After the controller checks for the existence of policy and sourcePVC parameters, if it doesn't find sourcePVC parameters, it creates a new unprotected PVC (source PVC) using parameters from the CTE-K8s PVC and CTE-K8s StorageClass. CTE-K8s then binds the unprotected PVC to a PV if any qualifying PVs are available on the cluster. If not, it requests for a new PV to be provisioned. Then the CTE-K8s PVC provisions the PVC as normal. After that, the Application Pod can use the CTE-K8s PVC claim.

CTE-K8s Storage Class definition

To support dynamic PVCs, three new parameters must be added to the CTE-K8s Storage Class definition:

- `source_storage_class`
- `default_policy`
- `allow_source_pvc_delete`

Example

Following is an example of an entire Persistent Volume Claim set with the new parameters:

```
apiVersion: storage.k8s.io/v1
kind: StorageClass
metadata:
  name: csi-test-sc
provisioner: csi.cte.cpl.thalesgroup.com
reclaimPolicy: Delete
volumeBindingMode: Immediate
allowVolumeExpansion: true
parameters:

  # Domain name or IP address of the CipherTrust Manager (Required)
  key_manager_addr: 192.168.70.1

  # Name of the CipherTrust Manager K8s Storage Group. (Required)
  k8_storage_group: test-group

  # Kubernetes Secret with CipherTrust Manager registration token (Required)
  registration_token_secret: cm-reg-token

  # Kubernetes secret with External CA signed client certificate (Optional)
  kubectrl create secret generic <secret-name> --from-file=<clientName>.crt=<client_cert.pem> --from-file=<clientName>.key=<client_key.pem> --from-file=<clientName>.passphrase=<passphrase>

  # Multiple client cert details can be added with same secret as well with abo
```

```

ve command
  external_ca_client_secret: <secret-name>

  # Small registration description to be displayed in the CipherTrust Manager
  (Optional)
  client_description: "Describe your K8s client"

  # Time in minutes to wait before unregistering from the CipherTrust Manager
  # once all volumes have been unguarded. Parameter must be added as a string
  # integer value. Default "10" minute. (Optional)
  registration_period: "10"

  # When specified, this parameter automatically adds the
  # csi.cte.cpl.thalesgroup.com/source_pvc parameter to the CTE-K8s PVC based
  # on the requested parameters (Optional)
  source_storage_class: some_sc_name

  # When specified, this parameter automatically adds the
  # csi.cte.cpl.thalesgroup.com/policy parameter to the CTE-K8s PVC based on
  # the requested parameters. (Optional) (Required if source_storage_class is s
  et)
  default_policy: <default_policy_name>

  # When specified and set to "true", this parameter automatically deletes the
  dynamic sourcePVC,
  # and possibly, the actual data volume, depending on the provisioner driver i
  mplementation.
  # If set to "false," you must manually delete the created source PVC. (Option
  al)
  allow_source_pvc_delete: "false"

```

New Persistent Volume Claim Usage

The added support for dynamic PVCs changes some of the rules for PVCs:

- The `source_pvc` and `policy` annotations in CTE-PVC are now optional if you use the new Storage Class parameters
- If you configured the `policy` annotation in the CTE-PVC, then CTE-K8s uses this policy regardless if `default_policy` is specified or not.
- If the `policy` annotation is not configured in the CTE-PVC, then CTE-K8s uses the `default_policy` from CTE-StorageClass.
- If both policy annotations are missing, then the deployment fails.
- If the `source_pvc` is configured in the CTE-PVC, then this source PVC is used, regardless of the `source_storage_class` parameter specified.
- If the `source_pvc` is not configured in the CTE-PVC, then CTE-K8s uses the `source_storage_class` parameter specified in CTE-StorageClass to provision dynamically. The `cte-csi` driver creates a source PVC (i.e. `cte-claim-unprotected-cprfnzjxjg3gpyabrqh5d`) using `source_storage_class` and the storage size parameter in the CTE-PVC request.

Example: Persistent Volume Claim

Using these new parameters, you could configure CTE for Kubernetes as follows:

```
apiVersion: v1
kind: PersistentVolumeClaim
metadata:
  name: cte-claim1
  annotations:
    csi.cte.cpl.thalesgroup.com/policy: policy_1
    csi.cte.cpl.thalesgroup.com/source_pvc: nfs-test-claim
spec:
  storageClassName: csi-test-sc
  accessModes:
    - ReadWriteMany
resources:
  requests:
    storage: 1Gi No longer ignored by the driver
```

Applying the CTE-PVC

To apply the CTE-PVC manifest, type:

```
kubectl apply -f cte-csi-claim.yaml
```

Based on the CTE Storage Class `volumeBindingMode` and the underlying source Storage Class `volumeBindingMode`, a new volume is provisioned at the time of the CTE-PVC deployment or App Pod deployment.

PVC status Example:

NAME	STATUS	VOL
UME	STORAGECLASS	
VOLUMEATTRIBUTESCLASS	AGE	
persistentvolumeclaim/cte-claim-restore		Boun
d pvc-b168e8d9-e26b-4515-aab2-91dc241ce74a	2Gi	RWX
t-sc <unset>	13m	cte-tes
persistentvolumeclaim/cte-claim-restore-unprotected-cprfnzjxjxg3gpyabrqh5d		Boun
d pvc-4183880c-6480-43e8-9564-b9f06fe557bf	2Gi	RWX
i-imm <unset>	13m	nfs-cs

- **CTE-PVC**: `cte-claim-restore`
- **Source PVC**: `cte-claim-restore-unprotected-<UID>`

CTE-CSI protected Persistent Storage Claim

Creating a CTE-CSI protected Persistent Storage Claim by deploying an application pod:

```
apiVersion: v1
```

```

kind: Pod
metadata:
  name: cte-csi-demo
spec:
  volumes:
    - name: test-vol
      persistentVolumeClaim:
        claimName: cte-claim1
  containers:
    - name: ubuntu
      image: ubuntu
      volumeMounts:
        - mountPath: "/data"
          name: test-vol
      command:
        - "sleep"
        - "604800"
      imagePullPolicy: IfNotPresent
      restartPolicy: Always

```

External Provisioner support with CTE-K8s for dynamically provision volume

If your driver is not capable of dynamically provisioning the persistent volume for a storage type, you can use an external provisioner for that specific storage type to create the volume dynamically and deploy with CTE for Kubernetes. Following are some external provisioners which provision data volumes dynamically for a storage class. You can use this storage class as the source StorageClass in cte-storageclass.yaml parameter (source_storage_class).

- [NFS Subdirectory External Provisioner](#)
- [NFS CSI driver for Kubernetes](#)
- [AWS-EFS CSI dynamic provisioning](#)
- [Drivers list for different type of storage that may be used for Dynamic Volume Provisioning](#)

After deploying a cte-claim1.yaml, the data persistent volume is created dynamically.

Creating a CTE for Kubernetes Claim Against the PVC

Note

For the next step, you must have your PV and PVC already deployed.

1. Create the following YAML file:

cte-csi-claim.yaml

```

apiVersion: v1
kind: PersistentVolumeClaim
metadata:
  name: cte-claim
  annotations:
    # The following must match your CTE Kubernetes Policy name.
    csi.cte.cpl.thalesgroup.com/policy: policy_1
    # NFS source persistent volume claim
    csi.cte.cpl.thalesgroup.com/source_pvc: nfs-test-claim
spec:
  storageClassName: <CHANGE to the storageclass name that you deployed. For
example: e.g. csi-test-sc>
  accessModes:
    - ReadWriteMany
resources:
  requests:
    storage: 1Ki

```

2. To deploy the `cte-csi-claim.yaml` script, type:

```
kubectl apply -f cte-csi-claim.yaml
```

Note

- AccessMode of CTE-PVC **must** be the same as the sourcePVC accessMode.
- Multiple CTE-PVC **cannot** use same sourcePVC (`csi.cte.cpl.thalesgroup.com/source_pvc: nfs-test-claim`) at the same time.

Individual Guard Policy Tuning

Note

In the code commands and responses, the term GuardPoint means Guard Policy.

Configuration

There are two scenarios for CTE for Kubernetes Guard Policy configuration tuning.

On the Guard

This is for creating a Guard Policy with the required configuration settings, other than the default values. Guard Policy creation occurs when you deploy an application pod using a CTE-PVC. Each CTE-PVC deployment results in the creation of a unique Guard Policy.

Note

- If the same CTE-PVC is used by multiple application pods deployed on the same node, then the pod will contain a single Guard Policy.
- If the same CTE-PVC is used by multiple application pods deployed on different nodes, then on each node there will be a unique Guard Policy and the same tuning configuration changes will be set on those Policies.

On the Run

Configuration settings while Guard Policy is active. Guard Policy active means application pod is already running with CTE-PVC and user want to configure a Guard Policy. Only debug log level configuration is supported on the run for now.

Tunable Parameters

Configurable Parameter	Default Value	Description	Status	On the Guard Tuning Support	On the Run Tuning Support
debug_all	4	Sets the sensitivity of the logs, can be adjusted later using `secfsd -log_level [4-8]	Change as needed	yes	yes
debug_extra	0	Debug level	Change as needed	yes	no
enable_xattr	0	Enables use of xattrs in the file system, default is off for best performance	Set to 1 if performing a restore from CTE with xattrs. Set to 0 for normal use.	yes	no
fileinfo_cache_timeout	100	Amount of milliseconds to keep file attribute data in cache	Change as needed	yes	no
loginuid	1	Enforce loginuid. Without this set,	Change as needed	yes	no

Configurable Parameter	Default Value	Description	Status	On the Guard Tuning Support	On the Run Tuning Support
		su can bypass security			
max_worker_threads	10	Maximum parallel threads allowed	Change as needed	yes	no
mixed_policy	1	If mixed modes needed (ex: apply key on read, no apply key on write), set this value; it causes an extra access check	Change as needed	yes	no
nfs_user	0	UID of specific NFS user to use	Change as needed	yes	no
parallel_writes	1	Allows non-overlapping writes to run in parallel	Change as needed	yes	no
splice	0	Allows use of splice call from FUSE	Change as needed	yes	no
writeback_cache_local	1	Uses writeback cache for local file systems (extx, xfs, btrfs)	Change as needed	yes	no
writeback_cache_nfs	0	Uses writeback cache for NFS	Change as needed	yes	no

Preparing CTE for Kubernetes deployment files

Creating a ConfigMap with tuning parameters

- ConfigMap **must** be in the same namespace as the CTE-PVC namespace.
- **On the Guard** ConfigMap settings require the prefix `guard` with the tuning parameter name. You can use multiple tuning parameters at same time to configure a Guard Policy.
- **On the Run** ConfigMap settings require the prefix `run` with the tuning parameter name.
- Create a ConfigMap with tuning parameters and key-value pairs.
- Following is a ConfigMap example:

gp-tuning-config-map.yaml

```

apiVersion: v1
kind: ConfigMap
  metadata:
    name: cte-claim-gp-tuning-cm
    #namespace: <ns1>           # If CTE-PVC will be deployed in ns1 namespace

  data:
    #guard.<config-parameter-name>: "<config-value>"           # On the Guard tuning example
    #run.<config-parameter-name>: "<config-value>"           # On the Run tuning example (This field can be added/updated on the Run)
    guard.debug_all: "8"
    guard.max_worker_threads: "20"
    guard.writeback_cache_nfs: "1"
    #run.debug_all: "8"

```

Where

- `<config-parameter-name>`: Supported tuning parameter name (See above table)
- `<config-value>`: value corresponding to the parameter. Make sure values are in double quotation marks ("").
- Apply the ConfigMap, type:

```
kubectl apply -f gp-tuning-config-map.yaml
```

Creating a CTE-PVC with tuning enabled for "On the Guard"

New annotation will require for this feature:

- `csi.cte.cpl.thalesgroup.com/guardpoint_tuning_configmap: <tuning-config-map-name>`
- `<tuning-config-map-name>`: ConfigMap name which contains the tuning parameters. For example, `cte-claim-gp-tuning-cm`.

cte-csi-claim.yaml

```

apiVersion: v1
kind: PersistentVolumeClaim
  metadata:
    name: cte-claim
    annotations:
      # GuardPolicy from CipherTrust Manager

```

```

csi.cte.cpl.thalesgroup.com/policy: policy_1
#(Following is not required if using dynamic provisioning)
csi.cte.cpl.thalesgroup.com/source_pvc: nfs-test-claim
csi.cte.cpl.thalesgroup.com/guardpoint_tuning_configmap: <tuning-config-m
ap-name>

spec:
  storageClassName: <CHANGE ME to the storageclass name deployed e.g. csi-test-s
c>
  accessModes:
    - ReadWriteMany
  resources:
    requests:
      storage: 1Ki

```

1. Apply the CTE PVC, type:

```
kubectl apply -f cte-csi-claim.yaml
```

Now you can use the CTE PVC with an application pod. All of the configuration changes take affect once the Guard Policy is created when the application pod deploys.

2. Validate the applied changes with the corresponding `cte-csi-node-xxxxx` pod log (with the `cte-csi` driver logLevel 5):

```
kubectl logs --namespace=kube-system cte-csi-node-xxxxx cte-csi
```

Example Response

```

[I0626 10:17:28.160501 3725529 guardpoint.go:1634] Guard Policy tuning is enab
led for cte-pvc[cte-claim] namespace[default] policy[policy_1] path[/tmp 2e1df
83a-33a5-11ef-823e-3e833176f6ce]
[I0626 10:17:28.166396 3725529 chroot.go:108] Executing /usr/bin/voradmin secf

```

Using "On the Run" tuning

Use the existing ConfigMap, or a new ConfigMap, with the data field `run.<config-parameter-name>:<config-value>`:

1. After adding/updating the parameter, apply the ConfigMap, type:

```
kubectl apply -f <gp-tuning-config-map.yaml>
```

Where

<gp-tuning-config-map.yaml>: ConfigMap yaml file which contains the tuning parameter

2. Add the annotation to the CTE PVC using the `kubectl annotate` command, type:

```
kubectl annotate pvc <cte-pvc-name> csi.cte.cpl.thalesgroup.com/guardpoint_tuning_configmap='<tuning-config-map-name>'
```

Where

- <cte-pvc-name>: CTE-PVC name, for example, `cte-claim`
- <tuning-config-map-name>: ConfigMap name which contains the tuning parameters. For example, `cte-claim-gp-tuning-cm`

After applying the annotation, the applied configuration takes effect within a minute.

3. Validate applied changes with the corresponding `cte-csi-node-xxxxx` pod log, type:

```
kubectl logs --namespace=kube-system cte-csi-node-xxxxx cte-csi
```

Example Response

```
[I0626 10:33:26.887047 3725529 guardpoint.go:1745] Runtime GuardPoint tuning is enabled. ConfigMap[cte-claim-gp-tuning] in CTE-PVC[cte-claim1] namespace[default] annotation for volumeID[2e1df83a-33a5-11ef-823e-3e833176f6ce] guardPolicy[pvc-clone-policy1] path[/tmp/2e1df83a-33a5-11ef-823e-3e833176f6ce] for regID[e51ad1bb-3809-46b2-8497-40aec3d9eee1]

```

Create a CTE-CSI protected Persistent Storage Claim by deploying an Application/Staging pod

To create a CTE-CSI protected Persistent Storage Claim by deploying an application pod:

1. Create the yaml file to deploy a pod and protect the contents of the Persistent Volume.

```

apiVersion: v1
kind: Pod
metadata:
  name: cte-csi-pod
spec:
  volumes:
    - name: test-vol
      persistentVolumeClaim:
        claimName: cte-test-claim1
  containers:
    - name: ubuntu
      image: ubuntu
      volumeMounts:
        - mountPath: "/data"
          name: test-vol
      command:
        - "sleep"
        - "604800"
      imagePullPolicy: IfNotPresent
      restartPolicy: Always

```

2. Deploy the pod, type:

```
kubectl apply -f cte-csi-pod.yaml
```

After the pod is successfully deployed and it running, you can see the client registered in K8s client.

The screenshot shows the 'K8s Clients' dashboard. At the top, there are four status bars: '2 Total Clients' (blue), '2 Errors' (red), '1 Messages' (yellow), and '1 Healthy' (green). Below these is a search bar and a table with 2 results. The table has columns for Status, Client Name, Agent Version, and Description. Both clients are in a 'Healthy' status.

Status	Client Name	Agent Version	Description
Healthy	writer-k8s-client-464836173	1.5.0.31	first writer policy client
Healthy	writer-k8s-client-464836173	1.5.0.31	Container Image Tigger service

At the bottom right, it says '2 K8s Clients' and '10 per page'.

3. To check the status of the pod, type:

```
kubectl get all
```

Response

NAME	READY	STATUS	RESTARTS
AGE			
pod/cte-csi-pod	1/1	Running	0
116m			
pod/cte-csi-user-pod	1/1	Running	0
134m			
pod/cte-staging-pod9jhtn	1/1	Running	0
133m			
pod/cte-staging-podt8jxs	1/1	Running	0
116m			

NAME	TYPE	CLUSTER-IP	EXTERNAL-IP
P	PORT(S)	AGE	
service/kubernetes	ClusterIP	10.96.0.1	<none>
443/TCP	224d		

After the pod is successfully deployed and running, you can see the clients registered in the Kubernetes client.

4. Login to the pod and check if the files are encrypted:

```
kubectl exec -it cte-csi-pod /bin/bash
```

Response

```
kubectl exec [POD] -- [COMMAND]
root@cte-csi-pod:/ cd /data/
root@cte-csi-pod:/data mkdir sub_dir
root@cte-csi-pod:/data cd sub_dir/
root@cte-csi-pod:/data/sub_dir echo "testfile" >> test
root@cte-csi-pod:/data/sub_dir
root@cte-csi-pod:/data/sub_dir cat test
testfile
```

5. Check the same file on the Server side:

```
root@aws-thales-dockerregistry:~ cd /nfs-share/sub_dir/
root@aws-thales-dockerregistry:/nfs-share/sub_dir ls -l
total 8
-rw-r--r-- 1 root root 4102 Dec 13 20:04 test
root@aws-thales-dockerregistry:/nfs-share/sub_dir cat test
```

```
EROV=====bu4廟41kCroot@aws-thales-dockerregistry:/nfs-share/sub_dir#
```

Using Taints and Tolerations

Note

Using Taints and Tolerations is **optional**.

You can apply Taints and Tolerations to the CTE for Kubernetes application pod that you are running. You can also create your staging pod with toleration.

Taints allow a node to repel a set of pods. **Tolerations** are applied to pods. Tolerations allow the scheduler to schedule pods with matching taints as long as it's allowed by the other associated parameters.

Taints and Tolerations work together to ensure that pods are not scheduled onto inappropriate nodes. Once one or more taints are applied to a node, the node should not accept any pods that do not tolerate the taints.

For more information, see [Kubernetes Taints and Tolerations](#).

Using Taints and Tolerations with CTE for Kubernetes

CTE for Kubernetes now supports nodes with taints. You can specify a toleration in a `pod_spec` for the staging pod of a CTE for Kubernetes volume. To do this, CTE for Kubernetes added annotation support to a CTE for Kubernetes PVC. This annotation uses a base64 encoded string for input. Kubernetes requires the pod to pass the info to the cluster as a single base64 encoded string. The only way to create this is to manually encode the yaml file that contains the Taints and Tolerations. CTE for Kubernetes takes the yaml file and extracts any toleration definitions contained in it and appends them to the staging pod when that PVC is mounted anywhere in the cluster. Any values in the YAML file that are not related to toleration are ignored.

Note

To apply Taints and Tolerations to a pod, you **must** first shut down the pod. Additionally, support for toleration **must** be added at PVC creation time. Modifying an existing PVC with the added toleration is **not** supported because the CTE PVC was not created with the required immutable volume attributes.

Applying Taints and Tolerations

1. Create and add the taint to a node, type:

```
kubectl taint nodes <nodeName> <keyName>=<valueName>:<taintEffect>
```

Example:

```
kubectl taint nodes node1 key1=value1:NoExecute
```

2. Create a tolerations yaml file. The tolerations must match the taint created in the previous step. The file should look similar to the following:

```
cat <cte_tolerations>.yaml
```

Response:

```
spec:
  tolerations:
  - key: "key1"
    operator: "Equal"
    value: "value1"
    effect: "NoExecute"
```

Note

The taint effect **NoSchedule** does not work with Taints and Tolerations for CTE for Kubernetes.

3. Write the tolerations yaml file to a text file while generating the base64 encoding and appending the file with the string, type:

```
cat <cte_tolerations>.yaml | base64 -w0
```

Response:

```
c3BlYzoKICB0b2x1cmF0aW9uczoKICAtIGtleTogImtleTEiCiAgICBvcGVyYXRvcjogIkVxdWFsIgogICAgdmFsdWU6ICJ2YWx1ZTEiCiAgICBlZmZlY3Q6ICJob0V4ZW51dGUicG==
```

4. Once the base64 string is generated, the PVC is generated. Append the value to the PVC. For example:

```
cat <cte_pvc_fileName>.yaml
```

Response:

```
apiVersion: v1
kind: PersistentVolumeClaim
metadata:
```

```

name: cte-csi-claim
annotations:
  csi.cte.cpl.thalesgroup.com/policy: <policyName>
  csi.cte.cpl.thalesgroup.com/source_pvc: <pvcName>-claim
  csi.cte.cpl.thalesgroup.com/spec_append: c3BlYzoKICB0b2xlcmlF0aW9uczoKI
CAAtIGtltTogImtltTEiCiAgICBvcGVyYXRvcjogIkVxdWFsIgogICAgdmFsdWU6ICJ2YWx1ZTEiCiA
gICBlZmZlY3Q6ICJob0V4ZWV1dGUlCg==
spec:
  storageClassName: <storageClassName>
  accessModes:
    - ReadWriteMany
resources:
  requests:
    storage: 10Gi

```

For more information, see the [Command line tool \(kubectl\)](#).

CTE Staging Container Resource Settings

This feature allows you to configure container resource settings for the CTE staging pod. This is useful if, for example, a default policy for resource settings is enabled for the container, but is not configured with CPU and memory resource limits, because this could cause the staging pod to terminate.

To configure:

1. Create a yaml file which contains the container resources:
 - a. Print the contents of the CTE tolerations file, type:

```
cat <cte_tolerations>.yaml
```

Response:

```

spec:
  containers:
    - name: <container-name>
      resources:
        limits:
          cpu: "500m"
          memory: "200Mi"
        requests:
          cpu: "500m"
          memory: "100Mi"

```

2. Generate the base64 encoded string, type:

```
cat <cte_tolerations>.yaml | base64 -w0
```

Response

```
c3BlYzoKwqAgY29udGFpbmVyczoKwqAgLSzOgrCoCDCoCDCoCBjcHU6ICI1MDBtIgrCoCDCoCD
CoCDCoCBtZW1.....sKgIMKgIMKgIMKgIG1lbW9yeTogIjEwME1pIgo=
```

3. Append the PVC parameter `csi.cte.cpl.thalesgroup.com/spec_append` with the base64 string, type:

```
cat <cte_pvc_fileName>.yaml
```

Response:

```
apiVersion: v1
kind: PersistentVolumeClaim
metadata:
  name: cte-csi-claim
  annotations:
    csi.cte.cpl.thalesgroup.com/policy: <policyName>
    csi.cte.cpl.thalesgroup.com/source_pvc: <source-PVC-Claim>
    csi.cte.cpl.thalesgroup.com/spec_append: c3BlYzoKwqAgY29udGFpbmVyczoKw
qAgLSzOgrCoCDCoCDCoCBjcHU6ICI1MDBtIgrCoCDCoCDCoCBtZW1.....sKgIMKg
IMKgIMKgIG1lbW9yeTogIjEwME1pIgo=
spec:
  storageClassName: <CTE-storageClassName>
  accessModes:
    - ReadWriteMany
resources:
  requests:
    storage: 10Gi
```

Note

You can use all of the supported spec append members with `csi.cte.cpl.thalesgroup.com/spec_append`. That means that you can enable/apply multiple features (toleration, container resource settings, or both features simultaneously).

For example, using both tolerations and container resource settings:

- `cat csi.cte.cpl.thalesgroup.com/spec_append`

Response:

```
spec:
  tolerations:
  - key: "testkey1"
    operator: "Equal"
    value: "testvalue1"
    effect: "NoExecute"
  containers:
  - name: ubuntu1
    resources:
      limits:
        cpu: "500m"
        memory: "200Mi"
      requests:
        cpu: "250m"
        memory: "100Mi"
```

Allow only Trusted Pods to mount to CTE for Kubernetes volumes

CTE for Kubernetes allows only trusted pods to access protected data volumes and attach to CTE for Kubernetes claims if you activate this optional feature. CTE for Kubernetes uses signature sets to validate the pod as trusted. Signatures are in the form of key-value pairs which contain the image name and the corresponding hash value. After mapping the image signature with the received signature set, CTE for Kubernetes will allow, or prevent, mounting of the the encrypted volume.

Overview of CTE for Kubernetes for Support for Trusted Pods

Support for Trusted Pods is disabled by default. At least one signature set, with a container image digest, must be attached to a security policy to enable this feature. When the request to mount/publish the volume is received:

1. CTE for Kubernetes determines whether Support for Trusted Pods is enabled or not by scanning for the presence of signature rules.
2. Support for Trusted Pods is skipped (default case) if the security policy does not include container signature sets.
3. CTE for Kubernetes fetches the digests for all containers in the running pod.
4. CTE for Kubernetes tries to match the digests of running pods to a container image signature set. Support for Trusted Pods is considered successful only if all digests within a running pod have an entry in same signature set.
5. CTE for Kubernetes checks the logs to determine if it succeeded. If no signature rules exist, the Support for Trusted Pods is disabled.

Note

Updating the signature set in the policy may lead to a small delay for CipherTrust Manager to push the signature back to the client. A Kubernetes timeout retry could also add a small delay.

- A new container named `cte-csi-signer` is added to a controller pod. It will monitor CTE for Kubernetes storage classes for the following operations: `creation`, `deletion` and `updating`. It manages automatic registration as a signer service to CipherTrust Manager.

Workflow for obtaining a Signature Set on CipherTrust Manager and adding it to a Policy

- After [signing the container image](#) for a specific storage class and namespace, it should display in CipherTrust Manager in the Kubernetes client.

- Add a container image source and select a client for signing in the Signature Set page.

3. Selecting a client for signing.

4. Displays a message after a successful signing operation.

Creating a Signature Set on CipherTrust Manager and adding it to the Policy

Create the signature set in CipherTrust Manager:

1. See [Creating Signature Sets for Container Images](#). Follow those instructions for creating your Signature Set.
2. Add the following as a signature rule in the Kubernetes policy to enable Trusted Pod enforcement:
 - Signature set, which contains all of the signatures for all of the containers to which you want to have access

Note

Unlike normal CipherTrust Manager signature sets, CTE for Kubernetes signature sets **do not** attach to process sets.

Data Transformation

- Using Initial Data Transformation for CTE for Kubernetes
- Applying Data Transformation Rotation for CTE for Kubernetes
- Decryption using Data Transformation with CTE for Kubernetes

Using Initial Data Transformation for CTE for Kubernetes

The Data Transformation utility is an application that encrypts data-in-place in a GuardPoint. To perform dataxform for CTE for Kubernetes, two additional steps are required:

1. An Data Transformation GuardPolicy, along with a CTE for Kubernetes production policy, must be added to the CTE for Kubernetes storage group on CipherTrust Manager.
2. You must add an Data Transformation policy name in the CTE for Kubernetes claim against the PVC. The name of the claim is `cte-csi-claim.yaml`.

For the standard Data Transformation steps, see [Data Transformation](#) for more information.

Prerequisites

- Verify that you have valid backup files of the data to be encrypted.

Note

You will need to stop **ALL** access and services to the data being encrypted during part of this procedure. Access will **NOT** be restored until the encryption process is complete. Make sure that you plan for this outage and that users know the data will be inaccessible for some time.

Create a Storage Group

Prior to the deployment of any `yaml` files for registration, you must create a [CTE for Kubernetes Storage Group](#).

Create Policies

In CipherTrust Manager, you must create policies before you can transform the data. See [Creating Policies](#) for more information.

1. Create an **Data Transformation policy** with **Policy Type**: CTE for Kubernetes.
2. Toggle the **Data Transformation** button to **on**. This policy is only for encrypting the clear text data in persistent volumes where the policy is applied.

Create Policy ✕

1 General Info 2 Security Rules 3 Key Rules 4 Data Transformation 5 Confirmation

Review the provided policy details.

1 General Info
 Name: dataxform-policy
 Policy Type: CTE for Kubernetes
 Description:

2 Security Rules

Resource Set	User Set	Process Set	Action	Effect
*			key_op	permit,applykey

3 Key Rules

Resource Set	Current Key Name
	clear_key

4 Data Transformation Rules

Resource Set	Transformation Key Name
	key?

[Back](#) [Save](#)

3. Create a **CTE for Kubernetes Production** policy with **Policy Type**: CTE for Kubernetes.
4. Make sure that the Data Transformation toggle is set to **off**.
5. For the key rule, you must use the **same key** as in the Data Transformation policy.

Create Policy ✕

1 General Info 2 Security Rules 3 Key Rules 4 Confirmation

Review the provided policy details.

1 General Info
 Name: csi-prod-policy
 Policy Type: CTE for Kubernetes
 Description:

2 Security Rules

Resource Set	User Set	Process Set	Action	Effect
*			el_ops	permit,audit,applykey

3 Key Rules

Resource Set	Key Name
	key?

[Back](#) [Save](#)

Apply GuardPolicies

- Add both policies, that you just created in the previous section, to the K8s Storage Group.

Adding an Annotation for Data Transformation to a claim

- Add an annotation for the Data Transformation policy to your `yaml` claim file. For example:

cte-csi-claim.yaml

```
apiVersion: v1
kind: PersistentVolumeClaim
metadata:
  name: cte-claim
  annotations:
    csi.cte.cpl.thalesgroup.com/dataxform_policy: <dataxformPolicyName>
    csi.cte.cpl.thalesgroup.com/policy: production-policy //This must match
    your CTE CSI Policy name.
    csi.cte.cpl.thalesgroup.com/source_pvc: nfs-test-claim // nfs source persistent
    volume claim
spec:
  storageClassName: <CHANGE to the storageclass name that you deployed. For example:
  e.g. csi-test-sc>
  accessModes:
    - ReadWriteMany
resources:
  requests:
    storage: 1Ki
```

Note

- The Data Transformation will start as soon as the protected pod is deployed using the above cte-claim. Check that the logs are updated or described in the Application Pod. You can check the status of Dataxform by describing the CTE-PVC with the following annotation:

```
csi.cte.cpl.thalesgroup.com/dataxform_status: <dxfs-status>
```

Where

```
<dxfs-status>: [running-<WorkerNodeName> | completed | invalidPolicy | failed]
```

Warning

- Do not delete the protected pod while Data Transformation is in progress.
- The `dataxform_auto_lock` file is created in the Guard Policy path. Do not edit/delete this file.

Applying Data Transformation Key Rotation to CTE for Kubernetes

Data encryption keys are the keys used to encrypt data in a Guard Policy. Key rotation is the process of changing the encryption key used to encrypt your Guard Policy data. Key Rotation is also called Rekeying. Changing Guard Policy encryption keys increases security. Rekeying with Data Transformation requires that you change the current key of the production policy on your Guard Policy to a new key.

Warning

All users and applications will be blocked from accessing the data until Data Transformation is finished executing. Make sure that you plan for this outage and that users know the data will be inaccessible for some time.

Performing a Key Rotation

Delete Pods and PVC

1. Delete all of the application pods which are using `cte-claim`:

```
kubect1 delete -f <applicationPodName>.yaml
```

Note

Users can also use the CTE PVC (`# kubect1 describe pvc <CTE-PVC>`) to find the list of all of the pods that are using a specific CTE PVC.

2. Delete the CTE PVC:

```
kubect1 delete -f cte-csi-claim.yaml
```

Create New Polices and Keys

Create a new Data Transformation and a new production **Policy**, with required **Key** rules on CipherTrust Manager.

Alternatively, (recommended), clone the original policies, (Data Transformation and Production policy) that you used to encrypt the data.

- If creating new policies, make sure to set **Policy Type: CTE for Kubernetes**.
- Toggle the Data Transformation button to **on** while creating the Data Transformation policy.
- Toggle the Data Transformation button to **off** while creating the production policy.

Updating Key Rules

Update the key rules, for both policies, by editing the Key Rule, and the Data Transformation Rule, and changing the Current Key Name and Transformation Key Name to reflect the new key to use.

For Example:

If the Guard Policy data is encrypted with Key1, and you want to rotate the key from Key1 to Key2:

Data Transformation clone/new policy key rule update:

```
Key Rules (Current Key Name): key1
Data Transformation Rules(Transformation Key Name): key2
```

Production clone/new policy key rule update:

```
Key Rules(Key Name): key2
```

Applying the New/Cloned Policies

1. Add the newly created/cloned policies to CipherTrust Manager K8s Storage Groups. See [Configuration Concepts](#) for more information about creating CTE for Kubernetes storage groups in CipherTrust Manager.
2. Update the data transformation and production policy names in the CTE claim yaml file (`cte-csi-claim.yaml`) with the following annotations.

```
csi.cte.cpl.thalesgroup.com/datatransform_policy: <NewDatatransformPolicy> // new
ly created datatransform policy
csi.cte.cpl.thalesgroup.com/policy: <NewProductionPolicy> // newl
y created production policy
```

Example

```
apiVersion: v1
```

```

kind: PersistentVolumeClaim
metadata:
  name: cte-claim
  annotations:
    csi.cte.cpl.thalesgroup.com/dataxform_policy: dataxform-key1-to-key2-rotation-policy // newly created dataxform standard policy
    csi.cte.cpl.thalesgroup.com/policy: csi-prod-with-key2-policy // newly created production policy
    csi.cte.cpl.thalesgroup.com/source_pvc: nfs-test-claim // nfs source persistent volume claim spec:
    storageClassName: <CHANGE ME to the storageclass name deployed e.g. csi-test-sc>
  accessModes:
    - ReadWriteMany
  resources:
    requests:
      storage: 1Ki

```

3. Deploy the CTE claim file `cte-csi-claim.yaml`:

```
kubectl apply -f cte-csi-claim.yaml
```

4. Add the `dataxform_cleanup` annotation to the NFS source PV from `nfs-pv.yaml`. See [Create a Persistent Storage \(PV\) YAML file description](#) for more information.

```
kubectl annotate pv <SOURCE_PV_NAME> csi.cte.cpl.thalesgroup.com/dataxform_cleanup='require'
```

****<SOURCE_PV_NAME>**: PersistentVolume name from `nfs-pv.yaml` file**

5. Deploy the Application Pod which uses the `cte-claim`.

```
kubectl apply -f <applicationPodName>.yaml
```

Note

- When Data Transformation is running, the Guard Policy does not display as active on CipherTrust Manager, because it does not send any Guard Policy details to CipherTrust Manager. Only after the production policy is applied to the Guard Policy do the details populate CipherTrust Manager.
- The Data Transformation will start rekeying as soon as the protected pod is deployed. Check that the

logs are updated or described in the Application Pod.

Warning

- Do not delete the protected pod while Data Transformation is in progress.
- The `dataxform_auto_lock` file is created in the Guard Policy path. Do not edit/delete this file.

Decryption using Data transformation with CTE for Kubernetes

Guard Policy data can be unencrypted using Data Transformation.

The steps are same as with the section [Applying Data Transformation Rotation for CTE for Kubernetes](#), except for policy creation which requires specific key rules for decryption.

Create policies for decryption with required keys on CipherTrust Manager

1. Create new policies (Data Transformation standard policy and Production policy) with required key rules.
 - Alternatively, clone the original policies that you used to encrypt the data.
2. Update the key rules for both of the policies by editing the Key Rule, and the Data Transformation Rule, and changing the Current Key Name and Transformation Key Name to `clear_key`.

For Example:

If Guard Policy data is encrypted with Key2:

Data Transformation clone/new policy key rule update:

```
Key Rules (Current Key Name): Key2
Data Transformation Rules(Transformation Key Name): Clear_key
```

Production clone/new policy key rule update:

```
Key Rules(Key Name): Clear_key
```

3. Save and apply the policies.

Volume Management

- Volume Cloning Support
- Volume Snapshot and Restoring
- Volume Resizing and Expansion

Volume Cloning Support

A clone is an exact duplicate of an existing Kubernetes Volume. It can be consumed as any standard Volume would be consumed. A Volume clone allows for specifying existing PVCs in the `dataSource` field of the `.yaml` file to indicate that you want to clone a volume.

Considerations

- Cloning support is only available with dynamic volume provisioning. Cloning cannot occur on static/manual volumes.

Make sure that the storage provisioning driver that you use supports dynamic volume provisioning and volume cloning support. Check the storage driver list and respective storage driver documentation ([CSI Drivers doc](#)) to ensure support.

- You can only clone a PVC when it exists in the same namespace as the destination PVC.
- Newly created PVCs are independent objects. They can be consumed, cloned, snapshot, or deleted independently and without consideration for the original source PVC. This means that the source is not linked to the newly-created clone so it can be modified or deleted without affecting the original clone.
- The source CTE-PVC must be bound and available.

Note

Do not create a clone of a CTE-PVC if a Pod is using it. This may cause data corruption because the PVC is not quiesced. If the source CTE-PVC is in use, then you must take down all of the pods before creating the clone. This will cause some downtime.

Cloning an existing CTE-PVC

Prerequisites

- The source CTE-PVC that you want to clone contains encrypted data and is bound and available on a system using dynamic provisioning.

Provisioning a Storage Class

In the following example:

- It uses a supported NFS-CSI driver
- The application pod is running with the CTE-PVC (cte-claim)
- The claim is using the CTE-StorageClass (cte-test-sc) and is bound and available
- `cte-test-sc` is using `nfs-csi-sc-imm` (`nfs.csi.k8s.io`) source storageClass for NFS

cte-csi-storageClass.yaml (CTE-SC)

```
apiVersion: storage.k8s.io/v1
kind: StorageClass
metadata:
  name: cte-test-sc
provisioner: csi.cte.cpl.thalesgroup.com
reclaimPolicy: Delete
volumeBindingMode: Immediate
allowVolumeExpansion: true
allow_source_delete: false
parameters:
  # Domain name or IP address of the CipherTrust Manager (Required)
  key_manager_addr: 192.168.70.1

  # Name of the CipherTrust Manager K8s Storage Group (Required)
  k8_storage_group: k8s-group1

  # Kubernetes Secret with CM registration token (Required)
  registration_token_secret: cm-reg-token

  # To provision a volume dynamically, add the underlying source storageClass.
  # CTE-K8s driver creates source_pvc dynamically on this source storageClass.
  # A new volume will be provisioned by the respective underlying provisioner.
  # (Optional) (Required only for Dynamic PVC)
  # Taking an nfs provisioner driver (nfs.csi.k8s.io) example: nfs-csi-sc-imm
  source_storage_class: <underlying_source_sc_name>

  # When specified and set to "true", this parameter is used to automatically
  # delete the dynamically provisioned sourcePVC. This might delete the actual
  # data volume, depending
  # on the underlying provisioner driver implementation. Default is set as "false". (Optional)
  allow_source_pvc_delete: "false"

  # When specified, this parameter is used to automatically add the
  # csi.cte.cpl.thalesgroup.com/policy parameter to the CTE-K8s PVC based on
  # the requested parameters. (Optional) (Required if source_storage_class is set)
  default_policy: <policy_1>

  # Time in minutes to wait before unregistering from the CipherTrust Manager
  # once all volumes have been unguarded. Parameter must be added as a string
  # integer value. Default "10" minute. (Optional)
```

```
registration_period: "10"
```

PVC Claim Example

```
apiVersion: v1
kind: PersistentVolumeClaim
metadata:
  name: cte-claim
  annotations:
    # If the following field is used, then this policy is used as the default_policy: <policy_1> in CTE-SC.
    csi.cte.cpl.thalesgroup.com/policy: policy_1
    # If the following field is used then the volume bounded with this pvc1 must be a dynamically provisioned volume, (optional)
    csi.cte.cpl.thalesgroup.com/source_pvc: <pvc1>
spec:
  storageClassName: cte-test-sc
  accessModes:
    - ReadWriteMany
  resources:
    requests:
      storage: 1Gi
```

Examples for PV, PVC, SC

kubectl get sc

```
:~/volumeSnapshot$ kubectl get sc,pvc,pv
NAME                                     PROVISIONER                                RECLAIMPOLICY
storageclass.storage.k8s.io/cte-test-sc  csi.cte.cpl.thalesgroup.com              Delete
Immediate                                true                                     13m
storageclass.storage.k8s.io/nfs-csi-imm  nfs.csi.k8s.io                           Delete
Immediate                                false                                    56d
```

Note

nfs-csi-sc-imm is the underlying source storageClass. Use in the CTE-SC (cte-csi-storageClass.yaml) parameter `source_storage_class: <underlying_source_sc_name>`

kubectl get pvc

```
NAME                                     CAPACITY  ACCESS MODES  STATUS  VOL
UME                                     STORAGECLASS
persistentvolumeclaim/cte-claim
c-b168e8d9-e26b-4515-aab2-91dc241ce74a  2Gi       RWX           Bound   pv
cte-test-sc
```

```
<unset>          13m
persistentvolumeclaim/cte-claim-unprotected-cprfnzjxjxg3gpyabrqh5d   Bound    pv
c-4183880c-6480-43e8-9564-b9f06fe557bf    2Gi      RWX      nfs-csi-imm
<unset>          13m
```

Note

cte-claim-unprotected-: name of the source PVC which is either created by the CTE-K8s driver if `csi.cte.cpl.thalesgroup.com/source_pvc: <pvc1>` is omitted in the source CTE-PVC, or any existing dynamically created source PVC used as `csi.cte.cpl.thalesgroup.com/source_pvc: cte-claim-unprotected-<UID#>` in the source CTE-PVC.

kubectl get pv

```
NAME                                     CAPACITY  ACCESS MOD
ES   RECLAIM POLICY   STATUS   CLAIM
STORAGECLASS VOLUMEATTRIBUTESCLASS  REASON  AGE
persistentvolume/pvc-4183880c-6480-43e8-9564-b9f06fe557bf    2Gi      RWX
Delete      Bound    default/cte-claim-unprotected-cprfnzjxjxg3gpyabrqh5d
nfs-csi-imm  <unset>          13m
persistentvolume/pvc-b168e8d9-e26b-4515-aab2-91dc241ce74a    2Gi      RWX
Delete      Bound    default/cte-claim
cte-test-sc  <unset>          13m
```

Verifying that the source CTE-PVC is valid to for cloning

1. Get the sourcePVC name which is attached to the source CTE-PVC, type:

```
kubectl get pv $(kubectl get pvc <Source_CTE-PVC_Name> -n <NameSpace> -o wide
--no-headers -o custom-columns=":spec.volumeName") -o wide --no-headers -o cus
tom-columns=":spec.csi.volumeAttributes" | awk '{for (i=1;i<=NF;i++){if ($i
~/csi.cte.cpl.thalesgroup.com\/source_pvc:/) {print $i}}}' | awk -F: '{print
$2}'
```

`<Source_CTE-PVC_Name>`: source CTE-PVC name. For example: `cte-claim`.

`<NameSpace>`: namespace in which the above CTE-PVC is deployed.

Example Response:

```
cte-claim-unprotected-<UID#>
```

2. Verify that the sourcePVC, if bounded with dynamically-provisioned volume, type:

```
kubectl get pv $(kubectl get pvc <SourcePVC_Name> -n <NameSpace> -o wide --no-headers -o custom-columns=":spec.volumeName") -o wide --no-headers -o custom-columns=":spec.csi"
```

- `<SourcePVC_Name>`: SourcePVC name obtained from previous command.
- `<NameSpace>`: namespace in which the source CTE-PVC is deployed.

Example Response

- If the source volume is provisioned-dynamically, then the output will contain data, for example:

```
map[driver:nfs.csi.k8s.io map[csi.storage.k8s.io/pv/name:pvc-caff4502-0123-4391-927a-5efa5cbb12d9 csi.storage.k8s.io/pvc/name:cte-claim-unprotected-mi5eclhwd4dyhjrjeqicbd csi.storage.k8s.io/pvc/namespace:default server:<some-IP> share:<share-path> storage.kubernetes.io/csiProvisionerIdentity:1724596308482-728-nfs.csi.k8s.io subdir:pvc-caff4502-0123-4391-927a-5efa5cbb12d9] volume Handle:<Some-IP>.#<share-path>#pvc-caff4502-0123-4391-927a-5efa5cbb12d9##]
```

- If the sourcePVC contains a volume which is not dynamically-provisioned then the output will not contain data.

Note

- If the sourcePVC contains a volume that is bounded but not dynamically-provisioned, then you cannot clone the source, CTE-PVC (for example: cte-claim).

Creating a Clone

To provision a volume clone:

1. Add a reference to an existing CTE Persistent Volume Claim (source CTE-PVC) in the same namespace of the data Source field of a new CTE Persistent Volume Claim (clone CTE-PVC).

cte-csi-claim-clone.yaml (clone CTE-PVC)

```
apiVersion: v1
kind: PersistentVolumeClaim
metadata:
  name: clone-of-cte-claim
  annotations:
    csi.cte.cpl.thalesgroup.com/policy: policy_1
    # The following field is not required. A new sourcePVC will be created
```

by the cte-k8s driver and a new volume will be provisioned with cloned data.

```
# csi.cte.cpl.thalesgroup.com/source_pvc: <source-pvc>
spec:
  storageClassName: cte-test-sc
  accessModes:
    - ReadWriteMany
  resources:
    requests:
      storage: 1Gi
```

Note

- The namespace of the clone, CTE-PVC (`cte-csi-claim-clone.yaml`), must be the same as the namespace of the source CTE-PVC (`cte-csi-claim.yaml`)
- You must specify a capacity value for `spec.resources.requests.storage` with the clone CTE-PVC. The value specified must be the same or larger than the capacity of the source volume.
- The `csi.cte.cpl.thalesgroup.com/source_pvc` annotation in the clone CTE-PVC (`cte-csi-claim-clone.yaml`) is not required. A new sourcePVC (`source_pvc`) is created by the CTE for Kubernetes driver and a new volume is created with the cloned data.
- The Policy used with the clone CTE-PVC (`cte-csi-claim-clone.yaml`) must be the same, as the policy used with the source CTE-PVC (`cte-csi-claim.yaml`).
- The underlying storage driver provisioned/used with the source CTE-PVC and the clone CTE-PVC must be the same. Cloning with different storage provisioners is not supported.
- You can use the same, or a different, CTE-Storage Class (`spec.storageClassName`) with the clone CTE-PVC, but the underlying source Storage Class driver must be the same for the source CTE-PVC and the clone CTE-PVC.
- You can use the same, or a different, volume Access Mode (`spec.accessModes`) with the clone CTE-PVC.

2. Deploy the clone CTE-PVC, type

```
kubectl apply -f cte-csi-claim-clone.yaml
```

Based on the CTE storage class `volumeBindingMode`, and the underlying source storage class `volumeBindingMode`, CTE for Kubernetes provisions a new volume with cloned data as follows:

CTE Storage Class (<code>cte-test-sc</code>) (<code>volumeBindingMode</code>)	Source Storage Class (<code><underlying_source_sc_name></code>) (<code>volumeBindingMode</code>)	Comment
Immediate	Immediate	Provision volume with cloned data when deploying the clone CTE-PVC (<code>cte-csi-claim-clone.yaml</code>).
Immediate	WaitForFirstConsumer	CTE for Kubernetes does not support this <code>volumeBindingMode</code> combination.
WaitForFirstConsumer	Immediate	Provision volume with cloned data after deploying the clone CTE-PVC (<code>cte-csi-claim-clone.yaml</code>) and the Application Pod on this CTE-PVC.
WaitForFirstConsumer	WaitForFirstConsumer	Provision volume with cloned data after deploying the clone CTE-PVC (<code>cte-csi-claim-clone.yaml</code>) and the Application Pod on this CTE-PVC.

Volume Snapshot and Restoring

Introduction

Kubernetes volume snapshots provide Kubernetes users with the ability to copy a volume at a specific point in time. You can use this copy to restore a volume back to a prior state, or to provision a new volume. Use snapshots to protect your workloads and achieve business-critical recovery point objectives in your disaster recovery plan, or if you have compliance needs to periodically save data.

Similar to how API resources `PersistentVolume` and `PersistentVolumeClaim` are used to provision volumes for users and administrators, `VolumeSnapshotContent` and `VolumeSnapshot` API resources are provided to create volume snapshots for users and administrators.

Terminology

- `VolumeSnapshotClass`: Similar to how `StorageClass` provides a method for administrators to describe the classes of storage they offer when provisioning a volume, `VolumeSnapshotClass` provides a method for describing the classes of storage when provisioning a volume snapshot.
- `VolumeSnapshot`: User requests a snapshot of a volume. It is similar to `PersistentVolumeClaim`.
- `VolumeSnapshotContent`: Snapshot taken from a volume in the cluster that has been provisioned by an administrator. It is a resource in the cluster just like a `Persistent Volume` is a cluster resource.

Considerations

- The CSI storage drivers that support provisioning volume snapshots, the ability to provision dynamic volumes, and can be used with the CTE for Kubernetes Volume Snapshot and Restore feature are referenced on the [Kubernetes CSI Drivers List](#).
- API Objects: `VolumeSnapshot`, `VolumeSnapshotContent`, and `VolumeSnapshotClass` are Custom Resource Definitions (CRD). They are not part of the core API.

A CRD is an extension of the Kubernetes API that is not necessarily available in the default Kubernetes installation. It represents a customization of a particular Kubernetes installation. Without the required CRDs installed, attempts to create a `VolumeSnapshot` fail. Validate the CRDs by typing:

```
kubectl api-resources -o wide | grep -i VolumeSnapshot
```

If the snapshot CRD is installed and uses the snapshot API request, make sure that the volume snapshot controller is deployed. Snapshot CRDs may get installed by default by installing the respective storage snapshot controller. Alternatively, it may require installing the snapshot CRD along with the snapshot controller installation. Check with the appropriate storage driver documentation for installation instructions for snapshot CRDs and the snapshot controller.

Volume Snapshot Types

There are two methods for provisioning snapshots:

Pre-provisioned

A cluster administrator creates these `VolumeSnapshotContents`. They carry the details of the volume snapshot, on the storage system, which is available for use by cluster users. They exist in the Kubernetes API and are available for consumption.

Note

This method **IS NOT** supported by CTE for Kubernetes.

Dynamically provisioned

You can take a snapshot dynamically from a `PersistentVolumeClaim`. The `VolumeSnapshotClass` specifies the storage provider-specific parameters to use when taking a snapshot. You can create a snapshot for CTE volumes (CTE-PVC) and you can restore using the new CTE-PVCs.

Note

This method **IS** supported by CTE for Kubernetes.

Setup

The following example assumes that:

- CTE for Kubernetes setup is available
- It uses Dynamically Provisioned volumes
- It uses the compatible NFS-CSI driver
- The Application Pod is running with a CTE-PVC (`cte-claim-restore`)
- `cte-claim-restore` is using CTE-StorageClass (`cte-test-sc`) and is bound and available
- `cte-test-sc` is using the `nfs-csi-sc-imm` (`nfs.csi.k8s.io`) source storageClass for NFS

cte-csi-storageclass.yaml (CTE-SC)

```
apiVersion: storage.k8s.io/v1
kind: StorageClass
metadata:
  name: cte-test-sc
provisioner: csi.cte.cpl.thalesgroup.com
reclaimPolicy: Delete
volumeBindingMode: Immediate
allowVolumeExpansion: true
parameters:
  # Domain name or IP address of the CipherTrust Manager (Required)
  key_manager_addr: 192.168.70.1

  # Name of the CipherTrust Manager K8s Storage Group. (Required)
  k8_storage_group: k8s-group1

  # Kubernetes Secret with CipherTrust Manager registration token (Required)
  registration_token_secret: cm-reg-token

  # To provision a volume dynamically, add the underlying source storageClass.
  # The CTE-K8s driver will create a source_pvc dynamically on this source stor
ageClass.
  # A new volume will be provisioned by the underlying provisioner. (Optiona
l) (Required only for Dynamic PVC)
  # Taking an NFS provisioning driver (`nfs.csi.k8s.io`) example: `nfs-csi-sc-i
mm`
  source_storage_class: <underlying_source_sc_name>

  # When specified and set to "true", this parameter will automatically
```

```

    # delete the dynamic sourcePVC. This might delete the actual data volume, depending
    # on the underlying provisioner driver implementation. Default is set to "false". (Optional)
    allow_source_pvc_delete: "false"

    # When specified, this parameter will automatically add the `csi.cte.cpl.thalesgroup.com/policy`
    # parameter to the CTE-K8s PVC based on the requested parameters. (Optional) (Required if `source_storage_class` is set)
    default_policy: <policy_1>

    # Time in minutes to wait before unregistering from the CipherTrust Manager
    # once all volumes have been unguarded. Parameter must be added as a string
    # integer value. Default "10" minute. (Optional)
    registration_period: "10"

```

The following three parameters are specific to dynamic provisioned (sourcePVC and sourcePV) in the above CTE-K8s Storage Class definition:

- `source_storage_class`
- `default_policy`
- `allow_source_pvc_delete`

cte-csi-claim.yaml (source CTE-PVC)

```

apiVersion: v1
kind: PersistentVolumeClaim
metadata:
  name: cte-claim-restore
  annotations:
    # If this field is used then this policy is used whether or not `default_policy` in CTE-SC is provided or not.
    csi.cte.cpl.thalesgroup.com/policy: policy_1
    # (optional) If this field is used then the volume bounded with this pvc1 must be a dynamically provisioned volume.
    #csi.cte.cpl.thalesgroup.com/source_pvc: <pvc1>
spec:
  storageClassName: cte-test-sc
  accessModes:
    - ReadWriteMany
  resources:
    requests:
      storage: 5Gi

```

Examples Scripts for PV, PVC, SC with the deployments listed above

kubectl get sc

NAME	PROVISIONER	RECLAIMPO

```

LICY    VOLUMEBINDINGMODE    ALLOWVOLUMEEXPANSION    AGE
storageclass.storage.k8s.io/cte-test-sc    csi.cte.cpl.thalesgroup.com    Delete
Immediate    true    13m
storageclass.storage.k8s.io/nfs-csi-imm    nfs.csi.k8s.io    Delete
Immediate    false    56d

```

- **CTE-SC:** `cte-test-sc`
- **Underlying source SC:** `nfs-csi-sc-imm`

kubectl get pvc

```

NAME                                STATUS    VOL

VOLUMEATTRIBUTESCLASS    AGE
persistentvolumeclaim/cte-claim-restore    Boun
d    pvc-b168e8d9-e26b-4515-aab2-91dc241ce74a    2Gi    RWX    cte-tes
t-sc    <unset>    13m
persistentvolumeclaim/cte-claim-restore-unprotected-cprfnzjxjxg3gpyabrqh5d    Boun
d    pvc-4183880c-6480-43e8-9564-b9f06fe557bf    2Gi    RWX    nfs-cs
i-imm    <unset>    13m

```

- **CTE-PVC:** `cte-claim-restore`
- **Source PVC:** `cte-claim-restore-unprotected-<UID>`

kubectl get pv

```

NAME                                CAPACITY    ACCESS MOD
ES    RECLAIM POLICY    STATUS    CLAIM    REASON    AGE
STORAGECLASS    VOLUMEATTRIBUTESCLASS
persistentvolume/pvc-4183880c-6480-43e8-9564-b9f06fe557bf    2Gi    RWX
Delete    Bound    default/cte-claim-restore-unprotected-cprfnzjxjxg3gpyab
rqh5d    nfs-csi-imm    <unset>    13m
persistentvolume/pvc-b168e8d9-e26b-4515-aab2-91dc241ce74a    2Gi    RWX
Delete    Bound    default/cte-claim-restore
cte-test-sc    <unset>    13m

```

- **CTE-PV:** `pvc-<UID>`
- **Source PV:** `pvc-<UID>`

Validate Source Setup for taking Snapshots

1. Get the `sourcePVC` name that is attached to the source CTE-PVC, type:

```

kubectl get pv $(kubectl get pvc <Source_CTE-PVC_Name> -n <NameSpace> -o wide
--no-headers -o custom-columns=":spec.volumeName") -o wide --no-headers -o cus

```

```
tom-columns=":spec.csi.volumeAttributes" | awk '{for (i=1;i<=NF;i++){if ($i ~ /csi.cte.cpl.thalesgroup.com\/source_pvc:/) {print $i}}}' | awk -F: '{print $2}'
```

- `<Source_CTE-PVC_Name>`: source CTE-PVC name, for example: `cte-claim-restore`
- `<NameSpace>`: namespace in which the above CTE-PVC is deployed

Response

```
cte-claim-unprotected-<UID>
```

2. Verify that the sourcePVC is bounded with a dynamically provisioned volume, type:

```
kubectl get pv $(kubectl get pvc <SourcePVC_Name> -n <NameSpace> -o wide --no-headers -o custom-columns=":spec.volumeName") -o wide --no-headers -o custom-columns=":spec.csi"
```

- `<SourcePVC_Name>`: SourcePVC name obtained from previously used command
- `<NameSpace>`: Namespace in which source CTE-PVC is deployed

Response

If the source volume is dynamically provisioned, then the output will contain data, for example:

```
map[driver:nfs.csi.k8s.io map[csi.storage.k8s.io/pv/name:pvc-caff4502-0123-4391-927a-5efa5cbb12d9 csi.storage.k8s.io/pvc/name:cte-claim-unprotected-mi5eclhw d4dyhjrjeqicbd csi.storage.k8s.io/pvc/namespace:default server:<some-IP> share:<share-path> storage.kubernetes.io/csiProvisionerIdentity:1724596308482-728-nfs.csi.k8s.io subdir:pvc-caff4502-0123-4391-927a-5efa5cbb12d9] volumeHandle:<Some-IP>.#<share-path>#pvc-caff4502-0123-4391-927a-5efa5cbb12d9##]
```

If the source volume **is not** dynamically provisioned, then the output will **not** contain data.

Note

If the sourcePVC has a bound volume which is not dynamically provisioned, then you cannot take a Volume Snapshot on the source CTE-PVC (i.e. `cte-claim-restore`).

Create a Snapshot

1. Create a `VolumeSnapshotClass` object to specify the CTE-K8s driver and `deletionPolicy` for your volume snapshot. You can reference `VolumeSnapshotClass` objects when you create `VolumeSnapshot` objects.

`cte-csi-snapshotclass.yaml`

```
apiVersion: snapshot.storage.k8s.io/v1
kind: VolumeSnapshotClass
metadata:
  name: cte-snapclass
  parameters:
    # Add the parameters if required for any storage specific. These parameters will be passed to the storage source snapshotClass by the CTE-K8s driver.
    <key1>: <value1>
    <key2>: <value2>
#The following field must be used as it is.
driver: csi.cte.cpl.thalesgroup.com
deletionPolicy: Delete
```

Volume snapshot classes have parameters that describe volume snapshots belonging to the volume snapshot class. Different parameters may be accepted depending on the specific storage driver. Users must provide those required parameters with CTE-SnapshotClass (`cte-csi-snapshotclass.yaml`).

****Sample Parameters****

The following are sample parameters that are used with different cloud storage provisioners. Check the specific storage driver documentation for the supported parameters based on the requirements.

```
parameters:
  snapshot-type: images
  image-family: <IMAGE_FAMILY>
  storage-locations: us-east2
  type: backup
  resourceGroup: <EXISTING_RESOURCE_GROUP_NAME>
  incremental: true
  # The driver field value is static. Do not change it.
  driver: csi.cte.cpl.thalesgroup.com
```

1. Apply the CTE-SnapshotClass manifest, type:

```
kubectl apply -f cte-csi-snapshotclass.yaml
```

2. Create a Volume Snapshot Object, which is a request for a snapshot of an existing `PersistentVolumeClaim` object.

```
cte-csi-snapshot.yaml
```

```
apiVersion: snapshot.storage.k8s.io/v1
kind: VolumeSnapshot
metadata:
  name: cte-claim-restore-snapshot
spec:
  volumeSnapshotClassName: cte-snapclass
  source:
    # CTE-PVC on which the user wants to take the snapshot
    persistentVolumeClaimName: cte-claim-restore
```

Note

The namespace of the Volume Snapshot (cte-claim-restore-snapshot) must be the same as the namespace of the source Persistent Volume Claim (cte-claim-restore). Creating a snapshot from volumeSnapshotContent **is not** supported with CTE for Kubernetes. You cannot reference volumeSnapshotContentName as a source (spec.source).

3. Apply the CTE-Snapshot manifest, type:

```
kubectl apply -f cte-csi-snapshot.yaml
```

Once the previous CTE-Snapshot manifest, (cte-csi-snapshot.yaml) deploys, the CTE-K8s driver creates a source Snapshot Class for the underlying storage driver. CTE for Kubernetes also creates a source Snapshot on the sourcePVC. Then, the underlying storage driver (for example: `nfs.csi.k8s.io`) takes a snapshot on a physical volume.

Examples

Reference the following examples for VolumeSnapshotClass (vsc), VolumeSnapshot (vs), and VolumeSnapshotContent (vsc) from the deployments listed in the previous section.

kubectl get vsc

```
NAME
DRIVER                                DELETIONPOLICY  AGE
volumesnapshotclass.snapshot.storage.k8s.io/cte-snapclass
csi.cte.cpl.thalesgroup.com          Delete          2m53s
volumesnapshotclass.snapshot.storage.k8s.io/cte-snapclass-sourcesnapshotclass-f61
0823c  nfs.csi.k8s.io          Delete          2m49s
```

- CTE-Snapshot Class: cte-snapclass

- Source Snapshot Class (underlying storage snapshotClass): `cte-snapclass-sourcesnapshotclass-<UID>` // This is created by CTE-K8s driver based on input provided in CTE-SnapshotClass (`cte-csi-snapshotclass.yaml`) and the source CTE-PVC provided in CTE-Snapshot (`cte-csi-snapshot.yaml`)

kubecttl get vsc

```

NAME
READYTOUSE    RESTORESIZE    DELETIONPOLICY    DRIVER    VOLUMES
NAPSHOTCLASS    VOLUMESNAPSHOT
VOLUMESNAPSHOTNAMESPACE    AGE
volumesnapshotcontent.snapshot.storage.k8s.io/snapcontent-67a7d12c-67f3-472f-95e
e-28f0f73d4a5c    true    1966888    Delete    nfs.csi.k8s.io
cte-snapclass-sourcesnapshotclass-f610823c    cte-claim-restore-snapshot-sourcesna
pshot-f610823c    default    2m49s
volumesnapshotcontent.snapshot.storage.k8s.io/snapcontent-f610823c-b567-42b9-955
8-d59c9487ad7b    true    0    Delete    csi.cte.cpl.thalesgr
oup.com    cte-snapclass    cte-claim-restore-snapshot
default    2m49s

```

- CTE-SnapshotContent: `snapcontent-<UID>`
- Source SnapshotContent: `snapcontent-<UID>`

kubecttl get vs

```

NAME
READYTOUSE    SOURCEPVC    SOURCESNAPSHOTCONTENT
RESTORESIZE    SNAPSHOTCLASS    SNAPSHOTCONTENT
CREATIONTIME    AGE
volumesnapshot.snapshot.storage.k8s.io/cte-claim-restore-snapshot
true    cte-claim-restore
0    cte-snapclass    snapcontent-f610823c-b
567-42b9-9558-d59c9487ad7b    2m28s    2m49s
volumesnapshot.snapshot.storage.k8s.io/cte-claim-restore-snapshot-sourcesnapshot-
f610823c    true    cte-claim-restore-unprotected-cprfnzjxxjxg3gpyabrqh5d
1966888    cte-snapclass-sourcesnapshotclass-f610823c    snapcontent-67a7d12c-6
7f3-472f-95ee-28f0f73d4a5c    2m29s    2m49s

```

- CTE-Snapshot: `cte-claim-restore-snapshot` // CTE for Kubernetes does not take any actual snapshot, that is why RESTORE SIZE is 0 for CTE-Snapshot
- Source Snapshot: `cte-claim-restore-snapshot-sourcesnapshot-<UID>` // Actual snapshot data is created by the underlying source driver (for example: `nfs.csi.k8s.io`)

Validate the Snapshot

Before restoring the volume from the snapshot, make sure that the snapshot is complete and ready to use. The snapshot status `READY_TO_USE` should be set to `true`. This indicates that the snapshot is successful. To verify, type:

```
kubectl get volumesnapshot -n <Namespace> -o custom-columns='NAME:.metadata.name,READY:.status.readyToUse'
```

- `<Namespace>`: Namespace in which the snapshot is deployed.

Verifying Snapshot Name

User can describe the snapshot to check the status:, type:

```
kubectl describe vs -n <Namespace> <CTE_Snapshot_Name>
```

- `<Namespace>`: Namespace in which the snapshot is deployed
- `<CTE_Snapshot_Name>`: CTE-Snapshot name, for example `cte-claim-restore-snapshot`

Restore the Volume Snapshot

You can reference a `VolumeSnapshot` in a `PersistentVolumeClaim` to provision a new volume with data from an existing volume, or restore a volume to a state that you captured in the snapshot. To reference a `VolumeSnapshot` in a `PersistentVolumeClaim`, add the `dataSource` field to your `PersistentVolumeClaim`.

Restore CTE-PVC (`cte-claim-restore.yaml`)

```
apiVersion: v1
kind: PersistentVolumeClaim
metadata:
  name: cte-claim-restore
  annotations:
    # Make sure that the policy is correct. The policy key must be used correctly. Check the policy
    # that is used the source CTE-PVC (i.e. cte-claim-restore)
    csi.cte.cpl.thalesgroup.com/policy: <policy_1>
    # The 'csi.cte.cpl.thalesgroup.com/source_pvc' annotation is not required. A new sourcePVC is
    # created by the cte-k8s driver and a new volume is provisioned with restored data
    #csi.cte.cpl.thalesgroup.com/source_pvc: <source-pvc>
spec:
  storageClassName: cte-test-sc
  accessModes:
    - ReadWriteOnce
  resources:
    requests:
      storage: 5Gi
  dataSource:
    kind: VolumeSnapshot
    # Name of the CTE-Snapshot to which the user wants to restore the data
    name: cte-claim-snapshot
    apiGroup: snapshot.storage.k8s.io
```

Notes and Considerations

- The namespace of the restore `PersistentVolumeClaim` **must** be the same as the namespace of the `VolumeSnapshot`.
- Make sure to use the correct policy (`csi.cte.cpl.thalesgroup.com/policy: <policy_1>`) with the restore CTE-PVC (`cte-csi-claim-restore.yaml`). The snapshot is taken on encrypted data, and after restoring the data, the correct key must be provided with the policy in order to decrypt and access the data. If the Key rules are not correct with the policy, then the data will be corrupted while accessing it. Check the source CTE-PVC (`cte-csi-claim.yaml`) policy for key information.
- Make sure that the restore CTE-PVC (`cte-csi-claim-restore.yaml`) is using the same underlying source storage driver as the source CTE-PVC (`cte-csi-claim.yaml`). Restoring a volume with a different source storage driver is not supported. For example, if the source CTE-PVC is using `pd.csi.storage.gke.io` as the underlying source driver and the snapshot was created with it, then restoring the volume with a different storage driver will fail to restore the volume.
- You can create/restore unlimited CTE-PVC's from volume snapshot, as long as the snapshot is available.

Apply the Manifest

Use the following `.yaml` script as an example when restoring a Volume Snapshot.

```
kubect1 apply -f cte-csi-claim-restore.yaml
```

Based on the CTE Storage Class `volumeBindingMode` and the underlying source Storage Class `volumeBindingMode`, a new volume is provisioned with restored data as follows:

CTE Storage Class (<code>cte-test-sc</code>) (<code>volumeBindingMode</code>)	Source Storage Class (<code><underlying_source_sc_name></code>) (<code>volumeBindingMode</code>)	Comment
Immediate	Immediate	Provision volume with restored data when deploying the restored CTE-PVC (<code>cte-claim-restore.yaml</code>).
Immediate	WaitForFirstConsumer	CTE for Kubernetes does not support this <code>volumeBindingMode</code> combination.
WaitForFirstConsumer	Immediate	Provision volume with restored data after deploying the restore CTE-PVC (<code>cte-claim-restore.yaml</code>) and the Application Pod on this CTE-PVC.
WaitForFirstConsumer	WaitForFirstConsumer	Provision volume with restored data after deploying the restore CTE-

CTE Storage Class (<code>cte-test-sc</code>) (<code>volumeBindingMode</code>)	Source Storage Class (<code><underlying_source_sc_name></code>) (<code>volumeBindingMode</code>)	Comment
		PVC (<code>cte-claim-restore.yaml</code>) and the Application Pod on this CTE-PVC.

Volume Resizing and Expansion

Overview

You can now resize an existing volume by editing the `PersistentVolumeClaim` (PVC) object. You no longer have to manually interact with the storage backend, or delete and recreate PV and PVC objects, to increase the size of a volume. Kubernetes will automatically expand the volume, using storage backend, and it will also expand the underlying file system in-use by the Pod, without requiring any downtime if the underlying storage provisioner can support it.

Prerequisites

- Before performing an expansion, make sure that the source volume (PV) is provisioned dynamically, by adding the underlying source `storageClass`. If not, volume expansion fails.
- Make sure that underlying storage driver allows for volume expansion. Check the respective storage provider's documentation to verify.

Method

Perform volume expansion by editing the existing `PersistentVolumeClaim` (PVC) object. You can expand the volume **online** or **offline** based on the specific storage driver support.

Online

Expands a PVC while the PVC is still in-use by the Pod.

- Pods referencing the resized volume do not need to be restarted. Instead, the file system will automatically be resized while in use as part of volume expansion.

Offline

Expanding a PVC which is not in-use by any Pod.

- If the underlying storage driver can only support offline expansion, users must take down their Pod before expanding the volume.

Note

- File system expansion does not happen until a pod references the resized volume, so if no pods referencing the volume are running file system expansion does not happen.
- Some storage drivers support Online expansion, some do not. Refer to the [Storage driver list](#) for your storage provider information.

Expanding the CTE-PVC Volume

You can use either command: `kubectl patch` or `kubectl edit` to expand the volume size.

1. Using the `kubectl patch` command:

```
kubectl patch pvc <CTE-PVC_Name> -n <Namespace> --type merge -p '{"spec":{"resources":{"requests":{"storage":"<New_Size>"}}}}'
```

Example

This example requests expansion to 5G:

```
kubectl patch pvc cte-claim -n ns1 --type merge -p '{"spec":{"resources":{"requests":{"storage":"5Gi"}}}}'
```

2. Using the `kubectl edit` command:

- a. Type:

```
kubectl edit pvc -n
```

Example

```
kubectl edit pvc cte-claim -n ns1
```

- a. Update the **resource > request > storage field** with the required size, for example 5Gi.

Validating volume expansion

The duration for volume expansion depends on the size of the new volume requested and the type of storage driver provisioner.

- You can verify it by viewing the `cte-csi-controller-xxx` log:

```
kubectl logs cte-csi-controller-6f669d4b94-8xdcl -n kube-system cte-csi
```

- For more details, describe the CTE-PVC and sourcePVC. To verify this information, type:

```
kubectl describe pvc <pvc_name> -n <Namespace>

kubectl get pvc <pvc_name> -n <Namespace> -o yaml
```

- Watch the `status.conditions` field of the CTE-PVC, and sourcePVC, to see if the resize has completed.
- Refer to the storage driver documentation for more specific details.

Unsupported Functions

- Shrinking persistent volumes is not supported.
- Only dynamically provisioned PVCs whose storage class has the `allowVolumeExpansion` parameter set to `true` are expandable.

Advanced Configuration and Troubleshooting

- [Using external certificates with CTE for Kubernetes](#)
- [Troubleshooting](#)

Using External Certificates with CTE for Kubernetes

You can use External Certificates for communication between CTE for Kubernetes and CipherTrust Manager. This is optional.

Note

Install external certificate before registering CTE for Kubernetes with CipherTrust Manager.

Overview

CipherTrust Transparent Encryption can now use an external certificate, available at a user-defined path, to communicate with CipherTrust Manager.

Prerequisites

The external certificate must be:

- On the file system
- In PEM format

A key pair must already exist for the client:

- Must have Encryption type of either:
 - sha256WithRSAEncryption
 - ecdsa-with-SHA384
- Must be Encrypted with a pass phrase

Initial setup

1. Obtain your external CA certificate.
2. Create a certificate using the external CA certificate and key.

CipherTrust Manager Setup

To setup CipherTrust Manager to communicate through an external certificate:

1. Import the CA certificate into the CipherTrust Manager, click **CA > External > Add External CA**.
2. In the **Add External CA** dialog, copy and paste the `<ca_certificate_name>.pem` file content from the UI page and provide a user-friendly name.

For more information, see [Using an Externally Generated Server Certificate for an Interface](#)

3. Add the CA certificate to the list of trusted sources for the web interface, click **Admin Settings > Interfaces > web > Edit > External Trusted CAs**.
4. Restart the web server, click **Admin Settings > Services > web > Restart**.
5. Create a registration token for the CTE agent. See [Creating a Registration Token](#) for more information.

Note

After adding an external certificate to CipherTrust Manager, you must associate the client profile with the registration token so that it is updated to use the external CA.

CTE for Kubernetes Setup for Client Registration

1. Add the Registration token to the configuration file `cte-csi-regtoken.yaml` with the

`registration_token` parameter.

```
apiVersion: v1
kind: Secret
metadata:
  name: cm-reg-token
type: Opaque
data:
# This is a base64 encoded registration token. To generate:
echo -n <CM REGISTRATION TOKEN STRING> | base64 -w 0
  cm-reg-token: <registration token in base64 format>
```

2. Create a Kubernetes secret(s) with client certificate details:

```
kubectl create secret generic <client-secret-name> --from-file=<clientName>.cr
t=client_cert.pem --from-file=<clientName>.key=client_key.pem --from-file=<cli
entName>.passphrase=<passphrase>
```

where:

- * `<client-secret-name>` = unique name for secret
- * `<clientName>` = unique name for client
- * `<passphrase>` = passphrase for client

Example

```
kubectl create secret generic <client-secret-name> --from-file=client1.crt=cli
ent_cert.pem --from-file=client1.key=client_key.pem --from-file=client1.passph
rase=passphrase
```

You can also use files from a **specific path** as a Partial or Absolute path:

```
kubectl create secret generic <client-secret-name> --from-file=<clientName>.cr
t=./client1/client_cert.pem --from-file=client1.key=./client1/client_key.pem
--from-file=client1.passphrase=./client1/passphrase
```

To create multiple client certificate details (certificate, key and passphrase) with the secret:

```
kubectl create secret generic <client-secret-name> --from-file=<client1Name>.c
rt=<client1_cert.pem> --from-file=<client1Name>.key=<client1_key.pem> --from-f
ile=<client1Name>.passphrase=<client1-passphrase> --from-file=<client2Name>.c
rt=<client2_cert.pem> --from-file=<client2Name>.key=<client2_key.pem> --from-f
ile=<client2Name>.passphrase=<client2-passphrase>
```

where:

- * `<client-secret-name>` = unique name for secret
- * `<clientName>` = unique name for client
- * `<passphrase>` = passphrase for client

Example

```
kubectl create secret generic client1-client2-secret --from-file=client1.crt=client1_cert.pem --from-file=client1.key=client1_key.pem --from-file=client1.passphrase=client1-passphrase --from-file=client2.crt=client2_cert.pem --from-file=client2.key=client2_key.pem --from-file=client2.passphrase=client2-passphrase
```

If certificates are on **different paths**, provide the filename with the path (Partial or Absolute path)

```
kubectl create secret generic client1-client2-secret --from-file=client1.crt=./client1/client_cert.pem --from-file=client1.key=./client1/client_key.pem --from-file=client1.passphrase=./client1/passphrase --from-file=client2.crt=./client2/client_cert.pem --from-file=client2.key=./client2/client_key.pem --from-file=client2.passphrase=./client2/passphrase
```

Note

There must be an additional client certificate detail added to the secret parameter `external_ca_client_secret: <client-secret-name>`. This additional detail is required for each storage class deployment. This is because there is an additional requirement for Signer Registration for each storage class. This Signer Registration is an additional default registration).

3. Create the storage-class yaml file with a client secret name:

While creating the storage-class configuration file `cte-storageclass.yaml` add the following parameter:

```
external_ca_client_secret: <client-secret-name>
```

Also make sure that the registration token secret name from the `cte-csi-regtoken.yaml` is correct and contains the following parameter:

```
registration_token_secret: cm-reg-token
```

cte-storageclass.yaml

```

apiVersion: storage.k8s.io/v1
kind: StorageClass
metadata:
  name: csi-test-sc
provisioner: csi.cte.cpl.thalesgroup.com
reclaimPolicy: Delete
volumeBindingMode: Immediate
allowVolumeExpansion: true
parameters:
  # Domain name or IP address of the CipherTrust Manager (Required)
  key_manager_addr: 192.168.70.1
  # Name of the CipherTrust Manager K8s Storage Group. (Required)
  k8_storage_group: test-group
  # Kubernetes Secret with CipherTrust Manager registration token (Required)
  registration_token_secret: cm-reg-Token
  # Kubernetes secret with External CA signed client certificate (Optional)
  external_ca_client_secret: <client-secret-name>
  # Description will be displayed in CipherTrust Manager (Optional)
  client_description: "K8s client"
  # Time in minutes to wait before unregistering from the CipherTrust Manager. Default is 10 minutes.
  # Once all volumes have been unguarded. Parameter must be added as a string integer value. (Optional)
  registration_period: "10"

```

Note

- Each storage-class will have its own client secret with a client certificate, key and passphrase details.
- If one storage-class is being used over multiple worker nodes, then the client secret will have multiple client details (certificate, key and passphrase)

Troubleshooting

This section contains the following troubleshooting topics:

Inspecting Deployment

Deployment of CTE for Kubernetes typically uses a single controller pod and at least one worker pod per Kubernetes node. Inspect the deployment using `kubectl get` commands to access basic output.

Example

Get the CTE for Kubernetes pod names that were deployed on the Kubernetes cluster, type:

```
NAMESPACE="kube-system"
kubectl get pods -n ${NAMESPACE} -o wide | grep cte-csi
```

Response

```
cte-csi-controller-0      5/5      Running    0         25h      192.168.77.182    node
1.example.com            <none>    <none>
cte-csi-node-28srz        4/4      Running    0         25h      192.168.77.181    node
1.example.com            <none>    <none>
cte-csi-node-cjzzn        4/4      Running    0         25h      192.168.76.68     contro
1.example.com            <none>    <none>
```

Getting the Agent version

The version of CTE for Kubernetes that you are running displays in the log files for each pod:

```
NAMESPACE="kube-system"
for podName in `kubectl get pods -n ${NAMESPACE} | grep cte-csi-[node,controller] | cut -d " " -f1`; do
    echo -n "${podName}: "
    kubectl logs -n ${NAMESPACE} ${podName} cte-csi | grep "Version:"
done
```

Response

```
cte-csi-controller-7d7d8bd46b-wbffd: I0308 17:25:13.608929 1 cte.go:139] Version: 1.6.0.xx
cte-csi-node-8qx5q: I0308 17:25:11.643673 2218968 cte.go:139] Version: 1.6.0.xx
cte-csi-node-h8q8q: I0308 17:25:13.465795 2205645 cte.go:139] Version: 1.6.0.xx
```

Inspecting Events

CTE for Kubernetes relies on Kubernetes event infrastructure for diagnostics of problems with a CTE for Kubernetes volume. Any errors in attaching a volume to a pod will display in the event logs. Look at all of the events in a Kubernetes namespace by typing:

```
NAMESPACE="kube-system"
kubectl get event -n ${NAMESPACE}
```

To target events of a specific pod, type:

```
PODNAME="my_application_pod"
NAMESPACE="kube-system"
kubectl get event -n ${NAMESPACE} --field-selector involvedObject.name=${PODNAME}
```

Inspecting logs

Examining logs for CTE for Kubernetes could offer supplementary insights that might not be conveyed through Kubernetes Events.

Deployment of CTE for Kubernetes is split between two different types of pods:

- **Controller Server:** Manages the volume manipulation (Dynamic Volume Provisioning, Volume Cloning, Volume Expansion, Volume Snapshot & Restore) activities. Denoted by a `cte-csi-controller-X` pod name `cte-csi-controller-X` pod name.
- **Node server:** Manages attaching CTE for Kubernetes volumes to pods. Denoted by a `cte-csi-node-XXXXX` pod name.

Inspecting the Controller Server Log

The logs for the CTE for Kubernetes controller server pod are distributed across two containers:

- The `cte-csi` server contains logs relevant to dynamic provisioning for CTE for Kubernetes persistent volumes, volume management (Volume cloning, Volume Resizing, Volume Snapshot & Restore, and Volume affinity).
- The `cte-csi-signer` contains logs relevant to the signer client. (The Signer client is used in the pod attestation feature). Node activities (node addition, deletion) for the feature is set to automatically cleanup for CTE clients.

Use the two relevant `kubectl` logs commands to view the logs, type:

```

NAMESPACE="kube-system"
kubectl logs -n ${NAMESPACE} cte-csi-controller-0 cte-csi
kubectl logs -n ${NAMESPACE} cte-csi-controller-0 cte-csi-signer

```

Inspecting the Node Server Log

The logs for the CTE for Kubernetes pods are distributed across two containers:

- The `cte-csi` container contains logs relevant to CTE for Kubernetes activity, encompassing details like volume mounting and registration
- The `cte-agent-logs` contain logs for the CTE encryption engine agent, VMD, CipherTrust Manager server communication logs, and file access logs.

Inspecting the Node Server requires first identifying which Kubernetes node the application pod is scheduled on. Once that node has been identified, find the CTE for Kubernetes node server running on that node.

After you obtain the pod name, use the two relevant `kubectl logs` commands to view the logs, type:

```

NAMESPACE="kube-system"
kubectl logs -n ${NAMESPACE} cte-csi-node-XXXXX cte-csi

```

```
kubectl logs -n ${NAMESPACE} cte-csi-node-XXXXX cte-agent-logs
```

Updating CTE-K8s Log level on a live CTE deployment

The CTE-K8s driver logging is useful to debug the kubernetes resources for CTE, and activity related to volumes, registration, mount, etc.

It currently has a log level of <1-5>. The default log level is set to 1, which provides minimal logging. You can set the Log Level from 1-5. Set the log level to 5 for the maximum debug logging information.

In CTE for Kubernetes v1.6.0 and subsequent versions, you can change this log level on a live CTE for Kubernetes deployment, without disrupting any running deployment. When you install CTE for Kubernetes, it creates a default ConfigMap, `cte-k8s-config` in the same namespace where the CTE-K8s driver/agent is installed.

By default CTE for Kubernetes is installed in the `kube-system` namespace. The namespace could be different, based on the CTE for Kubernetes installation command.

To verify the CTE for Kubernetes installation namespace, type:

```
kubectl get pods --all-namespaces -o wide | grep cte-csi-controller
```

In the ConfigMap, `cte-k8s-config`, the `log_level` parameter reports the CTE-K8s Log Level. You can update the `log_level` to change the CTE-K8s log level.

Updating the CTE-CTE-K8s Log Level

You can update the log level parameter with the `kubectl patch` or `kubectl edit` command:

To update with the `kubectl patch` command, type:

```
kubectl patch cm cte-k8s-config -n <CTE-K8s-Namespace> --type merge --patch '{ "data": { "log_level": "<LEVEL>" } }'
```

Where:

- `<CTE-K8s-Namespace>`: Namespace in which CTE for Kubernetes is installed.
- `<LEVEL>`: Log level: 1-5; 1 is for minimal logs and 5 for maximum logs.

Example:

```
kubectl patch cm cte-k8s-config -n kube-system --type merge --patch '{ "data": { "log_level": "5" } }'
```

To update with the `kubectl edit` command, type:

```
kubectl edit cm cte-k8s-config -n <CTE-K8s-Namespace>
```

- `<CTE-K8s-Namespace>`: Namespace in which CTE for Kubernetes is installed.

Note

Update the `log_level` value accordingly.

Problems with Registration

CTE for Kubernetes automatically registers to CipherTrust Manager based on demand for volumes on a node. Failure to register is typically due to the registration token being either invalid or the token has no more client capacity. These types of errors are reported back through Kubernetes so analyzing the log files of the troubled pod reveals the registration failure message seen by the agent.

Troubleshooting Trusted Pods failures

The following are two examples of trusted pod failures:

Example 1

In `cte-csi-node` logs, the following error indicates that a running pod digest was not found in any signature set attached to a security policy.

```
E0310 06:41:16.614410 1687839 server.go:106] GRPC error: rpc error: code = Internal desc = Pod did not pass attestation checks: rpc error: code = Internal desc = Found no signature set for container ubuntu with digest 2adf22367284330af9f832ffefb717c78239f6251d9d0f58de50b86229ed1427
```

Example 2

In `cte-csi-node` logs, the following error indicates that running pod digests cannot be matched to the same signature set. There were two containers (ubuntu and ubuntu2) with digests included in different signature sets. Partial matches are displayed to help with troubleshooting.

```
E0407 09:07:33.393609 1492044 server.go:106] GRPC error: rpc error: code = Internal desc = Pod did not pass attestation checks: rpc error: code = Internal desc = Pod attestation failed. Unable to match all pod digests to same signature set. Partial matches:
Signature set policy-sigset2: [ubuntu:8ae9bafbb64f63a50caab98fd3a5e37b3eb837a3e0780b78e5218e63193961f9]
Signature set policy-sigset3: [ubuntu2:69665d02cb32192e52e07644d76bc6f25abeb5410edc1c7a81a10ba3f0efb90a]
```

Backing up Databases after Encryption

After encrypting a database, CipherTrust Transparent Encryption cannot make a backup of the database. Both scheduled and manual backup fail. The problem was the user's policy. A policy used in this scenario must follow a few rules.

With a CBC_CS1 key, a guarded file is modified to have a 4096 byte header holding key information. When an **Apply Key** effect is specified, the CipherTrust Transparent Encryption code adjusts the length and file offset for

this header. Without an **Apply Key** effect, the size and access of the offset include the CBC_CS1 header.

Thales recommends that you modify the first rule of your policy. Remove the action entry for `f_rd_att` from the first rule and add a new rule before it:

```
**action**: f_rd_att

**effect**: Permit, Apply Key
```

Policy processing starts with the first rule and continues until a matching rule is found. The effect for the matching rule is then applied.

For the `f_rd_att` action, this results in the SECFS code including the CBC_CS1 key header and adjusts the file size value. Without the Apply Key effect, the file size includes the CBC_CS1 header size and the file appears as 4096 bytes larger than its real size.

FSGroupID is not working with NFS shared storage volume

The `fsgroup` ID Security Context option allows an administrator to change the permissions of volumes before a pod starts. Some users have found that when adding the `fsgroup` ID to the SecurityContext section in the pod yaml file, it does not work as expected in the NFS storage environment.

The reason is that the `fsgroup` ID Security Context option is not supported with NFS volumes. It is only supported with local storage. This is a limitation from Kubernetes and not an issue with the CTE-U fuse driver.

- See [Configure a Security Context for a Pod or Container](#) in the Kubernetes documentation for more information.

Kubernetes Node reboot procedure

If you need to reboot a Kubernetes node, you must follow the proper order for commands:

1. To stop scheduling new pods on a node, type:

```
kubectl cordon ${NODE_NAME}
```

2. To stop all running pods in the node, type:

```
kubectl drain --ignore-daemonsets --force ${NODE_NAME}
```

Note

Does not stop the DaemonSet. It allows CTE-K8s nodes to complete deregistration.

3. Check to see if a finalizer exists for that node, type:

```
kubect1 get storageclass ${CTE_STORAGE_CLASS} -o jsonpath='{.metadata.finalizers}' | grep ${NODE_NAME}
```

4. Finding a finalizer with the node name on a StorageClass is an indication that the node is still registered with CipherTrust Manager. CTE-K8s may need to wait for the deregistration period for a complete deregistration to occur. Once this command returns nothing, you can reboot, type:

```
reboot
```

5. After rebooting, you can resume scheduling the pods on a node, type:

```
kubect1 uncordon ${NODE_NAME}
```

Integrating CTE for Kubernetes with Rancher Kubernetes Management Platform

Rancher is an open source software platform that enables Enterprise Kubernetes Container Management. It provides a CNCF-certified (Cloud Native Computing Foundation) Kubernetes distribution that can run on any Kubernetes cluster or distribution. It solves common Kubernetes installation complexities by removing most host dependencies, thereby presenting a stable path for deployment, upgrades & rollbacks.

This document describes installing Rancher and deploying a few workloads to a Kubernetes cluster provisioned by Rancher.

Test Environment

- **CTE for Kubernetes Agent:** 1.2.0
- **CipherTrust Manager:** 2.12.0
- **OS:** Ubuntu 20.04
- **Rancher:** 1.5.1
- **Kubernetes cert-manager:** 1.5.1

Prerequisite

Create a 3-node Kubernetes cluster in which all of the worker nodes and master node are in the **Ready** state.

Policy and Policy Elements

CTE for Kubernetes Policy

Name	Access
	all_ops with Permit, Apply Key, Audit
	all_ops with Deny, Audit
Default	No Access

Steps to integrate Rancher with CTE for Kubernetes Cluster

You will need to use K3s for installation. K3s is a lightweight Kubernetes distribution created by Rancher Labs.

Create a Kubernetes cluster for Rancher

- Use the default K3s installation script, type:

```
curl -sfL https://get.k3s.io INSTALL_K3S_CHANNEL="v1.21" K3S_KUBECONFIG_MODE="644" sh -
```

Testing the cluster

In the previous step, K3s created a new Kubernetes cluster and installed the `kubectl` CLI which you can use to directly interact with the Kubernetes API.

- To list all the nodes in the cluster and check their status, type:

```
kubectl get nodes
```

System Response

```
All Pods are Running
```

Install Helm

Helm is a package manager for Kubernetes. It is used as the installation tool for Rancher when deploying Rancher onto a Kubernetes cluster.

1. Download Helm CLI, type:

```
curl https://raw.githubusercontent.com/helm/helm/master/scripts/get-helm-3 \ | bash
```

2. Check for the version, type:

```
helm version --client
```

3. Create a soft symlink between rancher, `/etc/rancher/k3s/k3s.yaml` and the Kubernetes config file, `~/.kube/config` so that helm can interact with your cluster, type:

```
mkdir -p ~/.kube ln -s /etc/rancher/k3s/k3s.yaml ~/.kube/config
```

4. Validate the connection, type:

```
helm ls --all-namespaces
```

Install Kubernetes Cert-Manager

Kubernetes cert-manager is an add-on that automates the management and issuance of TLS certificates from various issuing sources.

1. Obtain the latest version of the `cert-manager`, type:

```
kubectl apply --validate=false -f https://github.com/jetstack/certmanager/releases/download/v1.5.1/cert-manager.crds.yaml
```

2. Add the Helm repository for Jetstack:

```
helm repo add jetstack https://charts.jetstack.io
```

3. Install `cert-manager`.

```
helm install cert-manager jetstack/cert-manager --namespace cert-manager --version v1.5.1 --create-namespace
```

4. Once the Helm chart is installed, you can monitor the rollout status of `cert-manager`.

```
kubectl -n cert-manager rollout status deploy/cert-manager
```

System Response

```
Waiting for deployment cert-manager rollout to finish: 0 of 1 updated replicas are available... deployment "cert-manager" successfully rolled out
```

5. You can also monitor the rollout status of `cert-manager-webhook`.

```
kubectl -n cert-manager rollout status deploy/cert-manager-webhook
```

Install Rancher

Install Rancher in HA mode on your Rancher01 Kubernetes cluster.

1. Add rancher-stable as a Helm repository, type:

```
helm repo add rancher-stable https://releases.rancher.com/servercharts/stable
```

2. Install Rancher using the Helm install command, type:

```
helm install rancher rancher-stable/rancher \
--namespace cattle-system \
--set hostname=rancher.${vminfo:rancher01:public_ip}.sslip.io \
--set replicas=1 \
--set bootstrapPassword=Rancher0nK3s \
--create-namespace \
```

3. Verify that Rancher is successfully deployed, type:

```
kubectl -n cattle-system rollout status deploy/rancher
```

4. Get container details for the cattle-system namespace, type:

```
kubectl get pod -n cattle-system
```

5. List all pods in all namespaces, type:

```
kubectl get pods --all-namespaces
```

6. Verify Rancher is ready to access, type:

```
curl -kv https://rancher.${vminfo:Rancher01:public_ip}.sslip.io 2>&1 | grep
-q "dynamiclistener-ca"; if [ $? != 0 ]; then echo "Rancher isn't ready yet";
sleep 5; continue; fi; break; done; echo "Rancher is Ready";
```

Integrating CTE for Kubernetes with Tanzu Kubernetes Grid

Tanzu Kubernetes Grid is an enterprise-ready Kubernetes runtime that unifies management of Kubernetes clusters, vSphere-optimized pods, containerized workloads, and VMware virtual machines.

This document describes installing Tanzu and deploying a few workloads to a Kubernetes cluster.

Test Environment

- **CTE for Kubernetes Agent:** 1.4.0
- **CipherTrust Manager:** 2.15.0

-
- **OS:** ubuntu-2204-kube-v1.28.4+vmware.1-tkg.1.ova
 - **VMware Tanzu Kubernetes Grid:** 2.5.0
 - **VMware Tanzu CLI:** 1.1.0

Prerequisites

Prior to Setting up CipherTrust Transparent Encryption with Tanzu, you must:

- Download the OS `.ova` from the [VMware Tanzu product page](#)
- Install Tanzu CLI for use with Tanzu Kubernetes Grid v2.5
- Install Tanzu CLI Plugins for TKG v2.5
- Install Kubernetes CLI (kubectl)
- Prepare VMware vSphere Server
- Create an SSH Key Pair
- DeployStandalone Management Clusters

References

For more information about deploying Tanzu, reference the following documents:

- [Prepare to Deploy Management Clusters to vSphere](#)
- [Interoperability Result](#)

Deploying Standalone Management Clusters

1. On the system on which you downloaded and installed the Tanzu CLI, type:

```
tanzu management-cluster create -ui
```

2. Click **Deploy** for VMware vSphere.
3. Enter the vCenter Single Sign-On username and password for a user account that has the required privileges for the Tanzu Kubernetes Grid operation.

Note

The account name must include the domain, for example administrator@vsphere.local.

4. Click **Connect**.
5. If the **Disable Verification** option is deselected in the previous screen, then you must manually verify the SSL thumbprint of the vCenter Server certificate and click **Continue**.
6. If you are deploying a management cluster to a vSphere 7 or vSphere 8 instance, confirm whether you want to proceed with the deployment.
7. Select the Datacenter in which to deploy the management cluster from the Datacenter drop-down menu.
8. Manually paste the contents of the key into the text box to add your SSH public key and click **Next**.
9. In the Management Cluster Settings:
 - a. Select a size from the predefined CPU, memory, and storage configurations.

Note

Minimum configuration: 2 CPUs and 4 GB memory

- b. Enter a name for your management cluster.
 - c. Select the **Machine Health Checks** option if you want to activate it.

Note

You can activate, or deactivate, Machine Health Checks on clusters after deployment using the CLI.

- d. Select the **Enable Audit Logging** option if you want to record requests made to the Kubernetes API server.
 - e. For **Worker Node Instance Type**, select the configuration for the worker node virtual machine (VM).
 - f. For **Control Plane Endpoint Provider**, select **Kube-vip**.
 - e. For **Control Plane Endpoint**, enter a static virtual IP address, or FQDN, for API requests to the management cluster.

Management Cluster Settings

Development

Single control plane node. Recommended for a development environment.

Instance type:

MANAGEMENT CLUSTER NAME (OPTIONAL)

CONTROL PLANE ENDPOINT PROVIDER

WORKER NODE INSTANCE TYPE

MACHINE HEALTH CHECKS ☒ Enable

CONTROL PLANE ENDPOINT

ACTIVATE AUDIT LOGGING ☒ Enable

NEXT

10. Click **Next** two times until you get to the **vSphere Resources** screen.
 - a. Select the VM folder in which to place the management cluster VMs.
 - b. Select the vSphere datastores for the management cluster to use.

Note

The storage policy for the VMs can **only** be specified when you deploy the management cluster from a configuration file.

- c. For the **Specify Availability Zones**, choose where to place the management cluster nodes, and then fill in the specifics:

Resources

Resource Pool: /Tanzu-DS/host/10.10.10.10/Resources/TKG, VM Folder: /Tanzu-DS/vm, Datastore: /Tanzu-DS/datastore/datastore 2

Specify the Resources

VM FOLDER

Specify Availability Zones

☒ No AZs ☐ Cluster based AZs ☐ Host group based AZs

DATASTORE

CLUSTERS, HOSTS, AND RESOURCE POOLS

☒ TKG

NEXT

11. Configure the Kubernetes network. Use the IP addresses from the Kubernetes CIDR block. Click **Next** when finished.

Kubernetes Network Settings

CNI Provider: Antrea

Network Name: /Tanzu-DS/network/vm-network

Cluster Service CIDR: 100.64.0.0/12

Cluster Pod CIDR: 100.96.0.0/11

Proxy Settings

☐ Activate Proxy Settings

Next

12. Select the base OS image.

OS image: /Tanzu-DS/vm/Templates/ubuntu-2204-efi-kube-v1.28.4+vmware.1

OS Image with Kubernetes v1.28.4+vmware.1-tkg.1

OS IMAGE: /Tanzu-DS/vm/Templates/ubuntu-2204-efi-kube-v1.28.4+vm

Next

13. Finalize the deployment, click **Review configuration**.
14. Click **Deploy Management Cluster** to deploy the cluster.

Post Deployment

After the deployment completes, you can see one control plane and one worker node.

1. After the deployment completes, a configuration `yaml` file is created in `.../.config/tanzu/tkg/clusterconfigs/<random_name>.yaml`.
2. Create a copy of this `yaml` file and name it: `<newName>.yaml`.
3. Edit the `yaml` file. Provide a static IP address for the `VSPHERE_CONTROL_PLANE_ENDPOINT`.
4. Save the file.

Create a Workload Cluster

1. Create workload cluster, type:

```
tanzu cluster create workernew -f <newName>.yaml
```

2. Scale the worker node count to three, type:

```
tanzu cluster scale tkgwork01 --controlplane-machine-count 1 --worker-machine-count 3
```

3. Create a Tanzu cluster list, type:

```
tanzu cluster list
```

4. Get the Kubernetes node list, type:

```
kubectl get nodes
```

5. Retrieve the information about the current Kubernetes context, type:

```
kubectl config get-contexts
```

Installation

See [Install CTE for Kubernetes](#) for more information.

Policy and Policy Elements

Use a policy with the following access:

CTE for Kubernetes Policy

Name	Access
	all_ops with Permit, Apply Key, Audit
	all_ops with Deny, Audit
Default	No Access

CTE for Kubernetes

 - Installing and Using the CTE Signing Tool 3

CTE for Kubernetes Signing Tool

- [Signing Tool](#)

Signing Tool

- [Introduction to the Signing Tool](#)
- [Installing and Using the Signing Tool](#)

Introduction to the CTE Signing Tool

CTE for Kubernetes uses standard signature sets to test if a pod in the cluster has permission to use a CTE for Kubernetes Storage Group policy. Currently, CTE for Kubernetes is unable to pass signature sets to CipherTrust Manager like CipherTrust Transparent Encryption can. To alleviate this problem, Thales has created a utility that can populate CipherTrust Manager with signatures from other containers.

Specifically, the utility:

1. Calculates a list of binary paths.
2. Includes the URL and tag of a container from which to get the image.
3. Collects CipherTrust Manager authentication credentials.
4. Downloads the container image and collects signatures from it.
5. Calculates the SHA256 sum of all of the binary paths requested.
6. Requests authentication with CipherTrust Manager.
7. Pushes signatures collected from other containers to CipherTrust Manager.

Obtaining the Tool

This tool is available from the [Thales Support Portal](#). Search for **CipherTrust Transparent Encryption for Kubernetes**. The file will be a tar file. Decompress it with `tar -xvf`.

Installing and Using the CTE Signing Tool

To use this tool to gather signatures from other container images and then push them to CipherTrust Manager, complete the following steps:

1. Download a container image:
 - a. From a **public** repository, type:

```
./cte-sign --cdi --image=<image name> --tag=<image version> --arch=<amd64/arm64/..>
```

b. From a **private** repository, type:

```
./cte-sign --cdi --image=<image name with url> --tag=<image version> --repo-user=<repo username> --repo-password=<repo password> --arch=<amd64/arm64/..>
```

2. Get a list of signature set IDs from CipherTrust Manager, type:

```
./cte-sign --cm --signature-sets list --ip=<CM IP> --user=<CM username> --password=<CM password> --cm-domain=<CM Domain>
```

3. Create a signature set for the process set or Container Image Digest set, type:

```
./cte-sign --cm --signature-sets create --sigset-name=<signature-set-name> --sigset-type=<signature-set-type> --ip=<CM IP> --user=<CM username> --password=<CM password> --cm-domain=<CM Domain>
```

4. Send the signatures collected from the downloaded container image to CipherTrust Manager in a signature set ID, type:

```
./cte-sign --cm --signature-sets add-signatures --sigset-name=<signature-set-name> --path=<source-path> --ip=<CM IP> --user=<CM username> --password=<CM password> --cm-domain=<CM Domain>
```

5. Cleanup and remove the image directory, type:

```
./cte-sign --cleanup
```

6. Retrieve container image digests

a. Retrieve digests for pod spec yaml file:

```
./cte-sign --digest --podspec=<pod spec file name> --kubeconfig=<kubeconfig file path>
```

b. Retrieve digest for public image:

```
./cte-sign --digest --image=<image name> --tag=<image tag>
```

c. Retrieve digest for private image:

```
./cte-sign --digest --image=<image name> --tag=<image tag> --repo-user=<repo username> --repo-password=<repo password>
```

7. Retrieve and push Container Image Digest to CipherTrust Manager

a. Retrieve and push for public image:

```
./cte-sign --digest --push-to-cm --image=<image name> --tag=<image tag> --ip=<CM IP> --user=<CM username> --password=<CM password> --sigset-name=<signature-set-name> --cm-domain=<CM Domain>
```

b. Retrieve and push for private image:

```
./cte-sign --digest --push-to-cm --image=<image name> --tag=<image tag> --repo-user=<repo username> --repo-password=<repo password> --ip=<CM IP> --user=<CM username> --password=<CM password> --sigset-name=<signature-set-name> --cm-domain=<CM Domain>
```

c. Retrieve and push for public/private images using pod spec yaml file:

```
./cte-sign --digest --push-to-cm --podspec=<pod spec file name> --ip=<CM IP> --user=<CM username> --password=<CM password> --sigset-name=<signature-set-name> --cm-domain=<CM Domain>
```

CLI Argument Definitions

Argument	Definition
--arch	Image architecture: amd64, arm64, ...
--cleanup	Delete the container image files and directories.
--cm-domain	(Optional) Provide this option only if an operation belongs to a specific domain, other than the root domain.
--image	Container image name/URL.
--ip	CipherTrust Manager IP address.
--kubeconfig	kubeconfig file for retrieving pod digests.
--password	Password of CipherTrust Manager credential.
--path	The binary path from the downloaded container image, for the files that need to be pushed to CipherTrust Manager. ex: /usr/bin

Argument	Definition
--podspec	Pod specification yaml file.
--repo-password	Password/AccessToken for the private repository.
--repo-user	Username for private repository access.
--sigset-name	The signature set name where signatures will be contained.
--sigset-type	The signature set type. Application: for process signatures. Container-Image for container image signature.
--tag	Container image version.
--user	Username of CipherTrust Manager credential.

CipherTrust Transparent Encryption for Kubernetes

Challenge: Securing Applications for Kubernetes Environments

Modern applications are increasingly built using containers, which are microservices packaged with their configurations and dependencies. Kubernetes is an open-source software for deploying and managing these containers. Containerized applications can be delivered, deployed and managed faster with Kubernetes to provide improved efficiency through re-usable modular components, cost savings through optimized resource utilization and reduced licensing expenses. However, there are several risks:

- **Privileged user abuse.** By default, Docker processes run with root privileges, administrators have full access to all tenant secrets. This level of untethered access poses multiple risks. Organizations could be subject to privilege escalation attacks, if administrators have unchecked access to container images and the data stored within them.
- **Cross container access.** Poor configuration of permissions can result in multiple containers having access to information that should remain private. Further, when containers are hosted in shared virtualized or cloud environments, critical information can be exposed to third parties.

- **Compliance risks.** Many compliance mandates require stringent access controls and auditing data access. However, many security teams have limited controls available to manage and track access to data held within containers and images. As a result, these teams find it difficult to comply with relevant security policies and regulatory mandates.

Solution: CipherTrust Transparent Encryption for Kubernetes

CipherTrust Transparent Encryption for Kubernetes delivers in-container capabilities for encryption, access controls, and data access logging, that enables organizations to establish strong safeguards around data in Kubernetes environments. With this extension for CipherTrust Transparent Encryption, data protection can be applied on a per-container basis, both to secure data inside of containers and in external storage accessible from containers, all centrally managed from the CipherTrust Manager.

Benefits

CipherTrust Transparent Encryption for Kubernetes provides:

- **Compliance.** This extension of CipherTrust Transparent Encryption addresses compliance requirements and regulatory mandates for protecting sensitive data such as— payment cards, healthcare records or other sensitive assets.
- **Protection from Privileged-User Threats.** This solution offers encryption with data access controls, enabling privileged users, such as Docker or OpenShift cluster administrators, to operate as regular users, without gaining unauthorized access to sensitive data.
- **Achieve Robust Security.** CipherTrust Transparent Encryption for Kubernetes enforces data security policies wherever the container is stored or used – data centers, virtualized environments, even in cloud implementations. Deploy and use containers where needed for cost effectiveness, control, or performance without having to make any changes to applications, containers, or infrastructure sets.

- **Granular Access Controls and Visibility.** CipherTrust Transparent Encryption for Kubernetes offers the detailed visibility and control you need to comply with the most stringent policies and mandates. With this Kubernetes security solution, enterprises can establish granular access policies based on specific users, processes, and resource sets within containers. Finally, this solution can establish isolation between containers, so only authorized containers can access sensitive information.

CipherTrust Manager

The CipherTrust Manager centralizes key, policy, and log management for the CipherTrust Data Security Platform including CipherTrust Transparent Encryption. CipherTrust Manager is available in both virtual and physical form-factors that integrate with FIPS 140-2 validated Thales TCT Luna T-Series and third-party Hardware Security Modules (HSMs) for securely storing master keys with highest root of trust.

Features

- **Comprehensive Data Security Safeguards.** CipherTrust Transparent Encryption for Kubernetes extends CipherTrust Transparent Encryption, enabling security teams to establish data security controls inside of containers. With this extension, you can apply encryption, access controls, and data access logging on a per-container basis. Encryption can be applied to data generated and stored locally within the container and to data mounted in the container by network file systems.
- **Scalable Transparent Encryption.** Provides data security controls without having to make any changes to applications, containers or infrastructure sets. It enables a single policy to be applied to all containers within a Kubernetes cluster, or distinct policies applied to each container within a cluster. This solution can scale up or shrink down a Kubernetes environments as business needs change.

About Thales Trusted Cyber Technologies

Thales Trusted Cyber Technologies, a business area of Thales Defense & Security, Inc., is a trusted, U.S. provider of cybersecurity solutions dedicated to U.S. Government. We protect the government's most vital data from the core to the cloud to the edge with a unified approach to data protection. Our solutions reduce the risks associated with the most critical attack vectors and address the government's most stringent encryption, key management, and access control requirements.

For more information, visit www.thalestct.com

CipherTrust Transparent Encryption Container Security

Challenge: Building continuous container security into your CI/CD pipeline

As enterprises deploy containers with a continuous integration and delivery (CI/CD) pipeline, security must keep up. Container technologies provide significant benefits including increased portability, delivery and innovation, improved efficiency through reusable modular components, and cost savings through optimized resource utilization and reduced licensing expenses. However, there are also risks:

- **Privileged user abuse.** By default, Docker processes run with root privileges, and OpenShift cluster administrators have full access to all tenant secrets. This level of privileged access poses multiple risks. For example, container administrators may have unchecked access to images and the data stored within them, and organizations could be subject to privilege escalation attacks.
- **Cross container access.** Poor configuration of permissions can result in multiple containers having access to information that should remain private. Further, when containers are hosted in shared virtualized or cloud environments, critical information can be exposed to third parties.

- **Compliance risks.** Many compliance mandates require strong controls and auditing data access. However, many security teams have limited controls available to manage and track access to data held within containers and images. As a result, these teams find it difficult to comply with relevant internal security policies and regulatory mandates.

Solution: CipherTrust Transparent Encryption Container Security

CipherTrust Transparent Encryption Container Security delivers in-container capabilities for encryption, access controls, and data access logging, so organizations can establish strong safeguards around data in dynamic container environments. This solution from Thales is a software license for CipherTrust Transparent Encryption that enables security teams to establish controls inside of containers. With this extension, encryption, access controls, and data access audit logging can be applied on a per-container basis, both to data inside of containers and to external storage accessible from containers.

Benefits

CipherTrust Transparent Encryption Container Security provides:

- **Compliance.** This extension of CipherTrust Transparent Encryption delivers the encryption, data access control, and auditing capabilities you need to address compliance requirements and regulatory mandates. You can protect sensitive data — whether your organization manages payment cards, healthcare records or other sensitive assets.
- **Protection from Privileged-User Threats.** CipherTrust Transparent Encryption Container Security offers encryption with data access control, enabling privileged users, such as Docker or OpenShift cluster administrators, to work as usual, without unauthorized access to sensitive data.
- **Achieve Robust Security.** CipherTrust Transparent Encryption Container Security enforces data security policies wherever the container is stored or used – data centers, virtualized environments, even in cloud implementations. Deploy and use containers where needed for cost effectiveness, control, or performance without having to make any changes to applications, containers, or infrastructure sets.

Features

- **Comprehensive Data Security Safeguards.** CipherTrust Transparent Encryption Container Security extends CipherTrust Transparent Encryption, enabling security teams to establish data security controls inside of containers. With this extension, you can apply encryption, access control, and data access logging on a per-container basis. Encryption can be applied to data generated and stored locally within the container and to data mounted in the container by network file systems.
- **Transparent Encryption.** No changes to containers required. Establish data security controls without having to make any changes to applications, containers or infrastructure sets. The container security solution even supports common container microservices deployment models. This enables single policies that can apply to all containers running on a container host instance and allows distinct policies for each container or a mix of policy types.
- **Granular Access Controls and Visibility.** CipherTrust Transparent Encryption Container Security offers the detailed visibility and control you need to comply with the most stringent policies and mandates. With this container security solution, enterprises can establish granular access policies based on specific users, processes, and resource sets within containers. Finally, this solution can establish isolation between containers, so only authorized containers can access sensitive information.

About Thales Cloud Protection & Licensing

The people you rely on to protect your privacy rely on Thales to protect their data. When it comes to data security, organizations are faced with an increasing number of decisive moments. Whether the moment is building an encryption strategy, moving to the cloud, or meeting compliance mandates, you can rely on Thales to secure your digital transformation.

Decisive technology for decisive moments.

Solution Brief

CipherTrust Tokenization for Executive Peace of Mind

cpl.thalesgroup.com

THALES
Building a future we can all trust

When you need:

- **Compliance for security regulations such as PCI DSS**
- **Ciphertext that looks like your data**
- **Reduced audit scope and burden, proof you have done due diligence**

The Challenge

Executives today are under increasing pressure to protect sensitive customer data. Data breaches can result in financial penalties, public disclosure, and even personal liability. Regulations like PCI DSS, HIPAA, and GDPR demand strong safeguards for personal data—but achieving compliance without hindering operations is difficult.

Data protection solutions often exist in silos. Developers are burdened with crypto implementation. Policy enforcement is inconsistent and the audit trail is fragmented.

How Thales Can Help

Thales provides Tokenization as part of a unified Data Security Platform that supports Tokenization, Encryption, Data Masking and Redaction so that you have the right data protection for every type of data you have—regardless of where it resides; in an application or a database, on premises or in the cloud.

CipherTrust Tokenization provides both Vaulted and Vaultless Tokenization solutions enabling you to:

- Protect customer data whether it is in applications or databases
- Replace sensitive values with format-preserving tokens
- Choose vaulted or vaultless models to fit your systems
- Centralize control of policies, keys and audit trails

Both Vaulted and Vaultless options integrate with CipherTrust Manager and a FIPS 140-3 Level 3 HSM, helping you prove due diligence and reduce scope.

CipherTrust Tokenization Solutions

CipherTrust Vaulted Tokenization is available with:

- CipherTrust Vaulted Tokenization (CT-V) - offers non-mathematically reversible tokens to protect data via RESTful services, SOAP web services, Java SDKs and .Net SDKs within a customer's environment. Supports Oracle, Microsoft SQL Server, MySQL and Informix databases as its vault.

In contrast to vaulted tokenization, CipherTrust Vaultless Tokenization, does not store any sensitive user data, thereby reducing your potential attack surface and risk.

CipherTrust Vaultless Tokenization solutions include:

- CipherTrust Batch Data Transformation (BDT) - offers high-performance tokenization and encryption for databases and structured files
- CipherTrust Application Data Protection (CADP) - offers tokenization and encryption for field-level data protection as a simple-to-integrate library for developers
- CipherTrust RESTful Data Protection (CRDP) - offers tokenization and encryption for field-level data protection as a RESTful service
- CipherTrust Data Protection Gateway (DPG) - offers tokenization and encryption for transparent field-level data protection to any RESTful web service or microservice leveraging REST APIs
- CipherTrust Database Protection (CDP) - offers tokenization and encryption for transparent, column level data protection for a wide range of databases.

BDT, CADP, CRDP and DPG support Static Data Masking and Redaction. CADP, CRDP and DPG additionally support Dynamic Data Masking.

Thales helps you secure sensitive data across any system without operational complexity. And it gives you the ability to demonstrate accountability when it matters most.

Thales Solution Benefits

- Reduce PCI DSS compliance scope and associated audit burden
- Protect PII, PHI, and cardholder data even if systems are breached
- Avoid liability by proving data was protected and access was controlled
- Combine Tokenization with Data Masking and Redaction to deliver end-to-end control
- Enable innovation in cloud and analytics environments without increasing risk
- Tokenize data at rest, in motion, and in use

Core Use Cases

- Format-preserving Tokenization for applications and databases
- Vaulted or Vaultless protection for data in cloud, hybrid, or on-prem environments
- Tokenization, Encryption, Data Masking and Redaction on one platform

CipherTrust Vaultless Tokenization Solutions

Conclusion

Thales Tokenization solutions reduce executive exposure by removing sensitive customer data from high-risk systems. It simplifies compliance, lowers audit costs, and strengthens your ability to respond confidently to regulators, customers, and the board.

About The CipherTrust Data Security Platform

The award-winning CipherTrust Data Security Platform is an integrated set of data-centric solutions that remove complexity from data security, accelerate time to compliance, and secure cloud migrations. Thales is proud to have been recognized as an Overall Leader in the KuppingerCole Leadership Compass on Data Security Platforms as well as a Strong Performer in the Forrester Wave and to be featured in Gartner's Market Guide to Data Security Platforms.

The CipherTrust Platform unifies data discovery, classification, data protection, and centralized management for keys and secrets into a single platform. This results in fewer resources dedicated to security operations, ubiquitous compliance controls, and significantly reduced risk across your business.

About Thales

Thales is a global leader in cybersecurity, helping the most trusted organizations protect critical applications, data, identities, and software anywhere, at scale. Through Thales' integrated platforms, customers achieve better visibility of risks, defend against cyber threats, close compliance gaps, and deliver trusted digital experiences for billions of consumers every day.

CipherTrust Tokenization

Anonymizing Data for Security and Compliance

Tokenization reduces the cost and effort required to comply with internal security policies and regulatory mandates such as the European Union's Global Data Protection Regulation (GDPR) and the Payment Card Industry Data Security Standard (PCI-DSS).

CipherTrust Tokenization offers application-level tokenization services in two convenient solutions that deliver complete customer flexibility: Vaultless Tokenization with Dynamic Data Masking and Vaulted Tokenization. Both solutions secure and anonymize sensitive assets—whether they reside in the data center, big data environments or the cloud.

Key Advantages

Efficiently Reduce PCI DSS Compliance Scope

Tokenization can remove card holder data from PCI DSS scope, saving on costs associated with compliance.

Protect Personally Identifiable Information (PII)

With CipherTrust tokenization, PII protection is gained without encryption key management by the software developer

Architect for Your Requirements: Vaultless or Vaulted, and Cloud-Friendly

Both CipherTrust Tokenization solutions leverage CipherTrust Manager as a secure encryption key source. All-software, cloud friendly, is readily available, including with FIPS 140-2 Level 3 Root of Trust.

Vaultless Tokenization

CipherTrust Vaultless Tokenization protects data at rest while its policy-based Dynamic Data Masking capability protects data in use. A RESTful API in combination with centralized management and services enables tokenization implementation with a single line of code per field. Vaultless Tokenization is provided by dedicated, distributed-cluster-capable Tokenization Servers, offering full separation of duties. Tokenization management and configuration including an operational dashboard with convenient tokenization configuration workflows occurs in a graphical user interface.

Dynamic Data Masking policies define whether a tokenized field is returned fully or partially masked based on user identification controlled by an AD or LDAP server. For example, the policies could enable customer service representatives to see only the last four digits of credit card numbers, while account receivables staff could access the full credit card number.

Vaulted Tokenization

CipherTrust Vaulted Tokenization offers non-disruptive format-preserving tokenization with a wide range of existing formats and the ability to define custom tokenization formats.

Vaulted Tokenization provides a high level of security for data with the most sensitivity.

Architectural Choice is available by deploying the Vaulted Tokenization infrastructure on each application server or deploying it centrally on a web server with application servers using simply RESTful APIs for tokenization.

CipherTrust Data Security Platform

CipherTrust Tokenization is part of the CipherTrust Data Security Platform, which unifies data discovery, classification, data protection, and unprecedented granular access controls, all with centralized key management. This simplifies data security operations, accelerates time to compliance, secures cloud migrations and reduces risk across your business. You can rely on Thales CipherTrust Data Security Platform to help you discover, protect and control your organization's sensitive data, wherever it resides.

Introduction

Today's enterprise security teams have a lot on their plates and a lot on their minds. According to the Thales 2021 Global Data Threat Report, data breaches remain a widespread challenge. In the survey for the report, respondents indicated that 56% of organizations have ever experienced some form of data breach, with 41% of them having experienced a breach in the last 12 months. Breaches are a trailing indicator of security effectiveness. Turning to forward-looking metrics, 47% of respondents reported an increase in volume, severity and/or scope of cyberattacks!

But as you read this paper, consider that 46% of respondents said that they have avoided a breach notification because leaked data was encrypted or tokenized! Attacks are becoming more sophisticated and persistent while insider threats continue to be an Achilles heel. According to the 2017 Thales Data Threat Report¹, 88% feel at least somewhat vulnerable to data threats. The report also proves those concerns are well founded: 42% of organizations experienced a data breach at some point.

Tokenization is a critical tool for enterprises to meet compliance standards, and reduce the risk of loss posed by this increasingly hostile environment. Most often, tokenization has been a great way for enterprises to reduce the cost of their Payment Card Industry Data Security Standard (PCI DSS) audits. Tokens are used to replace credit card numbers, removing the need for many servers to undergo expensive yearly audits. But use cases for tokenization are expanding today to safeguard more types of data and in more environments as the locations where this data is used proliferate.

Driven by data privacy and sovereignty regulations around the world, the data types that need to be protected are no longer just credit cards, but also include U.S. Social Security numbers, Drivers Licenses, U.K. National Insurance numbers, Passport numbers, and National Identity numbers in many countries around the world among other data. And the need to use this sensitive data in advanced technology environments like cloud and big data leads to further complications.

In this white paper we'll first look at how CipherTrust Vaultless Tokenization works, key characteristics of the solution, and then examine sample implementations including PCI DSS compliance, customer contact centers, cloud, big data and more.

As noted earlier, tokenization is especially useful in PCI DSS compliance. In the past meeting requirements of the standard has been very complex and expensive, with extensive yearly audits of servers hosting credit card data required, or solutions that were limited in bandwidth and required extensive infrastructure to support.

CipherTrust Tokenization now offers a better way to meet these requirements. The solution's vaultless tokenization capabilities enable security teams to remove databases from PCI DSS scope, and so significantly reduce compliance cost and efforts. Implementations typically result in minimal disruption and administrative overhead and result in breakthroughs in operational efficiency.

CipherTrust Vaultless Tokenization leverages CipherTrust Manager as its key source and, of course, is a component of the CipherTrust Data Security Platform, which delivers a comprehensive range of data security and compliance controls that help IT teams efficiently address their requirements for encryption, privileged user access control, file access auditing, and more. With a single infrastructure, policy and encryption key management environment, the platform reduces the overall costs for organizations to implement and use data security tools while applying strong protections for data.

The Challenge

So many security demands, so little time

For today's security teams, it seems virtually everything is proliferating:

- **Threats.**

Risks posed by nation-states, cyber criminals, and malicious insiders continue to grow more sophisticated and more persistent

- **Data and repositories.**

The volume and diversity of assets and repositories that need to be protected continues to see explosive growth. Instead of just managing the traditional data center, which was challenging enough, there are now virtualized systems, big data environments, outsourced services, private clouds, public clouds, and hybrid models to contend with

- **Mandates and tools.**

As the number of repositories continues to grow, so do the number of systems that fall within the scope of PCI DSS and other regulations. Further, the scope and complexity of these regulatory mandates also continues to expand. As a result, security teams are compelled to deploy more safeguards and tools in order to establish the controls these mandates require. In particular, security teams face increased pressures to prepare for PCI DSS 3.0 audits, and adapt their security approaches as cardholder data moves into new environments—such as cloud and big data implementations—and is shared with outsourced service providers, such as analytics, development, and engineering firms

All this proliferation continues to place increasing demands on security teams—but these teams don't see their time, staffing, or budgets undergoing any commensurate expansion. To contend with these realities, many security professionals have explored the use of tokenization, which has the potential to provide a convenient way to protect sensitive assets. At a high level, tokenization is the process of replacing a sensitive record with a token, effectively a meaningless placeholder for the data that can't be exploited or reverted back to its original form

While tokenization offers the potential to address a wide range of security and compliance objectives, traditional tokenization tools and solutions have been far too costly and complex to procure and manage. These tools typically require security teams to invest in expensive appliances and contend with software agents that are difficult to deploy and manage. More than ever, security teams need to be able to leverage the benefits of tokenization—and they need to do so in a scalable, efficient, and cost effective manner.

The Solution

Efficiently de-identify sensitive data

The CipherTrust Data Security Platform offers tokenization capabilities that can dramatically reduce the costs and effort associated with complying with security policies and PCI DSS. With CipherTrust Vaultless Tokenization with Dynamic Data Masking, organizations can efficiently address objectives for securing sensitive assets and cardholder records— whether they reside in the data center, big data environments, or the cloud.

How vaultless tokenization works

For illustration purposes, we'll outline the process of tokenizing a credit card number. The CipherTrust Tokenization Server acts as a central hub for tokenizing records and managing access to tokens and clear-text data.

1. The customer submits a credit card number into an application.
2. The application submits the credit card number to the Tokenization Server via the REST API.
3. The Tokenization Server holds in memory a secure table created based on an AES-256 encryption key seed provided by the CipherTrust Manager. This table holds with random matches for credit card numbers – the token matching that card is identified.
4. Through the REST API, the Tokenization Server returns the token to the application.
5. The application server then submits the tokenized value into the database.

Deliver Robust Data Security

Strong access controls

Thales recommends creating at least two user accounts, or user groups from LDAP, be available on to the Tokenization Server:

- The first account or LDAP group with the permission to tokenize but not to detokenize, and the second account or LDAP group with the permission to detokenize
- The user account with tokenization privileges can then be utilized by multiple servers, including a public-facing web server, for example. This allows data to be tokenized immediately as it is brought in through applications
- Accounts or LDAP groups with permission to have detokenization privileges should be limited to a specific server that needs these permissions. For example, detokenization privileges could be restricted to a server that's responsible for submitting credit card numbers to a remote card processing service
- Any internal LDAP groups that have rights to detokenize data (Application administrators, for instance) should be strictly limited to the minimum number of members required

Tokenized data can be used with databases or files needed for development, QA and Test, or deployed to Big Data environments without risk to sensitive information. For credit card data, servers using tokenized information are removed from expensive and time consuming yearly audits as well. Further, Thales offers a high availability, standardsbased, FIPS 140-2 and Common Criteria validated policy management platform with the CipherTrust Manager that can provide maximum security for cryptographic keys and policies used with tokenization.

Flexible tokenization with dynamic data masking

CipherTrust Vaultless Tokenization also offers the flexibility to establish varying levels of data redaction. Security administrators can establish settings to have an entire field tokenized or to dynamically mask only part of a field, keeping the remainder in the original clear-text. When combined with LDAP-based integration to Active Directory and other directory services solutions, this capability enables uses such as call centers. One example of call center usage is limiting credit card number visibility for customer service representatives to the last four digits of a customer's credit card, while customer service supervisors can see the entire number.

The process of setting these policies is done using an intuitive administrative interface. Through the interface, administrators can choose exactly how they want data to be redacted, including specifying whether to replace a value with such characters as a pound sign, asterisk, or hyphen.

Dynamic Data Masking of Credit Cards for Customer Service

With CipherTrust Vaultless Tokenization, policies could be implemented so that a customer service supervisor could see credit card numbers in the clear, while a customer service representative would only see the last four digits.

Initial conditions:

- Credit card data in a product database is tokenized
- A policy is set for the customer services representatives group in LDAP that allows them to see only the last four digits of a credit card number
- A second policy allows members of the customer services supervisor group to see the entire number

Workflow

1. Customer service representative request to see a credit card number
2. The application calls the token from the production databases
3. The application server then passes the token and User ID information to the Tokenization Server using a RESTful API
4. The Tokenization Server calls directory services requesting group information for the User ID
5. Based on the User ID, customer services group membership, and the policy that customer services representatives can only view the last four numbers of a credit card, the token is processed, and the credit card number retrieved. Data is then dynamically masked, with the card number set to XXXX-XXXX-XXXX-4321, where 4321 are the last four digits of the actual card. XXXX-XXXX-XXXX-4321 is then returned to the application server
6. The application server displays XXXX-XXXX-XXXX-4321 to the customer services representative

Tokenization options

As well as offering the capability to dynamically mask data for display, CipherTrust Tokenization offers options for tokenizing a variety of fixed length data types – including Numeric, Text and Date formats. Options for data types to be tokenized include specific modes for:

- Numbers – Best for credit cards, U.S. Social Security numbers and other purely numeric data
- Text – All letters, all printable ASCII, All ASCII or AlphaNumeric for use with applications such as U.K. National Insurance numbers, drivers license numbers and others that include text only or mixed text and numbers
- Partial tokenization – Select only a portion of the fixed length field to be tokenized – keeping a portion of the data as the original information
- One-time use tokens – Used only when the data will never be de-tokenized
- Dates – including formats with various separators. Can also be modified with a start and end year
- Prefix – Prefixes can be appended to all tokens – for instance to designate a drivers license (DL)

Deployment and administrative simplicity

With CipherTrust Vaultless Tokenization, you can capitalize on a range of features that streamline upfront implementation and ongoing operations. CipherTrust Vaultless Tokenization

- **Enables efficient, enterprise-wide administration**

With the capabilities offered by the CipherTrust Data Security Platform, you can choose from a range of technologies and employ the mix that's optimally suited to an organizations specific projects and use cases. At the same time, enterprises gain the cost savings and operational benefits of working with solutions that can be centrally and uniformly managed. With the CipherTrust Data Security Platform from Thales, organizations can centrally manage keys for Vaultless Tokenization, as well as for CipherTrust Transparent Encryption, CipherTrust Application Data Protection, other CipherTrust products, and third-party devices.

- **Offers non-disruptive implementation**

With the solution's capabilities, you can restrict access to sensitive assets, yet at the same time, format the protected data in a way that reduces the operational impact typically associated with encryption and other obfuscation techniques. For example, organizations can tokenize a credit card field in a database, yet keep the tokenized information in a format that is compatible with associated applications. Further, tokens can appear to be real credit card numbers and pass LUHN validation, so tokenization does not break existing validation processes.

- **Eliminates manual efforts and complexity**

Tokenization occurs at the application layer, and it streamlines all the application development efforts associated with implementing tokenization in an enterprise. With the solution, developers don't have to manually institute identity management or redaction policies. CipherTrust Vaultless Tokenization offers an easy-to-use REST API for integration with the CipherTrust Tokenization Server, so that application developers can simply and quickly add tokenization and dynamic data masking to applications.

- **Provides investment protection**

Customers that have already invested in the CipherTrust Data Security Platform can get even more out of their investments. By leveraging existing CipherTrust Manager implementations (required for all CipherTrust Data Security Platform products), it is quick and cost effective to add Vaultless Tokenization through an all-software deployment.

Efficient scalability and agility

CipherTrust Vaultless Tokenization delivers the performance needed to address the operational demands of the most processing-intensive environments, enabling organizations to do millions of tokenization or detokenization operations per second. The Tokenization Server runs on virtual machines and can be quickly and efficiently scaled up and scaled down to accommodate changing workloads. For redundancy, Thales recommends deploying a cluster with at least two nodes. A three-node or four-node cluster multiplies the throughput, while providing added redundancy. Performance realized will vary depending on hardware platforms, cluster sizes, and client parallelism employed.

Key benefits

- **Reduce PCI DSS compliance effort and scope**

By leveraging CipherTrust Vaultless Tokenization, you can minimize the repositories and processes that can gain access to payment data in the clear, organizations can significantly reduce PCI DSS compliance costs and efforts.

- **Fully leverage cloud, big data, and outsourced models**

CipherTrust Vaultless Tokenization enables organizations to more fully leverage cloud services, big data models, and outsourced environments, while retaining the security controls required. For example, tokenized data can be easily migrated tokenized data to a public cloud, without exposing sensitive data to unauthorized access, even access by administrators in the cloud provider's environment.

- **Establish broad safeguards around sensitive assets**

Unlike other dynamic data masking tools, the CipherTrust solution tokenizes sensitive fields in the production database. As a result, enterprises can establish comprehensive safeguards around sensitive assets across the organization. Because the source and display data remain protected, this includes strong safeguards against cyberattacks from criminals and nation-states, as well as from insider abuse.

- **Minimize data security overhead and training**

With the CipherTrust Data Security Platform, enterprises can leverage a platform to centrally manage keys for Vaultless Tokenization and as well for the full range of the platform's encryption and access controls solutions. By leveraging a central platform that offers comprehensive capabilities, organizations can minimize the cost, effort, and training associated with managing point-products.

Sample implementations

PCI DSS 3.X Compliance

The more locations that hold primary account numbers (PANs), the more locations that fall under PCI DSS regulations. As the number of locations grow, so too do the cost and effort associated with establishing and sustaining compliance, preparing for audits, and so on. With CipherTrust Tokenization, you can tokenize PANs, and significantly restrict the number of users, processes, and repositories that can get access to this data in the clear. As a result, organizations can dramatically reduce compliance efforts and costs. Further, through such capabilities as Luhn check support, Vaultless Tokenization enables organizations to implement tokenization with minimal impact on applications and processes. In addition, the CipherTrust Data Security Platform offers many additional controls you need to address many PCI DSS requirements, including least privileged access controls, encryption, key management, and file access audit logs.

Customer contact centers

Vaultless Tokenization helps mitigate the threats that can be posed by support staff exploiting their access privileges to steal or leak sensitive data. Dynamic Data Masking can be effective both for securing sensitive data in internal contact centers and in outsourced or geographically distributed support environments. For example, enabling a support agent to see only the last 4 digits of a Social Security Number. As a result, agents can conduct any required customer verification processes, without being put in a position where they can maliciously or inadvertently leak sensitive and regulated PII.

Outsourced Development

For many organizations, application development is done by an increasingly dispersed set of teams, including geographically distributed employees as well as external contractors and service providers. While these distributed teams have helped improve the cost efficiency and agility of development efforts, they can pose significant challenges for those organizations that manage sensitive and regulated data. From initial development to testing and staging, developers need access to data repositories. If all data is left in the clear, it exposes a range of sensitive regulated data and intellectual property to any number of threats. With CipherTrust Vaultless Tokenization, organizations can quickly and efficiently provide internal and external development teams with access to corporate data repositories, while tokenizing the specific assets that pose security or compliance risks.

A complementary product, CipherTrust Batch Data Transformation, also helps organization to quickly tokenize large data sets for this purpose when needed.

Big Data

To capitalize on the opportunities presented by big data, organizations need to aggregate information from a broad range of repositories—and in the process can create massive collections of highly sensitive and proprietary data. The CipherTrust Data Security Platform enables organizations to fully leverage big data, without introducing risk to the business. Sensitive records can be tokenized before they are incorporated into big data repositories, so big data scientists, developers, and business analysts don't gain access to sensitive data that is not required for their work. At the same time, the solution's flexible tokenization options ensure that tokenized records don't disrupt big data migration, calculation, and analytics processes.

Cloud Services

When your organization moves to cloud computing models, whether infrastructure as a service (IaaS), software as a service (SaaS), platform as a service (PaaS), or hybrid approaches, you may offload a number of responsibilities and efforts, but your organization ultimately still bears responsibility for the security of its sensitive and regulated data. With CipherTrust Vaultless Tokenization, your organization can leverage the cloud models it needs, while managing tokenization policies locally. As a result, you can retain complete control and visibility over who can access sensitive assets in the clear, no matter where tokenized information ultimately resides.

Static Data Masking

Organizations can replace sensitive assets with tokens, so that outsourced application development and testing teams can run QA and analytics using realistic looking data, without having access to any sensitive assets. Once sensitive values in the database are tokenized, enterprises simply need to create a copy of the production database and give that copy to the outsourced development team. Since these teams don't have access to both the CipherTrust Tokenization Server and user credentials to detokenize, they won't be able to access sensitive data in the clear. This protects the business, maintains compliance, and enables outsource development teams to access and test realistic production data.

Just as noted above under Outsourced Development, CipherTrust Batch Data Transformation helps organization to quickly tokenize large data sets for this purpose when needed.

About Thales

The people you rely on to protect your privacy rely on Thales to protect their data. When it comes to data security, organizations are faced with an increasing number of decisive moments. Whether the moment is building an encryption strategy, moving to the cloud, or meeting compliance mandates, you can rely on Thales to secure your digital transformation.

Decisive technology for decisive moments.

PREFACE

The *CipherTrust Tokenization Server (CTS) Installation, Administration, and Programming Guide* describes how to install, configure, and manage CTS. This document also provides guidelines and some REST API documentation for developers to use when implementing CTS into their applications.

The CTS API service categories are:

- Tokenization
- Encryption (Crypto)
- Key Management
- Administration

NOTE: Additional REST API documentation is provided from the in-product help.

DOCUMENTATION VERSION HISTORY

The following table describes the documentation changes made for each document version.

Table 1: Documentation Changes

Product/Document Version	Date	Changes
2.6.0 v2	12/28/20	Corrected several API endpoint URIs that were changed to use “cts” instead of “vts,” which is incorrect. These URIs use the same “vts” component as before, to retain backward compatibility prior to the product name change.

Table 1: Documentation Changes

Product/Document Version	Date	Changes
2.6.0	11/03/20	Vormetric Tokenization Server (VTS) is now named CipherTrust Tokenization Server (CTS), to conform with several other former Thales Vormetric products adopting the brand name CipherTrust. The product version number continues to increment from the previous VTS version. Note that some names and labels still retain the historical “Vormetric” name. Support for SNMP v2c (community) and v3 has been added, with a new set of CLI commands also added to the network CLI category to manage SNMP support. Multiple syslog servers are now supported. The remote log CLI category now accepts multiple servers (specified as IP : PORT arguments) to the set and remove commands. Automated CTS cluster setup is now available in addition to manual cluster setup, for greater convenience and fewer errors. Set up and use a new apiadmin user in the cluster CLI category, and use remotejoin command. CTS is no longer supported on Docker. New installations of CTS 2.6.0 can be configured to use an EC2 key pair when cliadmin logs in via SSH instead of using a password. A healthcheck API endpoint has been added to get the current status of CTS and its individual services. JWT authentication expiration can be changed at the CLI from the default 10 minutes. This command is in the auth category. Tokenization requests can return the plaintext string together with the encrypted data in the response with the returnData parameter.
2.5.0 v2	02/25/20	Add more information about KeySecure servers, including registering VTS to KeySecure. Added explicit notes recommending authenticating with client certificates <i>with identities</i>, instead of using client certificates without identities. Several miscellaneous edits and minor text fixes
2.5.0	02/11/20	VTS now supports Gemalto Next-Gen KeySecure and SafeNet Classic KeySecure key management as an alternative to using Thales CipherTrust DSM. Added capability to send email notifications to administrators when the number of failed login attempts for a user reaches five (5). This email notification service is also used when the VTS server CPU or hard disk usage reaches 90% or higher. Added procedure for installing on KVM. Added details on installing VTS on Google Cloud Platform (GCP) The VTS Administration REST API is now available at a General Availability level.
2.4.1	10/04/19	Added support for LDAP on Linux Updated content in the CLI Reference and VTS Administration GUI chapters Added new section on configuring the settings.ini File for LDAP in the “Configuring the VTS System” chapter
2.4.0	08/27/19	Added OAuth support Added support for encrypting files larger than 5MB in size Added support for RSA 3K and 4K algorithms

Table 1: Documentation Changes

Product/Document Version	Date	Changes
2.3.0 v2	05/22/19	Fixed missing table data
2.3.0 v1	04/02/19	Added a clarification on key input sizes and their relationship with encryption modes Added information about importing and exporting keys Added new chapter: Admin REST API Added GCM code samples for encrypt, decrypt, and version key creation Added information about updated performance monitoring Updated CLI Reference with summaries of new CLI hierarchy of command categories Updated Installation and Configuration chapters
2.2.2 patch	11/13/18	• Added new topic: Create Super User • Minor edits to About Logging • Updates to describe how credentials are processed for Azure
2.2.2	10/12/18	2.2.2 documentation features and fixes, and new documentation framework and format.
2.2.0 GA	05/22/18	Update to GA version and format and style clean up.
2.2 Beta	04/9/18	Addition of crypto and key management services and APIs; redesigned GUI look-and-feel; new three-way authorization schema permitting user-based permissions to tokenize, encrypt, verify, sign, etc. with specific keys; support for client-certificate user authorization; support for custom character sets, including Chinese/Japanese/Korean (CJK) use cases; additional programmer's notes and links to external REST API documentation; all-new introduction and concepts material.
2.1.2 v2	1/29/2018	Minor updates, added notes to "Create a token group," updated install requirements section
2.1 v3	2/27/2017	Corrected VTS port configuration table, removed port 7024
2.1.1 v1	6/30/2017	Added support for VTS instances in AWS and Azure.

ASSUMPTIONS

This guide addresses three primary audiences:

- **Network administrators** who install the CipherTrust Tokenization Server (CTS) package and configure it using the CTS Administrator CLI
- **CTS GUI administrators** who assign and manage users, keys, and permissions in the CTS GUI

- **CTS application developers** who integrate CTS functionality into their application code using the CTS REST APIs

Introduction to CTS

The CipherTrust Tokenization Server (CTS) package is a platform-independent virtual appliance that comprises three security services and their associated tools. CTS works in conjunction with:

- A key manager (or keystore), such as Thales Data Security Manager (DSM), Thales KeySecure Classic, or Thales Next Generation KeySecure (now Thales CipherTrust Manager (CM))
- AD/LDAP servers (optionally)
- Remote logging servers (optionally)
- Load balancers (optionally)

This chapter includes the following sections:

- [“What is CTS?” on page 1](#)
- [“Understanding CTS Authentication and Authorization” on page 4](#)
- [“Understanding CTS Keys” on page 11](#)
- [“Tokenization Groups, Templates, and Masks” on page 13](#)
- [“About the CTS API” on page 16](#)

What is CTS?

This section describes the core services and components that make up CTS, as well as highlighting the specific benefits of the tokenization feature.

CTS core services

CTS offers three service categories for handling sensitive data:

- **Tokenization service:** Tokenization is used for replacing sensitive data with tokenized, or encrypted, data. Tokenized data retains the format of the original data while protecting it from theft or compromise. For example, if a company accepts customer credit card numbers, those numbers can be tokenized and stored as random-looking numbers, then detokenized by an employee or application with the proper permissions.

Tokenization is frequently used for sensitive data such as credit card numbers, social security numbers, drivers licenses, or other personally identifiable information (PII). *Data masking* can be applied to any detokenized data to hide sections of the data from different groups of users. For example, less-privileged database users might view only the last four digits of a detokenized credit card number, while a more privileged user could view the entire card number. The *CipherTrust Tokenization* REST APIs are used to integrate this functionality into a developer's application.

- **Key management services:** Using the CipherTrust Data Security Manager (DSM) or Gemalto SafeNet KeySecure as the key provider and repository, *users*-- whether human or machine-- can be granted permission to create, modify, find, import, export, and/or destroy encryption keys. The *CipherTrust Key Management* REST APIs are used to integrate this functionality into a developer's application.
- **Cryptographic services:** CTS also includes data encryption, decryption, sign, and verify services which can be tied to specific keys and user permissions. They can also be integrated into a developer's application using the *CipherTrust Cryptographic* REST APIs.

Components in a CTS deployment

A CTS deployment consists of the following components:

- CipherTrust Tokenization Server
- Keystore - Keystores that CTS supports include CipherTrust DSM (Data Security Manager), Gemalto SafeNet KeySecure Classic, and Gemalto SafeNet Next Generation KeySecure
- LDAP/Active Directory server (optional)
- Remote logging server (optional)
- Load balancer (optional)

CipherTrust Tokenization Server

The CTS server is a virtual appliance that manages the tokenization tasks for the DSM.

The CipherTrust Data Security Manager (DSM) must be installed and configured before deploying CTS.

The virtual appliance handles the following tokenization tasks:

- Receive REST API calls from the three service categories and return encrypted/detokenized data to requesting client
- Tokenize/detokenize, encrypt/decrypt, sign, and verify data using keys from the DSM
- Apply dynamic data masking as appropriate
- Authenticate users via user name/password

- Authenticate users via client certificates (optional)
- Apply user or user group profiles to determine user permissions
- Associate user permissions with particular keys

The CTS includes:

- **CTS Administrative CLI** used by the overall administrator to install, configure, and maintain the CTS server(s) and cluster.
- **CTS GUI** used by a GUI administrator to manage users, groups, permissions, data masks, and DSM-based keys.
- **REST APIs** that cover tokenization, cryptography, key management, and administration.

The server can be installed as an ISO or OVA image (including on a Hyper-V server), installed as a QCOW2 image on a Kernel-based Virtual Machine (KVM), shared as an Amazon Web Services Machine Image (AMI), or instantiated from the Microsoft Azure Marketplace or the Google Cloud Platform (GCP).

Keystore

Thales Data Security Manager (DSM), Gemalto SafeNet KeySecure Classic, or Gemalto Next Generation KeySecure.

IMPORTANT: The keystore must be installed and configured before deploying CTS. It provides and retains the keys used for tokenizing and encrypting data.

LDAP/Active Directory server (optional)

An AD/LDAP can be used to import and authenticate CTS users. It is accessed via LDAP or LDAPS.

Remote logging server (optional)

The network administrator can configure the CTS to send system log messages to a remote logging server.

Load balancer (optional)

To achieve High-Availability and scalable performance, CTS can be set up with multiple servers (nodes) to form a cluster. The cluster can operate as one coherent CTS system to be served by a load balancer.

Tokenization benefits

CipherTrust tokenization provides the following benefits:

- Replaces sensitive data in databases with tokens. This reduces the number of places in which plain text credit card numbers reside, and thus reduces the scope of complying with the Payment Card Industry Data Security Standard (PCI DSS) and corporate security policies.
- Preserves the format of data in a way that reduces the operational impact associated with encryption and other obfuscation techniques. For example, you can tokenize a credit card field in a database, yet keep the tokenized information in a format that is compatible with associated applications.
- Enables outsourcing application testing and running analytics without giving access to sensitive assets because the format of the data has been preserved. To outsource, you can create a copy of the production database and give that copy to the outsourced development team.
- Creates strong separation of duties between privileged administrators and data owners. In this way, IT administrators, such as hypervisor, cloud, storage, and system administrators can perform their tasks without access to the sensitive data residing on those systems.
- Enables dynamic data masking—the ability to establish varying levels of data redaction for different database users. For example, you can enable customer service personnel to access the last four digits of a customer’s credit card number, while an accounts payable representative can access the full credit card number.
- Integrates tokenization users with existing LDAP-based identity directories. Security teams can efficiently set granular tokenization policies for specific users and groups.

Understanding CTS Authentication and Authorization

In CTS, users are authenticated, granted permissions (to tokenize, detokenize, encrypt, hash, etc.), and associated with particular keys, using a three-way permissions matrix. It is important to understand the underlying assumptions about users, user groups, permissions, and keys in order to set up your CTS project appropriately.

What is a CTS “user?”

CTS makes no official distinctions between “human user accounts,” for real people, and “service user accounts,” representing daemons, scripts, processes, applications, or groups within applications with programmatic access to CTS services. Both are referred to as “users.”

From the point of view of the CTS system, the CTS REST APIs, and the application developer who wishes to incorporate CTS services into an application, a basic user account consists of:

- **user name/identifier**

- **password or client certificate** (If authentication is done from a client certificate, the password is not used. See [“Client certificates and user authentication” on page 6](#) for details.)

These attributes form the basis of user authentication.

NOTE: As a best practice in CTS, it is recommended to collect individual users into logical user groups and assign permissions at the group level. See also [“Understanding CTS user groups and permissions” on page 10](#).

User profiles

Users can be human or servers.

Human users

Of course, some users of CTS are real people. There are, first of all, the administrators, staff, and developers who use the CTS interface and/or the CTS APIs to install, configure, integrate, and maintain V TS services.

There are also human “end-users,” such as employees in a customer service department who may be assigned to a CTS user group authorized to detokenize credit cards and to view the last four digits of the card, based on the data mask that was applied to their user group.

Service users

However, most CTS usage consists of service users, where various servers and applications pass authentication, tokenization, encryption, and key information between themselves to complete a transaction of some kind.

For example:

A company may set up a structure to assign a financial application as User1 with a certain number of keys to perform certain operations. Within that same application, User2 might be a process that uses key2 to tokenize/detokenize credit cards, and User3 might be used to encrypt/decrypt social security numbers with key3.

CTS authentication basics

As described in [“What is a CTS “user?”” on page 4](#), authentication is based on credentials—either user name and password or a client certificate.

CTS will first seek to validate whether the credentials match entries in its local database. If not, and if AD/LDAP is configured, then it will check against AD/LDAP settings. When authentication is successful, the system will also check for CTS role assignment, any key association, and any active permissions.

AD/LDAP and user authentication

Companies can choose to use Active Directory/LDAP to store both human and service user accounts for CTS, to have a centralized way to manage them. If this approach is chosen, then the implementation involves cooperation between:

- **The network administrator**, to configure the connection between AD/LDAP and CTS;
- **The AD/LDAP administrator** and other organizational decision makers who decide which users should be imported into the CTS database, how to group them, what user group names to assign them in AD/LDAP, and what types of permissions should be granted on a group and/or individual basis;
- **The CTS GUI administrator**, who must manually enter the designated user group names into the CTS GUI before the user accounts are imported. See also [“Understanding CTS user groups and permissions” on page 10.](#)

NOTE: It is also possible to create local user accounts directly in CTS. This is useful in test or demo installations of CTS, or might be used for enhanced security, as no AD/LDAP administrator would have access to the local user credentials.

Client certificates and user authentication

Client certificates can be used for authentication. The certificate itself is a credential and can be safer than a password, as it cannot be easily shared, duplicated, written on a sticky note, or otherwise carelessly exposed.

Companies might enable simple client cert authentication, to verify that a machine has a valid cert to connect with CTS. Or they may choose a more sophisticated implementation. With CTS it is possible to use the common name (CN) inside a client cert and enter it into CTS as a user name, thereby taking advantage of the ability to assign granular permissions and/or associate particular keys to a client certificate. This is known as using a client certificate *“with identities.”*

NOTE: Thales highly recommends using client certificates with identities. If you use without identities, you must pass in a username/password along with the certificate, which can be a security vulnerability that client certificates are intended to prevent. The option to use certificates without identities is provided to maintain backward compatibility with the earlier basic authentication flow.

To implement client certs with granular permissions, an organization would need to:

- Have established an in-house Certificate Authority (CA)
- Have an exportable CA cert
- Issue any number of client certs (signed by the CA) that each contain a common name (CN)

- Go to the CTS CLI to:
 - Upload the CA cert to CTS
 - Enable using client certs with ID (See [“Enabling the Client Authentication Feature \(optional\)” on page 58.](#))
- Use the CTS graphical user interface (GUI) for:
 - Creating users and entering common names as user names (or import from Active Directory for LDAP)
 - Managing user permissions (If importing from LDAP, you can use the CTS CLI setting to designate a user group as the “active” user group thereby activating all members of the group.)
 - Associating key(s) with the cert/user
 - Assigning permissions to the cert/user

NOTE: CTS requires that all client certificates be in PEM format.

CTS authorization basics

CTS employs a multi-layered security model with separation of duties and granular permissions settings built in to it. It is also flexible, adaptive to individual corporate structures and policies. This structure implies some inherent complexity, but the concepts below form the foundational assumptions.

CTS roles

When a user is created in CTS, it can be assigned one or more of the following core CTS roles:

- **Superuser:** Can perform both read and write actions in the CTS GUI.
Superusers are GUI administrators who manage users, user groups, keys, tokenization groups, tokenization templates, data masks, and character sets. Superusers associate users with key(s) and assign the crypto, key, and tokenization permissions to other users. Superusers are automatically also “Staff.”
- **Staff:** Users with read-only permission to the CTS GUI.
- **Active:** Users must be “active” in order to have encryption, key, or tokenization permissions. Active users are those authorized to use the CTS REST APIs.

The role-based permissions (Active/Staff/Superuser) are incremental. With no role assigned, the user cannot access any CTS functionality. (This is equivalent to being deleted, but the information is retained in the database for possible reactivation.)

NOTE: When users are created directly in the CTS GUI, they are automatically assigned the status “active,” which can be disabled as needed.

If users are imported from AD/LDAP, the “active” designator is handled differently. See [“Understanding CTS user groups and permissions” on page 10](#) for details.

As of CTS 2.6.0, if Active is unchecked, the user cannot log in to the GUI even if assigned Superuser/Staff status.

Key-aware permissions matrix

The GUI Administrator can assign permissions based on user (or user group), action, and key, similar to the English sentence:

“User CTSuser1 may encrypt, decrypt, tokenize and detokenize with symmetric key Sym_key1.

Figure 1: Permissions available on symmetric keys

NOTE: Permissions can be assigned at the user and the user group level, and are additive. See also [“Understanding CTS user groups and permissions” on page 10](#).

Different types of keys (symmetric, asymmetric, and opaque objects) have different permissions available. See also [“Understanding CTS Keys” on page 11](#).

Tokenize and detokenize functionality require a couple of additional steps. See also [“Tokenization Groups, Templates, and Masks” on page 13.](#)

Other (non-key dependent) permissions

Users or user groups can be authorized to dynamically create and/or import key names and key material on the DSM, under the “Other Permissions” column of the Permissions main page.

NOTE: See also [“Creating static and dynamic keys” on page 12.](#)

- **Create** key: creates the key name and key material in the DSM; the key name will be listed in the CTS GUI.
- **Import** key: used to import any key from one DSM to another, or from an external system into the DSM. The imported key name will be listed in the CTS GUI.

Figure 2: “Create” and “Import” keys are distinct from the legacy Tokenize/Detokenize function

NOTE: The *Other Permissions* assignment window also includes check boxes for **Tokenize** and **Detokenize**, along with a warning about overriding symmetric key assignments ([Figure 2](#)).

This Tokenize/Detokenize feature is used during upgrade from earlier versions of CTS, as it grandfathers in the global tokenize/detokenize feature that was used previously.

NOTE: See [“Other permissions: tokenize/detokenize” on page 90](#) for usage tips.

Understanding CTS user groups and permissions

- **CTS role-based user groups:**

The three core CTS roles (Superuser/Staff/Active) are also three required core CTS user groups. An organization may choose to assign different group names, but the meanings are retained (see [“CTS roles” on page 7](#) for the definitions).

CTS GUI administrators must create at least three user groups that correspond to the roles Superuser/Staff/Active.

- **Assigning users to user groups two different ways:**

If importing from AD/LDAP, users will be sorted into their role groups from the CLI.

If entering users directly in the GUI, the administrator will assign the role(s) on the user’s page and then check the appropriate group(s).

- **Adding more user groups:**

Additional groups can be added to CTS for organizational purposes.

- **Assigning group permissions:**

Key-based and non-key-dependent permissions can be assigned at the user group level or the user level, but assigning at the group level is recommended.

- **Permissions are additive:**

Individual and group permissions are additive. For example, suppose Joe is a member of the user group “Finance,” which has permission to tokenize credit card numbers, and Joe is also a team lead granted user-level permission to detokenize. In total, Joe can tokenize and detokenize.

Users, user groups, and tokenization groups

To allow for abbreviated Tokenization REST API calls and to enable division of an organization into sub-organization either by location or department, CTS adds a so-called “tokenization group” concept. So, there could be a user group “Finance” in San Francisco, and another “Finance” user group in Paris, each associated with its own tokenization group.

NOTE: See also [“Tokenization Groups, Templates, and Masks” on page 13](#).

Understanding CTS Keys

CTS supports three types of keys: **symmetric**, **asymmetric**, and **opaque objects**, each of which uses different algorithms and can be used for different actions.

User permissions (to encrypt, decrypt, sign, verify, hash, or tokenize/detokenize) must be tied to particular keys. The *CipherTrust Key Management APIs* provide an array of static key management functions, as well as the ability dynamically to create or import keys to the DSM.

Key types, algorithms, and key states

The application developer, the DSM Administrator, and the CTS GUI Administrator work together to implement key handling in CTS.

Table 1: Key Summary Table

Key Type	Description	Algorithms	State
Symmetric	Oct or octet sequence. Used to: • tokenize • detokenize • encrypt • decrypt Symmetric keys are also used for tokenization, and while the symmetric keys are typical AES keys with 128 or 256 bits of key material, the algorithms are FPE (FF3) and FF1. Note: Versioned keys may not be used for tokenization, only non-versioned keys.	A128ECB - AES 128 ECB cipher mode A256ECB - AES 256 ECB cipher mode A128CBC - AES 128 CBC cipher mode A256CBC - AES 256 CBC cipher mode A128GCM - AES 128 GCM cipher mode A256GCM - AES 256 GCM cipher mode A128CBCPAD - AES 128 CBC-PAD cipher mode A256CBCPAD - AES 256 CBC-PAD cipher mode A128CTR - AES 128 CTR (counter) cipher mode A256CTR - AES 256 CTR (counter) cipher mode	At this time, only symmetric keys support states. On create and import, only a preactive or active state may be given. On a key update, all states can be given except for preactive. The following states are available: • Preactive • Active - Default when a key is created • Suspended • Compromised • Deactivated • Destroyed
Asymmetric	RSA key type. Used for: • encrypt • decrypt • sign • verify	RSA	N/A

Table 1: Key Summary Table

Key Type	Description	Algorithms	State
Opaque Object	Octet array. This is a Thales extension (not part of JOSE RFC-7518 spec). Used for • sign • verify Does not have the option of store on server.	HS1 - HMAC-SHA-1 HS224 - HMAC-SHA-224 HS256 - HMAC-SHA-256 HS384 - HMAC-SHA-384 HS512 - HMAC-SHA-512	N/A

Key input sizes

For CBC and ECB modes of encryption, the input size should be a multiple of the block size. Note that the AES block size is 16 bytes (128 bits).

If you do not use an input length that is a multiple of the block size, use CTR or CBC-PAD encryption.

Creating static and dynamic keys

Create keys with either a static or dynamic work flow:

Static work flow

In most cases, it is recommended to implement your application using static keys — that is, keys that will change their key material rarely, and thus are rarely created or destroyed in the DSM.

The implementation tasks for static key creation are:

- Decide which actions will be performed (encrypt/decrypt, tokenize/detokenize, sign/verify), and which types of keys will be needed to support those actions.
- **DSM Administrator:** Create CTS-specific keys in the DSM, giving them meaningful names.
NOTE: it is recommended to keep tokenization keys separate from other encryption/decryption keys.
- **CTS GUI Administrator:** Enter the appropriate key names into the CTS GUI, to be stored in the local CTS database and used for assigning encryption and tokenization permissions.
- **Application Developer:** Use the CipherTrust Key Management, Cryptography, and Tokenization APIs to perform the necessary functions in the application being integrated with CTS.

Do not use the REST API `create` or `import` key functions.

IMPORTANT: It is recommended to use a static key model with tokenization.

Dynamic work flow

In some cases, an organization may decide to automate key creation, rotation, or key import in the DSM, using the appropriate *CipherTrust Key Management* APIs.

If a key is deleted, all of the ciphertext the key was instrumental in creating is rendered unreadable.

In this case, the implementation team would need to:

- Decide which actions will be performed (encrypt/decrypt, tokenize/detokenize, sign/verify) and which types of keys will be needed to support those actions.
- **Application Developer:** Use the *CipherTrust Key Management* and *Cryptography* APIs to perform the necessary functions in the application being integrated into CTS, including `create` and/or `import` key functions.
- **CTS GUI Administrator:** Designate a user (possibly a non-human user) and grant the user permission to create and/or import keys.

Tokenization Groups, Templates, and Masks

In tokenization, sensitive data—such as credit card numbers or social security numbers—are replaced with an encrypted “*token*” which retains the format of the original data. When detokenizing, different users can be authorized to view the entire detokenized/unencrypted value, or authorized to see only a part of the value, with the rest hidden by a *data mask*.

CTS includes tokenization groups, templates, and data masks as convenience features to make implementing tokenization easier.

What is a tokenization group?

A *tokenization group* is a way to compartmentalize CTS at a department level or site level. Each tokenization group has a symmetric key associated with it. While the key management and encryption services refer to keys directly, the `tokenize/detokenize` services refer to a key indirectly – via the tokenization group.

NOTE: See also [“Managing tokenization groups” on page 79](#).

Figure 3: Have at least one symmetric key created when you create a tokenization group

The screenshot shows a 'New Tokenization Group' dialog box. It has a title bar with the text 'New Tokenization Group' and a close button. The dialog contains two fields: 'Name*' with a text input field containing the text 'name', and 'Key*' with a dropdown menu showing 'Sym_key1'. At the bottom right of the dialog are two buttons: 'Create' and 'Cancel'.

NOTE: Remember that all symmetric keys used for tokenization must be unversioned keys.

Tokenization template

Tokenization templates are used to supply parameters to the tokenization/detokenization operation which otherwise would have to be supplied individually in the REST API call, thus making the REST API call both easier to use and shorter. The CTS GUI administrator collaborates with the application developer to create tokenization templates with the appropriate settings, and to give the template a name that developers will use in their code.

NOTE: See also [“Managing tokenization templates” on page 84](#).

Figure 4: Create tokenization templates after creating tokenization groups and character sets.

Using data masks

When a user or user group is given detokenization privileges, a data mask must be applied that defines how much of the unencrypted data they are allowed to see. To create a mask that shows the entire data string, the CTS GUI Administrator would enter very large values in the **Show Left** and **Show Right** fields (999999).

NOTE: See also [“Managing data masks” on page 87](#).

Figure 5: New data mask creation.

A screenshot of a 'New Mask' dialog box. The dialog has a dark header bar with the title 'New Mask' and a close button. Below the header, there are four labeled input fields: 'Name*' with a placeholder 'Name of the mask', 'Show Left*' with a value of '0', 'Show Right*' with a value of '0', and 'Masking Character*' with a placeholder 'Masking Character'. At the bottom right of the dialog are two buttons: 'Create' (highlighted in blue) and 'Cancel'.

About the CTS API

CTS includes the following sets of REST API services: Encryption, Key Management, Tokenization, and Administration.

Tokenization/detokenization are simple-to-use REST APIs which provide format-preserving encryption and proprietary "RANDOM" tokenization, whereas the Encryption APIs offer a plethora of traditional non-format-preserving encryption methods, as well as two format-preserving ones (FF3 and FF1)

Encryption and Key Management APIs are described in the chapter ["Encryption and Key Management API Programming Notes" on page 107](#), and in an online reference guide. The Tokenization APIs (including the reference documentation, examples, and error codes) are described in the chapter ["Tokenization REST API" on page 133](#). The Administration APIs are described in ["Admin REST API" on page 155](#).

These APIs are also described in an online reference guide, under **Documentation** in the CTS Administration GUI navigation bar.

Installing and Upgrading CTS

This chapter describes how to install CTS. It is used by the **CTS network administrator** and contains the following sections:

- [“Overview” on page 17](#)
- [“Installation Prerequisites” on page 19](#)
- [“Choose an Installation Type and Deploy” on page 24](#)
- [“Upgrading CTS” on page 30](#)

Overview

The CTS solution consists of the following required components and optional components:

- CipherTrust Tokenization Server (CTS)
- A key manager (keystore), such as Vormetric Data Security Manager (DSM), Thales KeySecure Classic, or Thales CipherTrust Manager (CM)
- Active Directory (AD)/LDAP server (optional)
- Remote Logging server (optional)
- Load Balancer (optional)

NOTE: This chapter focuses on installing the CTS, with additional sections about upgrade, backup, and recovery. Chapter 3, [“Configuring the CTS System” on page 35](#), describes the follow-up configuration steps the network administrator performs to connect all the components and establish baseline settings.

CTS basic component architecture

CTS can be installed as a virtual machine (the more typical case) or as software on bare metal.

The CipherTrust Tokenization Server does most of the tokenization work and acts as a server for the additional cryptographic and key management API calls and features. It uses the other components for

specific tasks. It obtains encryption keys from the DSM and it uses those encryption keys to encrypt sensitive data. For users created in the AD/LDAP server, the Tokenization Server uses the AD/LDAP server to validate those users when they request data to be tokenized, detokenized, encrypted, etc. Users can also be created with the CTS GUI. These users are validated by the CTS itself.

Once the system has been installed and configured, the CTS supports the RESTful API calls from applications. Log messages can optionally be sent to a remote logging server.

IMPORTANT: A minimum of two nodes is recommended. This configuration ensures that the data is retained online, and provides for optimum availability. For higher performance, use a cluster with more than two nodes. It is also recommended to use a load balancer to automatically distribute load to all nodes in the cluster.

Figure 6: CTS Component Architecture (with DSM as keystore)

Installation Prerequisites

The CTS solution requires installing multiple components. The following sections describe each component and the information you must gather before integrating them into the CipherTrust Tokenization solution. The integration steps themselves are described in [“Choose an Installation Type and Deploy” on page 24](#).

- [“Keystore \(DSM, KeySecure Classic, or CM\) requirements” on page 19](#)
- [“CipherTrust Tokenization Server requirements” on page 19](#)
- (Optional) [“Active Directory/LDAP server requirements” on page 21](#)
- (Optional) [“Remote logging server” on page 23](#)
- [“Load balancer requirements” on page 23](#)
- [“Port configuration” on page 23](#)

Keystore (DSM, KeySecure Classic, or CM) requirements

A Vormetric DSM, KeySecure Classic, or CipherTrust Manager (CM) server provides the CipherTrust Tokenization Server with encryption keys.

For specific version compatibility requirements with CTS, check the *Vormetric/CipherTrust Data Security Platform DSM | VAE | CTS | VTS | VKM | VPTD | BDT Compatibility Matrix* document.

Note that CTS does not require a dedicated keystore ; it can be shared with other VDS applications. To install a new DSM, see the *CipherTrust Data Security Manager (DSM) Installation and Configuration Guide*. Refer to the corresponding documents for installing a new Thales KeySecure Classic or Thales CipherTrust Manager (CM) server.

Gather this keystore information for system configuration:

1. DSM , KeySecure, or CM server fully qualified hostname: _____
2. DSM , KeySecure, or CM IP address (or addresses, if multiple clustered servers): _____

CipherTrust Tokenization Server requirements

CipherTrust Tokenization Server can be installed on a physical server (bare metal) or as a virtual machine.

To run as a virtual machine, CTS supports the following hypervisors:

- VMware ESXi 6.0 or higher

- Amazon AWS EC2
- Microsoft Azure
- Microsoft Hyper-V
- Linux Kernel-based Virtual Machine (KVM)
- Google Cloud Compute Engine (GCP)

CTS builds are available in the following formats:

- ISO -- for physical machines, VMware ESXi, or Hyper-V
- OVA -- for VMware ESXi
- VHD -- for Hyper-V and Azure
- AMI -- for Amazon AWS
- qcow2 -- for KVM
- GCP -- for Google Cloud Compute Engine

Minimum system requirements:

RAM:

- 16GB minimum for RANDOM mode = none
- 24GB for RANDOM mode = numeric or alphanumeric
- 32GB for for RANDOM mode = both numeric and alphanumeric

CPU:

- 4 CPUs, x86, > 2.0Ghz recommended

Disk:

If CTS is installed as a virtual machine, the disk size is automatically created and allocated when the virtual machine is created from the build image.

If CTS is installed on a physical machine, a minimum of 85GB disk is required. ISO installation will fail if the disk is less than 85GB. Installation will also fail if RAM is less than 16GB.

Networking:

CTS supports DHCP or static IP addresses. IPv6 is not supported; only IPv4 is supported at this time.

CTS supports DNS or static entries in the `/etc/hosts` file. It is recommend to use DNS if available.

Gather this CipherTrust Tokenization Server information for system configuration:

1. Tokenization Server .ova image, .iso image, Amazon AWS ID, or Azure ID:
-

2. Tokenization Server system hostname:
-
3. Tokenization Server IP address:
-
4. Tokenization Server subnet prefix length:
-
5. Tokenization Server default gateway:
-
6. DNS Server IP address:
-

NOTE: If you don't use DNS to resolve hostnames, you can modify the /etc/hosts files. See [“The /etc/hosts file” on page 40](#).

Active Directory/LDAP server requirements

An optional AD/LDAP server can be used to generate users and authenticate their credentials when they request services.

See [“Understanding CTS Authentication and Authorization” on page 4](#) and [“AD/LDAP and user authentication” on page 6](#) for a conceptual basis on how AD/LDAP is used.

Requirements:

- Access to the AD/LDAP server containing users and groups that will have CTS privileges.
- For LDAPS, the LDAP server's CA certificate must be imported into the Tokenization Server.
- If you use the three example Active Directory groups below (ctsUsers, ctsManager, and ctsSuperuser), create these groups before completing the steps described in [“Configuring an AD/LDAP Server \(optional\)” on page 54](#).

Gather this AD/LDAP information for system configuration:

Table 2: AD/LDAP Configuration Information

Name	Description	Your Site Information
LDAP Server URI	Hostname, port and protocol of LDAP server. Example: ldaps://ads.example.com:636	

Table 2: AD/LDAP Configuration Information

Name	Description	Your Site Information
binding DN	FQDN of user that has access to the LDAP server Example: cts@ads.example.com	
binding password	The credential of above user Example: H838%i2hz9*%^86&^*	
user search scope	Search criteria of user object in AD/LDAP server Example: dc=corp,dc=example,dc=com	
user group search scope	Search criteria of user group inside AD/LDAP Example: cn=Users,dc=corp,dc=example,dc=com	
user search filter	Name of user field in AD/LDAP Example: sAMAccountName for AD, uid for LDAP	
Tokenization Server active user group	Group that user can access Tokenization Server RESTful API Example: cn=ctsUsers,cn=User,dc=corp,dc=example, dc=com	
Tokenization Server super user group	Group that can access the GUI and REST APIs. Example: cn=ctsSuperuser,cn=User,dc=corp,dc=example, dc=com	
group member selector	<u>UNIX/Linux LDAP only.</u> The LDAP attribute which designates a group member within a group. Example: member or memberUID	
group object class	<u>UNIX/Linux LDAP only.</u> The LDAP attribute that identifies a group of users. Example: posixGroup or groupOfNames	
user prefix	<u>UNIX/Linux LDAP only.</u> The LDAP attribute to be used to prefix the username when searching for username in the LDAP database Example: uid, cn, sn	
CA Certificate	For LDAPS only: Access to root and intermediate CA certificates for the LDAPS server in .pem file format. May require a Certificate Management tool	

Remote logging server

Optionally, you can redirect log messages to a remote logging server.

Gather the following remote logging server information for system configuration:

1. Remote logging server name or IP address:_____
2. Remote logging server port (TCP):_____

Load balancer requirements

A cluster of CTS nodes can be installed and run as one coherent CTS system using a load balancer. The load balancer acts as the main entry point for tokenization and crypto services to distribute load across all nodes in the cluster. This provides scalability and reliability of the system.

CTS supports the following methods of load balancing:

- Round-robin -- requests are distributed in a round-robin fashion.
- Least-connected -- allows the load balancer to control the load on some CTS nodes.
- IP-hash -- the client IP address is used to determine what server in a server group should be selected for the client request. This can be used for client's session sticky or persistent.

The load balancer must be able to use TLS1.1 and higher.

Port configuration

If the CipherTrust Tokenization Server must communicate with other components through a firewall, open the ports in the firewall as shown in the following tables. [Table 3](#) shows incoming traffic, and [Table 4](#) shows outgoing traffic.

NOTE: For a complete list of ports required for the DSM, see the *DSM Installation and Configuration Guide*.

[Table 3](#) describes each port you must open for incoming communication to the CTS.

Table 3: Incoming Ports to Configure for CipherTrust Tokenization Server

22	TCP	Management Console →CTS	Administration CLI SSH access.

Table 3: Incoming Ports to Configure for CipherTrust Tokenization Server

443	TCP	Browser → CTS Requester → CTS CLI → CTS	HTTPS access for Administration GUI and REST/JSON API. Download the zip file to perform upgrade.
5432	TCP	CTS ↔ CTS	This port is required if a cluster of more than one node is used. This port is used exclusively for communication between the CTS nodes in a cluster. If the cluster of nodes is inside a VPC or subnet, access to port 5432 should only be confined within the subnet or VPC. It is recommended that this 5432 port is firewalled off from anything other than the cluster nodes.

[Table 4](#) describes each CTS port you must open for outgoing communication from the CTS.

Table 4: Outgoing Ports to Configure for CipherTrust Tokenization Server

User-defined	TCP	CTS → Log Server	Remote logging
123	UDP	CTS ↔ NTP Server	Optional network time synchronization
389	TCP	CTS → LDAP Server	Optional LDAP connection
636	TCP	CTS → LDAPS Server	Optional LDAPS (LDAP over TLS) connection
8080	TCP	CTS → DSM	Default TCP/IP port for HTTP that is used once to perform the initial certificate exchange between a CTS host and DSM.
8443	TCP	CTS → DSM	TCP/IP port through which the CTS communicates with the DSM to exchange configuration. The CTS establishes a secure connection to the DSM via certificate exchange using this port.
8444	TCP	CTS → DSM	Upload CTS log messages to DSM
8446	TCP	CTS → DSM	Configuration exchange (policy/key pull) using Elliptic Curve Cryptography (Suite B)
8447	TCP	CTS → DSM	CTS uploads log messages to DSM using Elliptic Curve Cryptography

Choose an Installation Type and Deploy

There are several options for the network administrator to install the CipherTrust Tokenization Server:

- [“Install CTS as a virtual machine on VMware vSphere” on page 25](#)
- [“Install CTS on bare metal” on page 25](#)
- [“Install CTS in the AWS cloud” on page 26](#)

- [“Install CTS in the Azure cloud” on page 27](#)
- [“Install CTS on Hyper-V” on page 28](#)
- [“Install CTS on KVM” on page 29](#)
- [“Install CTS in Google Cloud Platform” on page 30](#)

Install CTS as a virtual machine on VMware vSphere

CTS can use a VMware ESXi hypervisor to create a virtual machine using the ISO or OVA build image. CTS supports ESXi version 6.0 or higher.

Refer to VMware ESXi documentation on how to create a VM using an ISO or OVA image.

It is recommended to use Thick Provisioning for hard disks.

For a multi-node setup, you can repeat this installation process for additional machines. You would then configure each node separately and join them in a cluster as described in [“Configuring CTS Nodes” on page 50](#).

To begin configuration, click the **Console** tab of the vSphere Client to log in to the CTS CLI as `cliadmin`, change the default password, accept the Service Level Agreement, and begin configuring CTS settings using the CTS CLI (see [“Configuring the CTS System” on page 35](#)).

Install CTS on bare metal

Although typically installed as a virtual machine, the CipherTrust Tokenization Server is also provided as an ISO image that can be installed on a bare metal host.

A bare metal host is a computer that does not run hypervisor software. Do not install the operating system on the host before installing CTS software, because the OS is included along with the CTS software in the installation package. When selecting the operating system, specify 64-bit CentOS version 7 or higher.

Make sure the computer meets the following minimum system requirements:

- Number of CPU cores: 4
- RAM: 15 GB minimum if RANDOM mode is none. 24 GB recommended if CTS will be used to tokenize credit card numbers longer than 16 digits. 24 GB if using numeric RANDOM mode or alphanumeric RANDOM mode, or 32 GB if using both modes.
- Hard disk space: 85 GB

To do a bare metal installation:

1. Obtain the installation file `cts-<release>.iso`.
2. Refer to the machine's documentation on how to boot and install from an ISO image.

Install CTS in the AWS cloud

Prerequisites

The following components are necessary for running a CTS in the cloud on Amazon Web Services.

- A VPC (Amazon's *Virtual Private Cloud*). If you plan to create a cluster of CTS machines, it is recommended that your cluster nodes use a VPC so that they communicate only with each other within the private cloud. Cluster communication does not need to be, and should not be, exposed on the Internet.
- A Subnet. If you choose to use a VPC, you will need to create a subnet and associate that subnet to that VPC. This subnet is where your CTS cluster nodes will get the IP addresses.
- A Security Group. Set your security group with the following minimum settings:

Incoming port 443 - Web and REST API access

Incoming port 22 - CLI access

Incoming port 5432 - Optional. Set this only if the machines in your cluster are not using a VPC to communicate with each other.

If you will be accessing your CTS strictly inside the VPC, you will still need a security group, but you can block all incoming ports. If your DSM is located inside the same VPC, you can block both incoming and outgoing ports.

- For best security, use SSH key pairs instead of passwords for SSH logins. If you choose to use an EC2 key pair when creating a CTS instance, the `cliadmin` will use that key (a private key) to log in by SSH. Password access will be disabled.

If you choose to not to use an EC2 key pair, the `cliadmin` will use a password to log in by SSH.

Upgrading an EC2 instance from VTS v2.5 or earlier retains the use of passwords for the `cliadmin`. Only newly-created instances from CTS v2.6 and above can use the SSH key pair in AWS.

Create the CTS instance

Follow this procedure to create the CTS.

1. Choose your AWS region.
2. Locate the AMI of the CTS image.

3. Select the AMI image and launch an instance.
4. Select Instance type: m4.xlarge - with recommended minimums of 4 vCPUs and 16GB memory.
5. Select the VPC to use for the installation.
6. Select the subnet.
7. Select **Auto-assign public IP**, if applicable.
8. Set the primary IP address. This will be the IP address of the VPC subnet, and it will be used by the VM for its cluster node IP address.
9. In the **Add Storage** menu, select delete on termination, if applicable. Do not change the size of the root volume.
10. Choose whether to have cliadmin log in via SSH with a password or with an EC2 key pair.

If you choose not to use an EC2 key pair, the cliadmin will use a password to log in by SSH.

If you choose an EC2 key pair, the cliadmin will use that key (private key) to log in by SSH. Password access will be disabled. You are prompted to select an existing key pair. Select the private key file (in PEM format), and make sure to confirm your selection before launching the new instance. Note that if an instance is configured to use an EC2 key pair, password access is blocked, and all password-related CLI commands are disabled.

Configuration notes

To begin configuration, ssh into the instance as cliadmin user, using the public IP address or the VPC IP address, and follow the steps in [“Configuring the CTS System” on page 35](#).

If you will be creating a cluster of CTS machines, create an instance for each node in the cluster. You would configure each node separately and join them in a cluster as described in [“Configuring CTS Nodes” on page 50](#). Note that when configuring a multi-node cluster, you will use the **VPC IP** address for the node_IP_address.

Install CTS in the Azure cloud

Create the Azure VM

1. Log in to the Azure web portal at <https://portal.azure.com>.
2. Go to the *Marketplace* screen and search for **CipherTrust Tokenization Server**. Select the desired version and click the **Create** button.
3. Supply the following information to create a virtual machine:
 - **VM name:** name of the VM you want to use, for example, my-CTS-2.3.0-azure-vm
 - **VM disk type:** SSD or HDD.

- **User name:** Not required by CTS but Azure needs this data to create a VM. This user name entry is not retained by CTS, and is not used as a CTS credential.
- **Authentication type:** Also not required by CTS but required for Azure to create a VM. This authentication type entry is not retained by CTS, and does affect the CTS configuration.
- **Resource group:** You may create a new resource group or use an existing one. If you plan to create a cluster of CTS machines, it is recommended that all cluster nodes use the same resource group, so that they can communicate with one another without having to use a public static IP address or enable an incoming port in the firewall.
- **Location:** For example, “West-US”
- **Subnet and subnet address range**
- **Static or dynamic public IP address:** Use a static IP address if you expect your cluster to span multiple resource groups

Configuration notes

To begin configuration, ssh into the instance as the `cliadmin` user using the public IP address, and follow the steps in [“Configuring the CTS System” on page 35](#).

Note that on Azure, you will not [“Configure the CTS network settings” on page 37](#). Azure automatically configures these parameters for the CTS VM:

- Internal and subnet IP addresses are provided to the VM through DHCP.
- For CTS clusters, create an instance for each node in the cluster. Then configure each node separately and join the nodes in a cluster.
- When creating or joining a cluster, if you have all the cluster nodes in the resource group, you must use the same **internal or subnet IP** address used by the VM.
- When adding a node to the cluster, you must always use the internal or subnet IP address of the new CTS VM node.

The network security group defines the firewall rules of the CTS virtual machine. At a minimum, incoming ports must allow port 22 (SSH) and port 443 (HTTPS).

If your cluster nodes are located in different resource groups, you also need to add port 5432 to the allowed incoming ports. However, if all your cluster nodes are in the same resource group, do not add port 5432, because nodes inside a resource group do not need any firewall permissions to communicate with one another.

Install CTS on Hyper-V

Install the CTS on a Hyper-V server using an `.iso` or VHD file.

Download the `.iso` or VHD file to the installation server.

Use the following steps to install the CTS on a Hyper-V server using an .iso or VHD image file.

1. Open Hyper-V Manager.
2. Select **Action > New > Virtual Machine**.
3. Choose **Generation 1**.

NOTE: Generation 2 is not supported.

4. Set the start up memory to 16GB.
5. Choose a network adapter.
6. For the VM, choose one of the following based on the type of file used:
 - .iso image - Use an existing hard disk: Select CTS VHD image file you've downloaded or copied.
 - VHD file - Install an operating system from a bootable CD/DVD-ROM: Navigate to and select the downloaded .iso file.
7. Select **Finish** to create the Virtual Machine
8. For .iso only: Select and start the Virtual Machine. This VM boots the mounted ISO image file and the CTS installation begins.

Install CTS on KVM

To install CTS on a Linux Kernel-based Virtual Machine (KVM):

1. Download the CTS image in qcow2 format. Place this image file into your KVM images directory.
2. Create a KVM virtual machine by importing the CTS qcow2 image. Use the following KVM parameters:
 - virt-type: kvm
 - os-type: linux
 - os-variant: centos7.0
 - vcpus: 4
 - ram: 16000
 - controller: type=scsi,model=virtio-scsi
 - disk: /var/lib/libvirt/images/cts-2.x.n.nnn.qcow2,bus=scsi
3. Connect to the console and log in as user cliadmin.

Install CTS in Google Cloud Platform

To install the CTS on the Google Cloud Platform (GCP):

1. Contact Thales Engineering Support and provide your GCP account for access to CTS images.
2. Log in to the GCP console and navigate to **Compute Engine > VM Instances > Create Instance**.
3. Set a name, region, and zone for your instance.
4. Select your machine configuration. Recommended settings:
 - General-purpose
 - N1 Series
 - 4 CPUs, 15GB memory
5. Select **Boot disk** and navigate to **Change -> Custom Images**.
6. In the **Show Images** tab, look for the project name that Thales Support has provided. Select that project.
7. Select the **Image** tab and look for the latest CTS GA release and select it. For example, **cts-240-216**.
8. Choose a boot disk type, for example, **Standard** or **SSD**.
NOTE: Do not change the disk size.
9. Close the *Boot disk* page by clicking **Select**.
10. In the **Firewall** setting, select **Allow HTTPS traffic**.
NOTE: Do not use SSH keys.
11. Click **Create** to begin creating the CTS instance.
12. Connect to the instance using SSH to begin the CTS setup.

Upgrading CTS

You can upgrade with the standard upgrade ZIP file only if you are upgrading from CTS v2.3 or higher. If you are upgrading from any CTS version earlier than v2.3, refer to the release notes for specific details based on the current version you are upgrading from.

If you are upgrading from CTS version 2.2.x or earlier, you must perform a backup and restore procedure as part of your upgrade. The backup includes users and groups, permissions, and settings. You can perform this backup either through the CTS GUI or REST APIs. Refer to [“Backing Up and Restoring the CTS” on page 96](#) for instructions on this backup step, and on the subsequent restore step.

Notes for upgrading a cluster

- All nodes in the cluster must be upgraded to the same CTS version. A CTS cluster must not operate nodes using different CTS versions.
- When upgrading nodes in a cluster, all CTS operations must be suspended. If this is not possible, you must perform a rolling upgrade. The nodes to be upgraded must be taken offline -- for example taken out of the load balancer -- before an upgrade is performed. When the load balancer is ready to use the upgraded nodes, all other nodes not yet upgraded must be taken offline. At any one time, the load balancer must not serve nodes running different CTS versions.
- While a node upgrade is in progress, it must not be interrupted. If it is interrupted or does not complete successfully, you must discard the node by removing it from the cluster. Create a new VM, upgrade it to the desired version, and rejoin it to the cluster. When joining the node to the cluster, it must have the same version as all other nodes in the cluster.
- All nodes in the cluster must be upgraded and must complete the upgrade before resuming operations.

Upgrades to AWS instances cannot use SSN key pairs

Upgrading an EC2 instance from VTS v2.5 or earlier retains the use of passwords for the `cliadmin` instead of SSH key pairs. Only newly-created instances from CTS v2.6 and above can use the SSH key pair in AWS.

Upgrade steps

If you have multiple nodes in a cluster, you can upgrade all nodes at the same time.

1. Obtain the upgrade ZIP file from your Thales sales or support representative, and place the file on a server that is accessible from CTS over either HTTP or FTP.
2. Although the upgrade ZIP file is encrypted and digitally signed, the HTTP server can use SSL (HTTPS) and basic authentication. The HTTPS server can also use a self-signed certificate.

3. Log in as cliadmin to the CTS virtual machine that you want to upgrade. In the following example command, substitute your own CTS hostname.

```
$ ssh -l cliadmin <Tokenization Server hostname>
cliadmin@<Tokenization_Server_IP_address> password: <Enter the cliadmin
password>
[...]
CipherTrust Tokenization Server Main Menu
main> ?

      Command          Description
      =====
auth          Authentication Setup
cluster       Cluster Setup
icapi         SafeNet ProtectApp Setup
network       Network Setup
system        System Setup
vae           VAE Configuration
vts           Tokenization Setup
quit|q|up|<ctrl-d>  Quit or return to previous menu
exit          Exit application

      Enter <command> to display usage
main>
```

4. At the main menu, enter:

```
main> vts upgrade --url <upgrade_zip_url>
```

Another option is to navigate to the **vts** submenu and enter the upgrade command directly:

```
main> vts
vts> upgrade <upgrade_zip_url>
```

5. Upgrade the CTS software with the upgrade command. In the example command below, substitute the location of your own upgrade ZIP file.

```
vts> upgrade <Upgrade Package URL>
```

Examples:

```
upgrade https://example.com/cts-upgrade-<version>.zip
upgrade https://username:password@example.com/cts-upgrade-<version>.zip
upgrade ftp://example.com/cts-upgrade-<version>.zip
```

Watch the output of the upgrade command while the upgrade is underway. After several progress messages, you should see a success message like the following:

```
Upgrade complete.
```

Depending on the type of upgrade, the system will be rebooted at the end for changes to take effect. You are prompted at the beginning of the upgrade for confirmation.

There are other options to perform an upgrade. Run `upgrade --help` for details:

Configuring the CTS System

This chapter describes how the network administrator uses the CTS CLI to configure the CTS environment, establish connections between the various components, and other system-level tasks. It contains the following sections:

- “Accessing the CLI”
- “Basic Configuration Steps”
- “Configuring CTS Nodes”
- “Configuring an AD/LDAP Server (optional)”
- “Configuring ADFS and LDAP for OAuth”
- “Configuring the settings.ini File for LDAP”
- “Restarting the CipherTrust Tokenization Server”

Accessing the CLI

The network administrator uses the CTS CLI to configure the CTS environment.

1. Access the CLI through a terminal emulator like PuTTY.
2. On first access, enter the default login and password:
login: cliadmin
Password: cliadmin123
3. On first access, you will be prompted to change the password.
Save and store your new password securely.
4. On first access, you will be prompted to review and sign the License Agreement.

CLI navigation cheat sheet

Table 5: CLI Navigation Summary and Guidelines

Navigation	Command	Example
Starting prompt	main>	
List CLI categories or the commands within categories	?	<pre>main> ? auth Authentication setup cluster Cluster Setup icapi SafeNet ProtectApp Setup network Network Setup system System Setup vae VAE Configuration vts Tokenization Setup quit q up <ctrl-d> Quit or return to previous menu exit Exit application</pre>
Open a category and display its commands	<category name> ?	<pre>main> cluster cluster> ? add Register a new node to a cluster apiadmin API admin user setup create Create New Cluster join Join node to a cluster remotejoin Remotely join nodes to a cluster remove Remove node from cluster show Show cluster status quit q up <ctrl-d> Quit or return to previous menu exit Exit application</pre>
Get help: See command usage and example output	<enter the command without a value>	<pre>network> checkport usage: checkport [-h] [--host HOST] [--port PORT [PORT ...]] Check port connection status of a host Optional arguments: -h, --help show this help message and exit --host HOST hostname or IP address of host --port PORT [PORT ...] port numbers to scan</pre>
Have CLI complete a category name, command, or argument when typing	Press <Tab>	Enter enough characters to uniquely identify a category, command, or argument, and then press the <Tab> key. The CTS CLI will complete it for you.
Return to the main level	up	<pre>main> cluster cluster> up main></pre>

Table 5: CLI Navigation Summary and Guidelines

Navigation	Command	Example
End the CLI session	<code>exit</code>	
NOTE: You must enter a category to execute any of its commands. For example, the reboot command is in the system category, so you must first enter system, then enter reboot.		

Basic Configuration Steps

The configuration steps in the following sections employ a subset of the CLI commands. See [“CTS CLI Reference” on page 99](#) for a summary of CLI commands. For complete usage details on any CLI command, run the command with the “-h” option.

NOTE: For multi-node installations, the basic configuration steps in this section must be completed on each node before you follow [“Configuring CTS Nodes”](#) as described on page 50.

Configure the CTS network settings

Configure the network setting for VMware and bare metal installations with a static IP implementation.

IMPORTANT: Network settings are required only for VMware and bare metal installations, with a static IP implementation. Do not attempt to set the IP address and gateway of the network interface if you are using CTS in an Azure, Amazon, or Google cloud. Cloud providers assign the IP addresses to the VM through DHCP.

To configure the CTS network settings, complete the following tasks:

- “Set the IP address for the CTS VM”
- “Configure the CTS DNS server” or use “The /etc/hosts file.”

Check the annotations you made under [“CipherTrust Tokenization Server requirements” on page 19](#) for the IP address, gateway address, and DNS values you will need.

Set the IP address for the CTS VM

1. Using the CTS CLI, navigate to the *network* commands menu.
2. There are two ways to set the IP address for the CTS VM: Interactive (with the *setup* command) or Non-interactive (with the *set* command).

Interactive

To set the IP address using the interactive mode, use the *setup* command followed by the network device name:

```
network> setup eth0
```

Using the *setup* command prompts you for the IP address, as well as other information required to set up the specified network device, such as subnet mask, gateway, and so on.

Non-interactive

To set up the IP address with the non-interactive mode, use the *set* command with the *--ipaddr* IPADDR option and argument value. With the same *set* command invocation you can also configure other network and device parameters with additional options:

```
vormetric> network set --help
usage: set [-h] [--onboot {yes,no}] [--dhcp] [--ipaddr IPADDR]
          [--netmask NETMASK] [--gateway GATEWAY] [--defroute {yes,no}]
          [--mtu MTU] [-y]
          device
Configure Network Interface
[. . .]
```

Table 6: Options and Arguments to the Non-interactive *set* Command

Option	Argument	Description
--onboot	yes no	Enable this device at boot time
--dhcp		Use DHCP
--ipaddr	IPADDR	Set the IPv4 address of this device to <i>IPADDR</i>
--netmask	NETMASK	Sets the netmask of this device to <i>NETMASK</i> (for example, 255.255.0.0)
--gateway	GATEWAY	Specify the gateway IP address as <i>GATEWAY</i>

Table 6: Options and Arguments to the Non-interactive set Command

Option	Argument	Description
--defroute	yes no	Set to yes to use this device as the default route. Default value is no . NOTE: Set only one device as the default route.
--mtu	MTU	Set the maximum transmission unit (MTU) value to <i>MTU</i>
-y		Do not prompt for confirmation

3. Verify the IP address configuration using the show command followed by the device name:

```
network> show eth0
```

Configure the CTS DNS server

If your network environment uses DNS, use the dns command to configure the nameservers:

```
network> dns --add IP [IP ...]
```

You can configure a maximum of three nameservers.

Show the DNS settings with the --show option:

```
network> dns --show
DNS resolver is using DHCP
Generated by DHCP:
  nameserver 192.168.100.199
  nameserver 192.0.0.299
```

NOTE: If you are using DHCP, using the dns command overrides the nameservers provided by the DHCP.

The /etc/hosts file

If you have hostnames that do not use DNS, you can use the local /etc/hosts file to resolve IP addresses. To update this file, run the CLI "system hosts" command, which includes options to add or remove IP addresses, and to show the hosts file contents.

```
main> system hosts
usage: hosts [-h] [--show] [--add IP [HOSTNAME ...]] [--remove IP]
Update hosts file
optional arguments:
  -h, --help            show this help message and exit
  --show                Show hosts file entries
  --add IP [HOSTNAME ...] Add/update hosts entry
  --remove IP           Remove hosts entry
```

For example:

```
main> system hosts --add 192.168.99.99 rgrimes
192.168.99.99      rgrimes
10.3.110.187      cts-builder2

main> system hosts --show
192.168.99.99      rgrimes
10.3.110.187      cts-builder2
```

NOTE: You must do this on *each* CTS, since entries in the hosts file are not replicated across CipherTrust Tokenization Servers.

Setting the CTS hostname

You must set a hostname for the CTS VM.

This hostname must match the hostname created on the DSM or other Thales keystore. The CTS will not register to the keystore if these names do not match.

To set the hostname of the CTS VM, run the system hostname command with the --set option in the CTS CLI:

```
main> system hostname --set your_cts_hostname
```

Importing a server certificate for TLS

Use the `vts server_certificate` command in the CTS CLI to import a server certificate. Enter the command without any options to see a detailed help message that explains all arguments to the command (some of which are deleted from the example shown below to save space):

```
main> vts server_certificate
usage: server_certificate [-h] [--import {certificate,key}]
                        [--create {csr,selfsigned,key}] [--size SIZE]
                        [--show {key,certificate}] [-y] [--country C]
                        [--state ST] [--locality L] [--organization O]
                        [--organizational_unit OU] [--common_name
HOSTNAME]
                        [--email EMAIL] [--dns [DNS [DNS ...]]]
                        [--days DAYS]

Server Certificate Utility

optional arguments:
  -h, --help                show this help message and exit
  --import {certificate,key}
                           import a certificate or private key
  --create {csr,selfsigned,key}
                           create a certificate signing request, a self-
signed certificate, or a new private key.
                           a certificate signing request is created using
[ . . . ]
```

Certificates in PEM format

All certificates used in CTS must be in PEM format. The following is an example of a certificate in PEM format:

```
-----BEGIN CERTIFICATE-----
MIIDrTCCAxagAwIBAgIBADANBgkqhkiG9w0BAQQFADCBnDEbMBkGA1UEChMSVGhl

SqHk9ZiE1boQaMzjNLU+KabTLpmL9uXvFA/i+gdenFHv
-----END CERTIFICATE-----
```

Option 1: Regenerating a self-signed server certificate

To generate a self-signed certificate run the `vts server_certificate` command with the `--create selfsigned` option:

```
main> vts server_certificate --create selfsigned
```

Enter answers to the informational questions and restart the web server when asked.

If your server requires a particular TLS protocol, you can set it by following the instructions in [“Specifying the TLS protocol version \(optional\)” on page 61](#).

Option 2: Importing an authenticated third-party server certificate (recommended)

To import an authenticated third-party CA certificate to the CTS, follow the steps below:

1. In the CTS CLI, go to the `vts` category, and enter `server_certificate --create csr` to generate a certificate request:

```
main> vts
vts> server_certificate --create csr
```

2. Follow the system prompts. A certificate request displays at the command line:

```
----- BEGIN CERTIFICATE REQUEST -----
. . .
----- END CERTIFICATE REQUEST -----
```

3. Copy and paste the certificate request including the "REQUEST" lines onto a third-party certificate request form, such as GoDaddy, Thawte, or Verisign.

4. After receiving the certificate, at the vts command category, run `server_certificate --import certificate` at the command line:

```
vt> server_certificate --import certificate
```

5. When prompted to continue, enter yes.
6. Note that the certificate must be in PEM format. Copy and paste the entire certificate including the CERTIFICATE lines, as shown in the example below:

```
-----BEGIN CERTIFICATE-----
MIID1TCCAr2gAwIBAgIJAMf9x1/DhPfPMA0GCSqGSIb3DQEBCwUAMIGAMQswCQYD
VQQGEwJVUzETMBEGA1UECAwKQ2FsaWZvcn5pYTERMA8GA1UEBwwIU2FuIEpvc2Ux
. . .
9hZV7uAAnRzqaodIPQYABwj58/eo8hMw4JfLfJwTavZuFt/hpnbxEECynd+s4
cLSgBd7x4aeDKt0vinSvBv2niyZyLOv1eg==
-----END CERTIFICATE-----
```

7. Enter `Ctrl-d` to end the input.
8. The CTS imports the certificate and tries to verify that the imported certificate matches the private key generated at the time the certificate was generated.
9. The system prompts you to restart the web server. Type yes.
10. The web server component of the CTS is restarted, and the new certificate takes effect. The system is set up using the third-party server certificate for TLS connections.

Registering CTS with the DSM

CTS can use as its keystore the Vormetric DSM, or either Thales KeySecure Classic or Thales CipherTrust Manager (CM) (formerly Next Generation KeySecure). For KeySecure or CM instructions, see [“Registering CTS with Thales KeySecure or Thales CM” on page 44](#).

See [“Keystore \(DSM, KeySecure Classic, or CM\) requirements” on page 19](#) for a list of the DSM prerequisites before configuring.

1. If your DSM hostname is not registered to the DNS, add the hostname to the `/etc/hosts` file. Go to the system submenu in the CTS CLI and enter: `hosts --add <dsm IP Address> <dsm hostname>`

```
system> hosts --add 192.168.34.12 dsm1
```

2. If you have not done so already, set the desired hostname of your CTS, using the hostname command under the system category menu.

```
system> hostname --set cts1
```

3. Ask the DSM Administrator to add the CTS VM hostname to DSM database as follows.

On the DSM Management Console click **Hosts > Add**. Enter:

Host Name: See [“Setting the CTS hostname”](#).

Agent type: Key

License type: Set as per your DSM licensing agreement

Communication Enabled: Checked

All other parameters can be left at the default. Refer to the DSM manual for details.

IMPORTANT: The hostname added to the DSM must match the hostname set on the CTS VM. If they do not match, registration will fail.

4. Return to the CTS CLI and register the CTS with the DSM.
 - a. Obtain the DSM hostname from the *DSM Management Console*.
 - b. Go to the vae category of the CLI and run the register command, supplying the hostname of the DSM as a parameter. For example:

```
main> vae
vae> register jw-dsm-1150.i.vormetric.com
Welcome to the CipherTrust Key Agent Registration Program
Agent Type: CipherTrust Key Agent
Agent Version: 6.2.0.53...
```

A successful registration results in the following message being displayed:

```
Successfully registered the CipherTrust Key Agent with the primary
CipherTrust Data Security Server on jw-dsm-1150.i.vormetric.com
```

5. Log into the DSM and navigate to the hostname of the CTS VM. A successful registration shows a fingerprint hash. This should match the fingerprint message in the output when the register command was run.

Registering CTS with Thales KeySecure or Thales CM

As an alternative to using a Vormetric DSM, you can register CTS with either a Thales KeySecure Classic or a Thales Next Generation KeySecure (or Thales CipherTrust Manager) server. To configure with DSM, see [“Registering CTS with the DSM” on page 43](#).

Complete the following procedure to register CTS with either a Thales KeySecure Classic or CM server. For easier reference throughout this procedure, the term “*KeySecure*” is used to refer to either Thales keystore server product, unless otherwise specified individually.

1. Create a user and set a password for it on the KeySecure server.
Besides client certificate authentication, KeySecure servers require user/password authentication for key access.
2. Optional: Create a user-group on the KeySecure server
In addition to granting key access to a user, key access can be granted to a group. Users belonging to that group have access to the group keys.
3. Create symmetric AES keys for CTS use on the KeySecure server using the properties below:
 - Key type: AES
 - Key size: 256 bits
 - Exportable: yes
 - Prevent keys from being deleted: yes
 - Key properties: Encrypt and Decrypt
 - Owner: CTS user in Step #1 above or
 - Group: group in Step #2 above
4. If not already created, create a local CA on the KeySecure server.
This will be used by CTS for client certificate authentication.
5. Create an NAE interface on the KeySecure server using the following properties:
 - Type: NAE
 - Port number: 9000
 - Mode: TLS; user must supply password; verify client certificate
 - Username Location in Certificate: CN
 - Local CA: (select)
 - Network interface: (select)
6. Set up CTS with IP(s), port, and user credentials to the KeySecure server.
Log in to the CTS CLI and run the **icapi --set** command:

```
main> icapi set --IP <keysecure_ip> --port 9000 --user <ctsuser>
```

When prompted, enter the password of the ctsuser on the KeySecure server.

If the KeySecure is a cluster of servers, supply all the IP addresses of the servers in the cluster. For example:

```
main> icapi set --IP ip1 ip2 ip3 --port 9000 --user <ctsuser>
```

Run the **icapi show --properties** command to inspect the settings made. For example:

```
main> icapi show --properties

Client_Cert_Authentication    yes
KEYSTORE_PASSWORD            *****
KEYSTORE_USER                 ctsuser
NAE_IP                        ['10.3.211.79']
NAE_Port                      9000
Protocol                      ssl
Version                       3.1
```

7. Register CTS to the KeySecure server, with either an automated registration or a manual registration.

Automated registration is available only with Next Generation KeySecure. It is currently not supported with KeySecure Classic. To register CTS to a KeySecure Classic server, skip the following sub-procedure (“To perform automated KeySecure registration”) and resume the procedure at “To perform manual KeySecure registration” on page 48 below.

- **To perform automated KeySecure registration:**

Log in to the CTS CLI and run the **icapi register** command. For example:

```
main> icapi register --host 10.3.211.79 --user <adminuser>
```

This command requires the user credentials on the KeySecure server that has admin rights to the local CA. It creates a client certificate on the CTS that is signed by the KeySecure server. This serves as the client certificate authentication whenever CTS connects to the KeySecure server.

This command prompts for the password of the KeySecure admin user, and the information to create the certificate.

For example:

```
main> icapi register --host 10.3.211.79 --user admin
password:

Running registration will delete any existing CA and client certificates.
Do you wish to continue? <y/n> [n] y
Country Name (2 letter code) [US]:
State or Province Name [California]:
Locality Name (e.g., city) [San Francisco]:
Organization Name (e.g., company):
Organizational Unit Name:
Common Name (eg, server's hostname) [cts-250-263-202]:
Created Private-Key: (2048 bit)
CA certificate updated
Client certificate updated
Registration complete
Keysecure signed certificate:
id                : f22e722f-4135-44c7-9e78-c03b1acc83da
ca                : kylo:kylo:naboo:localca:8d2889d6-45a4-4981-95e8-d1589238deb8
issuer            : /C=US/ST=MD/L=Belcamp/O=Gemalto/CN=KeySecure Root CA
notAfter          : 2030-02-09T21:05:22Z
serialNumber      : 195829222921448800841697297203339489128
sha1Fingerprint   : 4C5B96B0F0C3D6FCF06C905E49965E4BCF370824
sha256Fingerprint :
EB7E39AD001EF9B63F9DF1370569869813869B1D592F0130CF6CADB501E625F1
subject           : /C=US/ST=California/L=San Francisco/CN=cts-250-263-202
```

A successful registration will display the client certificate information and its fingerprint.
Log in to the KeySecure server and verify that the certificate information and fingerprint match.

Notes:

- If the KeySecure server has more than one Local CA, the automated registration uses the first Local CA found. If the desired Local CA is not the first on the list, use the **--caid** option to supply the ID of the desired Local CA. You can use the **show --LocalCAs** command to view the ID of all the local CAs on the KeySecure server:

```
main> icapi show --LocalCAs --user <adminuser>
```

- By default, the certificate is set to expire in 10 years. Use the **--days** option to set the desired expiration.

- The registration command can be run in non-interactive mode by supplying all parameters to the command. Run the **icapi register --help** command for details.

- **To perform manual KeySecure registration:**

Use the following procedure to register CTS to a KeySecure Classic server. You can also use this manual procedure with a Next Generation KeySecure server if you do not want to automatically register, or for some other reason cannot automatically register.

Some reasons for using manual registration include:

- Network connectivity from the CTS to KeySecure is not yet in place.
- The user performing auto-registration does not have administration credentials to the KeySecure server. The user credentials to perform registration must include permission to run REST APIs on the server, permission to download the Local CA, and permission to sign a certificate request.
- Access to the REST API (port 443) of the KeySecure server is blocked.
- An imported private key is desired instead of letting CTS generate a random key internally.
- A common client certificate is desired for several CTS servers, for example, with CTS servers in a cluster.

a. Create a certificate private key on the CTS:

```
main> icapi create --client_key
```

You may import a private key instead of letting CTS create one. Use the **icapi upload** command to import a private key.

b. Create a certificate signing request:

```
main> icapi create --csr
```

This command creates a certificate signing request using the private key you have created or imported.

c. Using the CSR you now generated, log in to the KeySecure server and locate the Local CA to sign the CSR.

The signed CSR produces a certificate in PEM format.

d. Import the signed certificate into the CTS using the **upload** command:

```
main> icapi upload --client_certificate
```

- e. Log in to the KeySecure server and download the Local CA. Import this certificate into the CTS using the **"icapi upload --CA_certificate"** command:

```
main> icapi upload --CA_certificate
```

8. Enable ICAP.

Run **"icapi enable yes"** command to enable CTS access to the KeySecure server. For example:

```
main> icapi enable yes
Restarting cts (via systemctl): [ OK ]
ICAPI properties updated
```

9. Test connectivity to the KeySecure server.

Use the **"icapi test --server_connection"** command to test server connectivity to the KeySecure server. For example:

```
main> icapi test --server_connection
Test server connection using user: cts-user1
10.3.211.79: OK
```

This command tests the connection and authentication to the KeySecure server. A successful authentication confirms correct KeySecure user credentials and a valid client certificate.

10. Test access to an AES key.

Use the **"icapi test --key"** command to test access to an AES key on the KeySecure server. For example, to test access to a KeySecure key named cts-key:

```
main> icapi test --key cts-key
cts-key: OK
```

This command tests if the saved user credentials provide proper access to the specified key. This test requires correct user and client certificate authentication to the KeySecure server.

Troubleshooting and automation tips

- Make sure the **"icapi test"** CLI commands pass before setting up CTS for tokenization use.
- Use the **"icapi show"** CLI command to inspect if the icapi agent is enabled or not, if certificates are created or uploaded, and if server settings are correct.
- All CLI commands can be run in non-interactive mode. This mode is ideal for automating setup.

Security tips

Consider the following guidelines when configuring CTS to ensure maximum security:

- When setting up the NAE interface, it is highly recommended to use the following mode for best security:
 - TLS, user must supply password, verify client cert

Although other modes are possible, anything other than the above would be less secure.

- When creating a user for CTS to use on the KeySecure server, do not use a user with admin privileges or access to any keys that CTS will not use. The Keystore user should only have 1) login access, 2) key access privileges, and 3) access to the keys that CTS will use.

Do not add the Keystore user to the "Key Users" group as this may allow the user access to keys that CTS does not use. Preferably, create a group for CTS, assign to that group all the keys that CTS will use, and then add the Keystore user to that group.

Configuring CTS Nodes

To set up a CTS system, a single VM or multiple VMs can be used to form a cluster of nodes operating as one coherent CTS system.

A cluster of nodes is useful to achieve scalability and redundancy of the system. You can set up a CTS cluster manually, or with an automated process.

It is highly recommended to use the automated cluster setup process, which is easier to implement and is much less error-prone, especially when the cluster contains more than two nodes.

A CTS system is set up by creating the first node in the cluster. At a minimum, a CTS system can run with just one node. It is still considered a cluster, but with only one node. More nodes can be subsequently added to the cluster.

NOTE: CTS supports up to ten nodes in a cluster.

Automated cluster setup

To automatically set up a cluster:

1. Log into the CLI and enable the apiadmin user on all nodes:

```
main> cluster apiadmin [--enable] [--setpasswd PASSWORD]
```

This password must be set on all nodes that will use the automated cluster feature. The password must be the same on all nodes.

2. Choose a node to start your cluster:

```
main> cluster create
```

3. On the same node, start joining other nodes to the cluster, by specifying the IP addresses of the other nodes:

```
main> cluster remotejoin NODE_IP [NODE_IP ...]
```

4. It is good practice to disable the apiadmin user after you have finished the automated cluster setup process with the --disable command:

```
main> cluster apiadmin --disable
```

5. To add a new node to an existing cluster at a later time, start by enabling the apiadmin user with the --enable command, and from a node in the cluster run the remotejoin command as before to add one or more nodes to that cluster.

Manual cluster setup

To manually create the first node and cluster, run the `create` command under the `cluster` category submenu. The command requires the following parameters:

- **IP** - IP address of this node. It is highly recommended to use the internal IP, for example, the VPC IP address of this node. The IP address is optional if creating a cluster node using existing data (with the --preserve option).
- **USERNAME** - WebUI Admin username.
- **PASSWORD** - WebUI Admin password.
- **EMAIL** - WebUI Admin email.

The `cluster create` command supports both interactive and non-interactive modes. See the `--help` option output for details on how to use:

```
main> cluster create --help
usage: create [-h] [-u USERNAME] [-p PASSWORD] [-e EMAIL] [--preserve] [-y]
              [IP]

Create new cluster with this node as first node

[. . .]
```

Once this command completes, you can log into the CTS Web UI using the credentials entered above. Load the Web UI by loading the node IP address or the external IP address of the VM:

- `https://node_IP`
- `https://external_IP`

Manually adding nodes to a cluster

The first node in a manually-created cluster (created in [“Configuring CTS Nodes” on page 50](#)) creates a CTS cluster but with only one node. To add more nodes to the cluster, use the `join` command under the `cluster` category menu.

IMPORTANT: Before running the `join` command, the `add` command must be run on the first node. This is a way of telling the first node that an additional node will be joining the cluster. Simply running the `join` command on the new node will not work. The first node must know about the new node by running the `add` command.

To add a second node to a cluster:

1. Log in to the CLI of the first node and run the `cluster add` command:

```
main> cluster add NODE2_IP
```

where `NODE2_IP` is the IP address of the new (second) node joining the cluster.

2. Log in to the CLI of the second node. Run the `add` command for the first node, and then the `join` command:

```
main> cluster add NODE1_IP
main> cluster join NODE2_IP NODE1_IP
```

The `join` command requires two parameters: `NODE2_IP` (the current, new node IP) and `NODE1_IP` (the existing cluster node IP).

The `add` command is optional and not necessary since the `join` command will take care of it. However, if you are joining a cluster already having more than one node in the cluster, you must run the `add` command for all nodes already in the cluster.

The `join` command only lets you select one `node_ip` to join for connectivity purposes, but you will need to tell the system all the other nodes in the cluster you are joining and that is accomplished by running the `add` command.

Example: Manually setting up a four-node CTS cluster

The following procedure shows how to manually set up a CTS system with four nodes, with IPs `NODE1_IP`, `NODE2_IP`, `NODE3_IP`, and `NODE4_IP`.

1. On node1, run the `create` command:

```
main> cluster create NODE1_IP
```

2. On node1, run the `add` command for all nodes:

```
main> cluster add NODE1_IP  
main> cluster add NODE2_IP  
main> cluster add NODE3_IP  
main> cluster add NODE4_IP
```

Note: The `add NODE1_IP` command above is redundant since `NODE1` is already joined to the cluster. But for clarity, this repetition shows that the system must be told of all nodes joining the cluster.

3. Repeat the same `add` commands shown in Step 2 on nodes `NODE2`, `NODE3`, and `NODE4`.
4. Log in to `NODE2` and run the `join` command:

```
main> cluster join NODE2_IP NODE1_IP
```

5. Log in to `NODE3` and run the `join` command:

```
main> cluster join NODE3_IP NODE1_IP
```

NODE3 can also be joined to the cluster using NODE2_IP as the second parameter instead of NODE1_IP. This is because NODE2 is already joined to the cluster. Any node can be used as the second parameter as long as that node is already joined to the cluster.

For example, the following is equivalent to the preceding example above:

```
main> cluster join NODE3_IP NODE2_IP
```

6. Repeat the join command for NODE4.

```
main> cluster join NODE4_IP NODE2_IP
```

Log into the GUI on all nodes and verify that they are all replicating. Changing a value in the GUI of one node should be reflected in the same changes on all other nodes.

IMPORTANT: To add a new node to a cluster, all nodes in the cluster must be online. No new nodes can be added if not all nodes in the cluster are online.

Removing a node from a cluster

The process of removing a cluster node is the same for a manually-created cluster as it is for an automatically-created one.

To remove a node from a cluster, run the `remove` command from one node -- any node except the node that will be removed. You only need to run the `remove` command on one node. All other nodes see this command and remove the node from their system.

As with adding a node to a cluster, to remove a node from the cluster, all nodes must be online so that they will know that a node is being removed.

Configuring an AD/LDAP Server (optional)

The Active Directory/LDAP server is optional. However, you can use it to import CTS users and CTS GUI Administrators. See [“Active Directory/LDAP server requirements” on page 21](#) before configuring. You must configure the AD/LDAP server on every node in your CTS HA cluster.

1. Go to the auth command category in the CTS CLI to see the ldap command.

```
main> auth
auth$ ?
```

Command	Description
=====	=====
ldap	LDAP Setup
oauth2	OAuth2 Setup

2. Like all CLI commands, you can type the command without a parameter and a usage example displays:

```
auth> ldap
usage: ldap [-h] [--show] [--setup] [--enable {true,false}]
           [--server SERVER_URI] [--bind_dn BIND_DN]
           [--bind_password PASSWORD] [--user_prefix PREFIX]
           [--user_search_filter FILTER]
           [--user_search_scope SCOPE] [--group_search_scope SCOPE]
           [--active_user_group GROUP] [--staff_user_group GROUP]
           [--super_user_group GROUP]
           [--ca_cert {import,remove,show}] [--test {bind_dn}]
           [--query_user NAME] [-y]

LDAP Setup

optional arguments:
-h, --help            show this help message and exit
--show                show LDAP settings
[ . . . ]
```

3. Disable, then enable LDAP support in the Tokenization Server:

```
auth> ldap --enable false
LDAP settings have been saved
auth> ldap --enable true
Restarting cts (via systemctl):          [ OK ]
LDAP settings have been saved
auth>
```

NOTE: If you disable LDAP support, then you can use only the CTS GUI to create users and groups.

4. Set the AD/LDAP server URI with the --server command (where the default port number for an LPDAS server is 636):

```
auth> ldap --server ldaps://<hostname_or_IP_address>:<Port>
```

or (where the default port number for an LDAP server is 389):

```
auth> ldap --server ldap://<hostname_or_IP_address>:<Port>
```

Example:

```
auth> ldap --server ldap://192.168.118.99:389
LDAP settings have been saved
auth>
```

5. Set the binding DN of the user who has access to the AD/LDAP server with password. Example:

```
ldap --bind_dn <FQDN of user with access to LDAP Server>
```

Example:

```
auth> ldap --bind_dn cts0@cts.vormetric.com
Enter Password :
Enter Password again :
Set LDAP Bind User DN SUCCESS
auth>
```

6. Set user search scope using user_search_scope command:

```
ldap --user_search_scope <User search scope>
```

Example:

```
auth> ldap --user_scope dc=cts,dc=vormetric,dc=com
LDAP settings have been saved
auth>
```

7. Set group search scope using the group_search_scope command:

```
ldap --group_search_scope <Group search scope>
```

Example:

```
auth> ldap --group_search_scope CN=Users, dc=cts,dc=vormetric,dc=com
LDAP settings have been saved
auth>
```

8. Set attribute field for user search filter using the user_search_filter command:

ldap --user_search_filter <Name of user field in AD/LDAP>

Example:

```
auth> ldap --user_search_filter sAMAccountName
LDAP settings have been saved
auth>
```

9. Set user prefix name using `user_prefix` command. The user prefix is the attribute that should be used to prefix the user name when searching for the user name in the LDAP database.

ldap --user_prefix <User prefix name. Example: uid or cn or sn>

Example:

```
auth$ user_prefix uid
Set LDAP USER PREFIX SUCCESS
```

10. Set the Tokenization Server active user group using the `active_user_group` command:

```
auth> ldap --active_user_group <Group whose members can access the
RESTful API>
```

In this example, any user who wants access to the CTS RESTful API must belong to the AD group `ctsUsers` within `Users` of the domain `cts.vormetric.com`:

```
auth> ldap --active_user_group cn=ctsUsers,cn=Users,dc=cts,dc=vormetric,dc=com
LDAP settings have been saved
auth>
```

11. Set the CTS superuser group using the `--super_user_group` command:

ldap --super_user_group <Group that can access the Tokenization Server GUI & APIs>

In this example, any user who requires access to the CTS GUI and REST APIs must belong to the AD group `ctsSuperuser` within `Users` of domain `cts.vormetric.com`:

```
auth> ldap --super_user_group cn=ctsSuperuser,cn=Users,dc=cts,dc=vormetric,dc=com
LDAP settings have been saved
auth>
```

12. *For LDAPS support only:* Import the CA certificate chain of the LDAP server to the built-in LDAPS client of the CTS. A Certificate Management tool like DigiCert or Certificate Manager tool is recommended to request the certificate, after which use the `--ca_cert` option to import the certificate into the CTS.

NOTE: The `--ca_cert` option uses an underscore (`_`) instead of a hyphen (`-`).

- a. Using a Certificate Management tool like DigiCert or Certificate Manager tool, download your intermediate and root certificates.

CTS requires all certificates to be in PEM format.

- b. Run `--ca_cert import` to import the certificate trust chain. Paste the entire body of each certificate in the order shown in the example, then terminate with `Ctrl-d` when finished.

Example:

```
auth> ldap --ca_cert import
Cut-and-paste below a CA Certificate in pem format. Press Ctrl-d when
done.
-----BEGIN CERTIFICATE-----
(Your Intermediate certificate: DigiCertCA.crt)
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
(Your Root certificate: TrustedRoot.crt)
-----END CERTIFICATE-----
Restarting cts (via systemctl):                [ OK ]
LDAP CA Certificate has been uploaded.
auth>
```

13. Execute the `--show` option to list the LDAP configuration:

```
auth> ldap --show
ENABLE                true
SERVER_URI            ldap://192.168.118.99:389
BIND_DN               cts0@cts.vormetric.com
BIND_PASSWORD         *****
USER_SEARCH_SCOPE     dc=cts,dc=vormetric,dc=com
GROUP_SEARCH_SCOPE    CN=Users,dc=cts,dc=vormetric,dc=com
USER_SEARCH_FILTER     SAMAccountName
ACTIVE_USER_GROUP     cn=ctsUsers,cn=Users,dc=cts,dc=vormetric,dc=com
SUPER_USER_GROUP
auth>
```

Enabling the Client Authentication Feature (optional)

See also: [“Client certificates and user authentication” on page 6.](#)

In addition to Basic Auth (username and password), the CTS server can authenticate clients using client certificates.

NOTE: Client certificates must be in PEM format.

To enable, client-certificate authentication must be enabled on every node of the CTS cluster. Perform the procedure below on each node.

Obtaining a client CA key and certificate

1. Log in to the CTS CLI.
2. Go to the vts menu and run: `client_certificate --upload`

NOTE: The `client_certificate` command uses an underscore (_) instead of a hyphen (-).

3. At the prompt, paste the text of the certificate. For example:

```
main> cts
vts> client_certificate --upload
Copy-and-paste a CA Certificate below in pem format. Press Ctrl-d when
done.
```

-----BEGIN CERTIFICATE-----

```
MIIDrTCCAxagAwIBAgIBADANBgkqhkiG9w0BAQQFADCBnDEbMBkGA1UEChMVSVGHl

```

```
-----END CERTIFICATE-----
```

4. Verify the uploaded certificate by using the `client_certificate --show` command.

```
vts> client_certificate --show
```

Enabling client cert authentication with or without identities

Client certificate authentication has two modes:

- Enable without identities
- Enable with identities

NOTE: Thales strongly recommends that you use client certificates **with identities**. If you use without identities, you must pass in a username/password along with the certificate, which can be a security vulnerability that client certificates are intended to prevent. The option to use certificates without identities is provided to maintain backward compatability with the earlier basic authentication flow.

To enable without identities, run:

```
vts> client_certificate --enable-without-id
```

To enable with identities (recommended), run:

```
vts> client_certificate --enable-with-id
```

Note: The CTS GUI administrator must enter the common name (CN) from the certificate as a user name. See [“Managing CTS Users” on page 73](#).

To disable client certificate authentication, run:

```
vts> client_certificate --disable
```

To check if client certificate authentication is enabled or not, run:

```
vts> client_certificate --status
```

Sample use in code

To use client-certificate authentication, include the client key and CA certificate when running the REST API.

Example without identity:

```
$ curl --tlsv1.2 -k --key client.key --cert client.crt \  
-X POST -u username:password \  
-d '{"tokengroup" : "t1" , "data" : "9453677629008564",  
"tokentemplate" : "Credit Card" }' \  

```

```
https://192.168.12.88/vts/rest/v2.0/tokenize  
Example with identity (recommended):  
$ curl --tlsv1.2 -k --key client.key --cert client.crt \  
-X POST \  
-d '{"tokengroup" : "t1" , "data" : "9453677629008564",  
"tokentemplate" : "Credit Card" }' \  
https://192.168.12.88/vts/rest/v2.0/tokenize
```

Specifying the TLS protocol version (optional)

Clients may require different versions of TLS protocol. You may specify what version of SSL/TLS is supported by CTS. If you opt in to this feature, you must specify the TLS version on every node in your CTS HA cluster.

To do this, log in to the CTS CLI and run:

```
vt> ssl_protocols --set [ TLSv1.2 | TLSv1.1 | TLSv1 v
```

where you specify the lowest protocol version allowed. TLS versions above the specified version are also allowed:

TLSv1 supports tlsv1, tlsv1.1, and tlsv1.2

TLSv1.1 supports tlsv1.1, and tlsv1.2

TLSv1.2 supports tlsv1.2

NOTE: The `ssl_protocols` command uses an underscore (_) instead of a hyphen (-).

Example:

```
main> vts  
vt> ssl_protocols --set TLSv1.1  
vt> ssl_protocols --status  
SSL Protocols: TLSv1.1 TLSv1.2  
vt>
```

Redirecting log messages to a remote log server (optional)

Optionally, you can redirect log messages to a remote logging server. If you opt in to this feature, it is recommended that you redirect log messages off every node in your CTS HA cluster to the remote log server. You can also add SIEM software (example: Splunk, QRadar) for logging. See the *VDS Security Intelligence User Guide*.

1. Go to the vts category in the CTS CLI and use the remotelog command:

```
main> vts
vts> remotelog
usage: remotelog [h] [--show] [--set HOST:PORT] [--enable] [--disable]
        [--check]
Set Remote Logging
[...]
```

2. Show the current remote log settings:

```
vts> remotelog --show
remote-host:514, disabled
vts>
```

3. To enable or disable the remote logging re-direct, use the --enable or --disable options, respectively:

```
vts> remotelog --enable
remote-host:514, enabled
vts>
```

4. To set the remote log server hostname and port, use the --set option with the *HOST:PORT* argument:

```
vts> remotelog --set new-remote-host:1099
new-remote-host:1099, enabled
vts>
```

You do not need to restart the CTS after changing the remote log server configuration.

NOTE: The current log level is set to 'INFO' level for operations and 'DEBUG' level for other packages. Use the `loglevel` command to show or set the log level.

Configuring OAuth

You need to save the following attributes in the `settings.ini` relative to the OAuth2 configuration:

- Method (basic/oauth)
- Redirect URI
- Provider name

These settings will enable the GUI to show the correct login page (Redirect button or basic username/password form).

Use the CLI to configure OAuth2. Log into the CLI and run the **oauth2** command under the auth menu.

```
main> auth oauth2
```

Use the **--name** option to set the provider name (or to disable entirely), and the **--uri** option to set the URI to the OAuth2 client. Use the **--import** option to import the public key or certificate (in PEM format).

Configuring ADFS and LDAP for OAuth

Follow these procedures to configure Active Directory Federated Services (ADFS) and LDAP for an OAuth authentication option.

To export a certificate for CTS use:

1. Open Server Manager.
2. Click **Tools** and select **AD FS Management**
3. Click **Certificates**.
4. Double-click on **Token-signing certificate**.
5. In the *certificate* window select **Details** tab.
6. Click **Copy to File...**
7. Click **Next**.
8. Select **Base64 format** and **Next**.
9. Enter file name.

To add an application group:

1. Open Server Manager.
2. Click **Tools** and select **AD FS Management**.
3. Right click **Application Groups** and select **Add Application Group** wizard.
4. Enter name and select **Native application accessing a web API**.
5. Copy **Client Identifier** to a template for later use.
6. Enter your CTS login URL in **Redirect URI** field (`https://<cts uri>/login`) and click **Add**.

7. Click **Next**.
8. Enter the same CTS URI as entered in previous step in the **Identifier** field and click **Add**.
9. Click **Next**.
10. Use default (**Permit everyone**) and click **Next**.
11. Click **Next** on the review page.
12. Click **Close**.

To add properties to a new group:

1. Double-click on the desired new group.
2. Select **<new group> - Web API** and click **Edit**.
3. Select **Issurance Transform Rules** and click **Add Rules**.
4. Select **Claim rule template: Send LDAP Attributes as Claims**.
5. Click **Next**.
6. Enter a rule name.
7. Add the following rules:
 - Token-Groups - Unqualified Names : Group
 - User-Principal-Name : UPN
 - SAM-Account-Name : Name
 - Surname : Surname
 - Given-Name : Given Name
8. Click **Finish**.
9. Click **OK**.

To test ADFS authentication:

```
curl -k -X POST https://<adfs server>/adfs/oauth2/token -d  
'grant_type=password&username=<user>&password=<password>&client_id=<client id>5&resource=https%3A%2F%2Fmickeymouse'
```

The expected response is:

```
{"access_token":"eyJ0eXA... mVSpzmW-FBDlg"}
```

Configuring the settings.ini File for LDAP

Set up the settings.ini file according to which LDAP scenario you implement:

- [“AD email” on page 65](#)
- [“AD DN” on page 66](#)
- [“Linux LDAP DN” on page 66](#)

To test your settings, use the CLI option **--query_user** to the **ldap** command:

```
auth> ldap --query_user NAME
```

AD email

The following is an example settings.ini configuration for an LDAP setup with AD email:

```
auth> ldap --show
SERVER_URI          ldap://10.3.118.98:389
BIND_DN             cts0@cts.vormetric.com
BIND_PASSWORD       *****
USER_PREFIX
USER_SEARCH_FILTER  sAMAccountName
USER_SEARCH_SCOPE    CN=Users,DC=cts,DC=vormetric,DC=com
GROUP_SEARCH_SCOPE  CN=Users,DC=cts,DC=vormetric,DC=com
ACTIVE_USER_GROUP    CN=ctsUsers,CN=Users,DC=cts,DC=vormetric,DC=com
STAFF_USER_GROUP     CN=ctsManager,CN=Users,DC=cts,DC=vormetric,DC=com
SUPER_USER_GROUP     CN=ctsAdmin,CN=Users,DC=cts,DC=vormetric,DC=com
ENABLE              true
```

AD DN

The following is an example settings.ini configuration for an LDAP setup with AD DN:

```
auth> ldap --show
SERVER_URI          ldap://10.3.118.98:389
BIND_DN             CN=cts User0,CN=Users,DC=cts,DC=vormetric,DC=com
BIND_PASSWORD       *****
USER_PREFIX         CN
USER_SEARCH_FILTER   cn
USER_SEARCH_SCOPE    CN=Users,DC=cts,DC=vormetric,DC=com
GROUP_SEARCH_SCOPE   CN=Users,DC=cts,DC=vormetric,DC=com
ACTIVE_USER_GROUP    CN=ctsUsers,CN=Users,DC=cts,DC=vormetric,DC=com
STAFF_USER_GROUP     CN=ctsManager,CN=Users,DC=cts,DC=vormetric,DC=com
SUPER_USER_GROUP     CN=ctsAdmin,CN=Users,DC=cts,DC=vormetric,DC=com
ENABLE              true
```

Linux LDAP DN

The following is an example settings.ini configuration for setup with LDAP DN on Linux:

```
auth> ldap --show
SERVER_URI          ldap://10.10.62.132:389
BIND_DN             uid=tuser1,ou=People,dc=i,dc=vormetric,dc=com
BIND_PASSWORD       *****
USER_PREFIX         uid
USER_SEARCH_FILTER   uid
USER_SEARCH_SCOPE    ou=People,dc=i,dc=vormetric,dc=com
GROUP_SEARCH_SCOPE    ou=Groups,dc=i,dc=vormetric,dc=com
ACTIVE_USER_GROUP    cn=ctsUsers,ou=Groups,dc=i,dc=vormetric,dc=com
STAFF_USER_GROUP     cn=ctsManager,ou=Groups,dc=i,dc=vormetric,dc=com
SUPER_USER_GROUP     cn=ctsAdmin,ou=Groups,dc=i,dc=vormetric,dc=com
ENABLE              true
```

Restarting the CipherTrust Tokenization Server

After all CLI configuration is completed:

1. Navigate to the vts commands menu:

```
main> vts  
vts>
```

2. Restart the web server component of the CTS:

```
vts> service --restart  
Restarting cts (via systemctl) [OK]  
vts>
```

CTS Administration in the GUI

This chapter contains the following sections:

- [“Logging into the CTS GUI” on page 69](#)
- [“Creating and Managing Passwords” on page 70](#)
- [“Managing CTS User Groups” on page 71](#)
- [“Managing CTS Users” on page 73](#)
- [“Specifying DSM Keys” on page 77](#)
- [“Tokenization Setup” on page 79](#)
- [“Applying Permissions to Users and User Groups” on page 88](#)
- [“Creating and Importing Keys” on page 90](#)
- [“Dashboard API Monitoring” on page 91](#)
- [“Administrator History Logs” on page 92](#)
- [“Backing Up and Restoring the CTS” on page 96](#)
- [“Key Rotation” on page 98](#)
- [“Monitoring via SNMP” on page 98](#)

Logging into the CTS GUI

Use the CTS administration GUI to

- create tokenization users and groups
- specify permissions for users and groups
- create token templates
- create token groups

To log into the CTS administration GUI:

1. Point your browser to the Tokenization Server:

```
https://<CTS name or IP address>/
```

2. Log in using the Admin user name and password you defined when you created the CTS cluster.
3. If you have implemented OAuth authentication, log in with those credentials.
4. The CTS GUI Home page is displayed.

Troubleshooting

A Tokenization Server Administration GUI login failure is indicated by the following error message:

```
nginx 504 Gateway Time-out error
```

In this scenario, consider the following problem/solution option:

- Problem: The Tokenization Server is not connected to the LDAP server.
- Solution: Restart the CTS service. Open the CTS CLI, and run the following command:

```
main> vts service --restart
```

Creating and Managing Passwords

The CTS uses a dynamic password policy control mechanism to ensure system security.

The CTS leverages a password checker library. If you try to create a password that does not pass the proactive password checking provided by this library, you are prompted to try another string. The policy can change dynamically based on several factors. The dynamic nature of the checking algorithm provides the most secure possible password policy options. When creating a system password, use the following guidelines:

- Use at least 1 digit, 1 uppercase letter, 1 lowercase letter, 1 special character, and use at least 8 characters in total.
- Do not use your name, the company name, or other familiar names in the password string.
- Do not use your birthday or any other personally or professionally meaningful dates in the password string.
- Include a combination of the following character types in the password string:

- Lowercase letters
- Uppercase letters
- Numbers
- Special characters

Managing CTS User Groups

User groups enable you to assign the same permissions to multiple users.

Review the following sections to familiarize yourself with user groups in CTS:

- [“CTS roles” on page 7](#)
- [“Understanding CTS user groups and permissions” on page 10](#)

If using AD/LDAP users, create at least three user groups, to correspond to the CTS roles:

- Superuser
- Staff
- Active

User groups must be defined on the LDAP system. The user group names must be entered into the CTS GUI before importing users.

Creating user groups

To create a user group:

1. Log into the CTS GUI and select **User Groups** from the navigation bar.
The All User Groups list is displayed.
2. Select **New User Group** and enter a name on the resulting page. Click **Create**.
The new group name appears in the **All User Groups** list, and is selectable from user pages and the *Permissions* page.

Assigning masks

You can assign a mask to a group when initially creating the user group (at the *New User Group* dialog), or any time later to an existing user group, by clicking the user group and adding a mask assignment at the *Update User Group* dialog.

Adding users to user groups

To add a user to an existing user group:

1. From the CTS GUI select **User Groups**.
2. Click on a group from the list.
3. Select users to add to the group, and click **Update**.

Figure 7: Update User Group Dialog

Deleting a user group

To delete a user group:

1. Log into the CTS GUI and select **User Groups** from the navigation bar.
2. Select the check box by a group
3. Click **Delete**

A dialog asks you to confirm the **Delete**.

IMPORTANT: If you delete a user group to which users and/or permissions have been associated, the user group is removed from any user belonging to it, and will delete any permissions assigned to it.

Managing CTS Users

Review the following sections to familiarize yourself with users in CTS:

- “What is a CTS “user?”” on page 4
- “CTS authentication basics” on page 5
- “CTS authorization basics” on page 7

The first step is to create or import users, as described in:

- “Creating a user manually”
- “Importing users from an AD/LDAP server”

NOTE: Thales recommends creating at least one user in the GUI before attempting the task manually.

Creating a user manually

The following subsections describe how to create a user manually:

1. “Creating basic user information” on page 73
2. “Updating user information” on page 74

Creating basic user information

1. Log into the CTS GUI and select **Users** from the navigation bar.
The list of All Users is displayed.
2. Select **New User**.
In the *New User* dialog, fill in the required information and click **Create**.

IMPORTANT: The User Name must contain only English letters, numbers, or the following special characters: “@” (at-sign), “.” (period), “+” (plus-sign), “-” (hyphen), or “_” (underscore).

NOTE: User names and passwords are case-sensitive. Application code that calls the CTS RESTful APIs must pass user names and passwords in the same case that are defined in the CTS GUI.

Updating user information

After you complete the steps described in [“Creating basic user information”](#), you can add more attributes to the basic user, including changing the CTS role and assigning to a user group.

1. Log into the CTS GUI, and select **Users** from the navigation bar.
2. Click on the User Name of interest.

3. Change CTS role, User Groups assignment, Mask, or Email, as needed.
4. Click **Change password here** to update the user's password.
5. Click **Update**.

Deleting a user manually

If you delete a user to which permissions have been associated, all permissions linked to the user are also deleted.

NOTE: It is generally recommended to uncheck the “Active” status for a user rather than completely delete the user.

1. Log into the CTS GUI, and select **Users** from the navigation bar ([Figure 2](#)).
2. Select the check box by a user, click **Delete**, and confirm Delete.

Importing users from an AD/LDAP server

Review the following sections to familiarize yourself with users in CTS:

- [“What is a CTS “user?”” on page 4](#)
- [“CTS authentication basics” on page 5](#)
- [“CTS authorization basics” on page 7](#)

AD/LDAP user import prerequisites

Before you import users, complete the following tasks:

- Have your AD/LDAP connection to CTS set up and configured using the CTS CLI, as described in [“Configuring an AD/LDAP Server \(optional\)” on page 54](#).
- Create the appropriate user groups in the CTS GUI, as described in [“Creating user groups” on page 71](#).
- Set up the AD/LDAP server to import and authenticate users and user groups.

To import CipherTrust Tokenization users from an AD/LDAP server:

1. Create three AD/LDAP server groups, one for REST API users (Tokenization/Crypto/Key Management) and the other two for CTS administrators who require GUI access. The group that has been designated as the “Superuser” group in the CLI will have read/write access in the GUI, whereas the group that has been designated as the “Staff” group in the CLI will have read-only access in the GUI.
2. Populate each group with the desired REST API (“active”) users and CTS administrators.

NOTE: The name with permission to access the REST APIs must match the name specified with the `active_user` command under the `auth` category of the CTS CLI. See [“Configuring an AD/LDAP Server \(optional\)” on page 54](#).

The name of the CTS users with read-only access to the GUI must match what was specified in the `staff_user` command of the `auth` category of the CLI.

The name of the CTS administrators’ group must match the name of the group that was specified in the `super_user` command of the `auth` category of the CTS CLI.

Example AD\LDAP server group names:

- `ctsUsers` - Users in this group can create and/or access data through the RESTful API.
- `ctsStaff` - Users in this group can access the CTS GUI (read only).
- `ctsAdmin` - Users in this group can access the CTS GUI (read/write)

NOTE: `staff_user` is valid only if the user also has `active_user` permission. `super_user` is valid only if the user has both `active_user` and `staff_user` permissions. Use corporate policy to define whether or not `staff_user` and `super_user` should actually be granted REST API permissions, and disallow by policy when necessary to maintain corporate standards or separation of duties.

3. Create three group permissions in the CTS GUI with the same names as the LDAP groups (example: `ctsUsers`, `ctsStaff`, `ctsAdmin`). Members of these AD/LDAP groups inherit these permissions.

An application program that uses Basic Auth (username/password) will try to authenticate to LDAP using these credentials. An application program that uses a client certificate for authentication will use the Bind user's username and password for looking up the client certificate's common name (CN) in LDAP. If the credentials are authorized, the LDAP user is imported into the user table of the CTS. Thus, there is no need to manually create the LDAP users in the GUI. Once the user has been added to the CTS, permissions can be modified with another group permission or individually.

NOTE: User names and passwords are case-sensitive. Application code that calls the REST APIs must pass user names and passwords in the same case that are defined in the AD/LDAP server.

Unlocking user accounts

As a security feature, users are locked out after six failed login attempts.

If a user fails to successfully login after six attempts, the account is locked for 15 minutes (to prevent brute force attacks). The maximum number of attempts and cool-off time duration can be modified in the CLI.

To unlock a user account:

1. Click **Logs** in the navigation menu.
2. Select the **Locked Accounts** tab.
The locked accounts are displayed
3. Click **Unlock** for the desired account(s).

NOTE: All successful and failed login attempts are displayed under the **Access Logs** tab in the **Logs** menu. Select **Success** or **Failed** from the pull-down menu to filter the list so that only the selected access type is shown

Specifying DSM Keys

Review “[Understanding CTS Keys](#)” to understand the definition and usage of symmetric keys, asymmetric keys, and opaque objects.

Creating a key name

Use the CTS GUI to enter a key name that corresponds to a key that has been created in the DSM and is to be used for CTS functions.

After the name has been entered into the CTS local database, the key is available to associate with user and user group permissions. Symmetric keys are also be available to associate with tokenization groups.

NOTE: The very first symmetric key entered into CTS needs to be entered from the GUI of the first cluster node. Please enter this key as soon as possible. It will be used to create large lookup tables for the “RANDOM” tokenization mode.

1. After “[Logging into the CTS GUI](#)”, select **Keys** from the navigation bar. The Keys List is displayed, with the **Symmetric Keys**, **Asymmetric Keys**, and **Opaque Objects** tabs in the top navigation.

Figure 8: Keys List in the Symmetric Keys Tab

2. Select the tab for the type of key you want (for example, **Symmetric Keys**) and click the **New Symmetric Key** button.

IMPORTANT: In CTS, the very first key generated cannot be renamed, edited, or destroyed. There is a warning when creating the key. Once this initial setup is complete, you create subsequent keys with the normal *New Symmetric Key* UI, for application FPE, and the like.

3. Enter the key name that was used in the DSM and click **Create**.
The key name is displayed on the Keys List and will show as available in the *Permissions* matrix and *Tokenization Group* pages.

Deleting key names

Deleting a key name from the CTS local database does not delete the key material (nor the key name) from the DSM. Deleting a key name deletes all tokenization groups, tokenization templates, and permissions associated to it.

1. Select **Keys** from the navigation bar.
The Keys List is displayed, with the **Symmetric Key**, **Asymmetric Keys**, and **Opaque Objects** tabs in the top navigation (Figure 8).
2. Select the tab for the type of key you want (for example, **Symmetric Keys**), click the check box by the desired key, and click **Delete**.
3. Confirm and click **Delete** again.

NOTE: The very first symmetric key entered into the CTS can serve as a regular key for all encryption, signing and tokenization operations, but it is also used to build internal cryptographic tables and hence must not (and cannot) be deleted.

Tokenization Setup

Review [“Tokenization Groups, Templates, and Masks” on page 13](#) for the concepts behind setting up tokenization in the CTS GUI.

IMPORTANT: Before setting up tokenization make sure you have specified the DSM keys

Although the GUI does not constrain you to one particular implementation path, one logical sequence is:

- [“Specifying DSM Keys”](#) for tokenization (must be symmetric keys).
- [“Creating tokenization groups”](#) and associate it with the appropriate key(s).
- [“Creating custom character sets”](#) as needed (optional).
- [“Creating a data mask”](#) for detokenization.
- [“Creating tokenization templates”](#) and associate the applicable tokenization group and character set.
- **Create users and user groups** as needed.
(See [“Managing CTS User Groups” on page 71](#) and [“Managing CTS Users” on page 73](#).)
- **Grant tokenization privileges to users and user groups** by going to their permissions page, selecting the symmetric key associated with the appropriate tokenization group, and checking the **Tokenize** box. (See [“Assigning key-based permissions” on page 88](#).)
- **Grant detokenization privileges to users and user groups** in the same way, assigning a **data mask** from the drop-down menu.

NOTE: See [“Other \(non-key dependent\) permissions” on page 9](#) for an explanation of the Tokenize/Detokenize check boxes listed under “Other Permissions” in the Permissions matrix. This feature is included primarily for legacy and upgrade purposes.

Managing tokenization groups

A *tokenization group* is a way to compartmentalize a CTS server into distinct data spaces, each of which is protected by an encryption key.

A tokenization group is used as a parameter in the Tokenization API calls, `tokenize` and `detokenize`. It allows application programmers to create islands of sensitive data that are available only to members of a particular tokenization group. To use tokenization, you must create at least one tokenization group.

Use case example

A credit card company accepts business from three retail outlets called *Store1*, *Store2*, and *Store3*. The three retail outlets require tokenization of the customer credit card numbers used at their store. You could enable this by creating three tokenization groups called *Store1*, *Store2*, and *Store3* (the tokengroup parameter is case-sensitive). The application code processing sensitive data must specify one of these tokengroup parameters in each tokenize and detokenize calls (see [“Tokenization REST API” on page 133](#)).

For example:

```
curl --tlsv1.2 -X POST -u EdYee:EdYee_password -d '{"tokengroup" :
"store1" , "data" : "9453677629008564", "tokentemplate" : "Credit
Card" }' https://192.168.12.88/vts/rest/v2.0/tokenize
```

To enable tokenization services for each group, an implementation team would:

1. Decide how many tokenization groups are required and what their precise names will be (Application programmer and CTS GUI Administrator)
2. Create tokenization groups that match the names to be used in the application code: *Store1*, *Store2*, and *Store3*. (CTS GUI Administrator)
3. Go to the DSM and:
4. Create tokenization group encryption keys.
 - Use key *Template*: **Default_SQL_Symmetric_Key_Template** for those keys
 - Set the *Key Type* to **Cached on Host**.
IMPORTANT: On a DSM (version 6.1 or later), make sure to choose the CBC Encryption Mode and not CBC_CS1.
 Be sure the administrator knows that the first key must be created on the first node installed, not on secondary or subsequent cluster nodes. **Do not delete this key.** (DSM Administrator)
5. Specify the appropriate tokengroup parameter in the tokenize and detokenize API calls. Using our example credit card company, the application code would specify *Store1*, *Store2*, or *Store3* for a REST call. (Application programmer)

Creating tokenization groups

Have at least one symmetric key created in the DSM and entered in the CTS GUI, as described in [“Specifying DSM Keys” on page 77](#).

1. Select **Tokenization > Tokenization Groups**.
The All Tokenization Groups list is displayed.

2. Click the **New Tokenization Group** button.
The New Tokenization Group creation page is displayed.

The screenshot shows a 'New Tokenization Group' dialog box. It has two input fields: 'Name*' with the value 'name' and 'Key*' with a dropdown menu showing 'Sym_key1'. At the bottom right, there are 'Create' and 'Cancel' buttons.

3. Enter a Tokenization Group **Name**.

NOTE: Tokenization group names are case-sensitive. Application code must pass tokenization group names in the same case that are defined in the CTS GUI.

4. Select a **Symmetric Key** from the drop-down list.

Warning! Do not delete keys used for tokenization. If you delete a key, you will have to recreate the corresponding tokenization group to regain access to your tokens. Do not use auto-key-rotation features with tokenization.

5. Click **Create**.

Deleting tokenization groups

Before deleting a tokenization group, make sure that tokens created with the symmetric key associated with this tokenization group are not stored anywhere within (or outside) of the organization.

Warning! Once the tokenization group used to create these tokens has been deleted, they can no longer be detokenized.

To delete a tokenization group:

1. Log into the CTS administration interface.
2. Select **Tokenization > Tokenization Groups**.
3. Select the group and click **Delete**.

Managing character sets

CTS now includes enhanced support for tokenizing international characters. In earlier versions, CTS supported three default character sets:

- All digits
- Alphanumeric
- All printable ASCII (not available for RANDOM Mode)

For FPE (FF3) and FF1 modes, you can also define a custom character set, which allows you to tokenize and detokenize UTF strings.

Creating custom character sets

To define a custom character set, you need to know the Unicode character range for the language(s) you want to support. For example, the range for Arabic is 0600-06FF, while the range for Thai is 0E00 - 0E7F.

To create a custom character set:

1. Select **Tokenization > Character sets**.

2. Click **New Character set**.

3. Enter a **Name** and **Range** or set of ranges for your set.
The maximum size of a custom UTF character set definition string is 1536.
This implies either 100 ranges, or 200 individual characters, or some combination thereof—for instance, 50 ranges plus 100 individual characters.
4. Click **Create**.
The new set appears in the All Character Sets list, and is available to apply to tokenization templates.

Editing character sets

To edit a character set, click on its name in the list. Predefined character sets cannot be edited and should not be deleted.

Applying character sets

The three predefined character sets always appear in the drop-down list of character sets when you create a tokenization template. Once a custom set has been defined, it appears in the tokenization template creation menu as well.

NOTE: See [“Creating tokenization templates” on page 84](#).

Deleting character sets

Before deleting a character set, make sure that tokens created with this character set are not stored anywhere within (or outside) of the organization.

Caution: After the character set used to create these tokens has been deleted, they can no longer be detokenized, unless the character set is recreated very precisely. Even the order of the characters in the character set matters.

To delete a character set:

1. Navigate to **Tokenization > Character Sets**.
2. Select the character set from the list, and click **Delete**.

Prototyping tokenization

CTS supports UTF-8 inside the `valuenam` field for "data" and "token".

Generate a file that has the JSON request in it containing this UTF-8 code, and then submit it via cURL.

A file can be submitted in cURL as shown here:

```
--data-binary @filename option.curl --tlsv1.2 -k -X POST -u  
superuser:ssl12345 https://127.0.0.1/vts/rest/v2.0/tokenize --  
data-binary @tokenizerequest.txt
```

Managing tokenization templates

Tokenization templates allow you to define the specifics of how you want your data tokenized and detokenized.

For example, you can specify that your data be Luhn checked before tokenizing, or that the last four digits of a data string be left unencrypted, or that an identifying prefix be attached to all tokens.

To use tokenization, at least one tokenization template must be created.

Creating tokenization templates

1. In the CTS GUI, select **Tokenization > Tokenization Templates**.
2. Click **New Tokenization Template**.
See [Figure 4](#) on page -15.
3. Enter the following values:

- **Name** - Give the new template a name. This name will be used in the API POST commands tokenize and detokenize.
- **Token group** - The tokenization group for which this template can be used. You must create at least one template for each tokenization group.
- **Format** - Specify which of the following formats to use when tokenizing data:
 - Format-preserving encryption (FPE) with or without a Luhn check. A Luhn check ensures that a submitted number is a valid credit card number.
Note: FPE is an alternate name for FF3.
 - Format-preserving encryption (FF1) with or without a Luhn check. A Luhn check ensures that a submitted number is a valid credit card number.
 - Random or Random with Luhn check. This format is optimized for use with numbers from 9 digits (without a Luhn digit, for instance SSNs) to 19 digits (including a Luhn digit), like credit card numbers or tax ID numbers. If the data includes more free-form text, such as names and addresses, either the FPE or FF1 format is preferable.

In a random or random-Luhn format, the template uses a pseudo-random number generator (PRNG) instead of an encryption algorithm. In addition, the very first symmetric key configured in the CTS GUI is not a true encryption key, but instead acts as a seed value for the PRNG.

- One of the supported date formats. Use this to anonymize dates. Between the month, date, and year portions of the date format, the input data can include one of the following separators: slash (/), comma (,), hyphen(-), or space (). Date formats are used along with the Start Year and End Year fields.

In a date format, if a two-digit year format is selected (for example, DDMMYY), the CTS assumes that the date is in the twenty-first century; that is, it assumes the first two digits of the year are 20.

- **Character Set** - The character set to use with tokenization.
- **Prefix** - (Optional) An optional prefix to be added to all tokens. Example: **CC**-1234-1234-1234-1234 or **SSN**:123-23-1234. Note that the format is no longer preserved with this feature.
- **Keep Left** - The number left digits to leave unencrypted. You need at least a total of two digits to tokenize. Cannot be left blank.
- **Keep Right** - The number right digits to leave unencrypted. You need at least a total of two digits to tokenize. Cannot be left blank.

- **Irreversible** - (Optional) Check this box if you never want the token to be detokenized. For example, if you have production data that you want to tokenize for test or development, and you know you'll never want to decrypt it.
- **Allow empty or 1 character inputs** - Enables null, empty, and one-character inputs, which are passed through. The token value returned is the original input value. The single-digit input supports both characters and numerals, and is available for all formats except RANDOM.

4. Click **Create**.

Minimum input characters with keepleft or keepright

If you configure using keepleft or keepright, note the following minimum numbers of input characters, according to tokenization format:

- For FPE: 2 characters plus the number of keepleft or keepright characters
- For RANDOM Numeric: 9 characters plus the number of keepleft or keepright characters
- For RANDOM Alphaumeric: 5 characters plus the number of keepleft or keepright characters

IMPORTANT: To edit a tokenization template, click on a template name.

Sample: Use a tokenization template in the REST API

Once you specify a tokenization template, it can be used in the RESTful API application code. This is shown in the following example:

```
curl --tlsv1.2 -X POST -u EdYee:EdYee_password -d '{"tokengroup" :
"store1", "data" : "9453677629008564", "tokenTemplate" :
"ctsUsersTemplate"}' https://192.168.12.88/vts/rest/v2.0/tokenize
```

Deleting tokenization templates

Before deleting a tokenization template, make sure that tokens created with this tokenization template are not stored anywhere within (or outside) of the organization. Once the tokenization template used to create these tokens has been deleted, they can no longer be detokenized, unless the tokenization template is recreated very precisely.

Caution: After the character set used to create these tokens has been deleted, they can no longer be detokenized, unless the character set is recreated very precisely. Even the order of the characters in the character set matters.

To delete a tokenization template:

1. Navigate to **Tokenization > Tokenization Templates**.
2. Select the tokenization template from the list, and click **Delete**.

Managing data masks

Tokenization data masks hide specified parts of detokenized data. A mask is required for detokenization, even if the user is authorized to view the entire unencrypted string of data.

Creating a data mask

Review [“Using data masks” on page 15](#).

To create a mask:

1. , Select **Tokenization > Masks**.
The All Masks list is displayed.
2. Click **New Mask** and enter the information on the *New Mask* dialog.
Some examples of data masks you could create:
 - A mask called SHOW_LAST_4 that shows the last four digits of a tokenized credit card: XXXX-XXXX-XXXX-7897
 - A mask called SHOW_FIRST_3 that shows only the first three digits of a social security number: 565-XX-XXXX.
 - A mask that shows everything (ALL_CLEAR): set **Show Left** and **Show Right** values to 999999.
3. Click **Create**.

Deleting a data mask

When a Mask is deleted, all user and user group permissions associated with that mask will be deleted.

Warning! This could result in production down time if a user is using the system and their permissions are deleted. They will be denied tokenization and detokenization rights. Be VERY sure these permissions are not in use before deleting the mask.

Applying Permissions to Users and User Groups

Review the following sections:

- [“Understanding CTS Authentication and Authorization” on page 4](#)
- [“Understanding CTS Keys” on page 11](#)

With CTS, users are authenticated, granted permissions (to tokenize, detokenize, encrypt, hash, etc.), and associated with particular keys, using a three-way permissions matrix.

NOTE: See additional help on the *Permissions* page by clicking the “i” icon in the upper right corner.

Assigning key-based permissions

The GUI Administrator assigns permissions based on user (or user group), action, and key, similar to the English sentence:

“User ctsuser1 may encrypt, decrypt, tokenize and detokenize with symmetric key key1.”

Before permissions can be assigned, you must:

- Create user groups and users
- [“Specifying DSM Keys”](#)

Use the following steps to assign key-based permissions:

1. Log in to the CTS GUI and select **Permissions**. The User Permissions list is displayed. If necessary, click **User Group** to see the User Group Permissions list. You can click the tabs to see the Symmetric Keys, Asymmetric Keys, and Opaque Objects assigned to a user (or group).

Figure 9: User Permissions List Page

2. Click a user or group name to see a user permissions summary page. You can review and change permissions there or from the list page. To continue from the list page:
3. Click the permission symbol for a particular user's key. The user permission matrix is displayed.

4. Assign permissions as needed and click **Apply**.

Assigning other permissions

The permissions in the “Other Permissions” category are those that are not tied to specific keys. They are assigned only once per user group, and apply to all key groups. Actions that are not supported in the API are not displayed.

Creating and Importing Keys

IMPORTANT: Review [“Creating static and dynamic keys” on page 12.](#)

To grant a user or user group permission to create keys on the DSM or to import keys to the DSM:

1. Log in to the CTS GUI and click **Permissions**. The User Permissions list is displayed.
(If necessary, click **User Groups** to access the User Group Permissions list.)
2. Click the permission symbol for a user in the **Other Permissions** column.
The Other Permissions assignment window is displayed.

3. Check **Create** and **Import**, as desired, and click **Apply**.

NOTE: The **Create** permission is assigned only once per user and applies to all type of keys.

The **Import** permission is assigned only once per user and applies to symmetric keys and opaque objects.

Other permissions: tokenize/detokenize

Select **Tokenize/Detokenize** to apply privileges at a global level, on all symmetric keys in the system.

If your system is upgraded from an earlier version, any users who had been granted tokenize/detokenize privileges have these boxes checked automatically.

Remember to de-select the global check boxes and reassign privileges on a per-key basis to take advantage of the more granular structure of CTS configuration options.

Dashboard API Monitoring

The CTS Dashboard provides graphical and tabular monitoring for:

- Tokenization activity
- Key Management activity
- Cryptography activity

Activity data is updated hourly, and can be sorted and filtered by:

- User (or all users)
- Date range
- Hour
- Day
- Week
- Month

The tabular view of the API data (shown below the graphical view) can be filtered by user or by user IP address (which can be used to check for access by unusual IP addresses). Clicking a user or IP address row in the table filters the graph view above it by that selection

Figure 10: API Activity on the Dashboard

Exporting Data

Click the **Export** button to export into a CSV file the data as currently filtered and shown in the dashboard.

Administrator History Logs

Most tokenization and detokenization log messages are in the file `tokenization.log`. You can get this via web download with credentials from the file `tokenization.log`. Example:

`https://ctshost.vormetric.com/log/tokenization.log`

These log messages also go to the syslog with the facility code `daemon`.

Other log files:

- `django.request.log` - Logs any user request coming from the Tokenization Server GUI.
- `uwsgi_cts.log` - Debug log.
- `clish.log` - CLI activities and events.

IMPORTANT: Log data added by the server or server framework are not included in the log files

View the Tokenization Server logs by clicking the **Logs** icon in the Tokenization Server GUI. (Audit log messages also go to the syslog with the facility code user.) From here you can:

- View audit logs, access logs (login and logout attempts), active sessions, locked accounts, and server CPU usage
- Export the logs

Viewing audit logs

To view the audit logs:

1. Log into the CTS GUI.
2. Click **Logs** in the navigation pane.
3. Click the **Audit Logs** tab.

Details are shown for each audited event, including:

- **Date** specifies when the event occurred.
- **User** is the Tokenization user.
- **Content Type** is the database table that was modified. *Tenant* involves Group Tokens, *Key* is encryption keys, *user* is for users, *groups* for groups, and so on.
- **Object Name** is the specific database object that was created or changed.
- **Modification** is the action that was performed.

NOTE: To set the CTS log level, see [“Set Log Levels” on page 141](#).

Viewing access logs

The access log shows information about all attempts to log into the server, and all logouts from it. The related information includes the access time, the IP address, username, and user agent (typically, a web browser). By default, all login attempts are listed, but the list can be filtered (by Status) to show only successful or only failed attempts.

To view the access logs:

1. Log into the CTS GUI.
2. Navigate to **Logs**.
3. Click the **Access Logs** tab.
4. Filter the listed results with the **Type** menu. When viewing the **Logins** access type, use the additional **Status** pull-down menu to filter by Successful or Failed login attempts.

Figure 11: Logs Page Showing Login Attempts

Name/Time	Status	IP/Device	Location	User Agent
1/10/2018 1:20:00 PM	Success	172.16.1.1	net	Mozilla/5.0 (Windows; MSIE 10.0; Trident/6.0; Chrome/44.0.2404.125; Safari/537.36)
1/10/2018 1:40:00 PM	Success	172.16.1.1	net	Mozilla/5.0 (Windows; MSIE 10.0; Trident/6.0; Chrome/44.0.2404.125; Safari/537.36)
1/10/2018 1:40:00 PM	Success	172.16.1.1	net	Mozilla/5.0 (Windows; MSIE 10.0; Trident/6.0; Chrome/44.0.2404.125; Safari/537.36)

1/10/2018 1:40:00 PM	Success	172.16.1.1	net	Mozilla/5.0 (Windows; MSIE 10.0; Trident/6.0; Chrome/44.0.2404.125; Safari/537.36)
1/10/2018 1:40:00 PM	Success	172.16.1.1	net	Mozilla/5.0 (Windows; MSIE 10.0; Trident/6.0; Chrome/44.0.2404.125; Safari/537.36)

Downloading (export) access or audit logs

To download the history logs for an administrator:

1. Log into the CTS GUI.
2. Navigate to **Logs**.
3. Click the **Audit Logs** or **Access Logs** tab.
4. Click the **Export** button for the Audit or Access Logs.

Showing active sessions

To see a list of active sessions of users currently logged into the server:

1. Log into the CTS GUI
2. Click **Logs** in the navigation pane.
3. Click the **Active Session** tab.

4. To end a user's session on the GUI, click the **End Session** button in the row for that user.

Figure 12: List of Active Sessions

Showing locked accounts

If a user fails to enter valid credentials more than five times, the user is locked from accessing the CTS for 15 minutes. View the details of locked accounts, including when the lock was activated and when it was released. Superusers can unlock an account before the 15 minute time limit is completed.

To view and manage locked accounts:

1. Log into the CTS GUI.
2. Click **Logs** in the navigation pane.
3. Click the **Locked Accounts** tab.
4. Unlock an account by clicking **Unlock** in the row of the desired user.

System logging

Audit log messages go to the syslog with the facility code user.

tokenization.log messages go to the syslog with the facility code daemon.

CLI log messages go to the syslog with the facility code local3.

Configuring syslog servers

Configure remote syslog servers with the CLI, with the command under the vts category. You can also set up multiple syslog servers with this command, with the --add and --remove commands.

The remoteLog command has utilities to check the connection status to the servers, and to send a sample log message to them.

Backing Up and Restoring the CTS

Create regular backups of the server to restore the CTS in the event of failure.

Even in a clustered scenario, system failure can occur. To minimize this risk back up your CTS implementation regularly using the administration interface or the REST API.

Use the CTS GUI to create a backup before upgrading your CTS version, and before any major server configuration changes. Maintain a regular backup schedule using the CTS REST API.

Restore the state of your CTS implementation using the administration interface. Backups restore the CTS to the saved version in the following scenarios:

- Restoring the application after system failure
- Restoring the application after upgrade failure
- Restoring the application due to unrecoverable system configuration errors.

NOTE: A backup cannot restore a system using a CTS version older than 2.2.2. A backup cannot be applied to any version of the CTS software that is older than the version in use when the backup was created.

Backing up the CTS in the GUI

Use the administration interface to create and save a backup.

Use the following steps to create a system archive:

1. Select **Backup** from the administration interface left hand navigation.
2. Click the **Create Backup** tab.
3. Accept the default values, and click **Backup now**.

The archive generates and is saved to your default download folder. The file name is created with the following syntax:

`backup_year-month-day.`

For example: `backup_2018-10-20`

Move the backup to your storage directory.

Managing backup tasks

Use the REST API to create a backup and automate system backup tasks.

You can use the Backup API to generate backups via any valid HTTP request. The syntax requires authentication using user credentials.

See the reference documentation for more information.

Restoring the CTS from a backup

If a complete system restore is required, make sure the CTS installation is complete before beginning this task.

NOTE: Make sure the CTS version leveraged for the backup is the same as the backup or newer than the backup, and is at least version 2.2.2

Use the following steps to restore the CTS to its last recorded working state using a backup.

1. Select **Backup** from the administration interface left hand navigation.
2. Click the **Restore** tab.
3. Click **Choose File** and navigate to the required backup archive.
4. Confirm the following back up details:
 - CTS version
 - Backup date
 - DSM hostname
 - Encryption key name

Make sure the same DSM that was registered to the CTS that was backed up is also registered to the new CTS. Also make sure that the key used to encrypt the backup file has been exported to the registered DSM, and that it has the exact same name.

5. Click **Restore**.

NOTE: Depending on the size of the backup, the restore process may take some time.

If this node is a member of an existing cluster, it is removed from the cluster. Any existing data on this node is destroyed.

A new cluster is created with this node as the first node but with data restored from the backup.

When the restore completes, this node has all data from the backup including login credentials.

NOTE: If user forgot the login credentials in the backup, run the `createsuperuser CLI` command to create a new user.

This node becomes a new node of a new cluster. It is no longer a member of any previous cluster.

IMPORTANT: If this node was a member of an existing cluster prior to the restore, it must be removed from that cluster. Failure to remove this node from its previous cluster prevents new nodes from joining that cluster.

The CTS is restored to the state of archive. When the task is complete, a banner appears, indicating that the restore is complete. The CTS reboots.

When the login screen appears, enter your credentials to access the restored application.

Key Rotation

Regular encryption key rotation can increase security and also satisfy some PCI DSS requirements. To rotate CTS keys, ask your DSM Administrator to run the DSM CLI command `security gencert` on the DSM that creates and stores the CTS keys.

Versioned keys are not permitted for tokenization.

Monitoring via SNMP

You can monitor disk partitions, files, load average, and processes by setting up SNMP polling. Configure SNMP at the CLI in the network category, and the `snmp` command.

When enabling SNMP, you must specify a whitelist of IP addresses for SNMP managers. CIDR control access is supported.

CTS supports both SNMP v3 and v2c. SNMP v3 supports password authentication, encryption, and a choice of encryption and password hashing algorithms.

CTS CLI Reference

The CipherTrust Tokenization Server Command Line Interface (CLI) is used to configure the CTS network and do other system-level tasks.

This chapter summarizes the following CLI categories and the commands within each:

- [“Authentication Setup Category” on page 99](#)
- [“Cluster Management Category” on page 100](#)
- [“ICAPI SafeNet Setup” on page 100](#)
- [“Network Management Category” on page 101](#)
- [“System Configuration Category” on page 103](#)
- [“VAE Configuration Category” on page 104](#)
- [“CTS Configuration Commands” on page 104](#)

This chapter provides a high-level overview of each command category. For complete usage details on each command and its options, run the command with the “- -help” option. For tips on navigating the CLI, see [“CLI navigation cheat sheet” on page 36](#).

NOTE: To access the CLI, see [“Access the CLI through a terminal emulator like PuTTY.” on page 35](#).

Authentication Setup Category

The `auth` category contains authentication setup commands -- for OAuth2 (`oauth2` command), for setting and reviewing optional OAuth2 settings, and the `ldap` command, whose options configure and review the LDAP Server settings.

As an alternative to specifying the various LDAP settings as options to the `ldap` command (for example, `auth ldap --server ldap://hostname:636`), you can run an interactive wizard that prompts you for each setting. Run this wizard with the `ldap --setup` command.

Cluster Management Category

The `cluster` category is a subset of CTS commands for use with cluster management.

Table 7: Cluster Management Commands

	Description
<code>add</code>	Add a node that can later create or be joined to an existing cluster. This command must be used on a node before that node can join a cluster. NOTE: Do not use with <code>remotejoin</code> .
<code>apiadmin</code>	API admin user setup, for automated cluster set up.
<code>create</code>	Create a CTS cluster.
<code>join</code>	Join a node to an existing CTS cluster. NOTE: Do not use with <code>remotejoin</code> .
<code>remotejoin</code>	Remotely join nodes to a cluster. Use in automated cluster setups.
<code>remove</code>	Remove a node from a cluster.
<code>show</code>	Show cluster settings.

ICAPI SafeNet Setup

Use the `icapi` category of CTS commands to set up, configure, and control SafeNet server support (via ICAPI).

Table 8: ICAPI Setup Commands

Command	Description
<code>create</code>	Create a private key, or certificate signing request.
<code>enable</code>	Enable or disable the ICAPI interface to SafeNet servers.
<code>register</code>	Register to a SafeNet KeySecure host.
<code>set</code>	Set ICAPI properties, such as IP addresses, ports, and user credentials to a KeySecure server.
<code>setup</code>	Perform an interactive setup of ICAPI properties (instead of using <code>set</code>).
<code>show</code>	Show ICAPI and SafeNet status and settings.
<code>test</code>	Test connection to a KeySecure server, or access to a specified key on the KeySecure server.

Table 8: ICAPI Setup Commands

Command	Description
upload	Upload a private key, signed certificate, or local CA certificate.

Network Management Category

Use the network category to set, modify, or delete system IP addresses, and to set up CipherTrust Tokenization Servers. The network category also contains commands for showing and testing network configurations

NOTE: Each server is assigned a unique IP address.

Table 9: Network Category Commands

Command	Description
arp	Manipulate the system ARP cache.
arping	Send ARP requests to a neighbor host
checkport	Check port connection status of a host
dns	Show or configure settings for the CTS DNS server(s)
ethtool	Query network driver and hardware settings
ifconfig	Show or configure a network interface
ip	Show or configure the CTS network interface settings
netstat	Print network connections
nslookup	Query internet name servers
ntpservice	NTP service
ping	Pings an IP address, host name, or FQDN
route	Set static route
service	Start/stop/restart network service
set	Configure network device interface

Table 9: Network Category Commands

Command	Description
setup	Network setup wizard
show	Show network device configuration
snmp	Show, set, or change SNMP (v2c or v3) server configuration, which can be used to monitor processes, load average, disk space, and file size
traceroute	Traces route to IP address or host name

Example Request:

```
network> ip address
```

Response:

```
1: lo: <LOOPBACK,UP,LOWER_UP> mtu 65536 qdisc noqueue state UNKNOWN group default
qlen 1000
    link/loopback 00:00:00:00:00:00 brd 00:00:00:00:00:00
    inet 127.0.0.1/8 scope host lo
        valid_lft forever preferred_lft forever
    inet6 ::1/128 scope host
        valid_lft forever preferred_lft forever
2: eth0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc mq state UP group
default qlen 1000
    link/ether 00:0c:29:47:22:72 brd ff:ff:ff:ff:ff:ff
    inet 10.3.201.140/16 brd 10.3.255.255 scope global dynamic eth0
        valid_lft 216sec preferred_lft 216sec
    inet6 fe80::20c:29ff:fe47:2272/64 scope link
        valid_lft forever preferred_lft forever
```

WARNING! Changes made using this command are not persistent. Use the setup command to change network settings permanently.

System Configuration Category

The system configuration category enables you to configure the CTS host settings (such as, hostname, console port, or timezone), and view and manage other common system administration tasks for the server (such as, reboot or shut down, or view disk space usage or currently logged-in users).

Table 10: System Category Commands

	Description
banner	Configure SSH banner
cpuid	Show detailed CPUid information
cpuinfo	Show CPU information
daemon	Show daemon services that are running
date	Print or Set the system date and time
df	Report file system disk space usage
free	Display amount of free and used memory in the system
host	DNS lookup utility
hostname	Set/Show Hostname
hosts	Update hosts file
lastlogin	Show last logged-in users
meminfo	Show memory information
reboot	Reboot system
shutdown	Shut down system
terminal	Show or terminate terminal (CLI) sessions
timezone	Set or show timezone
top	Display Linux processes
uname	Print system information
uptime	Show how long the system has been running
vmstat	Report virtual memory statistics
who	Show who is logged into the system

VAE Configuration Category

The `vae` category includes commands to register the Tokenization Server to the DSM..

Table 11: VAE Management Commands

	Description
<code>certificates</code>	VAE certificates utilities
<code>dsmkeepalive</code>	Enable or Disable DSM keepalive
<code>register</code>	Register the current CTS host to the DSM.
<code>show</code>	Show registration information.
<code>test</code>	Test to be sure the CTS has been successfully registered with the DSM.

CTS Configuration Commands

The `vt s` category is used to configure the CTS, set time parameters, configure GUI login behavior, and upgrade Tokenization Server software.

NOTE: The CTS configuration commands still retain the `vt s` category name to ensure backward-compatibility.

The `vt s` category consists of the following commands:

Table 12: CTS/VT S Category Commands

Command	Description
<code>batch_size_limit</code>	Tokenization Batch size limit.
<code>cliadmin</code>	Cliadmin user setup. NOTE: If CTS runs on an AWS EC2 and has been set to use an EC2 key pair, password access is disabled, and <code>cliadmin password</code> commands will fail with an error message. For example, a password cannot be disabled or unlocked. To view if the <code>cliadmin</code> is using an AWS SSH key pair, run <code>vt s cliadmin keys --list CLI</code> command. If the instance uses an EC2 key pair, an entry in the SSH keys will show <code>[ec2]</code>.

Table 12: CTS/VTs Category Commands

Command	Description
client_certificate	Enables client authentication by requiring clients to pass a client key and CA certificate to CTS. NOTE: For best security, enable client certificates <i>with</i> identities (the <code>--enable-with-id</code> option) instead of without identities.
cors	Class-Origin Resource Sharing (CORS)
create_superuser	Create a superuser local account for Web administrative GUI access
logfile	List, view, or tail log files
loglevel	Set log level
randommode	Random Mode utility
rate_limiting	Limit the amount of tokenization requests
remotelog	Set remote logging
restore	Restore system from backup
server_certificate	Creates the self-signed certificate or certificate signing request and import signed certificate.
service	CTS Service utility
show	Show the security settings.
smtp	Configure, view, or test email notifications and underlying SMTP setup
ssl_ciphers	Show or set SSL cipher suites. WARNING: Non-FIPS approved SSL ciphers will be deprecated in the future. It is highly recommended you configure CTS to use the default SSL cipher suite (with the <code>vtsssl_ciphers --setdefault</code> command), otherwise the server can be open to security vulnerabilities.
ssl_protocol	Specifies what version of the SSL (TLS) is supported by the CTS.
upgrade	Upgrade CTS.
weblogin	Web login setup.

Encryption and Key Management API Programming Notes

CTS includes several sets of REST API services: Encryption, Key Management, Tokenization, and Admin. The Tokenization APIs (including the reference documentation, examples, and error codes) are described in the chapter [“Tokenization REST API” on page 133](#). The Admin APIs are described in the chapter [“Admin REST API” on page 155](#).

This chapter provides concepts, guidelines, and examples for the Encryption and Key Management APIs. There are also online reference documents for these two sets of services.

This chapter contains:

- [“Reference Documentation” on page 107](#)
- [“Encryption and Key Management API Concepts” on page 108](#)
- [“Key Management Examples” on page 120](#)
- [“Cryptographic operation examples” on page 123](#)
- [“Versioned Key Management Examples” on page 130](#)

Reference Documentation

The CipherTrust Encryption and Key Management services have built-in online documentation. To access this documentation, you must be logged in.

CipherTrust Encryption RESTful API documentation

https://<CTS_hostname_or_IP_address>/vts/crypto/v1/doc

CipherTrust Key Management RESTful API documentation

https://<CTS_hostname_or_IP_address>/vts/km/v1/doc

Encryption and Key Management API Concepts

The concepts in this section provide background context for API programmers who will use the Encryption and Key Management APIs in their code.

NOTE: The data input format for the APIs is base64.

TES Resource Names (TESRN)

A TESRN is a reference to a resource with the Crypto and Key Management services, specifically a way to address keys. These are used throughout all the cryptographic and key management operations that require a key reference.

It has the following format:

```
tesrn:<managing-service>:[<domain>][:<resource>]:[resource-  
type]:<resource-id>[:<version>|<public>|<private>]
```

The intention is to be able to identify where the resource resides and whether the service can handle such or not. There exists some abbreviated ways to access keys:

Reference keys by label

Quickly get information about a key by using the key label in your request: *foo123* key would be "*foo123*". In TESRN format it would be "*tesrn:cts::label:foo123*". Note that the domain is empty, and the resource type, which is absent from the name, defaults to "key".

Other default key types

In addition, you may want to use an alias, UUID, or MUID instead of a key label. For these cases, refer to each respectively as shown in the following examples:

By Alias:

```
alias:myfoo
```

TESRN format:

```
tesrn:cts::alias:myfoo
```

By UUID:

```
uuid:7fa96ada-18c6-11e8-8dab-0800277415ff
```

TESRN format:

```
"tesrn:cts::uuid:7fa96ada-18c6-11e8-8dab-0800277415ff"
```

By MUID:

```
muid:7fa96ada-18c6-11e8-8dab-0800277415ff
```

```
urn:7fa96ada-18c6-11e8-8dab-0800277415ff
```

TESRN format:

```
"tesrn:cts::muid:91eb92c2-18c6-11e8-accb-0800277415ff91ec0054-18c6-11e8-b01e-0800277415ff"
```

By Label:

```
label:foo123
```

```
"tesrn:cts::label:foo123"
```

Legacy resource names

While not specific to the CTS services, it is worth mentioning WSOP (nShield Web Services Option Pack) as a future interoperability consideration. WSOP keys are accessed by UUID only. These key references are expressed as:

```
urn:c1d6f102-18c6-11e8-b2f9-0800277415ff
```

Algorithms and key types

The CipherTrust Encryption and Key Management APIs make references throughout the specification to *algorithm types*. The algorithm types have names that conform to the JOSE RFC-7518 Specification, plus a decision to extend the algorithm namespace (maintaining the JOSE syntax) to meet customer needs.

NOTE: The algorithm name will be **case insensitive** for use with the services. The complete list of algorithm names is listed in Table 13 on page 110. Key types also conform to the JOSE RFC-7518 section 6.1 specification. Although this section of the specification describes the key types as **case sensitive** for JOSE, the current implementation is **case insensitive** for key types.

Table 13: Key Types

	Description	Algorithms	State
Symmetric	Oct or octet sequence. Used for: - tokenize - detokenize - encrypt - decrypt Symmetric keys are also used for Tokenization, and while the symmetric keys are typical AES keys with 128 or 256 bits of key material, the algorithms are FPE (FF3) and FF1. Note: Versioned keys may not be used for tokenization, only non-versioned keys.	A128ECB - AES 128 ECB cipher mode A256ECB - AES 256 ECB cipher mode A128CBC - AES 128 CBC cipher mode A256CBC - AES 256 CBC cipher mode A128GCM - AES 128 GCM cipher mode A256GCM - AES 256 GCM cipher mode A128CBCPAD - AES 128 CBC-PAD cipher mode A256CBCPAD - AES 256 CBC-PAD cipher mode A128CTR - AES 128 CTR (counter) cipher mode A256CTR - AES 256 CTR (counter) cipher mode	At this time, only symmetric keys support states. On create and import, only a preactive or active state may be given. On a key update all states can be given except for preactive. The following states are available: - Preactive - Active - Default when a key is created - Suspended - Compromised - Deactivated - Destroyed
Asymmetric	RSA key type. Used for: - encrypt - decrypt - sign - verify	RSA	
Opaque object	Octet array. This is a Thales extension (not part of JOSE RFC-7518 spec). Used for - sign - verify Does not have the option of store on server. Size limit: 0-4096 bytes.	HS1 - HMAC-SHA-1 HS224 - HMAC-SHA-224 HS256 - HMAC-SHA-256 HS384 - HMAC-SHA-384 HS512 - HMAC-SHA-512	N/A

NOTE: EC Key type is an elliptic curve cryptographic key, which is currently not supported.

Opaque objects

An opaque object is a generic form of object that is securely stored on the DSM and is currently used by the underlying VAE PKCS11 library to implement some extensions that are not available natively on the DSM.

CTS and VAE primarily use opaque objects to represent HMAC keys. They are created or imported using the same endpoint as for symmetric and asymmetric keys, except that the key type (kty) must be opaque. If a wrapped key is provided, this becomes the key material used to create the opaque object key. If only a size is given, the CTS cryptographic service generates a key using the DSM true random number generator.

The size limit for an object is 4096 bytes. When size is omitted, or set to zero, and key bytes are present, the size is computed from the size of the byte sequence. When an opaque object has empty key bytes with no specific size defined, it creates an object.

NOTE: In this release opaque objects can only be used for signing and verifying. Opaque objects support cryptographic header versions 2.1 and 2.7 only.

Table 14: Opaque Object Creation Rules

	Key Bytes	Result
size = 0 (or omitted)	"" (or omitted)	returns error
size = 0 (or omitted)	present	sets size to the length of key bytes
size > 0	length does not match size	returns error
size > 0	"" (or omitted)	generates Opaque Object with size bit key
size > 0	length does not match size	returns error

Cryptographic headers

Cryptographic headers is a convenient feature that allows a ciphertext to be decrypted without knowledge of the specific key name and/or version that was used to encrypt it. When encrypting with headers enabled, the ciphertext includes bytes containing key information inserted before the encrypted data. To enable cryptographic headers, the **header** attribute must appear in the POST body for sign, verify, encrypt, and decrypt calls.

NOTE: The two versions of headers supported in this release are 2.1 and 2.7 (HDR_V21, HDR_V27).

Verify and decrypt also take an **all** header attribute value to let the service figure out the header version in a more transparent way for the caller.

Versioned keys

Key versioning is available for symmetric keys in the current release of CTS with the VAE library. The rules for versioned keys are different from conventional symmetric keys. In general:

- The label represents the key class. A reference to the key by label will always refer to the most recent activated key version.
- Every key version has its own UUID and MUID
- A key can be deleted by UUID or MUID
- Deleting version zero (0) of a key class by UUID or MUID, deletes the entire key class (all versions)
- Versioned keys can be used for signing, verifying, encryption and decryption
- To create a new versioned key, the create endpoint must have an **action** attribute set to **create**. A version number must also be supplied.

Some limitations for this release are:

- Inability to find a particular version of a key by label and version number
- Internal key IDs are not supported

Forcing refreshed key information from DSM

If a key is rotated on the DSM, then retrieving that key information via CTS API calls will reflect the key information prior to that DSM rotation. You can ensure refreshed key information is fetched by CTS API calls by appending “:refresh” to the end of the **kid** value of the API call. For example:

```
curl -X GET \
https://192.168.159.141/vts/km/v1/keys/vae-key-rotation-via-cryptoserver:refresh\
-H 'authorization: Basic dnRzcm9vdDpWb3JtZXRYaWMxMjMh' \
-H 'cache-control: no-cache' \
-H 'content-type: application/json' \
-H 'postman-token: 2a69ef4b-c849-8a97-1db5-2a9e93c594a1'

curl -X POST \
https://192.168.159.141/vts/crypto/v1/encrypt \
-H 'authorization: Basic dnRzcm9vdDpWb3JtZXRYaWMxMjMh' \
-H 'cache-control: no-cache' \
-H 'content-type: application/json' \
-H 'postman-token: 7fb55525-eea2-b12f-1add-66bdee3e34e4' \
-d '{ "plaintext": "NDU0NTQ1", "alg": "A128CTR", "params" :
{"iv": "Ff0lom2eDm0phLNHLvpUvA==" }
, "kid": "vae-key-rotation-via-cryptoserver:refresh" }'
{ "ciphertext": "6VhMegkk", "tag": "" }
```

This does not apply to keys that are rotated by CTS, which will always be current, only to keys rotated on the DSM.

Key states

Symmetric and asymmetric keys support states. The following states are available:

- Preactive - When a key was created to have a preactive state
- Active - Default when a key is created
- Suspended - A key has been suspended
- Compromised - Key is compromised
- Deactivated - Key is deactivated
- Destroyed - Key is destroyed

To set a key to the suspended, compromised, or deactivated state, call the modify endpoint (PATCH). A key can be set to the active state again only if it is in the suspended state.

Valid key operations

This table lists the valid key operations from the API. It does not include permissions related to authorization. See the Authorization section below for more details.

Table 15: Valid Key Operations

Operation	Symmetric Key	Versioned Symmetric Key	Asymmetric Key	Opaque Object
Create	yes	yes	yes	yes
Import	yes	yes	no	yes
Destroy	Key delete custom attribute delete	Delete key by UUID or MUID only Delete key of version 0 deletes entire set Delete custom attribute	Key delete custom attribute delete	Key delete custom attribute delete
Modify	custom attributes add alias key states key migration to versioned key	custom attributes add alias key states key rotation lifespan interval	custom attributes	custom attributes add alias
Find	By label/name By UUID By MUID By alias	By label/name - last version By UUID By MUID By alias	public key only By label/name	By label/name By UUID By MUID By alias
Export	clear_key kid for plain bytes wrapping key with A256CBC or A256CBCPAD	clear_key kid for plain bytes wrapping key with A256CBC or A256CBCPAD	no	no
Encrypt	Standard encryption cryptographic headers	Standard encryption cryptographic headers	Standard encryption only	no
Decrypt	Standard decryption cryptographic headers	Standard decryption cryptographic headers	Standard decryption only	no
Sign	HMAC signing cryptographic headers	HMAC signing cryptographic headers	RSA signing only	HMAC signing cryptographic headers

Table 15: Valid Key Operations (Continued)

Operation	Symmetric Key	Versioned Symmetric Key	Asymmetric Key	Opaque Object
Verify	HMAC verifying cryptographic headers	HMAC verifying cryptographic headers	RSA verifying only	HMAC verifying cryptographic headers

Wrapping keys

When importing or exporting a key, it is recommended to use a wrapping key in order not to compromise the key itself.

In the current version of the CTS Key Management module a wrapping key must be an AES 256-bit key, and only the CBC or CBCPAD ciphers may be used. The ideal method for wrapping a key on both import and export is to use asymmetric keys, however such is currently unsupported by the underlying libraries and services which implement the CTS Key Management module.

Importing an exporting key requires that the user has a wrapping key, and that such key is available on both the client and the DSM.

Importing with wrapping key

When importing with a wrapping key, the following steps need to be taken:

1. Create a 256-bit AES key that is known to the caller and the DSM. This is the wrapping key.
2. Encrypt the key bytes with the wrapping key using an AES-CBC or AES-CBCPAD cipher. This is the wrapped key.
3. Call the create endpoint and supply the base64-encoded wrapped key and the wrapping key ID.

Exporting with wrapping key

When exporting with a wrapping key, the following steps need to be taken:

1. Create a 256-bit AES key that is known to the caller and the DSM. This is the wrapping key.
2. Call the export endpoint, supplying a wrapping key ID. This will return a wrapped key.
3. Decrypt the base64 encode wrapped key using the wrapping key on the client side.

Importing and exporting using clear bytes

The API offers the ability to perform import and export function using raw key bytes, however such method is not recommended.

To import a key using clear bytes, omit the wrapping key ID or give the **clear_key** label. For exporting, give the **clear_key** label as the wrapping key ID. In both cases, the **alg** and the **iv** attributes must be omitted.

Authorization

Using any key on CTS requires user or group level authorization for a particular key. The following sections describe tasks associated with authorization:

- [“Creating and importing keys” on page 116](#)
- [“Managing keys” on page 116](#)
- [“Cryptographic operations” on page 116](#)
- [“Authorization operations” on page 117](#)

Creating and importing keys

This category covers both key import and key creation. A user or group that has either import, create, or both is allowed to add keys to the CTS. The difference between import from create is in the ability to add a wrapped key representing the key itself to the key creation request. This ability to create and import keys is set for each user through the CTS Administration UI.

If a user or group has create and/or import permissions, when invoking the corresponding API endpoint will create a key with all the permissions for key management and cryptographic operations. Any other user needing to perform operations on such keys, can only be added through the CTS Administration UI. If the user does not have permission to create or import, the corresponding creation endpoint will return an error.

Managing keys

A user or group may perform each of the following key management operations if he or she has permissions to perform such. This can be configured for each individual key from inside the CTS Administration UI. The allowed key management operations are:

- Destroy - Destroy a key
- Modify - Modify a key’s attributes
- Find - Look up or retrieve a specific key
- Export - Export a specific key. This only applies to symmetric keys.

Cryptographic operations

A user or group may perform each of the following cryptographic operations using a specific key if he or she has permissions to perform such as configured for each individual key from inside the CTS Administration UI. The allowed cryptographic operations available are:

- Encrypt - Encryption using a key
- Decrypt - Decryption using a key
- Sign - Sign with a given key
- Verify - Verify a signature with a given key

Authorization operations

Table 16, “Authorization Operations,” on page 117, shows the possible authorization operations when a key is or was created or imported via the API. The owner is the user who creates the key. This table only applies to authorization. Table 15, “Valid Key Operations,” on page 114 should be used to determine what are valid operations, without taking authorization into account.

Table 16: Authorization Operations

Operation	Owner	Group	Other user	Other Group
Create	Yes, if owner has create permission Owner can specify on create the permissions allowed though the usage attribute If usage attribute is not supplied, key will be created with all permissions	Yes, if owner has create permission granted through a group Owner can specify on create the permissions allowed though the usage attribute If usage attribute is not supplied, key will be created with all permissions	N/A	N/A
Import	Yes, if owner has import permission Owner can specify on import the permissions allowed though the usage attribute If usage attribute is not supplied, key will be imported with all permissions	Yes, if owner has import permission granted through a group Owner can specify on import the permissions allowed though the usage attribute If usage attribute is not supplied, key will be imported with all permissions	N/A	N/A
Destroy	Yes, if owner gave it permission on creation Key if removed from the CTS Authorization table unless it is a versioned key	No	No	No
Export	Yes, if owner gave it permission on import or create	No	No	No

Table 16: Authorization Operations (Continued)

Operation	Owner	Group	Other user	Other Group
Find	Yes, if owner gave it permission on import or create	No	No	No
Modify	Yes, if owner gave it permission on import or create	No	No	No
Encrypt	Yes, if owner gave it permission on import or create	No	No	No
Decrypt	Yes, if owner gave it permission on import or create	No	No	No
Sign	Yes, if owner gave it permission on import or create	No	No	No
Verify	Yes, if owner gave it permission on import or create	No	No	No

Size

All sizes throughout the API refer to size in bytes, with the exception of the key creation/import where the size is in bits. The maximum size for the random generator endpoint is 4096 bytes.

Payload limits

The total payload for any request is 5 MB. However, you can work around this size limit by using the chaining script shown in [“Encrypting and Decrypting Large Files” on page 126](#).

Date handling

Throughout the API specification, dates are all represented in RFC-3339 format. Any date that appears within the request or result body in JSON format will be in this format. As a general pointer, when using different programming languages in writing client code to access the APIs, we prepared the following:

Go

The time struct/interface in golang is already marshaled/unmarshaled for JSON in RFC339.

Python

Python requires the installation of a package that implements rfc3339. A "*pip install rfc3339*" will address most users needs.

```
Python rfc3339
import rfc3339, time
rfc3339.rfc3339(time.time())
```

PHP

RFC3339 is a predefined constant in date for PHP: `date(DATE_RFC3339)`

Bash/cURL

RFC-3339 dates can be obtained by typing: `date --rfc-3339=seconds`

C++/boost

```
#include <boost/date_time.hpp>
std::cout.imbue(std::locale(std::cout.getloc(), new
boost::local_time::local_time_facet("%Y-%m-%dT%H:%M:%S%F%Q")));
std::cout <<
boost::local_time::local_microsec_clock::local_time(boost::local_time::ti
me_zone_ptr()) << std::endl;
```

Successful responses

All successful requests return a 200 HTTP status.

All calls return a response body, except for destroy (DELETE) of a specific key which has an empty body.

In a batch or vectorized call, where a series of requests are done simultaneously, the result is always 200, and each element of the vector contains the corresponding result for each request, whether successful or not.

Error responses and error codes

Error responses from the cryptographic and key management layer only return a JSON body with the following format. Anything different from this format is from the NGINX reverse proxy or from other components.

For example:

```
{"error": "TES_INVALID_OBJECT_HANDLE", "message": "find object returned
an invalid handle", "status": 400, "timestamp": "2018-03-
08T11:56:38.793756418-08:00"}
```

The following table describes the response parameters by listing the attribute names and their corresponding descriptions:

Table 17: Response Parameters

Attribute	Description
error	This response parameter indicates an error is returned. The error codes start with a TES_ for service related error checking and a CKR_ for PKCS11 related error codes encountered.
message	
status	This response parameter provides the HTTP status code associated with the error. For a list of possible error codes see: Table 18, "Error HTTP Status Codes," on page 120.
timestamp	

Table 18: Error HTTP Status Codes

	Description
400	An HTTP 400 Bad Request status indicating that the user supplied a malformed or invalid request.
401	An HTTP 401 Unauthorized status indicating that the user need to login or authenticate before the request can be handled.
403	An HTTP 403 Forbidden status indicating that a logged in user does not have authorization to access or perform an operation on the given resource.
404	An HTTP 404 Not Found status indicating that the URL or resource (TESRN) references does not exist.
500	An HTTP 500 Server Internal Error indicating that an error occurred on the service side and that it may be available later.

Key Management Examples

Key creation

Key creation allows to create a key whose contents (key material or bytes) is generated by the DSM

IMPORTANT: You cannot create a key via the REST API and make it a seed key in one step. You must create the key and add it via the CTS GUI in separate steps. You cannot just pass in "seedkey" as a keyword to the create key REST API. If you do, the key is created, but it is not a seed key.

This example shows how to create an AES 128-bit key named foo123key:

Request:

```
POST /vts/km/v1/keys {  
  "size": 128, "name": "foo123key", "kty": "oct"  
}
```

Response:

```
200 OK  
{  
  "attributes": {"usage": ["encrypt", "decrypt", "sign", "verify", "destroy", "modify", "find", "export"], "size": 16}, "metadata": {"key_management": {"uuid": "9f3c2775-405b-33e8-91af-904faa0e551f", "caching_duration": 44640, "state": "active", "lifespan_unit": "days", "muid": "9f3c2775-405b-33e8-91af-904faa0e551f39b6aee0-6821-39f9-a186-9a9904abff32", "caching_enabled": true, "name": "foo123key"}}, "kid": "tesrn:vts::label:foo123key"}  
}
```

Key import

Key import is basically the same as a key create, however the request contains information on the wrappedkey and the wrapping key.

This request imports an AES 128-bit key named foo1234key with key bytes equal to: "HelloWorldAlways".

Request:

```
POST /vts/km/v1/keys{  
  "size": 128,  
  "name": "foo1234key",  
  "kty": "oct",  
  "wrappedkey": "SGVsbG9Xb3JsZEFsd2F5cw=="  
}
```

Response:

```
200 OK
{"attributes":{"usage":["encrypt","decrypt","sign","verify"],"size":16},
"metadata":{"key_management":{"uuid":"9f3c2775-405b-33e8-91af-904faa0e551f",
" caching_duration":44640,"state":"active","lifespan_unit":"days",
"muid":"9f3c2775-405b-33e8-91af-904faa0e551f39b6aee0-6821-39f9-a186-9a9904abff32",
" caching_enabled":true,"name":"foo123key"}},"kid":"tesrn:cts::label:foo1234key"}
```

Key delete

This example deletes a key named foo123key.

NOTE: Upon success, the HTTP status code must be 200.

Request:

```
DELETE /vts/km/v1/keys/foo123key
```

Response:

```
200 OK
```

Key update

Request:

```
PATCH /vts/km/v1/keys/fookey {"state": "suspended"}
```

Response:

```
200 OK
{"attributes":{"usage":["encrypt","decrypt","sign","verify","destroy","find"],
"size":16},
"metadata":{"key_management":{"uuid":"bfd2a7b7-20db-31d7-b22f-01e625a54961",
" caching_duration":44640,"state":"suspended",
" versioning_enabled":1,"lifespan_unit":"days",
"muid":"bfd2a7b7-20db-31d7-b22f-01e625a549618b0ce745-fcb2-3718-97b3-d4a0b415ac5d",
" caching_enabled":1,"name":"fookey"}},"kid":"tesrn:cts::label:fookey"}
```

Response:

```
200 OK
{"digest": "RfdwuYKwBn0l03ZMGB7r59S+P+T9/s8ufPJfcSQXNfE="}
```

Encryption examples

AES-256 CBC encryption example

Request:

```
POST /vts/crypto/v1/encrypt{
  "plaintext": "JLns9BI4Pa7TTrCaeJIjQQ==",
  "alg": "A256CBC",
  "params": {
    "iv": "tler+lrCnchFRJDCFs1F/A=="},
  "kid": "mykey123"
}
```

Response:

```
200 OK
{"u"ciphertext": "SZASu6Ts+01IMtb14+djhg==", "params": {}}
```

Simple AES-256 CTR encryption with headers example

Request:

```
POST /vts/crypto/v1/encrypt
{"plaintext": "JLns9BI4Pa7TTrCaeJIjQQ==", "alg": "A256CTR", "params":
{"iv": "tler+lrCnchFRJDCFs1F/A=="}, "kid": "myversionedkey",
"headers"="hdr_v2.7"}
```

Response:

```
200 OK
{"ciphertext":
"UktNQzIxMAD/////AAAABXV1awQAAAAAEDkKfAiGhjeLkp50NDgjPQT/////AAAAA2l
2AAAAABbhYmMxMjNkZWZnaDY3ODkw/////wAAAVjc3VtAAAAACAbtDVcSesXu7SYqoZ
xNR+hC6Cq8H3gE5xv5vvSzRhUrKcwnBu8", "params": {}}
```

Decryption examples

Simple AES-256 CBC encryption example

Request:

```
POST /vts/crypto/v1/decrypt
{"ciphertext":
"wInPTVRugkxP0KBm46yCo8lpQMaDDRo15bEwt9Mz629MKh7IqB9roh36ZkyIumLi",
"alg": "A256CBC", "params": {"iv": "ek5Lmcw0JATvux5PoSaZ6w=="},
"kid": "fookey"}
```

Response:

```
200 OK
{"plaintext":
"40idw01cBKKcF1tK4ZBdZg7yDe9KbvBP1npfs382HT+yz0Fb3CeCh/eBIhH7a1rb",
"params": {}}
```

Simple AES-256 CTR decryption with headers example

Request:

```
POST /vts/crypto/v1/decrypt
{"ciphertext":
"UktNQzIxMAD/////AAAABXV1awQAAAAAEDkKfAiGhjeLkp50NDgjPQT/////AAAAA2L
2AAAAABbhYmMxMjNkZWZnaDY3ODkw////wAAAAVjc3VtAAAAACAbtDVcSesXu7SYqoZ
xNR+hC6Cq8H3gE5xv5vvSzRhUrKcwnBu8", "alg": "A256CTR", "params":
{"iv": "tler+lrCnchFRJDCFs1F/A=="}, "headers"="all"}
```

Response:

```
200 OK
{"plaintext": "JLns9BI4Pa7TTrCaeJIjQQ==", "params": {}}
```

Encrypting and Decrypting Large Files

To handle files that are larger than the payload limit of 5 MB, use the following script to automatically break down a large file into a chain of smaller files for encryption, and to join these files and decrypt them:

```
#!/bin/bash

URL=http://localhost:8000/crypto/v1
KEY=cc01
IV="MTAwMDIwMDAzMDAwNDAwMA=="
CHUNKSIZE=256
FILE="/etc/hosts"
ALG="A256CTR"

BASE=`basename $FILE`
OIV=$IV
if [ ! -e ./$BASE ]
then
    cp $FILE .
fi
rm -f ${BASE}.* *-${BASE}.*
split -b $CHUNKSIZE ./$BASE ${BASE}-
NOMORE=0

echo "===== Encryption ====="
for i in ${BASE}.*
do
    if [ $NOMORE -eq 1 ]
    then
        break
    fi

    PTEXT=`cat $i | base64 -w 0`
    PAYLOAD=$(jq -n -r \
        --arg kid $KEY \
        --arg iv $IV \
        --arg pt "$PTEXT" \
        --arg alg $ALG \
        '{ plaintext: $pt, alg: $alg, kid: $kid, params: {iv: $iv} }'
    )
```

```

RESULT=`echo $PAYLOAD | curl -Ss -X POST -k -d @- -H "Accept: application/json"
$URL/encrypt`
    NEWIV=`echo $RESULT | jq -r '.params.iv'`
    CTEXT=`echo $RESULT | jq -r '.ciphertext'`
    if [ -z "$NEWIV" ] || [ "$NEWIV" == "null" ]
    then
        NOMORE=1
    fi
    IV=$NEWIV
    echo -n $CTEXT | base64 -d -w0 > ${i}.enc
done

cat ${BASE}/*.enc > ./${BASE}.enc
split -b $CHUNKSIZE ./${BASE}.enc enc-${BASE}-
IV=$OIV
NOMORE=0

echo "===== Decryption ====="
for i in enc-${BASE}-*
do
    if [ $NOMORE -eq 1 ]
    then
        break
    fi
    CTEXT=`cat $i | base64 -w0`

    PAYLOAD=$(jq -n -r \
        --arg kid $KEY \
        --arg iv $IV \
        --arg ct "$CTEXT" \
        --arg alg $ALG \
        '{ ciphertext: $ct, alg: $alg, kid: $kid, params: {iv: $iv} }'
    )

```

```
RESULT=`echo $PAYLOAD | curl -Ss -X POST -k -d @- -H "Accept: application/json"
$URL/decrypt`
NEWIV=`echo $RESULT | jq -r '.params.iv'`
PTEXT=`echo $RESULT | jq -r '.plaintext'`
if [ -z "$NEWIV" ] || [ "$NEWIV" == "null" ]
then
    NOMORE=1
fi
IV=$NEWIV
echo -n $PTEXT | base64 -d -w0 > ${i}.dec
done
cat enc-${BASE}/*.dec > ${BASE}.dec
diff ${BASE}.dec ${BASE}
echo diff status = $?
```

The large file is broken into chunks of size whose modulo 16 equals 0 (that is, into chunk sizes that are multiples of 16 bytes).

When submitting the chunks to the encryption endpoint, the response includes an IV that is used to encrypt the next chunk. If the payload length is not 16-byte aligned, the response does not return the next IV, assuming that chaining is complete.

For decryption, the same rules apply. The first call must use the same IV as the call used for encrypting. The ciphertext chunk size can be a different size from the original plaintext encryption request, as long as the chunks are 16-byte aligned.

For example a 1030 byte file can be encrypted in 8 chunks of 128 bytes each and a last one of 6 bytes. The same file once encrypted can be split in 3 chunks of 320 bytes and a last one of 70 bytes.

Sign

Simple HMAC-SHA256 sign example

Request:

```
POST /vts/crypto/v1/sign
{"alg": "HS256", "payload": "aGVsbG8gd29ybGQh", "kid": "mykey"}
```

Response:

```
200 OK
{"signature": "13pCxjIXjY8MNhsx69szyU0VraQc6Tn0C0irqCut0Ls="}
```

Verify

Simple HMAC-SHA256 verify example

Request:

```
POST /vts/crypto/v1/verify
{"alg": "HS256", "signature":
"13pCxjIXjY8MNhsx69szyU0VraQc6Tn0C0irqCut0Ls=", "payload":
"aGVsbG8gd29ybGQh", "kid": "mykey"}
```

Response:

```
200 OK
{"valid": 1}
```

Random

Simple random example

The following example shows a simple request to generate an 8-byte random number:

Request:

```
POST /vts/crypto/v1/random
{"seed": "q8qqyw==", "size": 8}
```

Response:

```
200 OK
{"random": "152LM5GzL8U="}
```

.....

This section shows how to use versioned keys within the Cryptographic and Key Management set of APIs.

Versioned key creation

Versioned key creation example

Creation of an AES 256-bit versioned key named *vkey256* with each version of the key with a lifespan of 7 days.

Request:

```
POST /vts/km/v1/keys
{"size": 256, "name": "vkey256", "kty": "oct", "versioning_enabled":
true, "version": 0, "version_action": "create", "lifespan_interval":
7}
```

Response:

```
200 OK
{"attributes": {"usage": ["encrypt", "decrypt", "sign", "verify",
"destroy", "modify", "find", "export"],
"size": 16},
"metadata": {"key_management": {"uuid": "9f3c2775-405b-33e8-91af-
904faa0e551f",
"caching_duration": 44640,
"state": "active",
"lifespan_unit": "days",
"muuid": "9f3c2775-405b-33e8-91af-904faa0e551f39b6aee0-6821-39f9-a186-
9a9904abff32",
"caching_enabled": True,
"name": "vkey256"}},
"kid": "tesrn:vts::label:vkey256"}
```

Versioned key import example

Creation of an AES 256-bit versioned key named *vkey256* with each version of the key with a lifespan of 7 days.

Request:

```
POST /vts/km/v1/keys
{"size": 256, "name": "vkey256", "kty": "oct", "versioning_enabled":
true, "version": 0, "lifespan_interval": 7, "wrappedkey":
"SGVsbG9Xb3JsZEFsd2F5cw=="}
```

Response:

```
200 OK
{"attributes": {"usage": ["encrypt", "decrypt", "sign", "verify",
"destroy", "modify", "find", "export"],
"size": 16},
"metadata": {"key_management": {"uuid": "9f3c2775-405b-33e8-91af-
904faa0e551f",
"caching_duration": 44640,
"state": "active",
"lifespan_unit": "days",
"moid": "9f3c2775-405b-33e8-91af-904faa0e551f39b6aee0-6821-39f9-
a186-9a9904abff32",
"caching_enabled": True,
"name": "vkey256"}},
"kid": "tesrn:cts::label:vkey256"}
```

Standard key to version key migration example

Creation of an AES 256-bit versioned key named *vkey256* with each version of the key with a lifespan of 7 days.

Request:

```
PATCH /vts/km/v1/keys/existingkey {"version_action": "migrate"}
```

Response:

```
200 OK
{
  "attributes": {
    "size": 32
  },
  "metadata": {
    "key_management": {
      "uuid": "7f460ca4-04e2-37d9-8d57-b2c36fbed55e",
      "caching_duration": 44640,
      "state": "active",
      "versioning_enabled": true,
      "moid": "7f460ca4-04e2-37d9-8d57-b2c36fbed55ecd222707-123a-
3df5-baef-c9b1f77ac3fb",
      "caching_enabled": 1,
      "name": "existingkey"
    }
  },
  "kid": "tesrn:cts::uuid:7f460ca4-04e2-37d9-8d57-b2c36fbed55e"
}
```

Version key rotation example

Rotation of an existing versioned key named `vkey256` with each version of the key with a lifespan of 7 days.

Request:

```
PATCH /vts/km/v1/keys {"version_action": "rotate"}
```

Response:

```
200 OK
{"attributes": {"usage": ["encrypt", "decrypt", "sign", "verify",
"destroy", "modify", "find", "export"],
"size": 16},
"metadata": {"key_management": {"uuid": "d0a031de-5102-3bba-80f4-
7019306da03e",
"cached_duration": 44640,
"state": "active",
"lifespan_unit": "days",
"muid": "d0a031de-5102-3bba-80f4-7019306da03ed0a031de-6821-39f9-
a186-9a9904abff32",
"cached_enabled": True,
"name": "vkey256"}},
"kid": "tesrn:cts::label:vkey256"}
```

Tokenization REST API

Learn about the CTS Tokenization API in this chapter. Also note that the Tokenization APIs are also described in an online reference guide, under **Documentation** in the CTS Administration GUI navigation bar.

The CipherTrust Tokenization API consists of:

- **tokenize** - A POST call that tokenizes data. A user submits sensitive data, the CipherTrust Tokenization Server returns a token. The token is then stored in the production database.
- **detokenize** - A POST call that detokenizes data. A user submits a token to the CipherTrust Tokenization Server and the actual data is returned detokenized. Permission settings for that user dynamically specify the appropriate data mask.
- **log** - Changes the log level. Four different log levels (error, info, debug and trace) can be selected. Chose 'error' or 'info' for normal operation, or 'debug' when instructed to do so by Thales eSecurity support.

This chapter includes the following sections:

- [“Using the API” on page 134](#)
- [“Create a Token” on page 134](#)
- [“Get Detokenize Resource Data” on page 138](#)
- [“Set Log Levels” on page 141](#)
- [“Tokenization Examples” on page 143](#)
- [“Tokenization API Call Failure Error Messages and Workarounds” on page 148](#)

NOTE: See [“Encryption and Key Management API Programming Notes” on page 107](#) for information about the Encryption and Key Management REST APIs. The Admin REST APIs are described in [“Tokenization REST API” on page 133](#).

Using the API

To enable tokenization, you do not have to change your database schema, because CipherTrust Tokenization preserves the format of your data. However, you must change your application code.

When a user makes a request to tokenize or detokenize, the username and password must be provided. This is a part of a REST request. The username/password is validated by either the AD/LDAP server or CTS, depending on where the user is defined.

NOTE: The data passed to and from the Tokenization Server—user name, tokenization group name, tokens, and sensitive data—is case-sensitive, and the application code that passes data to CTS must be aware of this.

NOTE: Tokenization input can be a normal text format.

Create a Token

Description

Use the tokenize endpoint to encrypt a data string to a token using format-preserving encryption (FPE or FF1).

Table 19: tokenize Endpoint Details

Data	Description
HTTP Request	<code>https://CTS_IP_Address/vts/rest/v2.0/tokenize</code>
Method	POST
CTS IP Address	The IP address of the CTS to access with the API call.
Response Format	JSON
Required Authentication	A valid user name and password must be passed as an argument. The values are case sensitive.

The parameters for tokenize endpoint are described in the table below:

Table 20: tokenize Parameters

Parameter	Required	Type	Description
tokengroup	Y	string	Defines a group name space in the configuration database. For example, let's say you are a credit card company and you want the CTS to support three departments supporting Store1, Store2, and Store3. You want employees in these departments to have access to data for those respective stores. Two actions are required: - The application code must specify a different tokengroup parameter in the POST calls for each group supported (example: Store1, Store2, and Store3). The tokengroup parameter is case-sensitive. - The CTS GUI administrator must create token groups that match the tokengroup parameter names used in the application code. If you do not support multiple token groups, then tokengroup will always be the same value. Example value: store1
data	Y	string	The data string to tokenize. The argument considers case and is limited to 128KiBs Example value: 1432445695309134
tokentemplate	Y	string	CTS GUI Administrator-defined name for a group of properties that define tokenization operation. Properties include the token group to which the template applies, the tokenization format (date, FPE or FPE with Luhn check, or FF1 or FF1 with Luhn check, or Random (lookup) or Random with Luhn check), number of leftmost or rightmost characters to <i>not</i> tokenize, whether you wish to never detokenize a tokenized entry, the character set used for tokenization, and an optional prefix for tokens. Example value: Credit Card
returnData	N	string	Tokenization requests can return the plaintext string together with the encrypted data in the response. To enable, add the "returnData" parameter and set it to true.

The tokenize endpoint response parameters, their types, and corresponding descriptions are listed in the table shown below:

Table 21: tokenize Response Parameters

	Type	Description
token	string	Token for the sensitive data. Example value: 2134234509874567
status	string	• Succeeded (if request succeeded) • Error (if request failed)
reason	string	If status is Error a reason is displayed. Otherwise the reason is omitted.
data	string	If returnData in the request is set to <code>true</code> , contains the plaintext string for the encrypted data.

Create token CURL example

NOTE: If you use the `--tlsv1.2` CURL Command syntax option, you must use CURL version 7.34 or higher.

Example Request:

```
curl -k -X POST -u Donald_Duckmiller:Panda45# -d '{"tokengroup" :  
"ctsUsers-t", "data" : "9453677629008564", "tokenTemplate" :  
"ctsUsersTemplate" }' https://192.168.118.140/vts/rest/v2.0/tokenize
```

NOTE: The user name (Donald_Duckmiller) and tokengroup (ctsUsers-t) are case sensitive.

Example Response

```
{"token": "CC-0332335756020172", "status": "Succeed"}
```

IMPORTANT: If FPE-luhn, FF1-luhn, or Random-luhn is selected in the Change Token Template page of the CTS GUI, the data must pass a Luhn check or tokenization will fail with the error message:

```
{"status":"error","reason":"Luhn check failed for input data."}
```

Tokenizing multiple data items

Up to 1,000 data items can be tokenized in a single curl command by submitting a JSON array in the REST request. For example, to tokenize four data items you might enter the following in a postccn.txt file:

Example Request:

```
cat postccn.txt

[{"tokengroup" : "ctsUsers-t" , "data" : "9453677629008564",
"tokentemplate" : "ctsUsersTemplate" }, {"tokengroup" : "ctsUsers-
t" , "data" : "9453677629008564", "tokentemplate" :
"ctsUsersTemplate" }, {"tokengroup" : "ctsUsers-t" , "data" :
"9453677629008564", "tokentemplate" : "ctsUsersTemplate"
}, {"tokengroup" : "ctsUsers-t" , "data" : "9453677629008564",
"tokentemplate" : "ctsUsersTemplate" }]

curl -k -X POST -u Donald_Duckmiller:Panda45# --data-binary
@postccn.txt https://192.168.118.140/vts/rest/v2.0/tokenize
```

Warning! Newlines are NOT allowed in the input.

Example Response:

```
[{"token":" 9465976792116170", "status":"Succeed"},
{"token":" 9465976792116170", "status":"Succeed"},
{"token":" 9465976792116170", "status":"Succeed"},
{"token":" 9465976792116170", "status":"Succeed"}]
```

The tokenized data is returned in the CURL Command syntax response, in order of submission.

Get Detokenize Resource Data

Description

Get detokenized data from a resource..

Table 22: detokenize Endpoint Details

	Description
HTTP Request	<code>https://CTS_IP_Address/vts/rest/v2.0/detokenize</code>
Method	POST
CTS IP Address	The IP address of the CTS to access with the API call.
Response Format	JSON
Required Authentication	A valid user name and password must be passed as an argument. The values are case sensitive.

Table 23: detokenize Request Parameters

Parameter	Required	Type	Description
token	Y	string	The token to detokenize. token is case-sensitive. Example value: 6029541314537206
tokengroup	Y	string	Defines a group name space in the configuration database. For example, let's say you are a credit card company and you want the CTS to support three departments supporting Store1, Store2, and Store3. You want employees in these departments to have access to data for those respective stores. Two actions are required: - The application code must specify a different tokengroup parameter in the POST calls for each group supported (example: Store1, Store2, and Store3). The tokengroup parameter is case-sensitive. - The CTS GUI administrator must create token groups that match the tokengroup parameter names used in the application code. If you do not support multiple token groups, then tokengroup will always be the same value. Example value: store1

Table 23: detokenize Request Parameters

Parameter	Required	Type	Description
tokentemplate	Y	string	CTS GUI Administrator-defined name for a group of properties that define tokenization operation. Properties include the token group to which the template applies, the tokenization format (either FPE or FPE with Luhn check, or FF1 or FF1 with Luhn check), number of leftmost or rightmost characters to <i>not</i> tokenize, whether you wish to never detokenize a tokenized entry, the character set used for tokenization, and an optional prefix for tokens. Example value: Credit Card

Table 24: detokenize Response Parameters

	Type	Description
data	string	The detokenized sensitive data. May be masked depending on the configuration. data is case sensitive and limited to 128KiB characters.
status		Succeeded (if request successful) or Error (if request failed).
reason	string	If status is Error , then a reason will be displayed. Otherwise the reason will be omitted.

Example:

NOTE: If you use the --tlsv1.2 CURL option, you must use CURL version 7.34 or higher.

Request:

```
curl -k -X POST -u tok-user1:Panda45# -d '{"tokengroup" : "ctsUsers-t" ,
"token" : "CC-0332335756020172", "tokentemplate" : "ctsUsersTemplate" }'
https://192.168.118.140/vts/rest/v2.0/detokenize
```

If the client authentication feature is enabled (See also [“Upgrading CTS” on page 30.](#)) the example syntax is as follows:

```
curl -k --key client.key --cert client.crt -X POST -u tok-
user1:Panda45# -d '{"tokengroup" : "ctsUsers-t" , "token" :
"CC-0332335756020172", "tokentemplate" : "ctsUsersTemplate"
}' https://192.168.118.140/vts/rest/v2.0/detokenize
```

Response:

```
{"data": "9453677629008564", "status": "Succeed"}
```

Detokenizing multiple data items

Up to 1,000 data items can be detokenized in a single curl command by adding multiple data items. For example, to detokenize four data items, you might enter the following in the *posttoken.txt* file:

Request:

```
cat posttoken.txt

[{"tokengroup": "ctsUsers-t", "token": "CC-0332335756020172",
"tokentemplate": "ctsUsersTemplate" }, {"tokengroup": "
ctsUsers-t", "token": "CC-0332335756020172", "tokentemplate"
: "ctsUsersTemplate" }, {"tokengroup": "ctsUsers-t", "token": "
CC-0332335756020172", "tokentemplate": "ctsUsersTemplate"
}, {"tokengroup": "ctsUsers-t", "token": "CC-
0332335756020172", "tokentemplate": "ctsUsersTemplate" }]

curl -k -X POST -u tok-user1:Panda45# --data-binary
@posttoken.txt https://192.168.118.140/vts/rest/v2.0/detokenize
```

Response:

```
[{"data": "9453677629008564", "status": "Succeed"}, {"data": "9453677
629008564", "status": "Succeed"}, {"data": "9453677629008564", "statu
s": "Succeed"}, {"data": "9453677629008564", "status": "Succeed"}]
```

The detokenized data is returned in the CURL response in corresponding order of submission.

NOTE: Newlines are NOT allowed in the input.

IMPORTANT: If FPE-luhn, FF1-luhn, or Random-luhn is selected in the Change Token Template page of the CTS GUI, the data must pass a Luhn check or detokenization will fail with the error message:

```
{"status": "error", "reason": "Luhn check failed for input data."}
```

Set Log Levels

Description

Set the log level for the REST API.

Table 25: log Endpoint Details

Data	Description
HTTP Request	https://CTS_IP_Address/vts/rest/v2.0/log
Method	POST
CTS IP Address	The IP address of the CTS to access with the API call.
Response Format	JSON
Required Authentication	None

Table 26: log Request Parameter

Parameter	Required	Type	Description
loglevel	Y	Enum	loglevel can take one of the following values: - error - Default value used in normal production environment. - debug - Use only when directed by support. - info - Do not use unless maximum logging is required. NOTE: The performance of tokenization and detokenization operations are severely affected by a log level of “debug” and substantially affected by a log level of “info.” For maximum throughput, use a loglevel of “error.”

Table 27: log Response Parameter

Parameter	Type	Description
status	string	Success (if request succeeded) or Error (if request failed).

Example:

NOTE: If you use the --tlsv1.2 cURL option, you must use CURL version 7.34 or higher.

Request:

```
curl -k --tlsv1.2 -X POST https://127.0.0.1/vts/rest/v2.0/log --data-binary '{"loglevel":"debug"}'
```

Response:

```
{"status":"success"}
```

Tokenization Examples

Java client example

    }
}
```

Tokenization API Call Failure Error Messages and Workarounds

These error messages may occur when an Tokenization API call is made.

Table 28: Error Message Reference

Message	Description
--tlsv1.2: is unknown	Only CURL version 7.34 or later supports the --tlsv1.2 option. If you get this error message, upgrade to CURL version 7.34 or higher.
API call aborted and no JSON vector elements are processed	These are error messages which pertain to the whole JSON vector. In other words, in these cases no vector elements are processed at all. The whole operation is aborted
User name and/or password mismatch.	Due to a wrong user name and/or password, access to the Tokenization Server is denied.
Unknown JSON keyword encountered. The valid keyword for the log request is loglevel.	For the REST API called "log", the only valid keyword on the left of the JSON value-name-value tuple is "loglevel".
Could not parse JSON input, perhaps it is too long.	An input size of 1 MByte cannot be exceeded. It could also mean that the JSON input is malformed.
User name and/or password missing	Either the user name, or the password, or both are missing from the request.
This user does not have permission to tokenize.	While the user exists and the password is correct, this particular user does not have the permission to tokenize. Consider assigning this user the permission to tokenize via the GUI.
User name found, but the user is not marked active.	While the user exists and the password is correct, this particular user is not marked as an active user. Consider marking this user an active user in the GUI.
Invalid operation. Use /vts/rest/v2.0/tokenize or /vts/rest/v2.0/detokenize	An invalid URL was specified. Allowed operations are /vts/rest/v2.0/tokenize, /vts/rest/v2.0/detokenize, or /vts/rest/v2.0/log.
No password specified.	While a user name was specified, the password is missing.
User name not found.	The specified user name exists neither in the local database which is configured via the GUI, nor in the optional LDAP database.
LDAP user found in local database, but LDAP is disabled.	Presumably due to a prior use of LDAP, an LDAP user was cached in the local database, but LDAP has since been disabled, disallowing authentication with this user. Prior to using LDAP users for authentication, at least one of the groups this user belongs to according to the LDAP database must be configured as a user group via the GUI.

Table 28: Error Message Reference (Continued)

Message	Description
API call aborted, one JSON vector element fails, others are processed	These messages pertain to only one element of the JSON vector. In these cases, one vector element may result in an error, but all other vector elements are still processed.
The length of the token exceeds 128 Kbytes.	The length of a token is limited to 128 KiB. However, the token supplied was longer than 128 KiB.
Unknown JSON keyword encountered. Valid keywords for the detokenize request are tokengroup, token and tokentemplate.	For the detokenize operation, only three specific keywords are allowed on the left side of a JSON tuple: "tokengroup", "token", and "tokentemplate". Please review and correct your JSON string.
The length of the data exceeds 128 Kbytes.	The length of the input data is limited to 128 KiB. However, the input data supplied was longer than 128 KiB.
Unknown JSON keyword encountered. Valid keywords for the tokenize request are tokengroup, data and tokentemplate.	For the tokenize operation, only three specific keywords are allowed on the left side of a JSON tuple: • tokengroup • data • tokentemplate
Please review and correct your JSON string.	A token group was specified in the JSON input, but it doesn't exist in the GUI-administered configuration database. Consider adding this token group via the GUI.
The requested key name was not found on the DSM	A key name was configured via the GUI and now used in an operation, however this key name does not exist on the DSM .
The token group specified was not found in the database	Consider creating this key name on the DSM .
tokengroup not specified in JSON request.	The JSON tuple named "tokengroup" is missing from a JSON vector element. A tokengroup must be specified.
The requested combination of tokentemplate and tokengroup was not found in the tokentemplate table.	Either the tokengroup specified has not been entered via the GUI, or the tokentemplate has not been entered via the GUI, or the token template of the same name has been entered, but for a different tokengroup. Please ensure that the tokentemplate you are trying to use has been entered for the tokengroup you are trying to use.
It is not allowed to specify the FPE-luhn token format with a non-zero keepright value.	After accounting for keepleft and keepright, not enough input characters are left to successfully tokenize the input. When you use the FPE token format, the number of input characters must exceed the sum of the Keep Left value and the Keep Right value by at least two. When you use the FPE-luhn token format, the number of input characters must exceed the sum of the Keep Left value and the Keep Right value by at least three.
There are not enough input characters for the detokenize operation.	At least two input characters are needed in the token in order to try to detokenize it.

Table 28: Error Message Reference (Continued)

Message	Description
Token format FPE-luhn is only compatible with an alphabet consisting of the 10 decimal digits (in ASCII encoding).	The FPE-luhn token format cannot be used with an alphabet containing letters and/or special characters. It must be used with an alphabet only containing the 10 digits.
After accounting for the keepleft and keepright requirements, not enough input characters left to tokenize.	When you use the FPE token format, the number of input characters must exceed the sum of the keepleft value and the keepright value by at least two.
Luhn check failed for input data.	The token format FPE-luhn was specified, but the input data sports an incorrect Luhn checksum. Please check your input data, or change the token format from FPE-luhn to FPE.
After accounting for keepleft and keepright, there are not enough input characters present to successfully tokenize.	When you use the FPE token format, the number of input characters must exceed the sum of the keepleft value and the keepright value by at least two. When you use the FPE-luhn token format, the number of input characters must exceed the sum of the keepleft value and the keepright value by at least three.
Token does not begin with the prefix specified in the database.	While a certain token prefix is specified in the token template which is being used in the JSON input, the token seen in the JSON input does not sport this particular token prefix.
The specified token only contains the prefix and no payload.	While the token seen in the JSON input sports the correct token prefix, there are no other characters present in the token.
Luhn check failed for input token.	The token format FPE-luhn was specified, but the token specified sports an incorrect Luhn checksum. Please check your input data.
There are not enough input characters present to successfully detokenize.	When you use the FPE token format, the number of input characters, not counting the token prefix, must exceed the sum of the keepleft value and the keepright value by at least two. When you use the FPE-luhn token format, the the number of input characters, not counting the token prefix, must exceed the sum of the keepleft value and the keepright value by at least three.

API Reference

For the complete Tokenization API reference, open the CTS GUI and navigate to:

Documentation > Tokenization API

Key Management Service REST API

Use the CTS Key Management Service (KMS) REST APIs to manage CTS keys.

Requirements

To use the KMS REST APIs, use:

- The CipherTrust Token Server 2.3.0 or newer
- Any keystore version compatible with CTS 2.3.0

Base URL

The following is the base URL for KMS REST API operations:

```
/vts/km/v1
```

Authentication

JSON Web Token (JWT) is a compact, URL-safe means of representing claims to be transferred between two parties. The claims in a JWT are encoded as a JavaScript Object Notation (JSON) object that is used as the payload of a JSON Web Signature (JWS) structure or as the plaintext of a JSON Web Encryption (JWE) structure, enabling the claims to be digitally signed or MACed and/or encrypted.

By default, JWT authentication expires in 10 minutes. This setting can be changed using the CLI, under the auth menu.

Retrieve a Token Request

Request:

```
curl -X POST \  
-H "Content-Type: application/json" \  
-d '{"username":"admin","password":"Password123!"}' \  
https://{server_address}/api/api-token-auth/
```

Response:

```
{ "token": "eyJ0eXA [...] KnA74" }
```

Refresh a Token Request

Request:

```
curl -X POST \  
-H "Content-Type: application/json" \  
-d '{"token":"<EXISTING_TOKEN>"}' \  
https://{server_address}/api/api-token-refresh/
```

Response:

```
{ "token": "eyJ0eXA [...] KnA74" }
```

Operations

Table 29: Paths

Path	Operations	Description
/keys	POST	Create or Import a key.
/keys/{id}	DELETE	Delete the path specified key.
	GET	Retrieve the path specified key.
	PATCH	Update the path specified key.
	POST	Export the path specified key.

Object Format

The response format for all requests is a JSON object.

API Reference

For the complete API reference, open the CTS GUI and navigate to:

Documentation > Key Management API

Response Codes

HTTP status codes are grouped into five categories:

- 1xx for informational
- 2xx for success
- 3xx for redirection
- 4xx for client errors
- 5xx for server errors

Admin REST API

The CTS Administration REST API allows you to manage the administration of the CTS. After completing the administrative tasks, you will be able to run the tokenize and detokenize data commands.

To use the Admin REST API you must be using:

- The Tokenization Server version 2.3.0 or newer
- Any keystore server version compatible with CTS 2.3.0

Base URL

The following is the base URL for Admin REST API operations:

```
https://<server_address>/api/
```

Authentication

JSON Web Token (JWT) is a compact, URL-safe means of representing claims to be transferred between two parties. The claims in a JWT are encoded as a JavaScript Object Notation (JSON) object that is used as the payload of a JSON Web Signature (JWS) structure or as the plaintext of a JSON Web Encryption (JWE) structure, enabling the claims to be digitally signed or MACed and/or encrypted.

By default, JWT authentication expires in 10 minutes. This setting can be changed using the CLI, under the auth menu.

Retrieve a token request

Request:

```
curl -X POST \  
-H "Content-Type: application/json" \  
-d '{"username":"admin","password":"Password123!"}' \  
https://{server_address}/api/api-token-auth/
```

Response:

```
{ "token": "eyJ0eXA [...] KnA74" }
```

Refresh a token request

Request:

```
curl -X POST \  
-H "Content-Type: application/json" \  
-d '{"token":"<EXISTING_TOKEN>"}' \  
https://{server_address}/api/api-token-refresh/
```

Response:

```
{ "token": "eyJ0eXA [...] KnA74" }
```

Responses

This section describes request response codes and response pagination details.

Response codes

HTTP status codes are grouped into five categories:

- 1xx for informational
- 2xx for success
- 3xx for redirection
- 4xx for client errors
- 5xx for server errors

Pagination

Requests that return multiple items will be paginated to 25 items.

Responses include a "count" field, which specifies the total number of objects available via pagination. Responses also include a "next" and "previous" field. If "count" is superior to 25, these fields contain a URL path to access the objects located respectively after or before.

Request:

```
GET https://{{server_address}}/api/v1/users/?limit=100&offset=400
```

Response:

```
HTTP 200 OK
{
  "count": 1023
  "next": "https://{{server_address}}/api/users/?limit=100&offset=500",
  "previous": "https://{{server_address}}/api/users/?limit=100&offset=300",
  "results": [ ... ]
}
```

Operations

The CTS Admin REST API supports the following operations:

Searching

To search objects, add the attribute `?search=` at the end of the URL followed by the pattern you want to look for. All the objects containing that pattern in one of their attributes will be included in the Response.

Request:

```
GET https://{{server_address}}/api/users/?search=robert
GET https://{{server_address}}/api/groups/?search=finance
```

Ordering

To query object in a specific order, add the attribute `?ordering=` at the end of the URL followed by the attribute you want to order by.

Ordering examples:

Order users by username

```
GET https://{server_address}/api/v1/users/?ordering=username
```

You may also specify reverse orderings by prefixing the field name with '-', like so:

```
GET https://{server_address}/api/v1/users/?ordering=-username
```

Multiple orderings may also be specified:

```
GET https://{server_address}/api/v1/users/?ordering=username,email
```

Object format

The response format for all requests is a JSON object.

Creating objects

To create a new object, send a POST request to the class URL containing the contents of the object. For example:

```
curl -X POST \
  -H '{"Authorization": "JWT '+<token>'}" \
  -H "Content-Type: application/json" \
  -d '{"name": "User1", ...}' \
  https://{server_address}/api/{some_resource}/
```

Retrieving objects

To retrieve a list of objects, send a GET request to the class URL. For example:

```
curl -X GET \
  -H '{"Authorization": "JWT '+<token>'}" \
  -H "Content-Type: application/json" \
  https://{server_address}/api/{some_resource}/
```

Updating objects

To edit an object, send a PUT request to the URL containing the new content with the object's ID. For example:

```
curl -X PUT \
  -H '{"Authorization':'JWT '+<token>}' \
  -H "Content-Type: application/json" \
  -d '{"name":"User1", ...}' \
  https://{server_address}/api/{some_resource}/:id
```

Deleting objects

To delete an object, send a DELETE request to the class URL with the object's ID. For example:

```
curl -X DELETE \
  -H '{"Authorization':'JWT '+<token>}' \
  -H "Content-Type: application/json" \
  https://{server_address}/api/{some_resource}/:id
```

Backing up CTS

Schedule automatic backups of the CTS.

```
GET https://<CTS_IP_Address>/api/backup/create
```

This request must be preceded by a successful authentication request. Use the secure token provided with the response in the *<auth token>* portion of this example..

Table 30: Set backup Endpoint Details

	Description
HTTP Request	https://{CTS_IP_Address}/api/backup/create
Method	GET
CTS IP Address	The IP address of the CTS to access with the API call.
Response Format	JSON
Required Authentication	Yes

Example cURL Requests

Authentication:

```
curl -X POST\
-H "Content-Type: application/json" \
-d '{username:"ctsuser","password:"Password123!"}' \
https://cts_server_address/api/api-token-auth
```

Backup request:

```
curl -X GET\
-H '{Authorization::"JWT <token>"}'\
-d '{username:"ctsuser","password:"Password123!"}' \
https://cts_server_address/api/backup/create -o backup.zip
```

Unauthenticated Healthcheck

Description

Use the healthcheck endpoint to get the status of the CTS. This endpoint integrates with load balancers to ensure all the daemons are running, and the tokenization server is healthy. An HTTP response code not equal to 200 indicates failure in CTS. The HTTP response also provides a display of status of all services, in JSON format.

Table 31: Healthcheck Endpoint Details

Data	Description
HTTP Request	https://CTS_IP_Address/healthcheck
Method	GET
VTS IP Address	The IP address of the VTS to access with the API call.
Response Format	JSON

The unauthenticated healthcheck response parameters and their respective types are described in the table shown below:

Table 32: Unauthenticated Healthcheck Response Parameters

	Type	Description
status	string	•200 (if request succeeded) •503 (if one of the daemons is not running)
	string	Configured services are listed along with each one's status (for example: {"name": "vaed", "status": "started"})

Healthcheck example

Example Request:

```
curl -k -X GET https://CTS_IP_Address/healthcheck
```

Example Response:

```
HTTP/1.1 200 OK
Date: Thu, 29 Oct 2020 22:51:16 GMT
Content-Type: application/json
Content-Length: 310
Connection: keep-alive
Server: VTS server
Cache-Control: max-age=0, no-cache, no-store, must-revalidate
Pragma: no-cache
X-Frame-Options: SAMEORIGIN
X-Content-Type-Options: nosniff
X-XSS-Protection: 1; mode=block
Strict-Transport-Security: max-age=31536000; includeSubdomains; preload
Content-Security-Policy: default-src 'self'

{
  "services": [
    {
      "name": "vtsauthz",
      "status": "Started"
    },

Segurança da informação para proteção dos dados pessoais

Afinal, como aplicar boas práticas de Segurança da Informação quando do tratamento de dados pessoais?

A Lei Geral de Proteção de Dados (LGPD) veio estabelecer responsabilidades e direitos sobre os tratamentos de dados pessoais e a Segurança é um dos princípios que permeia tal atividades.

Nesse contexto, a citada legislação apresenta uma seção específica sobre Segurança e Sigilo dos dados e dispõe sobre a adoção de medidas técnicas e administrativas aptas a proteger os dados pessoais de acessos não autorizados e de situações acidentais ou ilícitas de destruição, perda, alteração, comunicação ou qualquer forma de tratamento inadequado ou ilícito.

Mas como adotar medidas técnicas e administrativas? Quais são essas medidas?

Dentre tantas respostas para tais questões, a ANONIMIZAÇÃO é uma solução viável para aplicação da segurança dos dados de sua companhia.

O que é ANONIMIZAÇÃO?

O processo de anonimização, conforme apresentado no art. 5º, XI da Lei Geral de Proteção de Dados (LGPD), refere-se à “utilização de meios técnicos razoáveis e disponíveis no momento do tratamento, **por meio dos quais um dado perde a possibilidade de associação, direta ou indireta, a um indivíduo.**”.

A anonimização está relacionada ao uso de meios técnicos **razoáveis** para a transformação de um dado pessoal em dado anônimo, tornando impossível ou muito difícil a identificação de um indivíduo determinado por meio dos dados apresentados. O aspecto da razoabilidade da anonimização refere-se ao fato de que, para que certo dado seja considerado anonimizado, é necessário que, sem a realização de um esforço excessivo, não seja possível o reconhecimento de um indivíduo a partir da análise dos dados.

“ ANONIMIZAÇÃO, conforme a LGPD, é utilização de meios técnicos razoáveis e disponíveis no momento do tratamento, por meio dos quais um dado perde a possibilidade de associação, direta ou indireta, a um indivíduo.”

A Lei Brasileira inclusive traz também a definição do que é DADO ANONIMIZADO:

“...dado relativo a titular que não possa ser identificado, considerando a utilização de meios técnicos razoáveis e disponíveis na ocasião de seu tratamento.”

E por que ANONIMIZAR um dado pessoal?

Simple: a ANONIMIZAÇÃO AFASTA a aplicação da LGPD.

“Art. 1º Esta Lei dispõe sobre o tratamento de DADOS PESSOAIS, inclusive nos meios digitais, por pessoa natural ou por pessoa jurídica de direito público ou privado, com o objetivo de proteger os direitos fundamentais de liberdade e de privacidade e o livre desenvolvimento da personalidade da pessoa natural.”

Na maioria das leis que tratam sobre proteção de dados pessoais há sempre a menção acerca do processo de anonimização e de pseudonimização, sendo este último uma espécie de anonimização reversível dos dados, isto é, a partir deste processo ainda é possível a identificação posterior de indivíduos através da reassociação dos dados.

Na lei brasileira tais conceitos encontram-se no art. 5, XI (anonimização) e art. 13, § 4º (pseudonimização). À título de exemplo, ainda pode-se observar as descrições destes processos na lei de proteção de dados peruana, quando trata do procedimento de anonimización (processo irreversível de anonimização) e procedimento de disociación (processo reversível de anonimização); na lei argentina, que trata os procedimentos em apenas uma categoria chamada de disociación de datos; na lei mexicana, também sob uma única definição de disociación; entre outros.

É importante pontuar que para que os dados sejam considerados verdadeiramente anonimizados, é necessário que o processo impossibilite a reassociação dos dados posteriormente, de modo a tornar os titulares identificáveis. A fragilidade de grande parte das soluções de anonimização já é de conhecimento científico e prático, como observado abaixo:

Assim, o que se propõe a partir da utilização da solução CipherTrust Platform, é a garantia de um processo de anonimização eficaz e seguro, que garante a integridade dos dados tratados e o total anonimato dos titulares envolvidos na atividade.

“ Detentores de dados, incluindo agências governamentais, frequentemente removem todos os identificadores explícitos, tais como nome, endereço e número de telefone, de dados para que outras informações nos dados possam ser compartilhadas, de forma incorreta acreditando que as identidades dos indivíduos não podem ser determinadas. Ao contrário, a desidentificação dos dados não oferece garantia de anonimato.”²

Violação de dado pessoal

Considera-se como violação de dado pessoal todo e qualquer incidente de segurança que consiga atingir a integridade dos dados pessoais armazenados por determinado agente de tratamento, afetando a qualidade da informação e invadindo a privacidade dos titulares cujos dados foram atingidos.

Reforça-se que para que seja configurada uma violação de dado pessoal é necessário que os dados envolvidos no incidente sejam capazes de identificar ou de tornar identificável uma pessoa por meio de seu tratamento, portanto, sem a possibilidade de reconhecimento de indivíduos através dos dados, como no caso de dados anonimizados, não há a ocorrência de violação de dados pessoais, apenas configura-se um incidente de segurança na estrutura interna informacional da empresa.

Todas as empresas estão em maior ou menor medida expostas ao risco de sofrerem um ataque cibernético, o que pode ter repercussões reputacionais e atingir negativamente a continuidade dos negócios, sendo extremamente prejudicial às partes envolvidas, tanto aos titulares com dados vazados, quanto à empresa.

A anonimização como ação mitigadora de riscos aos titulares

A anonimização é uma ação necessária para todas as empresas que realmente prezam pela segurança de sua base de dados, até porque tal processo auxilia na melhor organização interna da base e também porque é a forma mais efetiva de garantir a segurança dos dados pessoais dos titulares.

Os riscos aos titulares são mitigados porque a utilização a anonimização de dados desvincula a informação do indivíduo, excluindo o tratamento do âmbito da LGPD, assegurando, portanto, um tratamento legítimo e sem afetar a privacidade.

¹ BIONI, Bruno Ricardo. Compreendendo o conceito de anonimização e dado anonimizado. In: ESCOLA PAULISTA DE MAGISTRATURA. **Cadernos Jurídicos: Direito Digital e Proteção de Dados Pessoais, vol. 1, n. 1.** São Paulo: Escola Paulista da Magistratura, 2000

² SAMARATI, Pierangela; SWEENEY, Latanya. Protecting Privacy when Disclosing Information: Anonymity and Its Enforcement through Generalization and Suppression. California: Technical Report SRI-CSL, 1998.

Tokenização Ciphertrust

A plataforma de segurança de dados CipherTrust possui como uma de suas maiores vantagens o processo de tokenização, oferecendo soluções que protegem e tornam anônimos os ativos confidenciais - quer eles residam no data center, em ambientes de big data ou na nuvem.

Os melhores atributos deste processo são: (i) por meio da utilização de tokenização e anonimização dos dados pela CipherTrust, afastar a necessidade de uma adequação mais robusta do banco de dados à normas de proteção de dados como a LGPD e a PCI DSS, o que diminui bastante os gastos de adequação da empresa; (ii) garantir uma melhor e mais eficiente proteção dos dados pessoais dos titulares cujos dados estão envolvidos na atividade de tratamento; (iii) e o fato de ser totalmente “tailor made” para a realidade da empresa, apresentando soluções que são flexíveis e eficazes para a segurança informacional da empresa e dos titulares.

Assim, convidamos a todos os interessados em terem um ambiente informacional mais seguro e atento às necessidades dos titulares, que testem a Plataforma de Segurança de Dados CipherTrust da Thales para criarem um futuro digital e responsável. A Thales pode ajudar a sua organização a cumprir com muitos dos requisitos da LGPD.

About Thales

The people you rely on to protect your privacy rely on Thales to protect their data. When it comes to data security, organizations are faced with an increasing number of decisive moments. Whether the moment is building an encryption strategy, moving to the cloud, or meeting compliance mandates, you can rely on Thales to secure your digital transformation.

Decisive technology for decisive moments.

11	About Thales

Introduction

Today's enterprise security teams have a lot on their plates and a lot on their minds. According to the Thales 2021 Global Data Threat Report, data breaches remain a widespread challenge. In the survey for the report, respondents indicated that 56% of organizations have ever experienced some form of data breach, with 41% of them having experienced a breach in the last 12 months. Breaches are a trailing indicator of security effectiveness. Turning to forward-looking metrics, 47% of respondents reported an increase in volume, severity and/or scope of cyberattacks!

But as you read this paper, consider that 46% of respondents said that they have avoided a breach notification because leaked data was encrypted or tokenized! Attacks are becoming more sophisticated and persistent while insider threats continue to be an Achilles heel. According to the 2017 Thales Data Threat Report¹, 88% feel at least somewhat vulnerable to data threats. The report also proves those concerns are well founded: 42% of organizations experienced a data breach at some point.

Tokenization is a critical tool for enterprises to meet compliance standards, and reduce the risk of loss posed by this increasingly hostile environment. Most often, tokenization has been a great way for enterprises to reduce the cost of their Payment Card Industry Data Security Standard (PCI DSS) audits. Tokens are used to replace credit card numbers, removing the need for many servers to undergo expensive yearly audits. But use cases for tokenization are expanding today to safeguard more types of data and in more environments as the locations where this data is used proliferate.

Driven by data privacy and sovereignty regulations around the world, the data types that need to be protected are no longer just credit cards, but also include U.S. Social Security numbers, Drivers Licenses, U.K. National Insurance numbers, Passport numbers, and National Identity numbers in many countries around the world among other data. And the need to use this sensitive data in advanced technology environments like cloud and big data leads to further complications.

In this white paper we'll first look at how CipherTrust Vaultless Tokenization works, key characteristics of the solution, and then examine sample implementations including PCI DSS compliance, customer contact centers, cloud, big data and more.

As noted earlier, tokenization is especially useful in PCI DSS compliance. In the past meeting requirements of the standard has been very complex and expensive, with extensive yearly audits of servers hosting credit card data required, or solutions that were limited in bandwidth and required extensive infrastructure to support.

CipherTrust Tokenization now offers a better way to meet these requirements. The solution's vaultless tokenization capabilities enable security teams to remove databases from PCI DSS scope, and so significantly reduce compliance cost and efforts. Implementations typically result in minimal disruption and administrative overhead and result in breakthroughs in operational efficiency.

CipherTrust Vaultless Tokenization leverages CipherTrust Manager as its key source and, of course, is a component of the CipherTrust Data Security Platform, which delivers a comprehensive range of data security and compliance controls that help IT teams efficiently address their requirements for encryption, privileged user access control, file access auditing, and more. With a single infrastructure, policy and encryption key management environment, the platform reduces the overall costs for organizations to implement and use data security tools while applying strong protections for data.

The Challenge

So many security demands, so little time

For today's security teams, it seems virtually everything is proliferating:

- **Threats.**

Risks posed by nation-states, cyber criminals, and malicious insiders continue to grow more sophisticated and more persistent

- **Data and repositories.**

The volume and diversity of assets and repositories that need to be protected continues to see explosive growth. Instead of just managing the traditional data center, which was challenging enough, there are now virtualized systems, big data environments, outsourced services, private clouds, public clouds, and hybrid models to contend with

- **Mandates and tools.**

As the number of repositories continues to grow, so do the number of systems that fall within the scope of PCI DSS and other regulations. Further, the scope and complexity of these regulatory mandates also continues to expand. As a result, security teams are compelled to deploy more safeguards and tools in order to establish the controls these mandates require. In particular, security teams face increased pressures to prepare for PCI DSS 3.0 audits, and adapt their security approaches as cardholder data moves into new environments—such as cloud and big data implementations—and is shared with outsourced service providers, such as analytics, development, and engineering firms

All this proliferation continues to place increasing demands on security teams—but these teams don't see their time, staffing, or budgets undergoing any commensurate expansion. To contend with these realities, many security professionals have explored the use of tokenization, which has the potential to provide a convenient way to protect sensitive assets. At a high level, tokenization is the process of replacing a sensitive record with a token, effectively a meaningless placeholder for the data that can't be exploited or reverted back to its original form

While tokenization offers the potential to address a wide range of security and compliance objectives, traditional tokenization tools and solutions have been far too costly and complex to procure and manage. These tools typically require security teams to invest in expensive appliances and contend with software agents that are difficult to deploy and manage. More than ever, security teams need to be able to leverage the benefits of tokenization—and they need to do so in a scalable, efficient, and cost effective manner.

The Solution

Efficiently de-identify sensitive data

The CipherTrust Data Security Platform offers tokenization capabilities that can dramatically reduce the costs and effort associated with complying with security policies and PCI DSS. With CipherTrust Vaultless Tokenization with Dynamic Data Masking, organizations can efficiently address objectives for securing sensitive assets and cardholder records— whether they reside in the data center, big data environments, or the cloud.

How vaultless tokenization works

For illustration purposes, we'll outline the process of tokenizing a credit card number. The CipherTrust Tokenization Server acts as a central hub for tokenizing records and managing access to tokens and clear-text data.

1. The customer submits a credit card number into an application.
2. The application submits the credit card number to the Tokenization Server via the REST API.
3. The Tokenization Server holds in memory a secure table created based on an AES-256 encryption key seed provided by the CipherTrust Manager. This table holds with random matches for credit card numbers – the token matching that card is identified.
4. Through the REST API, the Tokenization Server returns the token to the application.
5. The application server then submits the tokenized value into the database.

Deliver Robust Data Security

Strong access controls

Thales recommends creating at least two user accounts, or user groups from LDAP, be available on to the Tokenization Server:

- The first account or LDAP group with the permission to tokenize but not to detokenize, and the second account or LDAP group with the permission to detokenize
- The user account with tokenization privileges can then be utilized by multiple servers, including a public-facing web server, for example. This allows data to be tokenized immediately as it is brought in through applications
- Accounts or LDAP groups with permission to have detokenization privileges should be limited to a specific server that needs these permissions. For example, detokenization privileges could be restricted to a server that's responsible for submitting credit card numbers to a remote card processing service
- Any internal LDAP groups that have rights to detokenize data (Application administrators, for instance) should be strictly limited to the minimum number of members required

Tokenized data can be used with databases or files needed for development, QA and Test, or deployed to Big Data environments without risk to sensitive information. For credit card data, servers using tokenized information are removed from expensive and time consuming yearly audits as well. Further, Thales offers a high availability, standardsbased, FIPS 140-2 and Common Criteria validated policy management platform with the CipherTrust Manager that can provide maximum security for cryptographic keys and policies used with tokenization.

Flexible tokenization with dynamic data masking

CipherTrust Vaultless Tokenization also offers the flexibility to establish varying levels of data redaction. Security administrators can establish settings to have an entire field tokenized or to dynamically mask only part of a field, keeping the remainder in the original clear-text. When combined with LDAP-based integration to Active Directory and other directory services solutions, this capability enables uses such as call centers. One example of call center usage is limiting credit card number visibility for customer service representatives to the last four digits of a customer's credit card, while customer service supervisors can see the entire number.

The process of setting these policies is done using an intuitive administrative interface. Through the interface, administrators can choose exactly how they want data to be redacted, including specifying whether to replace a value with such characters as a pound sign, asterisk, or hyphen.

Dynamic Data Masking of Credit Cards for Customer Service

With CipherTrust Vaultless Tokenization, policies could be implemented so that a customer service supervisor could see credit card numbers in the clear, while a customer service representative would only see the last four digits.

Initial conditions:

- Credit card data in a product database is tokenized
- A policy is set for the customer services representatives group in LDAP that allows them to see only the last four digits of a credit card number
- A second policy allows members of the customer services supervisor group to see the entire number

Workflow

1. Customer service representative request to see a credit card number
2. The application calls the token from the production databases
3. The application server then passes the token and User ID information to the Tokenization Server using a RESTful API
4. The Tokenization Server calls directory services requesting group information for the User ID
5. Based on the User ID, customer services group membership, and the policy that customer services representatives can only view the last four numbers of a credit card, the token is processed, and the credit card number retrieved. Data is then dynamically masked, with the card number set to XXXX-XXXX-XXXX-4321, where 4321 are the last four digits of the actual card. XXXX-XXXX-XXXX-4321 is then returned to the application server
6. The application server displays XXXX-XXXX-XXXX-4321 to the customer services representative

Tokenization options

As well as offering the capability to dynamically mask data for display, CipherTrust Tokenization offers options for tokenizing a variety of fixed length data types – including Numeric, Text and Date formats. Options for data types to be tokenized include specific modes for:

- Numbers – Best for credit cards, U.S. Social Security numbers and other purely numeric data
- Text – All letters, all printable ASCII, All ASCII or AlphaNumeric for use with applications such as U.K. National Insurance numbers, drivers license numbers and others that include text only or mixed text and numbers
- Partial tokenization – Select only a portion of the fixed length field to be tokenized – keeping a portion of the data as the original information
- One-time use tokens – Used only when the data will never be de-tokenized
- Dates – including formats with various separators. Can also be modified with a start and end year
- Prefix – Prefixes can be appended to all tokens – for instance to designate a drivers license (DL)

Deployment and administrative simplicity

With CipherTrust Vaultless Tokenization, you can capitalize on a range of features that streamline upfront implementation and ongoing operations. CipherTrust Vaultless Tokenization

- **Enables efficient, enterprise-wide administration**

With the capabilities offered by the CipherTrust Data Security Platform, you can choose from a range of technologies and employ the mix that's optimally suited to an organizations specific projects and use cases. At the same time, enterprises gain the cost savings and operational benefits of working with solutions that can be centrally and uniformly managed. With the CipherTrust Data Security Platform from Thales, organizations can centrally manage keys for Vaultless Tokenization, as well as for CipherTrust Transparent Encryption, CipherTrust Application Data Protection, other CipherTrust products, and third-party devices.

- **Offers non-disruptive implementation**

With the solution's capabilities, you can restrict access to sensitive assets, yet at the same time, format the protected data in a way that reduces the operational impact typically associated with encryption and other obfuscation techniques. For example, organizations can tokenize a credit card field in a database, yet keep the tokenized information in a format that is compatible with associated applications. Further, tokens can appear to be real credit card numbers and pass LUHN validation, so tokenization does not break existing validation processes.

- **Eliminates manual efforts and complexity**

Tokenization occurs at the application layer, and it streamlines all the application development efforts associated with implementing tokenization in an enterprise. With the solution, developers don't have to manually institute identity management or redaction policies. CipherTrust Vaultless Tokenization offers an easy-to-use REST API for integration with the CipherTrust Tokenization Server, so that application developers can simply and quickly add tokenization and dynamic data masking to applications.

- **Provides investment protection**

Customers that have already invested in the CipherTrust Data Security Platform can get even more out of their investments. By leveraging existing CipherTrust Manager implementations (required for all CipherTrust Data Security Platform products), it is quick and cost effective to add Vaultless Tokenization through an all-software deployment.

Efficient scalability and agility

CipherTrust Vaultless Tokenization delivers the performance needed to address the operational demands of the most processing-intensive environments, enabling organizations to do millions of tokenization or detokenization operations per second. The Tokenization Server runs on virtual machines and can be quickly and efficiently scaled up and scaled down to accommodate changing workloads. For redundancy, Thales recommends deploying a cluster with at least two nodes. A three-node or four-node cluster multiplies the throughput, while providing added redundancy. Performance realized will vary depending on hardware platforms, cluster sizes, and client parallelism employed.

Key benefits

- **Reduce PCI DSS compliance effort and scope**

By leveraging CipherTrust Vaultless Tokenization, you can minimize the repositories and processes that can gain access to payment data in the clear, organizations can significantly reduce PCI DSS compliance costs and efforts.

- **Fully leverage cloud, big data, and outsourced models**

CipherTrust Vaultless Tokenization enables organizations to more fully leverage cloud services, big data models, and outsourced environments, while retaining the security controls required. For example, tokenized data can be easily migrated tokenized data to a public cloud, without exposing sensitive data to unauthorized access, even access by administrators in the cloud provider's environment.

- **Establish broad safeguards around sensitive assets**

Unlike other dynamic data masking tools, the CipherTrust solution tokenizes sensitive fields in the production database. As a result, enterprises can establish comprehensive safeguards around sensitive assets across the organization. Because the source and display data remain protected, this includes strong safeguards against cyberattacks from criminals and nation-states, as well as from insider abuse.

- **Minimize data security overhead and training**

With the CipherTrust Data Security Platform, enterprises can leverage a platform to centrally manage keys for Vaultless Tokenization and as well for the full range of the platform's encryption and access controls solutions. By leveraging a central platform that offers comprehensive capabilities, organizations can minimize the cost, effort, and training associated with managing point-products.

Sample implementations

PCI DSS 3.X Compliance

The more locations that hold primary account numbers (PANs), the more locations that fall under PCI DSS regulations. As the number of locations grow, so too do the cost and effort associated with establishing and sustaining compliance, preparing for audits, and so on. With CipherTrust Tokenization, you can tokenize PANs, and significantly restrict the number of users, processes, and repositories that can get access to this data in the clear. As a result, organizations can dramatically reduce compliance efforts and costs. Further, through such capabilities as Luhn check support, Vaultless Tokenization enables organizations to implement tokenization with minimal impact on applications and processes. In addition, the CipherTrust Data Security Platform offers many additional controls you need to address many PCI DSS requirements, including least privileged access controls, encryption, key management, and file access audit logs.

Customer contact centers

Vaultless Tokenization helps mitigate the threats that can be posed by support staff exploiting their access privileges to steal or leak sensitive data. Dynamic Data Masking can be effective both for securing sensitive data in internal contact centers and in outsourced or geographically distributed support environments. For example, enabling a support agent to see only the last 4 digits of a Social Security Number. As a result, agents can conduct any required customer verification processes, without being put in a position where they can maliciously or inadvertently leak sensitive and regulated PII.

Outsourced Development

For many organizations, application development is done by an increasingly dispersed set of teams, including geographically distributed employees as well as external contractors and service providers. While these distributed teams have helped improve the cost efficiency and agility of development efforts, they can pose significant challenges for those organizations that manage sensitive and regulated data. From initial development to testing and staging, developers need access to data repositories. If all data is left in the clear, it exposes a range of sensitive regulated data and intellectual property to any number of threats. With CipherTrust Vaultless Tokenization, organizations can quickly and efficiently provide internal and external development teams with access to corporate data repositories, while tokenizing the specific assets that pose security or compliance risks.

A complementary product, CipherTrust Batch Data Transformation, also helps organization to quickly tokenize large data sets for this purpose when needed.

Big Data

To capitalize on the opportunities presented by big data, organizations need to aggregate information from a broad range of repositories—and in the process can create massive collections of highly sensitive and proprietary data. The CipherTrust Data Security Platform enables organizations to fully leverage big data, without introducing risk to the business. Sensitive records can be tokenized before they are incorporated into big data repositories, so big data scientists, developers, and business analysts don't gain access to sensitive data that is not required for their work. At the same time, the solution's flexible tokenization options ensure that tokenized records don't disrupt big data migration, calculation, and analytics processes.

Cloud Services

When your organization moves to cloud computing models, whether infrastructure as a service (IaaS), software as a service (SaaS), platform as a service (PaaS), or hybrid approaches, you may offload a number of responsibilities and efforts, but your organization ultimately still bears responsibility for the security of its sensitive and regulated data. With CipherTrust Vaultless Tokenization, your organization can leverage the cloud models it needs, while managing tokenization policies locally. As a result, you can retain complete control and visibility over who can access sensitive assets in the clear, no matter where tokenized information ultimately resides.

Static Data Masking

Organizations can replace sensitive assets with tokens, so that outsourced application development and testing teams can run QA and analytics using realistic looking data, without having access to any sensitive assets. Once sensitive values in the database are tokenized, enterprises simply need to create a copy of the production database and give that copy to the outsourced development team. Since these teams don't have access to both the CipherTrust Tokenization Server and user credentials to detokenize, they won't be able to access sensitive data in the clear. This protects the business, maintains compliance, and enables outsource development teams to access and test realistic production data.

Just as noted above under Outsourced Development, CipherTrust Batch Data Transformation helps organization to quickly tokenize large data sets for this purpose when needed.

About Thales

The people you rely on to protect your privacy rely on Thales to protect their data. When it comes to data security, organizations are faced with an increasing number of decisive moments. Whether the moment is building an encryption strategy, moving to the cloud, or meeting compliance mandates, you can rely on Thales to secure your digital transformation.

Decisive technology for decisive moments.

CipherTrust Application Data Protection

Developer-Friendly APIs for Data Protection

CipherTrust Application Data Protection offers developer-friendly software tools for encryption key management as well as application-level encryption of sensitive data. Protecting data at the application layer can provide the highest level of security, as it can take place immediately upon data creation or first processing and can remain encrypted regardless of its data life cycle state – during transfer, use, backup or copy. The solution is flexible enough to encrypt any type of data passing through an application. CipherTrust Application Data Protection can be deployed on premises or in private or public cloud infrastructure to secure data even when it is migrating from one environment to another, without any modifications to existing encryption or data processing policies.

Architectural Overview

CipherTrust Application Data Protection harmonizes interactions between developers and IT operations who share a common goal of data security. Developers enjoy language bindings appropriate to their projects. Operations can leverage choices among Crypto Service Providers that run on a wide range of operating systems. Further, the product includes many operational features that enhance performance and availability to ensure that security imposes a minimal to zero impact on business operations.

CipherTrust Application Data Protection operates with CipherTrust Manager, providing an architecture that centralizes encryption keys for applications. For enhanced separation of duties, CipherTrust Manager defines granular controls on both key users and key operational use.

One of several architectural choices for CipherTrust Application Data Protection

Developer-Friendly Data Protection APIs

Adding data protection to the software development process can be optimized by saving software engineers from having to master cryptography, deal with the challenge of finding high quality encryption keys as well as a safe store for them and mastering complex APIs without a comprehensive collection of sample code. CipherTrust Application Data Protection from Thales offers well-documented Crypto APIs with a wide range of language bindings, integrated with a range of industry-standard Crypto Service Providers that enable fast development of data protection for integration into mission-critical applications.

Development Libraries and APIs

Supported CipherTrust Application Data Protection language bindings and APIs include Java, C, and C# for .NET Core and .NET; XML Open Interface; RESTful APIs; KMIP client

Core Cryptographic Functions

Like a hardware security module (HSM) such as Thales Luna, CipherTrust Application Data Protection core cryptographic functions include, among many others including encrypt/decrypt, Sign, Hash (SHA) and HMAC

The solution also offers support for versioned keys for encryption and decryption, signing and HMAC. Versioned keys can reduce the risk of data loss in the event of a compromised key.

Crypto Service Providers and Supported Operating Systems

In the following table, • indicates that a CipherTrust Application Data Protection crypto service provider binary is available for the operating system.

Abbreviations key:

- CAPI = C (language) API
- CSP = Crypto Service Provider (Windows)
- CNG = Crypto Next Generation [Provider]
- JCE = Java Crypto Engine

	CAPI	PKCS#11	CSP/CNG	JCE
Linux	•	•		•
Windows Server	•	•	•	•
AIX	•	•		•
HP-UX				•
Solaris		•		•
MacOS	•			

Choosing where to encrypt

Crypto operations on the application server: For many uses cases, and, in particular for the most latency-sensitive workloads CipherTrust Application Data Protection libraries on the application server include all crypto functions. Keys are cached for use on the application server. Keys are encrypted when not in use and obfuscated in memory when in use.

Crypto operations retained on CipherTrust Manager:

CipherTrust Application Data Protection offers the possibility of retaining all encryption keys on CipherTrust Manager and forwarding encryption and decryption requests there. Retaining keys on CipherTrust Manager offers the highest key security. To support performance and availability for crypto operations on CipherTrust Manager, CipherTrust Application Data Protection libraries on the application server offer the following tools:

- Connection pooling
- Single- and multi-tiered load balancing

Crypto Service Aggregation Point

Applications can also choose to make RESTful API crypto requests to the CipherTrust Application Data Protection Web Services. This Web Services option can perform crypto operations locally or act as a centralized forwarder to CipherTrust Manager. Web Services option offers the same key protections for local operations as CipherTrust Application Data Protection libraries.

Rich Crypto Ecosystem

CipherTrust Application Data Protection has integrations for Microsoft SQL Server Always Encrypted, Microsoft Online Certificate Status Protocol (OCSP), Hashi Vault, HortonWorks, Apache HTTP and NGINX Servers, Lieberman ERPM, and many others.

About Thales

The people you rely on to protect your privacy rely on Thales to protect their data. When it comes to data security, organizations are faced with an increasing number of decisive moments. Whether the moment is building an encryption strategy, moving to the cloud, or meeting compliance mandates, you can rely on Thales to secure your digital transformation.

Decisive technology for decisive moments.

CipherTrust Vaultless Tokenization (CT-VL)

Administration

Overview

CipherTrust Vaultless Tokenization (CT-VL) is a platform-independent appliance (virtual machine or bare-metal) that offers REST-API services to protect sensitive data. CT-VL offers three service categories for protecting sensitive data:

- **Tokenization Service:** Tokenization is used for replacing sensitive data with tokenized, or encrypted, data. Tokenized data retains the format of the original data while protecting it from theft or compromise. For example, if a company accepts customer credit card numbers, those numbers can be tokenized and stored as random-looking numbers, then detokenized by an employee or application with the proper permissions.

Tokenization is frequently used for sensitive data such as credit card numbers, social security numbers, drivers licenses, or other personally identifiable information (PII). Data masking can be applied to any detokenized data to hide sections of the data from different groups of users. For example, less-privileged database users might view only the last four digits of a detokenized credit card number, while a more privileged user could view the entire card number.

CT-VL uses the CipherTrust Manager (CM) to store the AES keys to tokenize and detokenize sensitive data.

- **Cryptographic Services:** CT-VL can be used to protect sensitive data using encryption. It can be used to encrypt, decrypt, sign, and verify data which can be tied to specific keys and user permissions. CT-VL uses the CipherTrust Manager to store the keys for encryption.
- **Key Management Services:** CT-VL can be used to manage keys stored on the CipherTrust Manager. It can create, modify, search, import, export, and many other operations, keys on the CM.

All the services above are available as REST-APIs which can be used to integrate into the end-user's application.

To achieve high performance and reliability (in the form of redundancy), multiple CT-VL appliances (virtual machines) can be configured to form a cluster. The cluster can operate as one coherent CT-VL system that could be served by a load balancer.

CT-VL can run as a virtual machine and is supported on many hypervisors and cloud platforms, namely, VMware vSphere, Kernel-based Virtual Machine (KVM), HyperV, Amazon Web Services (AWS), Microsoft Azure Marketplace, and Google Cloud Platform (GCP).

CT-VL can also run on a physical machine (bare-metal). The software product is available in ISO format installable on bare metal machines. All settings applicable to a virtual machine are also applicable to the physical machine.

Note

CipherTrust Vaultless Tokenization (CT-VL), formerly known as Vormetric Tokenization Server (VTS) and CipherTrust Tokenization Server (CTS), has been renamed to conform with several other former Thales Vormetric products adopting the brand name CipherTrust.

Interfaces

CT-VL has three forms of user-interface:

- **Command-Line Interface (CLI):** This interface is available using the SSH protocol. It is used by the administrators to install, configure, and maintain the CT-VL virtual machine and cluster.
- **Web User Interface:** This interface is used by the administrators to manage users, groups, keys, policies (templates), permissions, data masking, and other administrative functions used for tokenization.
- **REST API:** This interface is used for tokenization, cryptographic, and key management operations. Administrative operations are also available using REST APIs. These APIs are also documented in YAML files located under Documentation in the CT-VL Administration WebUI.

Component Architecture

Multiple CT-VL appliances can be set up to form a cluster to achieve high performance and availability. CT-VL in a cluster uses bi-directional replication to synchronize data across all virtual machines. In addition, CT-VL supports connection to multiple CipherTrust Managers in a cluster to achieve high availability for key access.

- A minimum of two CT-VL nodes in a cluster is recommended for redundancy.
- A maximum of 16 nodes are supported.
- A load balancer can be used to achieve higher performance by using multiple virtual machines and automatically distributing the load across all nodes in the cluster.

Below is the CT-VL architecture diagram:

Authentication and Authorization

CT-VL requires a CipherTrust Manager to obtain the keys to tokenize and encrypt sensitive data. Keys used are

not persistent and never stored on the CT-VL virtual machine. It only caches keys in memory for a brief period to achieve high performance.

In addition to locally created users and groups, CT-VL can also use a Windows AD or LDAP server to authenticate users performing tokenization, encryption, and key management. They can be used for identity management to map users and groups for tokenization policies (templates), encryption policies, and key management access.

Moreover, CT-VL supports client-certificate identity and authentication.

Refer to [Understanding CT-VL Authentication and Authorization](#) for further information.

Supported Tokenization Algorithms

CT-VL supports the following tokenization algorithms:

- FF3
- FPE-luhn
- Dates
- Random
- Random-luhn
- FF1
- FF1-luhn

Supported Character Sets

CT-VL supports the following character sets for tokenization:

- Numeric
- Alphanumeric
- Printable ASCII
- Custom character sets

Supported Cryptographic Operations

CT-VL supports the following cryptographic operations:

- Encrypt
- Decrypt
- Sign

-
- Verify

Supported Tokenization Operations

CT-VL supports the following tokenization operations:

- Tokenize
- Detokenize

Supported Key Operations

CT-VL supports the following key operations:

- Create
- Import
- Destroy
- Modify
- Find
- Export

Quick Start

This quick start guide describes the concise steps to set up and run a CT-VL appliance to perform tokenization, encryption, and key management. This guide focuses on using a virtual machine hosted on VMware vSphere ESXi. For other options to run a CT-VL appliance, see [Alternative Deployments](#).

Prerequisites for Installing CT-VL

Prerequisites for installing CT-VL as a VM are listed below:

Note

For the complete list of prerequisites for all CT-VL deployment options, see [CT-VL Deployment Prerequisites](#).

- CipherTrust Manager 2.11.1 LTS or higher.
- VMWare vSphere ESXi Server 6.0 or higher.
- CT-VL OVA image version 2.6.0 or higher.

- For optimal performance, the recommended settings for a CT-VL VM are 4 CPUs and 16GB memory.

Installing CT-VL

Steps for installing CT-VL as a VM are listed below:

1. Create a CT-VL virtual machine
2. Log in to the VM
3. Set up the VM network
4. Register VM with the Key Manager
5. Initialize the CT-VL cluster

1. Creating a CT-VL Virtual Machine

Obtain a CT-VL ISO or OVA image file, for example - `cts-2.6.0.205.ova` and deploy it to create a virtual machine. Refer to the *VMware ESX User Guide* on *how to create a virtual machine using an ISO or OVA image*. It is recommended to use Thick Provisioning for hard disks.

For a multi-node setup, you can repeat this installation process for additional machines. You would then configure each node separately and join them in a cluster. See [Configuring CT-VL Nodes](#) for details.

2. Initial Log In

Power up the CT-VL virtual machine that you have created. Open the virtual machine console and log in using the following credentials:

Note

CT-VL supports serial console for GCP and Azure Cloud platforms. You may also perform the initial login using SSH if networking is already available.

```
login: cliadmin
password: cliadmin123
```

This initial log-in will prompt you to change the password of the `cliadmin` user.

3. Network Setup

Networking for CT-VL can either use DHCP or the static IP configuration.

DHCP Network Setup

DHCP Network Setup

The CT-VL virtual machine supports DHCP to set up networking. It is enabled by default and if your network has a DHCP server, the CT-VL VM will use it automatically to obtain an IP address and configure its network at power-up.

To determine the IP address obtained by the VM from DHCP, log in to the VM console. Note: The CT-VL runs the Open VM Tools software. With this, you view the IP address used by the VM from the vSphere ESXi host or vCenter.

Static Network Setup

Static (non-DHCP) Network Setup

If your network does not have DHCP server or if DHCP is not desired, you can set up networking using a static IP address.

To do so, perform the following steps:

1. Log in to the console of the VM and run the command below to set up networking.

```
main> network setup eth0
```

The CLI command above will run interactively.

2. When prompted, supply the network configuration, that is, IP address, netmask, and gateway.
3. A non-interactive command is also available to set up the network. Supply the -h option to display usage.

```
main> network set -h
usage: set [-h] [--onboot {yes,no}] [--dhcp] [--ipaddr IPADDR]
          [--netmask NETMASK] [--gateway GATEWAY] [--defroute {yes,no}]
          [--mtu MTU] [-y]
          device
```

4. Run the 'network dns' command to configure DNS. Supply the -h option to display usage.

```
main> network dns -h
usage: dns [-h] [--show] [--add IP [IP ...]] [--remove IP [IP ...]]
          [--useDHCP {yes,no}] [-y]
```

4. Register the CT-VL VM with CipherTrust Manager (CM)

You can register the CT-VL VM with CipherTrust Manager (CM) as the key manager. For complete set of steps, see [Registering CT-VL VM with CipherTrust Manager](#).

Perform the following steps to register the CT-VL VM with CipherTrust Manager:

Log in to the CM server

1. Create an NAE interface.
2. Choose a port number for the NAE interface and set the mode to "TLS, verify client cert, user must supply password."
3. For the CipherTrust Manager 2.11 and above, enable **Allow unregistered clients**.
4. Set a local CA for the NAE interface.
5. Create a CM user for CT-VL use.
6. Create AES key(s) for CT-VL use. Preferably, use 256 bits for key size.
7. Set the AES key(s) to be exportable.
8. Set the AES key(s) to be accessible by the CM user created in #4 above.

Log in to the CT-VL VM

1. Run the CLI command below to configure the CM server.

```
icapi setup
```

This command runs an interactive setup to configure connectivity to the CM server. Follow the prompts to supply the IP address of the CM, port number of the NAE interface, CM user, and password. The CM user supplied must have access to the keys that will be used by CT-VL.

2. Run the CLI command below to register the CT-VL VM to the CM server.

```
icapi register --host <ipaddress> --user <admin>
```

where:

ipaddress - IP address of the CM server.

admin - name of a user on the CM with admin access to sign certificates.

3. Enable CM for CT-VL use.

```
icapi enable yes
```

4. Test connectivity to the CM server.

Run the CLI command below to test if CT-VL can connect and authenticate to the CM server.

```
icapi test --server_connection
```

5. Test access to a key on the CM.

Run the CLI command below to test if CT-VL has access to a key.

```
icapi test --key keyname
```

5. Initialize the CT-VL Cluster

Even if you have only one CT-VL server, you need to create and initialize a cluster. Run the command below to initialize the CT-VL cluster.

```
cluster create
```

This command is interactive. You will be prompted to supply a username, password, and email. This user will be created on the CT-VL VM and will serve as the initial administrative user to the WebUI.

Configuring CT-VL

Complete the following steps to configure CT-VL:

I. Configure CT-VL Tokenization API

Browse to the hostname or IP address `https://<ct-vl_ipaddress>/` of the VM.

Log in to the CT-VL Web user interface using the username and password created during cluster initialization.

II. Create Users

1. Navigate to the Users menu.
2. Select the 'New User' button and specify the appropriate details to create users. At a minimum, users created must have 'Active' permission to allow access to tokenization, encryption, and key management REST-APIs. To allow access to the WebUI, users must have 'Staff' or 'Superuser' permissions. Setting users with 'Staff' permission will allow WebUI access but read-only. Setting users with 'Superuser' permission will allow WebUI access with read-write.

III. Create Keys

1. Navigate to the Keys menu.
2. Select the 'Symmetric Keys' tab.

3. Create symmetric keys you will use for tokenization, encryption, or key management. The name of the keys supplied must match the name of keys on the Key Manager.

IV. Create Token Groups

1. Navigate to the **Tokenization > Token Groups** Menu.
2. Create a token group and assign a key that it will use.

V. Create Token Templates

1. Navigate to the 'Tokenization Templates' Menu.
2. Create a Tokenization Template and set a name and token group for it.
3. Select a Format algorithm, e.g., FPE.
4. Select a Character Set, e.g., All digits.

VI. Set Key Permissions

1. Navigate to the 'Permissions' Menu.
2. Select a user and key.
3. Select the permissions you will require for the user. For tokenization operations, select 'Tokenize' and/or 'Detokenize'. For cryptographic operations, options are: Encrypt, Decrypt, Sign, and Verify. For key management operations, options are: Destroy, Modify, Export, and Find.

Note

To know more about CT-VL token groups, token templates, and data masks, see the [Tokenization Groups, Templates, and Masks](#).

Run a sample tokenization, detokenization, cryptographic operation.

Complete the required operations:

- [Tokenize Data](#)
- [Detokenize Data](#)
- [Encrypt Data](#)
- [Decrypt Data](#)

Tokenize Plaintext Data

Use a REST-API client to tokenize a plaintext numeric data.

Request POST Parameters

Parameter	Type	Description
data	string	Plaintext data to be tokenized.
tokengroup	string	Name of the token group.
tokentemplate	string	Name of the token template.

Request

```
curl -k -u vtsuser -X POST 'https://ipaddress/vts/rest/v2.0/tokenize' \
-H 'content-type: application/json' \
-d '{"tokengroup": "TG1", "tokentemplate": "TT1", "data": "1111222233334444"}'
```

Response

```
{
  "token": "6300847582017130",
  "status": "Succeed"
}
```

Detokenize Tokenized Data

Use a REST-API client to detokenize a tokenized data.

Request POST Parameters

Parameter	Type	Description
token	string	Encrypted data to be detokenized.
tokengroup	string	Name of the token group.
tokentemplate	string	Name of the token template.

Request

```
curl -k -u vtsuser -X POST 'https://ipaddress/vts/rest/v2.0/detokenize' \
-H 'content-type: application/json' \
-d '{"tokengroup": "TG1", "tokentemplate": "TT1", "token": "6300847582017130"}'
```

Response

```
{
  "data": "1111222233334444",
  "status": "Succeed"
}
```

Encrypt Plaintext Data

Use a REST-API client to encrypt a plaintext data.

Request POST Parameters

Parameter	Type	Description
plaintext	string	Plaintext data to be encrypted. This needs to be encoded in base64 format.
alg	string	Encryption algorithm.
kid	string	Name of key to use.
iv	string	Initialization vector string encoded in base64 format.

Sample POST request data for encryption:

```
{
  "plaintext": "9mBirbK+VZLR/x6gDlGioQ==",
  "alg": "A256CBCPAD",
  "kid": "key1",
  "params": {
    "iv": "aKcjACEIDh0x0AX0SCQoqQ=="
  }
}
```

Request

```
curl -k -u vtsuser -X POST 'https://ipaddress/vts/crypto/v1/encrypt' \
-H 'content-type: application/json' \
--data @encrypt_data.yaml
```

Response

```
{
  "ciphertext": "WPn2Py8oC7kM1MRTtf4xYxho+UnbVYmTKmKibC9X2+o=",
  "tag": ""
}
```

Decrypt Ciphertext Data

Use a REST-API client to decrypt a ciphertext data.

Request POST Parameters

Parameter	Type	Description
ciphertext	string	Ciphertext data to be decrypted. This needs to be encoded in base64 format.
alg	string	Encryption algorithm.
kid	string	Name of key to use.
iv	string	Initialization vector string encoded in base64 format.

Sample POST request data for decryption:

```
{
  "ciphertext": "WPn2Py8oC7kM1MRTtf4xYxho+UnbVYmTKmKibC9X2+o=",
  "alg": "A256CBCPAD",
  "kid": "key1",
  "params": {
    "iv": "aKcjACEIDh0x0AX0SCQoqQ=="
  }
}
```

Request

```
curl -k -u vtsuser -X POST 'https://ipaddress/vts/crypto/v1/decrypt' \
-H 'content-type: application/json' \
--data @decrypt_data.yaml
```

Response

```
{
  "plaintext": "9mBirbK+VZLR/x6gDlGioQ=="
}
```

Alternative Deployments

CipherTrust Vaultless Tokenization can be deployed in the following ways:

Note

- For AWS and Google Cloud Platforms, contact Thales Customer Support to obtain access to CT-VL images. Refer to the cloud provider user guide to know how to create a virtual machine on the platform.
- For Microsoft Azure Cloud platform, go to Azure Marketplace and look for the latest version of CT-VL. For other platforms, download the CT-VL image from Thales Customer Support Portal.

- Installing CT-VL as a Virtual Machine on VMware vSphere
- Installing CT-VL on Bare Metal
- Installing CT-VL on AWS Cloud
- Installing CT-VL on Azure Cloud
- Installing CT-VL on Azure Stack Hub
- Installing CT-VL on Hyper-V
- Installing CT-VL on KVM
- Installing CT-VL on Google Cloud Platform
- Installing CT-VL on Alibaba Cloud

For the list of all prerequisites, see [CT-VL Deployment Prerequisites](#).

CT-VL Deployment Prerequisites

All Prerequisites

- CipherTrust Manager 2.11.1 LTS or higher.
- VMWare vSphere ESXi Server 6.0 or higher; Hyper-V; AWS, Azure, Google, and KVM cloud Platforms.
- Intel x86_64 physical machine (bare metal) can also be used in lieu of a virtual machine. Where virtual machines are mentioned in this document, it is also applicable to physical machines.
- CT-VL ISO, OVA, or cloud images with version 2.5 or higher. For physical machines, the disk size must be at least 85GB.
- For optimal performance, the recommended settings for a CT-VL VM are 4 CPUs and 16GB memory.

Active Directory/LDAP Server Requirements

An optional AD/LDAP server can be used to generate users and authenticate their credentials when they request services.

See [Understanding CT-VL Authentication and Authorization](#) for a conceptual basis on how AD/LDAP is used.

Requirements:

- Access to the AD/LDAP server containing users and groups that will have CT-VL privileges.
- For LDAPS, the LDAP server's CA certificate must be imported into the Tokenization Server.

Load Balancer Requirements

A cluster of CT-VL nodes can be installed and run as one coherent CT-VL system using a load balancer. The load balancer acts as the main entry point for tokenization and crypto services to distribute load across all nodes in the cluster. It provides scalability and reliability to the system.

CT-VL supports the following methods of load balancing:

- **Round-robin:** Requests are distributed in a round-robin fashion.
- **Least-connected:** Allows the load balancer to control the load on some CT-VL nodes.
- **IP-hash:** The client IP address is used to determine what server in a server group should be selected for the client request. This can be used for client's session sticky or persistent.

The load balancer must be able to use TLS1.1 and higher.

Port Configuration

If CT-VL must communicate with other components through a firewall, open the ports in the firewall as mentioned in the following tables.

Below table describes each port you must open for incoming communication to CT-VL:

Port No.	Protocol	Communication	Description
22	TCP	Management Console → CT-VL	Administration CLI SSH access.
443	TCP	Browser → CT-VL Requester → CT-VL CLI → CT-VL	HTTPS access for Administration GUI and REST/JSON API.
5432	TCP	CT-VL ↔ CT-VL	This port is required if a cluster of more than one node is used. This is used exclusively for communication between the CT-VL nodes in a cluster.

Below table describes each CT-VL port you must open for outgoing communication from CT-VL:

Port No.	Protocol	Communication	Description
User-defined	TCP	CTS → Log Server	Remote logging.
123	UDP	CT-VL ↔ NTP Server	Optional network time synchronization.
389	TCP	CT-VL → LDAP Server	Optional LDAP connection.
636	TCP	CT-VL → LDAPS Server	Optional LDAPS (LDAP over TLS) connection.

Installing CT-VL as a Virtual Machine on VMware vSphere

Prerequisites

- VMware ESXi hypervisor, ESXi version 6.0 or higher.
- Minimum recommended settings for the CT-VL VM: 4 CPUs, 16GB memory.

Installation

CT-VL can use a VMware ESXi hypervisor to create a virtual machine using the ISO or OVA build image. CT-VL supports ESXi version 6.0 or higher. Refer to VMware ESXi documentation on how to create a VM using an ISO or OVA image.

It is recommended to use Thick Provisioning for hard disks.

For a multi-node setup, you can repeat this installation process for additional machines. You would then configure each node separately and join them in a cluster as described in [Configuring CT-VL Nodes](#).

Configuration

To begin configuration, click the **Console** tab of the vSphere Client to log in to the CTS CLI as cliadmin, change the default password, accept the Service Level Agreement, and begin configuring CTS settings using the CTS CLI.

See [Configuring CT-VL](#) for further information.

Installing CT-VL on Bare Metal

Although typically deployed as a virtual machine, the CipherTrust Vaultless Tokenization (CT-VL) server can be installed using an ISO image and run on a bare metal machine.

A bare metal host is a computer that does not run hypervisor software. Do not install the operating system on the host before installing CT-VL, because the OS is included along with the CT-VL software in the installation package. When selecting the operating system, specify 64-bit CENTOS version 7 or higher.

Prerequisites for Installing CT-VL on Bare Metal

- Intel x86_64 physical machine.
- Number of CPU cores: 4.
- RAM: 16 GB minimum if RANDOM mode is none. 24 GB recommended if CT-VL will be used to tokenize credit card numbers longer than 16 digits. 24 GB if using numeric RANDOM mode or alphanumeric RANDOM mode, or 32 GB if using both modes.
- Hard disk space: 85 GB.

Installation Steps

To do a bare metal installation:

1. Obtain the installation file `ctvl-<release>.iso`.
2. Refer to the machine's documentation on how to boot and install from an ISO image.

Installing CT-VL on AWS Cloud

Note

Contact Thales Customer Support to obtain access to the CT-VL AMI image in Amazon Web Services Cloud.

Installation Prerequisites

Following components are necessary for running a CT-VL in the cloud on Amazon Web Services (AWS):

- **Minimum recommended settings for CT-VL VM:** 4 CPUs, 16GB memory.
- **A VPC (Amazon's Virtual Private Cloud):** If you plan to create a cluster of CT-VL machines, it is recommended that your cluster nodes use a VPC so that they communicate only with each other within the private cloud. Cluster communication does not need to be, and should not be, exposed on the Internet.
- **A Subnet:** If you choose to use a VPC, you will need to create a subnet and associate that subnet to that VPC. This subnet is where your CT-VL cluster nodes will get the IP addresses.
- **A Security Group:** Set your security group with the following minimum settings:
 - Incoming port **443** - Web and REST API access.
 - Incoming port **22** - CLI access.

-
- Incoming port **5432** - Optional. Set this only if the machines in your cluster are not using a VPC to communicate with each other.

If you will be accessing your CT-VL strictly inside the VPC, you will still need a security group but you can block all incoming ports.

- For best security, use SSH key pairs instead of passwords for SSH logins. If you choose to use an EC2 key pair when creating a CT-VL instance, the cliadmin will use that key (a private key) to log in by SSH. Password access will be disabled.
- If you choose not to use an EC2 key pair, the cliadmin will use a password to log in by SSH.
- Upgrading an EC2 instance from CT-VL v2.5 or earlier retains the use of passwords for the cliadmin. Only newly-created instances from CT-VL v2.6 and above can use the SSH key pair in AWS.

Create the CT-VL Instance

Follow this procedure to create the CT-VL instance:

1. Choose your AWS region.
2. Locate the AMI of the CT-VL image.
3. Select the AMI image and launch an instance.
4. Select Instance type: **m4.xlarge** - with recommended minimums of 4 vCPUs and 16GB memory.
5. Select the VPC to use for the installation.
6. Select the subnet.
7. Select Auto-assign public IP, if applicable.
8. Set the primary IP address. This will be the IP address of the VPC subnet, and it will be used by the VM for its cluster node IP address.
9. In the Add Storage menu, select **delete on termination**, if applicable. Do not change the size of the root volume.
10. Choose whether to have **cliadmin** log in via SSH with a password or with an EC2 key pair.
 - If you choose not to use an EC2 key pair, the **cliadmin** will use a password to log in by SSH.
 - If you choose an EC2 key pair, the **cliadmin** will use that key (private key) to log in by SSH. Password access will be disabled. You are prompted to select an existing key pair.
Select the private key file (in PEM format), and make sure to confirm your selection before launching the new instance.

Note

If an instance is configured to use an EC2 key pair, password access is blocked, and all password-related CLI commands are disabled.

Configuration Notes

To begin configuration, `ssh` into the instance as the `cliadmin` user using the public IP address or the VPC IP address, and follow the steps in [Configuring CT-VL](#).

If you will be creating a cluster of CT-VL machines, create an instance for each node in the cluster. You would configure each node separately and join them in a cluster as described in [Configuring CT-VL Nodes](#).

Note

When configuring a multi-node cluster, you must use the VPC IP address for the `node_IP_address`.

Installing CT-VL on Azure Cloud

Note

To obtain the CT-VL image for Azure, go to Azure MarketPlace, and look for "CipherTrust Vaultless Tokenization" v2.6 or higher.

Prerequisites to Install CT-VL on Azure Cloud

- A virtual machine and a Subnet.
- Minimum recommended settings for a CT-VL VM: 4 CPUs, 16GB memory.

Note

- The network security group defines the firewall rules of the CT-VL virtual machine. At a minimum, incoming ports must allow port 22 (SSH) and port 443 (HTTPS).
- If your cluster nodes are located in different resource groups, you also need to add port 5432 to the allowed incoming ports. However, if all your cluster nodes are in the same resource group, do not add

port 5432, because nodes inside a resource group do not need any firewall permissions to communicate with one another.

Create the Azure VM

1. Log in to the [Azure web portal](#).
2. Go to the *Marketplace* screen and search for **CipherTrust Vaultless Tokenization**. Select the desired version, and click the **Create** button.
3. Supply the following information to create a virtual machine:
 - **VM name:** name of the VM you want to use, for example, `my-CT-VL-2.3.0-azure-vm`.
 - **VM disk type:** SSD or HDD.
 - **User name:** Not required by CT-VL, but Azure needs this data to create a VM. This user name entry is not retained by CT-VL and is not used as a CT-VL credential.
 - **Authentication type:** Also not required by CT-VL, but required for Azure to create a VM. This authentication type entry is not retained by CT-VL and does affect the CT-VL configuration.
 - **Resource group:** You may create a new resource group or use an existing one. If you plan to create a cluster of CT-VL machines, it is recommended that all cluster nodes use the same resource group, so that they can communicate with one another without having to use a public static IP address or enable an incoming port in the firewall.
 - **Location:** For example, "West-US".
 - **Subnet and subnet address range:**
 - **Static or dynamic public IP address:** Use a static IP address if you expect your cluster to span multiple resource groups.

Configuration Notes

To begin configuration, `ssh` into the instance as the `cliadmin` user using the public IP address, and follow the steps in [Configuring the CT-VL System](#).

Note that on Azure, you will not configure the CT-VL network settings. Azure automatically configures these parameters for the CT-VL VM:

- Internal and subnet IP addresses are provided to the VM through DHCP.
- For CT-VL clusters, create an instance for each node in the cluster. Then configure each node separately, and join the nodes in a cluster.

- When creating or joining a cluster, if you have all the cluster nodes in the resource group, you must use the same internal or subnet IP address used by the VM.
- When adding a node to the cluster, you must always use the internal or subnet IP address of the new CT-VL VM node.

Installing CT-VL on Azure Stack Hub

Note

To obtain the CT-VL image for Azure Stack Hub, download the CT-VL VHD image from Thales Customer Support Portal.

Prerequisites to Install CT-VL on Azure Stack Hub

- A virtual machine and a subnet.
- Minimum recommended settings for a CT-VL VM: 4 CPUs, 16GB memory.

Note

- The network security group defines the firewall rules of the CT-VL virtual machine. At a minimum, incoming ports must allow port 22 (SSH) and port 443 (HTTPS).
- If your cluster nodes are located in different resource groups, you also need to add port 5432 to the allowed incoming ports. However, if all your cluster nodes are in the same resource group, do not add port 5432, because nodes inside a resource group do not need any firewall permissions to communicate with one another.

Create the Azure VM

1. Log in to Azure Stack Hub.
2. Upload the CT-VL VHD image into the Azure Stack Hub storage container. The CT-VL VHD image is of dynamic format. To upload a VHD image to Azure Stack Hub, the VHD image must be in fixed format. Convert the VHD image to fixed format before uploading to the Azure Stack Hub storage container. If you use the 'azure-vhd-utils' tool, you can use the dynamic VHD image to upload and it will convert automatically to fixed format when it saves to the Azure Stack Hub.
3. Navigate to Virtual Machines menu. Supply the following information to create a virtual machine:

-
- **VM name:** name of the VM you want to use, for example, `my-CT-VL-2.3.0-azure-vm`.
 - **VM disk type:** SSD or HDD.
 - **User name:** Not required by CT-VL, but Azure needs this data to create a VM. This user name entry is not retained by CT-VL and is not used as a CT-VL credential.
 - **Authentication type:** Also not required by CT-VL, but required for Azure to create a VM. This authentication type entry is not retained by CT-VL and does affect the CT-VL configuration.
 - **Resource group:** You may create a new resource group or use an existing one. If you plan to create a cluster of CT-VL machines, it is recommended that all cluster nodes use the same resource group, so that they can communicate with one another without having to use a public static IP address or enable an incoming port in the firewall.
 - **Location:** For example, "West-US".
 - **Subnet and subnet address range:**
 - **Static or dynamic public IP address:** Use a static IP address if you expect your cluster to span multiple resource groups.

Configuration Notes

To begin configuration, `ssh` into the instance as the `cliadmin` user using the public IP address, and follow the steps in [Configuring the CT-VL System](#).

Note that on Azure, you will not configure the CT-VL network settings. Azure automatically configures these parameters for the CT-VL VM:

- Internal and subnet IP addresses are provided to the VM through DHCP.
- For CT-VL clusters, create an instance for each node in the cluster. Then configure each node separately, and join the nodes in a cluster.
- When creating or joining a cluster, if you have all the cluster nodes in the resource group, you must use the same internal or subnet IP address used by the VM.
- When adding a node to the cluster, you must always use the internal or subnet IP address of the new CT-VL VM node.

Installing CT-VL on Hyper-V

Prerequisites for Installing CT-VL on Hyper-V

- The `.iso` image or `VHD` file.
- Minimum recommended settings for the CT-VL VM: 4 CPUs, 16GB memory.

Installation Steps

Note

- Install the CT-VL instance on a Hyper-V server using an ISO or VHD image file.
- Download the `ctvl-<release>.iso` or `ctvl-<release>.vhd` file to the Hyper-V server.

Use the following steps to install the CT-VL on a Hyper-V:

1. Open Hyper-V Manager.
2. Select **Action** > **New** > **Virtual Machine**.
3. Choose **Generation 1**.
4. Set the start up memory to 16GB.
5. Choose a network adapter.
6. For the VM, choose one of the following based on the type of image file to be used:
 - **VHD image:** Use an existing hard disk: Select CT-VL VHD image file you have downloaded or copied.
 - **ISO image:** Install an operating system from a bootable CD/DVD-ROM. Navigate to and select the downloaded ISO file.
7. Select **Finish** to create the Virtual Machine.
8. For ISO installation: Select and start the Virtual Machine. The VM will boot the mounted ISO image file and install the CT-VL.

Installing CT-VL on KVM

Prerequisites to Install CT-VL on KVM

Minimum recommended settings for the CT-VL VM: 4 CPUs, 16GB memory.

Installation Steps

Below are the steps to install CT-VL on a Linux Kernel-based Virtual Machine (KVM):

1. Download the CT-VL image in `qcow2` format. Place this image file into your KVM images directory.
2. Create a KVM virtual machine by importing the CT-VL `qcow2` image. Use the following KVM parameters:

- **virt-type:** kvm
- **os-type:** linux
- **os-variant:** centos7.0
- **vcpus:** 4
- **ram:** 16000
- **controller:** type=scsi,model=virtio-scsi
- **disk:** /var/lib/libvirt/images/cts-2.x.n.nnn.qcow2,bus=scsi

3. Connect to the console, and log in as user `cliadmin`.

Installing CT-VL on Google Cloud Platform

Note

Contact Thales Customer Support to obtain access to the CT-VL disk image in Google Cloud Platform.

Prerequisites for Installing CT-VL on Google Cloud Platform

Machine configuration recommended settings:

- General-purpose
- N1 Series
- 4 CPUs, 16GB memory

Installation Steps

To install the CT-VL on Google Cloud Platform (GCP) using the image:

1. Contact Thales Customer Support, and provide your GCP account and region details for access to the CT-VL disk image.

Note

CT-VL is also available as a tar image file. Thales Customer Support places the image Tar file in the `gs://cts-release` support folder. Refer to the cloud provider user guide to know how to convert the tar file

to a disk image and create a virtual machine on the platform.

2. Log in to the GCP console and navigate to **Compute Engine > VM Instances > Create Instance**.
3. Set a name, region, and zone for your instance.
4. Select your machine configuration as per the prerequisites.
5. Select **Boot disk**, and navigate to **Change > Custom Images**.
6. In the Show Images tab, look for the project name that Thales Support has provided and select that project.
7. Select the Image tab and look for the latest CT-VL GA release and select it. For example, ctvl-240-216.
8. Choose a boot disk type, for example, Standard or SSD.

Note

Do not change the disk size.

9. Close the Boot disk page by clicking Select.
10. In the Firewall setting, select **Allow HTTPS traffic**.

Note

Do not use SSH keys.

11. Click **Create** to begin creating the CT-VL instance.
12. Connect to the instance using SSH to begin the CT-VL setup.

Installing CT-VL on Alibaba Cloud

Installation Prerequisites

Following are the prerequisites for installing CT-VL on Alibaba Cloud:

- Minimum recommended settings for CT-VL instance are 4 CPUs and 16GB memory.

-
- If you want to create a cluster of CT-VL machines, it is recommended that cluster nodes should use a Virtual Private Cloud (VPC) so that they communicate only with each other within the private cloud. Cluster communication does not need to be exposed to the Internet.
 - If you choose to use a VPC, you will need to create a subnet and associate that subnet to that VPC. This subnet is where your CT-VL cluster nodes will get the IP addresses.
 - Set your security group with the following minimum settings:
 - Incoming port 443: Web and REST API access.
 - Incoming port 22: CLI access.
 - Incoming port 5432: Optional. Set this only if the nodes in CT-VL cluster are not using a VPC to communicate with each other.

Optional: Create your own CT-VL Alibaba Image

You may create your own CT-VL Alibaba image and use that to create a CT-VL instance (VM). To create your own CT-VL image, upload **CT-VL QCOW2** image file to your OSS storage, and then launch **Import Image** task.

CT-VL Alibaba image can be created:

- [Using WebUI](#)
- [Using CLI](#)

Using WebUI

Following are the steps to create CT-VL Alibaba image using WebUI:

1. Log in to [OSS Console](#).
2. Create a bucket repository if you have not done so.
3. Navigate to your OSS bucket.
4. Select **Upload** to upload **CT-VL QCOW2** image file.
5. Log in to [ECS Console](#) and navigate to **Instances > Images**.
6. Select **Import Image Manually**.
7. Supply the following image information:
 - OSS Object Address: File URL from OSS storage.
 - Image Name: ctvl-2.6.7.21.
 - Operating System: Linux.

- System Disk Size: 85GB.
- System Architecture: x86_64.
- Platform: Other Linux.
- Image Format: QCOW2.
- License Type: BYOL.
- Image Description: CipherTrust Vaultless Tokenization.

Note

- Do not select platform other than "**Other Linux**".
- Do not change the System Disk Size (85GB).

Using CLI

Following are the steps to create CT-VL Alibaba image using CLI:

1. Upload CT-VL QCOW2 image file to Alibaba Object Storage.

Example:

```
$ ossutil64 cp ctvl-2.6.7.21.qcow2 oss://ct-vl/builds/
```

2. Import image.

Example:

```
$ aliyun ecs ImportImage \  
--RegionId us-west-1 \  
--Description "CipherTrust Vaultless Tokenization" \  
--ImageName "ctvl-2.6.7.21" \  
--LicenseType BYOL \  
--DiskDeviceMapping.1.Format QCOW2 \  
--DiskDeviceMapping.1.DiskImageSize 85 \  
--DiskDeviceMapping.1.OSSObject "builds/ctvl-2.6.7.21.qcow2" \  
--DiskDeviceMapping.1.OSSBucket "ct-vl" \  
--Architecture x86_64 \  
--OSType Linux \  
--Platform 'Others Linux'
```

Note

Do not change the System Disk Size (85GB).

Sample Output Response:

```
{
  "ImageId": "m-rj9dwoc45p5gxvyfw812",
  "RegionId": "us-west-1",
  "RequestId": "9EFC096A-AB3F-3373-AC67-91C19915C003",
  "TaskId": "t-rj9dwoc45p5gxvybupew"
}
```

Create a CT-VL Instance (VM)

Following are the steps to create a CT-VL instance (VM) using a CT-VL image shared by Thales Customer Service Support or your own imported image from **CT-VL QCOW2** image file:

1. Log in to Alibaba Cloud and go to Elastic Compute Service.
2. Select a Region. For example: Singapore, US (Silicon Valley).
3. Select Create Instance.
4. Select a Billing Method. For example: Subscription or Pay-As-You-Go.
5. Select Zone. For example: Zone A or Zone B.
6. Select an Instance Type:
 - Architecture: x86-Architecture.
 - Category: General Purpose or Compute Optimized.
 - Instance Type:
 - Minimum: 4 CPUs, 16GB Memory.
 - Recommended: 8 CPUs, 32GB Memory.
7. Select Quantity.
 - Minimum: Two instances for a 2-node cluster.
8. Select Image.

-
- For image you created from **CT - VL QCOW2** image file , select **Custom**.
 - For image shared by Thales Customer Service Support, select **Shared Image** and look for CT-VL.

9. Select Storage.

- Enhanced SSD or Standard SSD.
- Use 85GB as shown (DO NOT CHANGE).
- Optional: Release with Instance or Disk Encryption.

10. Select Network Type: VPC.

11. Optional: Select Public IP Address: Assign Public IPv4 Address.

12. Select Security Group. Security group must allow SSH and HTTPS access.

13. Select Logon Credentials: Set Later.

Note

Key Pair is currently not supported. If you select Key Pair, it will be ignored.

14. Provide Instance Name.

15. Select Create Instance.

Tasks

This section contains the following articles:

- [Configuring CT-VL through the Command Line](#)
- [Registering CT-VL VM with Key Manager](#)
- [Configuring CT-VL Nodes](#)
- [Configuring an AD/LDAP Server](#)
- [Configuring ADFS and LDAP for OAuth](#)
- [Configuring LDAP Settings.ini File](#)
- [Working with CT-VL GUI](#)
- [Dashboard API Monitoring](#)

-
- Administrator History Logs
 - Backing Up and Restoring CT-VL
 - Upgrading CT-VL
 - Monitoring Through SNMP

Configuring CT-VL through the Command Line

This topic describes how the network administrator uses the CT-VL Command Line Interface (CLI) to configure the CT-VL environment, establish connections between the various components, and other system-level tasks.

Accessing the CLI

The network administrator uses the CT-VL CLI to configure the CT-VL environment as described below:

1. Access the CLI through a terminal emulator like PuTTY.
2. On first access, enter the default login and password:

login: `cliadmin`

Password: `cliadmin123`

3. On first access, you will be prompted to change the password. **Save and store your new password securely.**
4. On first access, you will be prompted to review and sign the License Agreement.

Refer to [CT-VL CLI Navigation Summary and Guidelines](#) for description about CT-VL CLI commands.

Basic Configuration Steps

Note

- The configuration steps in the following sections employ a subset of the CLI commands. See [CT-VL CLI Reference](#) for a summary of CLI commands. For complete usage details on any CLI command, run the command with the `--help` option.
- For multi-node installations, the basic configuration steps in this section must be completed on each node before you [Configure CT-VL Nodes](#).

Configure the CT-VL Network Settings

Configure the network settings for VMware and bare metal installations with a static IP implementation.

Note

Network settings are required only for VMware and bare metal installations, with a static IP implementation. Do not attempt to set the IP address and gateway of the network interface if you are using CTS in an Azure, Amazon, or Google Cloud Platform. Cloud providers assign the IP addresses to the VM through DHCP.

To configure the CT-VL network settings, complete the following tasks:

- Set the IP address for the CT-VL VM.
- Configure the CT-VL DNS server or use the `/etc/hosts` file.

Check [Deployment Prerequisites](#) for the IP address, gateway address, and DNS values you will need.

Set the IP Address for the CT-VL VM

1. Using the CT-VL CLI, navigate to the *network* commands menu.
2. There are two ways to set the IP address for the CT-VL VM: Interactive (with the `setup` command) or Non-interactive (with the `set` command).

Interactive

To set the IP address using the interactive mode, use the `setup` command followed by the network device name:

```
network> setup eth0
```

Using the `setup` command prompts you for the IP address, as well as other information required to set up the specified network device, such as subnet mask, gateway, and so on.

Non-interactive

To set up the IP address with the non-interactive mode, use the `set` command with the `--ipaddr IPADDR` option and argument value. With the same `set` command invocation, you can also configure other network and device parameters with additional options:

```
ct-vl> network set --help
usage: set [-h] [--onboot {yes,no}] [--dhcp] [--ipaddr IPADDR]
[--netmask NETMASK] [--gateway GATEWAY] [--defroute {yes,no}]
[--mtu MTU] [-y]
device
Configure Network Interface
[. . .]
```

Options and Arguments to the Non-interactive `set` Command:

Option	Argument	Description
<code>--onboot</code>	yes	no
<code>--dhcp</code>		Use DHCP
<code>--ipaddr</code>	IPADDR	Set the IPv4 address of this device to IPADDR
<code>--netmask</code>	NETMASK	Sets the netmask of this device to NETMASK (for example, 255.255.0.0)
<code>--gateway</code>	GATEWAY	Specify the gateway IP address as GATEWAY.
<code>--defroute</code>	yes	no
<code>--mtu</code>	MTU	Set the maximum transmission unit (MTU) value to MTU
<code>-y</code>		Do not prompt for confirmation

3) Verify the IP address configuration using the `show` command followed by the device name:

```
network> show eth0
```

Configure the CT-VL DNS Server

If your network environment uses DNS, use the `dns` command to configure the nameservers:

```
network> dns --add IP [IP ...]
```

You can configure a maximum of three nameservers.

Show the DNS settings with the `--show` option:

```
network> dns --show
DNS resolver is using DHCP
Generated by DHCP:
nameserver 192.168.100.199
nameserver 192.0.0.299
```

Note

If you are using DHCP, using the `dns` command overrides the nameservers provided by the DHCP.

The `/etc/hosts` file

If you have hostnames that do not use DNS, you can use the local `/etc/hosts` file to resolve IP addresses. To

update this file, run the CLI `system hosts` command, which includes options to add or remove IP addresses, and to show the `hosts` file contents.

```
main> system hosts
usage: hosts [-h] [--show] [--add IP [HOSTNAME ...]] [--remove IP]
Update hosts file
optional arguments:
-h, --help show this help message and exit
--show Show hosts file entries
--add IP [HOSTNAME ...]
Add/update hosts entry
--remove IP Remove hosts entry
```

For example:

```
main> system hosts --add 192.168.99.99 rgrimes
192.168.99.99 rgrimes
10.3.110.187 cts-builder2
main> system hosts --show
192.168.99.99 rgrimes
10.3.110.187 cts-builder2
```

Note

You must do this on each CT-VL, since entries in the hosts file are not replicated across CipherTrust Vaultless Tokenization Server.

Setting the CT-VL Hostname

Set a hostname for the CT-VL VM. This hostname will be used to identify the CT-VL when the CipherTrust Manager issues a client-certificate.

To set the hostname of the CT-VL VM, run the `system hostname` command with the `--set` option in the CT-VL CLI:

```
main> system hostname --set your_cts_hostname
```

Importing a Server Certificate for TLS

Use the `ct-vl server_certificate` command in the CT-VL CLI to import a server certificate.

Enter the command without any options to see a detailed help message that explains all arguments to the command (some of which are deleted from the example shown below to save space):

```
main> ct-vl server_certificate
usage: server_certificate [-h] [--import {certificate,key}]
[--create {csr,selfsigned,key}] [--size SIZE]
[--show {key,certificate}] [-y] [--country C]
```

```
[--state ST] [--locality L] [--organization O]
[--organizational_unit OU] [--common_name HOSTNAME]
[--email EMAIL] [--dns [DNS [DNS ...]]] [--days DAYS]
Server Certificate Utility
optional arguments:
-h, --help show this help message and exit
--import {certificate,key}
import a certificate or private key
--create {csr,selfsigned,key}
create a certificate signing request, a self-signed certificate, or a new private key.
a certificate signing request is created using [ . . . ]
```

Certificates in PEM Format

All certificates used in CT-VL must be in PEM format. The following is an example of a certificate in PEM format:

```

-----BEGIN CERTIFICATE-----
MIIDrTCCAxagAwIBAgIBADANBgkqhkiG9w0BAQQFADCBnDEbMBkGA1UEChMSVGHl

-----END CERTIFICATE-----

```

Option 1: Regenerating a Self-signed Server Certificate

To generate a self-signed certificate, run the `ct-vl server_certificate` command with the `--create selfsigned` option:

```
main> ct-vl server_certificate --create selfsigned
```

Enter answers to the informational questions, and restart the web server when asked.

Option 2: Importing an Authenticated Third-party Server Certificate (Recommended)

To import an authenticated third-party CA certificate to the CT-VL, follow the steps below:

1. In the CT-VL CLI, go to the `ct-vl` category, and enter `server_certificate --create csr` to generate a certificate request:

```
main> ct-vl
ct-vl> server_certificate --create csr
```

2. Follow the system prompts. A certificate request displays at the command line:

```
----- BEGIN CERTIFICATE REQUEST -----
. . .
----- END CERTIFICATE REQUEST -----
```

3. Copy and paste the certificate request including the "REQUEST" lines onto a third-party certificate request form, such as GoDaddy, Thawte, or Verisign.
4. After receiving the certificate, at the `ct-vl` command category, run `server_certificate --import certificate` at the command line:

```
ct-vl> server_certificate --import certificate
```

5. When prompted to continue, enter `yes`.
6. Note that the certificate must be in PEM format. Copy and paste the entire certificate including the CERTIFICATE lines, as shown in the example below:

```
-----BEGIN CERTIFICATE-----
MIID1TCCAr2gAwIBAgIJAMf9x1/DhPfPMA0GCSqGSIb3DQEBCwUAMIGAMQswCQYD
VQQGEwJVUzETMBEGA1UECAwKQ2FsaWZvcn5pYTERMA8GA1UEBwwIU2FuIEpvc2Ux
. . .
9hZV7uAAnRzqaodIPQYAQBwbj58/eo8hMw4JflfJwTavZuFt/hpnbxEECynd+s4
cLSgBd7x4aeDKt0vinSvBv2niyZyL0v1eg==
-----END CERTIFICATE-----
```

7. Enter `Ctrl-d` to end the input.
8. The CT-VL imports the certificate and tries to verify that the imported certificate matches the private key generated at the time the certificate was generated.
9. The system prompts you to restart the web server. Type `yes`.
10. The web server component of the CT-VL is restarted, and the new certificate takes effect. The system is set up using the third-party server certificate for TLS connections.

Registering CT-VL with CM
Configuring CT-VL Nodes
Configuring an AD/LDAP Server
Configuring ADFS and LDAP for OAuth
Configuring the settings.ini file for LDAP
Restarting CT-VL server

Restarting CT-VL

After all CLI configuration is completed:

1. Navigate to the ct-vl commands menu:

```
main > **ct-vl**
ct-vl
```

2. Restart the web server component of CT-VL:

```
ct-vl> service --restart
Restarting ct-vl (via systemctl)   [OK]
ct-vl>
```

Registering CT-VL VM with CipherTrust Manager

Complete the following procedure to register CT-VL with the CipherTrust Manager (CM) server.

1. Create a user and set a password for it.

Besides client certificate authentication, CM servers require user/password authentication for key access.

2. **Optional:** Create a user-group on the CM server.

In addition to granting key access to a user, key access can be granted to a group. Users belonging to that group have access to the group keys.

3. Create symmetric AES keys for CT-VL use on the CM server using the properties below:

- Key type: **AES**
- Key size: **256 bits**
- Exportable: **yes**
- Prevent keys from being deleted: **yes**

- Key properties: **Encrypt** and **Decrypt**
- Owner: **CT-VL user in Step #1 above**
- Group: **Group in Step #2 above**

Note

Check for [Recommendations for Secure Initialization Vector](#) in encryption requests.

4. If not already created, create a local CA on the CM server.

This will be used by CT-VL for client certificate authentication.

5. Create an NAE interface on the CM server using the following properties:

- Type: **NAE**
- Port number: **9000**
- Mode: **TLS**; user must supply password; verify client certificate
- Username Location in Certificate: **CN**
- Local CA: (select)
- Network interface: (select)

6. Set up CT-VL with IP(s), port, and user credentials to the CM server.

- a. Log in to the CT-VL CLI and run the `icapi --set` command:

```
icapi set --IP <CM_ip> --port 9000 --user ctvluser
```

- b. If the `ctvluser` is under a domain, supply the domain name as shown below. Take note of the double bar (pipe) character separating the `domainname` and `ctvluser`.

```
icapi set --IP <CM_ip> --port 9000 --user domainname|ctvluser
```

- c. When prompted, enter the password of the `ctvluser` on the CM server.
- d. If the key manager is a cluster of servers, supply all the IP addresses of the servers in the cluster. For example:

```
icapi set --IP ip1 ip2 ip3 --port 9000 --user <ct-vl-user>
```

- e. Run the **icapi show --properties** command to inspect the settings made. For example:

```
main> icapi show --properties
Client_Cert_Authentication yes
KEYSTORE_PASSWORD *****
KEYSTORE_USER ctvluser
NAE_IP ['10.3.211.79']
NAE_Port 9000
Protocol ssl
Version 3.1
```

7. Register CT-VL to the CM server with either an automated registration or a manual registration.

- To perform automated registration:

- a. Log in to the CT-VL CLI and run the **icapi register** command. For example:

```
main> icapi register --host 10.3.211.79 --user <adminuser>
```

This command requires the user credentials on the CM server that has admin rights to the local CA. It creates a client certificate on the CT-VL that is signed by the CM server. This serves as the client certificate authentication whenever CT-VL connects to the CM server.

This command prompts for the password of the CM admin user and the information to create the certificate.

For example:

```
main> icapi register --host 10.3.211.79 --user admin password:
Running registration will delete any existing CA and client certificates.
Do you wish to continue? <y/n> [n] y
Country Name (2 letter code) [US]:
State or Province Name [California]:
Locality Name (e.g., city) [San Francisco]:
Organization Name (e.g., company):

subject : /C=US/ST=California/L=San Francisco/CN=ctvl-250-263-202

```

A successful registration will display the client certificate information and its fingerprint.

- b. Log in to the CM server and verify that the certificate information and fingerprint match

Notes:

- If the CM server has more than one Local CA, the automated registration uses the first Local CA found. If the desired Local CA is not the first on the list, use the **--caid** option to supply the ID of the desired Local CA. You can use the **show --LocalCAs** command to view the ID of all the local CAs on the CM server:

```
main> icapi show --LocalCAs --user <adminuser>
```

- By default, the certificate is set to expire in 10 years. Use the **--days** option to set the desired expiration.
- The registration command can be run in non-interactive mode by supplying all parameters to the command. Run the **icapi register --help** command for details.
- To perform manual CM registration:

Use the following procedure to register CT-VL to a CM server. You can also use this manual procedure if you do not want to automatically register, or for some other reason cannot automatically register.

Some reasons for using manual registration include:

- Network connectivity from CT-VL to CM is not yet in place.
- The user performing auto-registration does not have administration credentials to the CM server. The user credentials to perform registration must include permission to run REST APIs on the server, permission to download the Local CA, and permission to sign a certificate request.
- Access to the REST API (port 443) of the CM server is blocked.
- An imported private key is desired instead of letting CT-VL generate a random key internally.
- A common client certificate is desired for several CT-VL servers, for example, with CT-VL servers in a

cluster.

Steps:

- a. Create a certificate private key on the CT-VL:

```
main> icapi create --client_key
```

You may import a private key instead of letting CT-VL create one. Use the **icapi upload** command to import a private key.

- b. Create a certificate signing request:

```
main> icapi create --csr
```

This command creates a certificate signing request using the private key you have created or imported.

- c. Using the CSR you now generated, log in to the CM server and locate the Local CA to sign the CSR.

The signed CSR produces a certificate in PEM format.

- d. Import the signed certificate into the CT-VL using the upload command:

```
main> icapi upload --client_certificate
```

- e. Log in to the CM server and download the Local CA. Import this certificate into the CT-VL using the **icapi upload --CA_certificate** command:

```
main> icapi upload --CA_certificate
```

Note

When a self-signed certificate has been added, chain construction stops. In this case, it must fully match a trust anchor, otherwise chain building fails. If you are using a self-signed NAE server certificate, add the issuer of the self-signed certificate to the Trusted CAs list on the client even if the root CA is already added to this list.

The NAE server certificate will be considered a self-signed certificate if the **Issuer** and **Subject** fields are the same in the certificate.

8. Enable ICAPI.

Run **icapi enable yes** command to enable CT-VL access to the CM server. For example:

```
main> icapi enable yes
Restarting vts (via systemctl):      [ OK ]
ICAPI properties updated
```

9. Test connectivity to the CM server.

Use the **icapi test --server_connection** command to test server connectivity to the CM server. For example:

```
main> icapi test --server_connection
Test server connection using user: vts-user1
10.3.211.79: OK
```

This command tests the connection and authentication to the CM server. A successful authentication confirms correct CM user credentials and a valid client certificate.

10. Test access to an AES key.

Use the **icapi test --key** command to test access to an AES key on the CM server. For example, to test access to a CM key named vts-key:

```
main> icapi test --key vts-key
vts-key: OK
```

This command tests if the saved user credentials provide proper access to the specified key. This test requires correct user and client certificate authentication to the CM server.

Troubleshooting and Automation Tips

- Make sure the **icapi test** CLI commands pass before setting up CT-VL for tokenization use.
- Use the **icapi show** CLI command to inspect if the icapi agent is enabled or not, if certificates are created or uploaded, and if server settings are correct.
- All CLI commands can be run in non-interactive mode. This mode is ideal for automating setup.

Security Tips

Consider the following guidelines when configuring CT-VL to ensure maximum security:

- When setting up the NAE interface, it is highly recommended to use the following mode for best security:
 - TLS, user must supply password, verify client cert.
 - Although other modes are possible, anything other than the above would be less secure.
- When creating a user for CT-VL to use on the CM server, do not use a user with admin privileges or access to

any keys that CT-VL will not use. The Keystore user should only have the following:

- login access.
- key access privileges.
- access to the keys that CT-VL will use.

Note

Do not add the Keystore user to the "Key Users" group as this may allow the user access to keys that CT-VL does not use. Preferably, create a group for CT-VL, assign to that group all the keys that CT-VL will use, and then add the Keystore user to that group.

Configuring CT-VL Nodes

To set up a CT-VL system, a single Virtual Machine (VM) or multiple VMs can be used to form a cluster of nodes operating as one coherent CT-VL system.

A cluster of nodes is useful to achieve scalability and high availability. You can set up a CT-VL cluster manually, or using an automated process.

It is highly recommended to use the automated process. It is easier to follow and less error-prone, especially when setting up a cluster of more than two nodes.

A CT-VL system is set up by creating the first node in the cluster. At a minimum, a CT-VL system can run with just one node. It is still considered a cluster, but with only one node. Additional nodes can then be added to the cluster.

Note

CT-VL supports up to 16 nodes in a cluster.

Automated Cluster Setup

To automatically set up a cluster:

1. Log into the CLI and enable the `apiadmin` user on all nodes will join the CT-VL cluster. Enabling the `apiadmin` user requires setting a password. By enabling the `apiadmin` user, the primary node will be able to access a remote node and join it to the cluster:

```
main> cluster apiadmin [--enable] [--setpasswd PASSWORD]
```

2. Choose a node to start your cluster. Log into the CLI and run the command below. This `create` command

will initialize the node as the first node of the cluster:

```
main> cluster create
```

3. On the same node, start joining other nodes to the cluster, by running the `remotejoin` command specifying the IP addresses of the other nodes you wish to join the cluster:

```
main> cluster remotejoin NODE_IP [NODE_IP ...]
```

4. It is recommended to disable the `apiadmin` user after you have finished the automated cluster setup. Run the command below on all nodes to disable `apiadmin` access:

```
main> cluster apiadmin --disable
```

5. To add a new node to the cluster at a later time, re-enable the `apiadmin` user on all nodes of the cluster. Run the `remotejoin` command as before to add more nodes to that cluster:

Note

The `remotejoin` command can be run from any active node in the cluster.

Warning

Since a node joining a cluster will mirror the data of the cluster, any existing data in that node will be destroyed.

```
main> cluster remotejoin NODE_IP [NODE_IP ...]
```

Manual Cluster Setup

Similar to automated setup above, choose a node to start your cluster. Run the `cluster create` command to initialize the node as the first node of the cluster. The command requires the following parameters:

- **IP** - IP address of this node. It is highly recommended to use the internal IP, for example, the VPC IP address of this node. The IP address is optional if creating a cluster node using existing data (with the `--preserve` option).
- **USERNAME** - WebUI Admin username.

- **PASSWORD** - WebUI Admin password.
- **EMAIL** - WebUI Admin email.

The `cluster create` command supports both interactive and non-interactive modes. See the `--help` option output for details on how to use:

```
main> cluster create --help
usage: create [-h] [-u USERNAME] [-p PASSWORD] [-e EMAIL] [--preserve] [-y]
[IP]
usage: create [-h] [-u USERNAME] [-p PASSWORD] [-e EMAIL] [--preserve] [-y]
[IP]
```

Once this command completes, you can log in to the CT-VL Web UI using the credentials entered above. Load the Web UI by loading the node IP address or the external IP address of the VM:

- `https://node_IP`
- `https://external_IP`

Manually Adding Nodes to a Cluster

Unlike the automated process above, manually adding nodes to a cluster is more complicated. This process does not require `apiadmin` access. A node joining a cluster must be initiated from the node that is joining.

Although the node joining will only contact one active node in the cluster, all other active nodes in the cluster must be informed of the new node that is joining.

Similarly, the node that is joining must be informed of all the active nodes in the cluster. This aspect is crucial since data from each node in the cluster must be able to replicate on all nodes in the cluster. Informing a node is done by using the `cluster add` command.

Similar to the automated process, a cluster is created by choosing the first node of the cluster. This is done by running the `cluster create` command. This will create a cluster but with only one node.

Note

Before running the `join` command, the `add` command must be run on the first node. This is a way of telling the first node that an additional node will be joining the cluster. Simply running the `join` command on the new node will not work. The first node must know about the new node by running the `add` command.

To add a second node to a cluster:

1. Log in to the CLI of the first node and run the cluster add command:

```
main> **cluster add NODE2_IP**
```

where `NODE2_IP` is the IP address of the new (second) node joining the cluster.

2. Log in to the CLI of the second node. Run the **add** command for the first node, and then the **join** command:

```
main> **cluster add NODE1_IP**  
main> **cluster join NODE2_IP NODE1_IP**
```

The **join** command requires two parameters: **NODE2_IP** (the current, new node IP) and **NODE1_IP** (the existing cluster node IP).

The **add** command is optional and not necessary since the **join** command will take care of it. However, if you are joining a cluster already having more than one node in the cluster, you must run the **add** command for all nodes already in the cluster.

The **join** command only lets you select one node_ip to join for connectivity purposes, but you will need to tell the system all the other nodes in the cluster you are joining and that is accomplished by running the **add** command.

Example: Manually Setting up a Four-node CT-VL Cluster

The following procedure shows how to manually set up a CT-VL system with four nodes, with IPs **NODE1_IP**, **NODE2_IP**, **NODE3_IP**, and **NODE4_IP**.

1. On node1, run the **create** command:

```
main> **cluster create NODE1_IP**
```

2. On node1, run the **add** command for all nodes:

```
main> **cluster add NODE1_IP**  
main> **cluster add NODE2_IP**  
main> **cluster add NODE3_IP**  
main> **cluster add NODE4_IP**
```

Note

The **add NODE1_IP** command above is redundant since **NODE1** is already joined to the cluster. But for clarity, this repetition shows that the system must be told of all nodes joining the cluster.

3. Repeat the same **add** commands shown in Step 2 on nodes **NODE2**, **NODE3**, and **NODE4**.
4. Log in to **NODE2** and run the **join** command:

```
main> **cluster join NODE2_IP NODE1_IP**
```

5. Log in to **NODE3** and run the **join** command:

```
main> **cluster join NODE3_IP NODE1_IP**
```

Note

NODE3 can also be joined to the cluster using NODE2_IP as the second parameter instead of NODE1_IP. This is because NODE2 is already joined to the cluster. Any node can be used as the second parameter as long as that node is already joined to the cluster. **For example**, the following is equivalent to the preceding example above:

```
main> **cluster join NODE3_IP NODE2_IP**
```

6. Repeat the `join` command for NODE4.

```
main> **cluster join NODE4_IP NODE2_IP**
```

Log in to the GUI on all nodes and verify that they are all replicating. Changing a value in the GUI of one node should be reflected in the same changes on all other nodes.

Note

To add a new node to a cluster, all nodes in the cluster must be online. No new nodes can be added if not all nodes in the cluster are online.

Remove a Node from a Cluster

The process of removing a cluster node is the same for a manually-created cluster as it is for an automatically-created one.

To remove a node from a cluster, run the `remove` command from one node -- any node except the node that will be removed. You only need to run the `remove` command on one node. All other nodes see this command and remove the node from their system.

As with adding a node to a cluster, to remove a node from the cluster, all nodes must be online so that they will know that a node is being removed.

Note

- The order of the list of the CipherTrust Managers used by CT-VL does not matter. CT-VL picks a CipherTrust Manager to be used in a round-robin manner.

- The CipherTrust Manager used to register CT-VL does not have preference for usage. After a CT-VL is registered, it only retains the certificate of the CipherTrust Manager when registered. That certificate is present on all the CipherTrust Managers in the cluster (due to replication), thus CT-VL thinks all of them are the same.

CT-VL may continue to add more CipherTrust Managers to the CipherTrust Manager cluster without registering. It may even remove the original CipherTrust Manager from the cluster when registered without having any impact.

Configuring an AD/LDAP Server

The Active Directory/LDAP server is optional. However, you can use it to import CT-VL users and CT-VL GUI Administrators. See [Active Directory/LDAP Server Requirements](#) before configuring. You must configure the AD/LDAP server on every node in your CT-VL HA cluster.

1. Go to the `auth` command category in the CT-VL CLI to see the `ldap` command.

```
main> auth
auth$ ?
      Command      Description
      =====
      ldap          LDAP Setup
      oauth2        OAuth2 Setup
```

2. Like all CLI commands, you can type the command without a parameter and a usage example is displayed:

```
auth> ldap
usage: ldap [-h] [--show] [--setup] [--enable {true,false}]
           [--server SERVER_URI] [--bind_dn BIND_DN]
           [--bind_password PASSWORD] [--user_prefix PREFIX]
           [--user_search_filter FILTER]
           [--user_search_scope SCOPE] [--group_search_scope SCOPE]
           [--active_user_group GROUP] [--staff_user_group GROUP]
           [--super_user_group GROUP]
           [--ca_cert {import,remove,show}] [--test {bind_dn}]
           [--query_user NAME] [-y]

LDAP Setup

optional arguments:
-h, --help            show this help message and exit
--show               show LDAP settings
```

```
[ . . . ]
```

3. Disable, then enable LDAP support in the Tokenization Server:

```
auth> ldap --enable false
LDAP settings have been saved
auth> ldap --enable true
Restarting cts (via systemctl):      [ OK ]
LDAP settings have been saved
auth>
```

Note

If you disable LDAP support, then you can use only the CT-VL GUI to create users and groups.

4. Set the AD/LDAP server URI with the `--server` command (where the default port number for an LPDAS server is 636):

```
auth> ldap --server ldaps://<hostname_or_IP_address>:<Port>
```

or (where the default port number for an LDAP server is 389):

```
auth> ldap --server ldap://<hostname_or_IP_address>:<Port>
```

Example:

```
auth> ldap --server ldap://192.168.118.99:389
LDAP settings have been saved
auth>
```

5. Set the binding DN of the user who has access to the AD/LDAP server with password. Example:

```
ldap --bind_dn <FQDN of user with access to LDAP Server>
```

Example:

```
auth> ldap --bind_dn cts0@cts.vormetric.com
Enter Password :
```

```
Enter Password again :  
Set LDAP Bind User DN SUCCESS  
auth>
```

6. Set user search scope using `user_search_scope` command:

```
ldap --user_search_scope <User search scope>
```

Example:

```
auth> ldap --user_scope dc=cts,dc=vormetric,dc=com  
LDAP settings have been saved  
auth>
```

7. Set group search scope using the `group_search_scope` command:

```
ldap --group_search_scope <Group search scope>
```

Example:

```
auth> ldap --group_search_scope CN=Users, dc=cts,dc=vormetric,dc=com  
LDAP settings have been saved  
auth>
```

8. Set attribute field for user search filter using the `user_search_filter` command:

```
ldap --user_search_filter <Name of user field in AD/LDAP>
```

Example:

```
auth> ldap --user_search_filter sAMAccountName  
LDAP settings have been saved  
auth>
```

9. Set user prefix name using `user_prefix` command. The user prefix is the attribute that should be used to prefix the user name when searching for the user name in the LDAP database.

```
ldap --user_prefix <User prefix name. Example: uid or cn or sn>
```

Example:

```
auth$ user_prefix uid
Set LDAP USER PREFIX SUCCESS
```

10. Set the Tokenization Server active user group using the `active_user_group` command:

```
auth> ldap --active_user_group <Group whose members can access the RESTful AP
I>
```

In this example, any user who wants access to the CTS RESTful API, must belong to the AD group `ctsUsers` within Users of the domain `cts.vormetric.com`:

```
auth> ldap --active_user_group cn=ctsUsers,cn=Users,dc=cts,dc=vormetric,dc=com
LDAP settings have been saved
auth>
```

11. Set the CT-VL superuser group using the `--super_user_group` command:

```
ldap --super_user_group <Group that can access the Tokenization Server GUI & A
PIs>
```

In this example, any user who requires access to the CTS GUI and REST APIs, must belong to the AD group `ctsSuperuser` within Users of domain `cts.vormetric.com`:

```
auth> ldap --super_user_group cn=ctsSuperuser,cn=Users,dc=cts,dc=vormetric,d
c=com
LDAP settings have been saved
auth>
```

12. **For LDAPS Support Only:** Import the CA certificate chain of the LDAP server to the built-in LDAPS client of CT-VL. A Certificate Management tool like DigiCert or Certificate Manager tool is recommended to request the certificate, after which use the `--ca_cert` option to import the certificate into the CT-VL.

Note

The `--ca_cert` option uses an underscore (`_`) instead of a hyphen (`-`).

- a. Using a Certificate Management tool like DigiCert or Certificate Manager tool, download your intermediate and root certificates.

Note

CT-VL requires all certificates to be in PEM format.

- b. Run `--ca_cert` import to import the certificate trust chain. Paste the entire body of each certificate in the order shown in the example, then terminate with Ctrl-d when finished.

```
auth> ldap --ca_cert import
Cut-and-paste below a CA Certificate in pem format. Press Ctrl-d when done.
-----BEGIN CERTIFICATE-----
(Your Intermediate certificate: DigiCertCA.crt)
-----END CERTIFICATE-----
-----BEGIN CERTIFICATE-----
(Your Root certificate: TrustedRoot.crt)
-----END CERTIFICATE-----
Restarting cts (via systemctl): [ OK ]
LDAP CA Certificate has been uploaded.
auth>
```

13. Execute the `--show` option to list the LDAP configuration:

```
auth> ldap --show
ENABLE true
SERVER_URI ldap://192.168.118.99:389
BIND_DN cts0@cts.vormetric.com
BIND_PASSWORD *****
USER_SEARCH_SCOPE dc=cts,dc=vormetric,dc=com
GROUP_SEARCH_SCOPE CN=Users,dc=cts,dc=vormetric,dc=com
USER_SEARCH_FILTER sAMAccountName
ACTIVE_USER_GROUP cn=ctsUsers,cn=Users,dc=cts,dc=vormetric,dc=com
SUPER_USER_GROUP
auth>
```

Configuring ADFS and LDAP for OAuth

Follow these procedures to configure Active Directory Federated Services (ADFS) and LDAP for an OAuth authentication option.

Export Certificate

Below are the steps to export a certificate for CT-VL:

-
1. Open Server Manager.
 2. Click **Tools** and select **ADFS Management**.
 3. Click **Certificates**.
 4. Double-click on **Token-signing certificate**.
 5. In the *certificate* window, select **Details** tab.
 6. Click **Copy to File...**
 7. Click **Next**.
 8. Select **Base64 format** and click **Next**.
 9. Enter file name.

Add an Application Group

Below are the steps to add an application group:

1. Open Server Manager.
2. Click **Tools** and select **ADFS Management**.
3. Right click **Application Groups** and select **Add Application Group** wizard.
4. Enter name and select **Native application accessing a web API**.
5. Copy **Client Identifier** to a template for later use.
6. Enter your CT-VL login URL in **Redirect URI field** (<https://login>) and click **Add**.
7. Click **Next**.
8. Enter the same CT-VL URI as entered in previous step in the **Identifier** field and click **Add**.
9. Click **Next**.
10. Use default (**Permit everyone**) and click **Next**.
11. Click **Next** on the review page.
12. Click **Close**.

Add Properties to a New Group

Below are the steps to add properties to a new group:

1. Double-click on the desired new group.
2. Select - **Web API** and click **Edit**.
3. Select **Issurance Transform Rules** and click **Add Rules**.
4. Select **Claim rule template: Send LDAP Attributes as Claims**.
5. Click **Next**.
6. Enter a rule name.
7. Add the following rules:
 - Token-Groups - Unqualified Names : Group
 - User-Principal-Name : UPN
 - SAM-Account-Name : Name
 - Surname : Surname
 - Given-Name : Given Name
8. Click **Finish**.
9. Click **OK**.

Test ADFS Authentication

To test ADFS authentication:

```
curl -k -X POST https://<adfs server>/adfs/oauth2/token -d  
'grant_type=password&username=<user>&password=<password>&client_id=<client_id>5&resource=https%3A%2F%2Fmickeymouse'
```

The expected response is:

```
{"access_token": "eyJ0eXA... mVSpzmW-FBDlg"}
```

Configuring LDAP Settings.ini File

Set up the `settings.ini` file according to which LDAP scenario you implement:

- AD Email
- AD DN
- Linux LDAP DN

To test your settings, use the CLI option `--query_user` to the `ldap` command:

```
auth> ldap --query_user NAME
```

AD Email

The following is an example `settings.ini` configuration for an LDAP setup with AD email:

```
auth> ldap --show
SERVER_URI ldap://10.3.118.98:389
BIND_DN cts0@cts.vormetric.com
BIND_PASSWORD *****
USER_PREFIX
USER_SEARCH_FILTER sAMAccountName
USER_SEARCH_SCOPE CN=Users,DC=cts,DC=vormetric,DC=com
GROUP_SEARCH_SCOPE CN=Users,DC=cts,DC=vormetric,DC=com
ACTIVE_USER_GROUP CN=ctsUsers,CN=Users,DC=cts,DC=vormetric,DC=com
STAFF_USER_GROUP CN=ctsManager,CN=Users,DC=cts,DC=vormetric,DC=com
SUPER_USER_GROUP CN=ctsAdmin,CN=Users,DC=cts,DC=vormetric,DC=com
ENABLE true
```

AD DN

The following is an example `settings.ini` configuration for an LDAP setup with AD DN:

```
auth> ldap --show
SERVER_URI ldap://10.3.118.98:389
BIND_DN CN=cts User0,CN=Users,DC=cts,DC=vormetric,DC=com
BIND_PASSWORD *****
USER_PREFIX CN
USER_SEARCH_FILTER cn
USER_SEARCH_SCOPE CN=Users,DC=cts,DC=vormetric,DC=com
GROUP_SEARCH_SCOPE CN=Users,DC=cts,DC=vormetric,DC=com
ACTIVE_USER_GROUP CN=ctsUsers,CN=Users,DC=cts,DC=vormetric,DC=com
STAFF_USER_GROUP CN=ctsManager,CN=Users,DC=cts,DC=vormetric,DC=com
SUPER_USER_GROUP CN=ctsAdmin,CN=Users,DC=cts,DC=vormetric,DC=com
ENABLE true
```

Linux LDAP DN

The following is an example `settings.ini` configuration for setup with LDAP DN on Linux:

```
auth> ldap --show
SERVER_URI ldap://10.10.62.132:389
BIND_DN uid=tuser1,ou=People,dc=i,dc=vormetric,dc=com
BIND_PASSWORD *****
USER_PREFIX uid
USER_SEARCH_FILTER uid
USER_SEARCH_SCOPE ou=People,dc=i,dc=vormetric,dc=com
GROUP_SEARCH_SCOPE ou=Groups,dc=i,dc=vormetric,dc=com
ACTIVE_USER_GROUP cn=ctsUsers,ou=Groups,dc=i,dc=vormetric,dc=com
```

```
STAFF_USER_GROUP cn=ctsManager,ou=Groups,dc=i,dc=vormetric,dc=com  
SUPER_USER_GROUP cn=ctsAdmin,ou=Groups,dc=i,dc=vormetric,dc=com  
ENABLE true
```

Working with CT-VL GUI

Use the CT-VL administration GUI to:

- Create tokenization users and groups.
- Specify permissions for users and groups.
- Create token templates.
- Create token groups.

Logging into the CT-VL GUI

To log in to the CT-VL administration GUI:

1. Point your browser to the Tokenization Server:

```
https://<CT-VL name or IP address>/
```

2. Log in using the Admin user name and password you defined when you created the CT-VL cluster.
3. If you have implemented OAuth authentication, log in with those credentials.

The CT-VL GUI Home page is displayed.

Troubleshooting

The CipherTrust Vaultless Tokenization Server Administration GUI login failure is indicated by the following error message:

```
nginx 504 Gateway Time-out error
```

In this scenario, consider the following problem/solution option:

- **Problem:** The Tokenization Server is not connected to the LDAP server.
- **Solution:** Restart the CT-VL service. Open the CT-VL CLI, and run the following command:

```
main> vts service --restart
```

Creating and Managing Passwords

CT-VL uses a dynamic password policy control mechanism to ensure system security.

CT-VL leverages a password checker library. If you try to create a password that does not pass the proactive password checking provided by this library, you are prompted to try another string. The policy can change dynamically based on several factors.

The dynamic nature of the checking algorithm provides the most secure possible password policy options.

When creating a system password, use the following guidelines:

- Use at least 1 digit, 1 uppercase letter, 1 lowercase letter, 1 special character, and use at least 8 characters in total.
- Do not use your name, the company name, or other familiar names in the password string.
- Do not use your birthday or any other personally or professionally meaningful dates in the password string.
- Include a combination of the following character types in the password string:
 - Lowercase letters
 - Uppercase letters
 - Numbers
 - Special characters

Managing CT-VL User Groups

User groups enable you to assign the same permissions to multiple users.

Refer to [CT-VL Roles](#) and [Understanding CT-VL User Groups and Permissions](#) to familiarize yourself with user groups in CT-VL.

If you are using AD/LDAP users, create at least three user groups, to correspond to the CT-VL roles:

- Superuser
- Staff
- Active

User groups must be defined on the LDAP system. The user group names must be entered into the CT-VL GUI before importing users.

Creating User Groups

To create a user group:

- 1) Log in to the CT-VL GUI and select **User Groups** from the navigation bar. **All User Groups** list is displayed.

2) Select **New User Group** and enter a name on the resulting page. Click **Create**. The new group name appears in the **All User Groups** list, and is selectable from user pages and the *Permissions* page.

Assigning Masks

You can assign a mask to a group when initially creating the user group (at the *New User Group* dialog), or any time later to an existing user group, by clicking the user group and adding a mask assignment at the *Update User Group* dialog.

Adding Users to User Groups

To add a user to an existing user group:

- 1) From the CT-VL GUI, select **User Groups**.
- 2) Click on a group from the list.
- 3) Select users to add to the group, and click **Update**.

Deleting a User Group

To delete a user group:

1. Log in to the CT-VL GUI and select **User Groups** from the navigation bar.
2. Select the check box by a group.
3. Click **Delete**. A dialog box appears asking you to confirm your action.

Note

If you delete a user group to which users and/or permissions have been associated, the user group is removed from any user belonging to it, and will delete any permissions assigned to it.

Managing CT-VL Users

Refer to [Understanding CT-VL Authentication and Authorization](#) for details on CT-VL users and CT-VL authentication and authorization basics.

You can perform the following to manage CT-VL users:

- Create a user manually.
- Import users from an AD/LDAP server.

Creating a User Manually

Creating Basic User Information

1. Log in to the CT-VL GUI and select **Users** from the navigation bar. The list of **All Users** is displayed.
2. Select **New User**. In the **New User** dialog, fill in the required information and click **Create**.

Note

- The username must contain only English letters, numbers, or the following special characters: “@” (at-sign), “.” (period), “+” (plus-sign), “-” (hyphen), or “_” (underscore).
- Usernames and passwords are case sensitive. Application code that calls the CT-VL RESTful APIs must pass usernames and passwords in the same case that are defined in the CT-VL GUI.

Updating User Information

After you complete the steps described in [Creating Basic User Information](#), you can add more attributes to the basic user, including changing the CT-VL role and assigning to a user group.

1. Log in to the CT-VL GUI, and select **Users** from the navigation bar.
2. Click on the username of interest.
3. Change CT-VL role, User Groups assignment, Mask, or Email, as needed.
4. Click **Change password here** to update the user’s password.
5. Click **Update**.

Deleting a User Manually

If you delete a user to which permissions have been associated, all permissions linked to the user are also deleted.

Note

It is generally recommended to uncheck the **Active** status for a user rather than completely delete the user.

1. Log in to the CT-VL GUI, and select **Users** from the navigation bar.
2. Select the check box by a user, click **Delete**, and confirm the deletion.

Importing Users from an AD/LDAP Server

Refer to [CT-VL Roles](#) and [Understanding CT-VL User Groups and Permissions](#) to familiarize yourself with user groups in CT-VL.

AD/LDAP User Import Prerequisites

Before you import users, complete the following tasks:

- Set up your AD/LDAP connection to CT-VL, and configure it using the CT-VL CLI. See [Configuring an AD/LDAP Server](#) for instructions.
- Create the appropriate user groups in the CT-VL GUI as described in [Creating User Groups](#).
- Set up the AD/LDAP server to import and authenticate users and user groups.

To import CipherTrust Tokenization Server users from an AD/LDAP server:

1. Create three AD/LDAP server groups, one for REST API users (Tokenization/Crypto/Key Management) and the other two for CT-VL administrators who require GUI access.
The group that has been designated as the “Superuser” group in the CLI will have read/write access in the GUI, whereas the group that has been designated as the “Staff” group in the CLI will have read-only access in the GUI.
2. Populate each group with the desired REST API (“active”) users and CT-VL administrators.

Note

- The name with permission to access the REST APIs must match the name specified with the `active_user` command under the `auth` category of the CT-VL CLI. See [Configuring an AD/LDAP Server](#) for further information.
- The name of the CT-VL users with read-only access to the GUI must match what was specified in the `staff_user` command of the `auth` category of the CLI.
- The name of the CT-VL administrators' group must match the name of the group that was specified in the `super_user` command of the `auth` category of the CT-VL CLI.

Example of AD/LDAP server group names:

- `ct-vlUsers` - Users in this group can create and/or access data through the RESTful API.
- `ct-vlStaff` - Users in this group can access the CT-VL GUI (read only).
- `ct-vlAdmin` - Users in this group can access the CT-VL GUI (read/write)

Note

- `staff_user` is valid only if the user also has `active_user` permission.
- `super_user` is valid only if the user has both `active_user` and `staff_user` permissions.
- Use corporate policy to define whether or not `staff_user` and `super_` users should actually be granted REST API permissions, and disallow by policy when necessary to maintain corporate standards or separation of duties.

3. Create three group permissions in the CT-VL GUI with the same names as the LDAP groups (example: `ct-vlUsers` , `ct-vlStaff`, `ct-vlAdmin`). Members of these AD/LDAP groups inherit these permissions.
 - An application program that uses Basic Auth (username/password) will try to authenticate to LDAP using these credentials.
 - An application program that uses a client certificate for authentication will use the Bind user's username and password for looking up the client certificate's common name (CN) in LDAP.
 - If the credentials are authorized, the LDAP user is imported into the user table of the CT-VL. Thus, there is no need to manually create the LDAP users in the GUI.
 - Once the user has been added to the CT-VL, permissions can be modified with another group permission or individually.

Note

User names and passwords are case sensitive. Application code that calls the REST APIs must pass usernames and passwords in the same case that are defined in the AD/LDAP server.

Unlocking User Accounts

As a security feature, users are locked out after six failed login attempts.

If a user fails to successfully login after six attempts, the account is locked for 15 minutes (to prevent brute force attacks). The maximum number of attempts and cool-off time duration can be modified in the CLI.

To unlock a user account:

1. Click **Logs** in the navigation menu.
2. Select the **Locked Accounts** tab. The locked accounts are displayed.

3. Click **Unlock** for the desired account(s).

Note

All successful and failed login attempts are displayed under the **Access Logs** tab in the **Logs** menu. Select **Success** or **Failed** from the pull-down menu to filter the list so that only the selected access type is shown.

Specifying CT-VL Keys

Refer to [Understanding CT-VL Keys](#) to understand the definition and usage of symmetric keys, asymmetric keys, and opaque objects.

Creating a Key Name

Use the CT-VL GUI to enter a key name that corresponds to a key that has been created in the CipherTrust Manager, and is to be used for CT-VL functions.

After the name has been entered into the CT-VL local database, the key is available to associate with user and user group permissions. Symmetric keys are also be available to associate with tokenization groups.

Note

The very first symmetric key entered into CT-VL needs to be entered from the GUI of the first cluster node. Enter this key as soon as possible, it will be used to create large lookup tables for the “RANDOM” tokenization mode.

1. After [Logging into the CT-VL GUI](#), select **Keys** from the navigation bar. The Keys List is displayed, with the **Symmetric Keys**, **Asymmetric Keys**, and **Opaque Objects** tabs in the top navigation.
2. Select the tab for the type of key you want (for example, **Symmetric Keys**), and click the **New Symmetric Key** button.

Note

In CT-VL, the very first key generated cannot be renamed, edited, or destroyed. There is a warning when creating the key. Once this initial setup is complete, you can create subsequent keys with the normal **New Symmetric Key UI**, for application FPE.

3. Enter the key name that was used in the CipherTrust Manager and click **Create**. The key name is displayed on the Keys List and will show as available in the **Permissions matrix** and **Tokenization Group** pages.

Deleting a Key Name

Deleting a key name from the CT-VL local database does not delete the key material (nor the key name) from the CipherTrust Manager. Deleting a key name deletes all tokenization groups, tokenization templates, and permissions associated to it.

1. Select **Keys** from the navigation bar. The Keys List is displayed, with the **Symmetric Key**, **Asymmetric Keys**, and **Opaque Objects** tabs in the top navigation.
2. Select the tab for the type of key you want (for example, **Symmetric Keys**), click the check box by the desired key, and click **Delete**.
3. Confirm and click **Delete** again.

Note

The very first symmetric key entered into the CT-VL can serve as a regular key for all encryption, signing, and tokenization operations, but it is also used to build internal cryptographic tables and hence must not (and cannot) be deleted.

Tokenization Setup

Refer to [Tokenization](#), [Templates](#), and [Masks](#) for the concepts behind setting up tokenization in the CT-VL GUI.

Note

Before setting up tokenization, make sure you have specified the CM keys.

Creating Tokenization Groups

Have at least one symmetric key created in the CM and entered in the CT-VL GUI, as described in [Specifying CT-VL Keys](#).

1. Select **Tokenization > Tokenization Groups**. The *All Tokenization Groups* list is displayed.
2. Click the **New Tokenization Group** button. The *New Tokenization Group* creation page is displayed.
3. Enter a Tokenization Group **Name**.

Note

Tokenization group names are case sensitive. Application code must pass tokenization group names in the same case that are defined in the CT-VL GUI.

4. Select a **Symmetric Key** from the drop-down list.

Warning

- Do not delete keys used for tokenization. If you delete a key, you will have to recreate the corresponding tokenization group to regain access to your tokens.
- Do not use auto-key-rotation features with tokenization.

5. Click **Create**.

Deleting Tokenization Groups

Before deleting a tokenization group, make sure that tokens created with the symmetric key associated with this tokenization group are not stored anywhere within (or outside) of the organization.

Warning

Once the tokenization group used to create these tokens has been deleted, they can no longer be detokenized.

To delete a tokenization group:

1. Log in to the CT-VL administration interface.
2. Select **Tokenization > Tokenization Groups**.
3. Select the group and click **Delete**.

Managing Character Sets

CT-VL now includes enhanced support for tokenizing international characters. In earlier versions, CT-VL supported three default character sets:

- All digits

-
- Alphanumeric
 - All printable ASCII (not available for RANDOM Mode)

For FPE (FF3) and FF1 modes, you can also define a custom character set, which allows you to tokenize and detokenize UTF strings.

Creating Custom Character Sets

To define a custom character set, you need to know the Unicode character range for the language(s) you want to support. For example, the range for Arabic is 0600-06FF, while the range for Thai is 0E00 - 0E7F.

To create a custom character set:

1. Select **Tokenization > Character sets**.
2. Click **New Character set**.
3. Enter a **Name** and **Range** or set of ranges for your set. The maximum size of a custom UTF character set definition string is 1536. This implies either 100 ranges, or 200 individual characters, or some combination thereof—for instance, 50 ranges plus 100 individual characters.
4. Click **Create**. The new set appears in the **All Character Sets** list, and is available to apply to tokenization templates.

Editing Character Sets

To edit a character set, click on its name in the list. Predefined character sets cannot be edited and should not be deleted.

Applying Character Sets

The three predefined character sets always appear in the drop-down list of character sets when you create a tokenization template. Once a custom set has been defined, it appears in the tokenization template creation menu as well.

See [Tokenization Template](#) for information about CT-VL tokenization templates.

Deleting Character Sets

Before deleting a character set, make sure that tokens created with this character set are not stored anywhere within (or outside) of the organization.

Caution

After the character set used to create these tokens has been deleted, they can no longer be detokenized, unless the character set is recreated very precisely. Even the order of the characters in the character set matters.

To delete a character set:

1. Navigate to **Tokenization > Character Sets**.
2. Select the character set from the list, and click **Delete**.

Prototyping Tokenization

CT-VL supports UTF-8 inside the `valuenam` field for "data" and "token".

Generate a file that has the JSON request in it containing this UTF-8 code, and then submit it via cURL.

A file can be submitted in cURL as shown here:

```
--data-binary @filename option.curl --tlsv1.2 -k -X POST -u
superuser:ssl12345 https://127.0.0.1/vts/rest/v2.0/tokenize --
data-binary @tokenizerequest.txt
```

Managing Tokenization Templates

Creating Tokenization Templates

1. In the CT-VL GUI, select **Tokenization > Tokenization Templates**.
2. Click **New Tokenization Template**.
3. Enter the values described in [Managing Tokenization Templates](#) field table.

Sample: Use a Tokenization Template in the REST API

After you specify a tokenization template, it can be used in the RESTful API application code. This is shown in the following example:

```
curl --tlsv1.2 -X POST -u EdYee:EdYee_password -d '{"tokengroup" :
"store1" , "data" : "9453677629008564", "tokenTemplate" :
"ctsUsersTemplate" }' https://192.168.12.88/vts/rest/v2.0/tokenize
```

Deleting Tokenization Templates

Before deleting a tokenization template, make sure that tokens created with this tokenization template are not stored anywhere within (or outside) of the organization. Once the tokenization template used to create these tokens has been deleted, they can no longer be detokenized, unless the tokenization template is recreated very precisely.

Caution

After the character set used to create these tokens has been deleted, they can no longer be detokenized,

unless the character set is recreated very precisely. Even the order of the characters in the character set matters.

To delete a tokenization template:

1. Navigate to **Tokenization > Tokenization Templates**.
2. Select the tokenization template from the list, and click **Delete**.

Managing Data Masks

Tokenization data masks hide specified parts of detokenized data. A mask is required for detokenization, even if the user is authorized to view the entire unencrypted string of data.

See [Data Masks](#) for more information on data masks used in CT-VL.

Creating a Data Mask

To create a data mask:

1. Select **Tokenization > Masks**. The **All Masks list** is displayed.
2. Click **New Mask** and enter the information on the **New Mask** dialog.

Some examples of data masks you could create:

- A mask called SHOW_LAST_4 that shows the last four digits of a tokenized credit card: XXXX-XXXX-XXXX-7897.
- A mask called SHOW_FIRST_3 that shows only the first three digits of a social security number: 565-XX-XXXX.
- A mask that shows everything (ALL_CLEAR): set Show Left and Show Right values to 999999.

3. Click **Create**.

Deleting a Data Mask

When a data mask is deleted, all user and user group permissions associated with that mask will be deleted.

Warning

This could result in production down time if a user is using the system and their permissions are deleted. They will be denied tokenization and detokenization rights. Be VERY sure these permissions are not in use before deleting the mask.

Applying Permissions to Users and User Groups

With CT-VL, users are authenticated, granted permissions (to tokenize, detokenize, encrypt, hash, etc.), and associated with particular keys, using a three-way permissions matrix.

Assigning Key-based Permissions

The CT-VL GUI Administrator assigns permissions based on user (or user group), action, and key, similar to the English sentence:

"User ctsuser1 may encrypt, decrypt, tokenize and detokenize with symmetric key key1."

Before permissions can be assigned, you must:

- Create user groups and users.
- Specify CT-VL Keys

Use the following steps to assign key-based permissions:

1. Log in to the CT-VL GUI and select **Permissions**. The User Permissions list is displayed. If necessary, click **User Group** to see the User Group Permissions list.
You can click the tabs to see the Symmetric Keys, Asymmetric Keys, and Opaque Objects assigned to a user (or group).
2. Click a user or group name to see a user permissions summary page. You can review and change permissions there or from the list page. To continue from the list page:
3. Click the permission symbol for a particular user's key. The user permission matrix is displayed.
4. Assign permissions as needed and click **Apply**.

Assigning Other Permissions

The permissions in the "Other Permissions" category are those that are not tied to specific keys. They are assigned only once per user group, and apply to all key groups. Actions that are not supported in the API are not displayed.

Creating and Importing Keys

To grant a user or user group permission to create keys on the CT-VL or to import keys to the CT-VL:

1. Log in to the CT-VL GUI and click **Permissions**. The User Permissions list is displayed. (If necessary, click **User Groups** to access the User Group Permissions list.)
2. Click the permission symbol for a user in the **Other Permissions** column. The Other Permissions assignment window is displayed.
3. Check **Create** and **Import**, as desired, and click **Apply**.

Note

- The **Create** permission is assigned only once per user and applies to all type of keys.
- The **Import** permission is assigned only once per user and applies to symmetric keys and opaque objects.

Other Permissions: Tokenize/Detokenize

Select **Tokenize/Detokenize** to apply privileges at a global level, on all symmetric keys in the system.

If your system is upgraded from an earlier version, any users who had been granted tokenize/detokenize privileges have these boxes checked automatically.

Remember to de-select the global check boxes and reassign privileges on a per-key basis to take advantage of the more granular structure of CT-VL configuration options.

Dashboard API Monitoring

The CT-VL Dashboard provides graphical and tabular monitoring for:

- CipherTrust Vaultless Tokenization activity
- CipherTrust Key Management activity
- CipherTrust Cryptography activity

Activity data is updated hourly, and can be sorted and filtered by:

- User (or all users)
- Date range
- Hour
- Day
- Week
- Month

The tabular view of the API data can be filtered by user or by user IP address (which can be used to check for access by unusual IP addresses). Clicking a user or IP address row in the table filters the graph view above it by that selection.

Exporting Data

Click the **Export** button to export into a CSV file the data as currently filtered and shown in the Dashboard.

Administrator History Logs

Most tokenization and detokenization log messages are in the file `tokenization.log`. You can get this via web download with credentials from the file `tokenization.log`.

Example:

`https://ctshost.vormetric.com/log/tokenization.log`

These log messages also go to the syslog with the facility code `daemon`.

Other log files:

- `django.request.log` - Logs any user request coming from the CipherTrust Vaultless Tokenization Server GUI.
- `uwsgi_cts.log` - Debug log.
- `clish.log` - CLI activities and events.

Note

Log data added by the server or server framework are not included in the log files.

View the CipherTrust Vaultless Tokenization Server logs by clicking the **Logs** icon in the CipherTrust Vaultless Tokenization Server GUI. (Audit log messages also go to the syslog with the facility code `user`).

From here you can:

- View audit logs, access logs (login and logout attempts), active sessions, locked accounts, and server CPU usage.
- Export the logs.

Viewing Audit Logs

To view the audit logs:

1. Log in to the CT-VL GUI.
2. Click **Logs** in the navigation pane.
3. Click the **Audit Logs** tab.

Details are shown for each audited event, including:

- **Date** specifies when the event occurred.
- **User** is the CipherTrust Vaultless Tokenization Server user.

-
- **Content Type** is the database table that was modified. *Tenant* involves Group Tokens, *Key* is encryption keys, *user* is for users, *groups* for groups, and so on.
 - **Object Name** is the specific database object that was created or changed.
 - **Modification** is the action that was performed.

Viewing Access Logs

The access log shows information about all attempts to log in to the server, and all logouts from it. The related information includes the access time, the IP address, username, and user agent (typically, a web browser). By default, all login attempts are listed, but the list can be filtered (by Status) to show only successful or only failed attempts.

To view the access logs:

1. Log in to the CT-VL GUI.
2. Navigate to **Logs**.
3. Click the **Access Logs** tab.
4. Filter the listed results with the **Type** menu. When viewing the **Logins** access type, use the additional **Status** pull-down menu to filter by Successful or Failed login attempts.

Downloading (Export) Access or Audit Logs

To download the history logs for an administrator:

1. Log in to the CT-VL GUI.
2. Navigate to **Logs**.
3. Click the **Audit Logs** or **Access Logs** tab.
4. Click the **Export** button for the Audit or Access Logs.

Showing Active Sessions

To see a list of active sessions of users currently logged in to the server:

1. Log in to the CT-VL GUI.
2. Click **Logs** in the navigation pane.
3. Click the **Active Session** tab.
4. To end a user's session on the GUI, click the **End Session** button in the row for that user.

Showing Locked Accounts

If a user fails to enter valid credentials more than five times, the user is locked from accessing the CT-VL for 15 minutes. View the details of locked accounts, including when the lock was activated and when it was released. Superusers can unlock an account before the 15 minute time limit is completed.

To view and manage locked accounts:

1. Log in to the CT-VL GUI.
2. Click **Logs** in the navigation pane.
3. Click the **Locked Accounts** tab.
4. Unlock an account by clicking **Unlock** in the row of the desired user.

System Logging

Audit log messages go to the syslog with the facility code `user`.

`tokenization.log` messages go to the syslog with the facility code `daemon`.

CLI log messages go to the syslog with the facility code `local3`.

Configuring Syslog Servers

Configure remote syslog servers with the CLI, with the command under the CT-VL category. You can also set up multiple syslog servers with this command, with the `--add` and `--remove` commands.

The `remotelog` command has utilities to check the connection status to the servers, and to send a sample log message to them.

Backing Up and Restoring CT-VL

Create regular backups of the server to restore CT-VL in the event of failure. Even in a clustered scenario, system failure can occur. To minimize this risk, backup your CT-VL implementation regularly using the administration interface or the REST API.

Use the CT-VL GUI to create a backup before upgrading your CT-VL version and before any major server configuration changes. Maintain a regular backup schedule using the CT-VL REST API.

Restore the state of your CT-VL implementation using the administration interface. Backups restore the CT-VL to the saved version in the following scenarios:

- Restoring the application after system failure.
- Restoring the application after upgrade failure.
- Restoring the application due to unrecoverable system configuration errors.

Note

A backup cannot restore a system using a CT-VL version older than 2.2.2. A backup cannot be applied to any version of the CT-VL software that is older than the version in use when the backup was created.

Backing up CT-VL in the GUI

Use the administration interface to create and save a backup.

Use the following steps to create a system archive:

1. Select **Backup** from the administration interface left hand navigation.
2. Click the **Create Backup** tab.
3. Accept the default values, and click **Backup now**.

The archive generates and is saved to your default download folder. The file name is created with the following syntax:

`backup_year-month-day`

For example:

`backup_2018-10-20`

Move the backup to your storage directory.

Managing Backup Tasks

Use the REST API to create a backup and automate system backup tasks.

You can use the Backup API to generate backups via any valid HTTP request. The syntax requires authentication using user credentials.

Restoring the CT-VL from a Backup

If a complete system restore is required, make sure the CT-VL installation is complete before beginning this task.

Note

Make sure the CT-VL version leveraged for the backup is the same as the backup or newer than the backup and is at least version 2.2.2.

Use the following steps to restore the CT-VL to its last recorded working state using a backup:

1. Select **Backup** from the administration interface left hand navigation.

2. Click the **Restore** tab.
3. Click **Choose File** and navigate to the required backup archive.
4. Confirm the following back up details:
 - CT-VL version
 - Backup date
 - Encryption key name
5. Click **Restore**.

Note

Depending on the size of the backup, the restore process may take some time.

If this node is a member of an existing cluster, it is removed from the cluster. Any existing data on this node is destroyed.

A new cluster is created with this node as the first node but with data restored from the backup.

When the restore completes, this node has all data from the backup including login credentials.

Note

If the user forgets the login credentials in the backup, run the `createsuperuser` CLI command to create a new user.

This node becomes a new node of a new cluster. It is no longer a member of any previous cluster.

Note

If this node was a member of an existing cluster prior to the restore, it must be removed from that cluster. Failure to remove this node from its previous cluster prevents new nodes from joining that cluster.

The CT-VL is restored to the state of archive. When the task is complete, a banner appears, indicating that the restore is complete. The CT-VL reboots.

When the login screen appears, enter your credentials to access the restored application.

Key Rotation

Regular encryption key rotation can increase security and also satisfy some PCI DSS requirements. To rotate CT-VL keys, ask your CT-VL Administrator to run the CT-VL CLI command `security gencert` on the CM that creates and stores the CT-VL keys.

Versioned keys are not permitted for tokenization.

Upgrading CT-VL

You can upgrade with the standard upgrade ZIP file only if you are upgrading from CT-VL v2.3 or higher. If you are upgrading from any CT-VL version earlier than v2.3, refer to the release notes for specific details based on the current version you are upgrading from.

If you are upgrading from CT-VL version 2.2.x or earlier, you must perform a backup and restore procedure as part of your upgrade. The backup includes users and groups, permissions, and settings. You can perform this backup either through the CT-VL GUI or REST APIs.

Refer to [Backing Up and Restoring CT-VL](#) for instructions on this backup step, and on the subsequent restore step.

Notes for Upgrading a Cluster

- All nodes in the cluster must be upgraded to the same CT-VL version. A CT-VL cluster must not operate nodes using different CT-VL versions.
- When upgrading nodes in a cluster, all CT-VL operations must be suspended. If this is not possible, you must perform a rolling upgrade. The nodes to be upgraded must be taken offline, for example, taken out of the load balancer before an upgrade is performed.
When the load balancer is ready to use the upgraded nodes, all other nodes not yet upgraded must be taken offline.
At any one time, the load balancer must not serve nodes running different CT-VL versions.
- While a node upgrade is in progress, it must not be interrupted. If it is interrupted or does not complete successfully, you must discard the node by removing it from the cluster.
Create a new VM, upgrade it to the desired version, and rejoin it to the cluster. When joining the node to the cluster, it must have the same version as all other nodes in the cluster.
- All nodes in the cluster must be upgraded, and must complete the upgrade before resuming operations.

Upgrades to AWS Instances Cannot Use SSH Key Pairs

Upgrading an EC2 instance from CT-VL v2.5 or earlier retains the use of passwords for the cliadmin instead of SSH key pairs. Only newly-created instances from CT-VL v2.6 and above can use the SSH key pair in AWS.

Upgrade Steps

If you have multiple nodes in a cluster, you can upgrade all nodes at the same time.

1. Obtain the upgrade ZIP file from your Thales sales or support representative, and place the file on a server

that is accessible from CT-VL over either HTTP or FTP.

- Although the upgrade ZIP file is encrypted and digitally signed, the HTTP server can use SSL (HTTPS) and basic authentication. The HTTPS server can also use a self-signed certificate.
- Log in as `cliadmin` to the CT-VL virtual machine that you want to upgrade. In the following example command, substitute your own CT-VL hostname.

```
$ ssh -l cliadmin <Tokenization Server hostname>
cliadmin@<Tokenization_Server_IP_address> password: <Enter the cliadmin
password>
[...]
CipherTrust Tokenization Server Main Menu
main> ?
Command                Description
=====
auth                    Authentication Setup
cluster                 Cluster Setup
icapi                   ProtectApp Setup
network                 Network Setup
system                  System Setup
vae                     VAE Configuration
vts                     Tokenization Setup
quit|q|up|<ctrl-d>      Quit or return to previous menu
exit                    Exit application

Enter <command> to display usage
main>
```

- At the main menu, enter:

```
main> vts upgrade --url <upgrade_zip_url>
```

Another option is to navigate to the vts submenu and enter the upgrade command directly:

```
main> vts
vts> upgrade --url <upgrade_zip_url>
```

Examples:

```
upgrade https://example.com/ctvl-upgrade-<version>.zip
upgrade https://username:password@example.com/ctvl-upgrade-<version>.zip
upgrade ftp://example.com/ctvl-upgrade-<version>.zip
```

Watch the output of the **upgrade** command while the upgrade is underway. After several progress messages, you should see a success message like the following:

```
Upgrade complete.
```

Depending on the type of upgrade, the system will be rebooted at the end for changes to take effect. You are prompted at the beginning of the upgrade for confirmation.

There are other options to perform an upgrade. Run **upgrade --help** for details.

Monitoring Through SNMP

You can monitor disk partitions, files, load average, and processes by setting up SNMP polling. Configure SNMP at the CLI in the **network** category and the **snmp** command.

When enabling SNMP, you must specify a whitelist of IP addresses for SNMP managers. CIDR control access is supported.

CT-VL supports both SNMP v3 and v2c. SNMP v3 supports password authentication, encryption, and a choice of encryption and password hashing algorithms.

Note

SNMP traps are not supported.

Supported MIB OIDs

Below are some MIB OIDs that CT-VL supports:

CPU Load Average Monitoring

```
1 minute load average  .1.3.6.1.4.1.2021.10.1.3.1
5 minute load average  .1.3.6.1.4.1.2021.10.1.3.2
15 minute load average .1.3.6.1.4.1.2021.10.1.3.3
```

System Uptime

```
.1.3.6.1.2.1.1.3.0
```

Memory Statistics

```
Total Memory      .1.3.6.1.4.1.2021.4.5.0
Total Memory Used  .1.3.6.1.4.1.2021.4.6.0
Total Memory Free  .1.3.6.1.4.1.2021.4.11.0
Total Swap Space   .1.3.6.1.4.1.2021.4.3.0
```

```
Total Availabe Swap .1.3.6.1.4.1.2021.4.4.0
```

Disk Statistics:

```
Total size of disk partition .1.3.6.1.4.1.2021.9.1.6.1
Total disk space used .1.3.6.1.4.1.2021.9.1.8.1
Total available disk space .1.3.6.1.4.1.2021.9.1.7.1
```

Examples

Below are examples using the `snmpwalk` command.

Get Total Memory on CT-VL VM

```
snmpwalk -v 2c -c mystring ctvl-ip .1.3.6.1.4.1.2021.4.5.0
UCD-SNMP-MIB::memTotalReal.0 = INTEGER: 16431432 kB
```

Get System Uptime

```
snmpwalk -v 2c -c mystring ctvl-ip .1.3.6.1.2.1.1.3.0
DISMAN-EVENT-MIB::sysUpTimeInstance = Timeticks: (22329) 0:03:43.29
```

Note

- SNMP on CT-VL is disabled by default. Use the CLI to enable access.
- SNMP manager(s) must be set to allow access to CT-VL.

Configuring SNMP

1. To configure SNMP, use the `network snmp` CLI command.

```
main> network snmp
usage: snmp command [options]SNMP Configurationcommands:
  user          SNMPv3 user setup
  community     SNMPv2c community access. Do not set if you don't want to enable SNMPv2
  monitor       Monitor Services Setup (processes, load average, disk space, and file size)
  manager       SNMP Managers Setup
  service       Enable, disable, and show SNMP Service
```

system SNMP System Information Setup

2. Create a user.

```
main> network snmp user
usage: user [-h] [--show] [--add USERNAME] [--delete USERNAME [USERNAME ...]]
          [--authpass PASSWORD] [--privpass PASSWORD] [-x {DES,AES}]
          [-a {MD5,SHA}]
```

3. Create a community string.

```
main> network snmp community
usage: community [-h] [--show] [--add STRING] [--delete STRING] [-y]
```

4. Enable SNMP as SNMP is disabled by default.

```
main> network snmp service --enable
```

5. Set SNMP managers who will access CT-VL.

```
main> network snmp manager
usage: server [-h] [--show] [--add IP [IP ...]] [--remove IP [IP ...]]
```

6. Monitor disk, file, load, and processes.

```
main> network snmp monitor
usage: monitor [-h] [--show] [--set {disk,file,load,proc}]
          [--delete {disk,file,load,proc}] [--value VALUE]
```

Examples

This section contains the following pages:

- [Cryptographic Operation Examples](#)
- [Key Management Examples](#)
- [Versioned Key Management Examples](#)
- [Tokenization Examples](#)

Cryptographic Operation Examples

This section shows the examples of the CipherTrust cryptographic operation along with the examples related to encryption, decryption, encrypting and decrypting large files, sign, verify, and random.

A user or group may perform each of the following cryptographic operations using a specific key if he or she has permissions to perform such as configured for each individual key from inside the CT-VL Administration UI.

The allowed cryptographic operations available are:

- **Encrypt** - Encryption using a key.
- **Decrypt** - Decryption using a key.
- **Sign** - Sign with a given key.
- **Verify** - Verify a signature with a given key.

Cryptographic Headers

Cryptographic headers is a convenient feature that allows a ciphertext to be decrypted without knowledge of the specific key name and/or version that was used to encrypt it. When encrypting with headers enabled, the ciphertext includes bytes containing key information inserted before the encrypted data.

To enable cryptographic headers, the `header` attribute must appear in the POST body for sign, verify, encrypt, and decrypt calls.

Verify and decrypt also take an `all` header attribute value to let the service figure out the header version in a more transparent way for the caller.

CipherTrust Cryptographic Operation Examples

Simple SHA-256 Digest Example

Request

```
curl -k -u vtsuser -X POST 'https://127.0.0.1/vts/crypto/v1/digest' \
-d '{"alg": "S256", "payload": "Ef+4MkU6ukzQSMbHxH4rxoVF/xKHyg=="}' \
-H 'content-type: application/json'
```

Response

```
{
  "digest": "RfdwuYKwBn0l03ZMGB7r59S+P+T9/s8ufPJfcSQXNfE="
}
```

Encryption Examples

AES-256 CBC Encryption Example

Request

```
curl -k -u vtsuser -X POST 'https://127.0.0.1/vts/crypto/v1/encrypt' \
-d '{"plaintext": "JLns9BI4Pa7TTrCaeJIjQQ==", "alg": "A256CBC", "params": {"iv":
"tler+lrCnchFRJDCFs1F/A=="}, "kid": "mykey123"}' \
-H 'content-type: application/json'
```

Response

```
{
  "ciphertext": "SZASu6Ts+01IMtb14+djhg==",
  "params": {}
}
```

Simple AES-256 CTR Encryption with Headers Example

Request

```
curl -k -u vtsuser -X POST 'https://127.0.0.1/vts/crypto/v1/encrypt' \
-d '{"plaintext": "JLns9BI4Pa7TTrCaeJIjQQ==", "alg": "A256CTR", "params":{"iv":
"tler+lrCnchFRJDCFs1F/A=="}, "kid": "myversionedkey", "headers"="hdr_v2.7"}' \
-H 'content-type: application/json'
```

Response

```
{
  "ciphertext": "UktNQzIxMAD/////AAAABXV1awQAAAAAEDkKfAiGhjeLkp50NDgjpQT/////AA
AAA2l2AAAAABhYmMxMjNkZWZnaDY3ODkw/////wAAAAVjc3VtAAAAACAbtDVcSesXu7SYqoZxNR+hC6C
q8H3gE5xv5vvSzRhUrKcwnBu8",
  "params": {}
}
```

Decryption Examples

Simple AES-256 CBC Encryption Example

Request

```
curl -k -u vtsuser -X POST 'https://127.0.0.1/vts/crypto/v1/decrypt' \
-d '{"ciphertext": "wInPTVRugkxP0KBm46yCo8lpQMaDDRo15bEWt9Mz629MKh7IqB9roh36ZkyIu"
```

```
mLi", "alg": "A256CBC", "params": {"iv": "ek5Lmcw0JATvux5PoSaZ6w=="}, "kid": "foo
key"}' \
-H 'content-type: application/json'
```

Response

```
{
  "plaintext": "40idw01cBKKcF1tK4ZBdZg7yDe9KbvBP1npfs382HT+yz0Fb3CeCh/eBIhH7a1r
b",
  "params": {}
}
```

Simple AES-256 CTR Decryption with Headers Example

Request

```
curl -k -u vtsuser -X POST 'https://127.0.0.1/vts/crypto/v1/decrypt' \
-d '{"ciphertext": "UktNQzIxMAD/////AAAAABXV1awQAAAAAEDkKfAiGhjeLkp50NDgjPQT/////A
AAAA2l2AAAAABBBhYmMxMjNkZWZnaDY3ODkw////wAAAAVjc3VtAAAAACAbtDVcSesXu7SYqoZxNR+hC6
Cq8H3gE5xv5vvSzRhUrKcwnBu8", \
"alg": "A256CTR", "params":{"iv": "tler+lrCnchFRJDCFs1F/A=="}, "headers"="all"}' \
-H 'content-type: application/json'
```

Response

```
{
  "plaintext": "JLns9BI4Pa7TTrCaeJIjQQ==",
  "params": {}
}
```

Encrypting and Decrypting Large Files

To handle files that are larger than the payload limit of 5 MB, use the following script to automatically break down a large file into a chain of smaller files for encryption, and to join these files and decrypt them:

```
#!/bin/bash
URL=http://localhost:8000/crypto/v1
KEY=cc01
IV="MTAwMDIwMDAzMDAwNDAwMA=="
CHUNKSIZE=256
FILE="/etc/hosts"
ALG="A256CTR"
BASE=`basename $FILE`
OIV=$IV
if [ ! -e ./ $BASE ]
then
cp $FILE .
```

```

fi
rm -f ${BASE}.* *-${BASE}.*
split -b $CHUNKSIZE ./${BASE} ${BASE}-
NOMORE=0
echo "===== Encryption ====="
for i in ${BASE}.*
do
if [ $NOMORE -eq 1 ]
then
break
fi
PTEXT=`cat $i | base64 -w 0`
PAYLOAD=$(jq -n -r \
--arg kid $KEY \
--arg iv $IV \
--arg pt "$PTEXT" \
--arg alg $ALG \
'{ plaintext: $pt, alg: $alg, kid: $kid, params: {iv: $iv} }'
)
RESULT=`echo $PAYLOAD | curl -Ss -X POST -k -d @- -H "Accept: application/json"
$URL/encrypt`
NEWIV=`echo $RESULT | jq -r '.params.iv'`
CTEXT=`echo $RESULT | jq -r '.ciphertext'`
if [ -z "$NEWIV" ] || [ "$NEWIV" == "null" ]
then
NOMORE=1
fi
IV=$NEWIV
echo -n $CTEXT | base64 -d -w0 > ${i}.enc
done
cat ${BASE}.*.enc > ./${BASE}.enc
split -b $CHUNKSIZE ./${BASE}.enc enc-${BASE}-
IV=$0IV
NOMORE=0
echo "===== Decryption ====="
for i in enc-${BASE}.*
do
if [ $NOMORE -eq 1 ]
then
break
fi
CTEXT=`cat $i | base64 -w0`
PAYLOAD=$(jq -n -r \
--arg kid $KEY \
--arg iv $IV \
--arg ct "$CTEXT" \
--arg alg $ALG \
'{ ciphertext: $ct, alg: $alg, kid: $kid, params: {iv: $iv} }'
)
RESULT=`echo $PAYLOAD | curl -Ss -X POST -k -d @- -H "Accept: application/json"
$URL/decrypt`
NEWIV=`echo $RESULT | jq -r '.params.iv'`
PTEXT=`echo $RESULT | jq -r '.plaintext'`
if [ -z "$NEWIV" ] || [ "$NEWIV" == "null" ]
then
NOMORE=1
fi
IV=$NEWIV
echo -n $PTEXT | base64 -d -w0 > ${i}.dec

```

```
done
cat enc-`${BASE}`-*.dec > `${BASE}`.dec
diff `${BASE}`.dec `${BASE}`
echo diff status = $?
```

The large file is broken into chunks of size whose modulo 16 equals 0 (that is, into chunk sizes that are multiples of 16 bytes).

When submitting the chunks to the encryption endpoint, the response includes an IV that is used to encrypt the next chunk. If the payload length is not 16-byte aligned, the response does not return the next IV, assuming that chaining is complete.

For decryption, the same rules apply. The first call must use the same IV as the call used for encrypting. The ciphertext chunk size can be a different size from the original plaintext encryption request, as long as the chunks are 16-byte aligned.

For example a 1030 byte file can be encrypted in 8 chunks of 128 bytes each and a last one of 6 bytes. The same file once encrypted can be split in 3 chunks of 320 bytes and a last one of 70 bytes.

Sign

Simple HMAC-SHA256 Sign Example

Request

```
curl -k -u vtsuser -X POST 'https://127.0.0.1/vts/crypto/v1/sign' \
-d '{"alg": "HS256", "payload": "aGVsbG8gd29ybGQh", "kid": "mykey"}' \
-H 'content-type: application/json'
```

Response

```
{
  "signature": "13pCxjIXjY8MNhsx69szyU0VraQc6Tn0C0irqCut0Ls="
}
```

Verify

Simple HMAC-SHA256 Sign Example

Request

```
curl -k -u vtsuser -X POST 'https://127.0.0.1/vts/crypto/v1/verify' \
-d '{"alg": "HS256", "signature": "13pCxjIXjY8MNhsx69szyU0VraQc6Tn0C0irqCut0Ls=",
  "payload": "aGVsbG8gd29ybGQh", "kid": "mykey"}' \
-H 'content-type: application/json'
```

Response

```
{
  "valid": 1
}
```

Random

Simple Random Example

The following example shows a simple request to generate an 8-byte random number:

Request

```
curl -k -u vtsuser -X POST 'https://127.0.0.1/vts/crypto/v1/random' \
-d '{"seed": "q8qqyw==", "size": 8}' \
-H 'content-type: application/json'
```

Response

```
{
  "random": "152LM5GzL8U="
}
```

Authorization Operations

Below table shows the possible authorization operations when a key is / was created or imported via the API. The owner is the user who creates the key.

Operation	Owner	Group	Other User	Other Group
Create	Yes, if owner has create permission Owner can specify on create the permissions allowed though the usage attribute If usage attribute is not supplied, then key will be created with all permissions	Yes, if owner has create permission granted through a group Owner can specify on create the permissions allowed though the usage attribute If usage attribute is not supplied, then key will be created with all permissions	N/A	N/A
Import	Yes, if owner has import permission	Yes, if owner has import permission	N/A	N/A

Operation	Owner	Group	Other User	Other Group
	Owner can specify on import the permissions allowed though the usage attribute If usage attribute is not supplied, then key will be imported with all permissions	granted through a group Owner can specify on import the permissions allowed though the usage attribute If usage attribute is not supplied, then key will be imported with all permissions		
Destroy	Yes, if owner gave permission on creation	No	No	No
Export	Yes, if owner gave permission on import or create	No	No	No
Find	Yes, if owner gave permission on import or create	No	No	No
Modify	Yes, if owner gave permission on import or create	No	No	No
Encrypt	Yes, if owner gave permission on import or create	No	No	No
Decrypt	Yes, if owner gave permission on import or create	No	No	No
Sign	Yes, if owner gave permission on import or create	No	No	No
Verify	Yes, if owner gave permission on import or create	No	No	No

Key Management Examples

This section shows the examples of the CipherTrust key management as listed below:

- Key States
- Creating and Importing Keys
- Managing Keys

-
- Valid Key Operations
 - Key Creation
 - Key Import
 - Key Delete
 - Key Update
 - Key Retrieval
 - Key Export
 - Wrapping Keys
 - Importing with Wrapping Key
 - Exporting with Wrapping Key
 - Importing and Exporting Using Clear Bytes

Key States

Symmetric and asymmetric keys support the following states:

- **Preactive** - When a key was created to have a preactive state.
- **Active** - Default when a key is created.
- **Suspended** - A key has been suspended.
- **Compromised** - Key is compromised.
- **Deactivated** - Key is deactivated.
- **Destroyed** - Key is destroyed.

Note

- To set a key to the suspended, compromised, or deactivated state, call the modify endpoint (**PATCH**).
- A key can be set to the active state again only if it is in the suspended state.

Creating and Importing Keys

This category covers both **key import** and **key creation**. A user or group that has import, create, or both

permissions is allowed to add keys to CT-VL.

The difference between import from create is in the ability to add a wrapped key representing the key itself to the key creation request. This ability to create and import keys is set for each user through the CT-VL Administration UI.

Note

- If a user or group has create and/or import permissions, invoking the corresponding API endpoint will create a key with all the permissions for CipherTrust key management and cryptographic operations.
- Any other user needing to perform operations on such keys, can only be added through the CT-VL Administration UI.

If the user does not have permission to create or import, the corresponding creation endpoint will return an error.

Managing Keys

A user or group may perform each of the following key management operations if he or she has permissions to perform such. This can be configured for each individual key from inside the CT-VL Administration UI.

The allowed key management operations are:

- **Destroy** - Destroy a key.
- **Modify** - Modify a key's attributes.
- **Find** - Look up or retrieve a specific key.
- **Export** - Export a specific key. This only applies to symmetric keys.

Valid Key Operations

Below table lists the valid key operations from the API. It does not include permissions related to authorization. See the [Authorization Operations](#) section for more details.

Operation	Symmetric Key	Versioned Symmetric Key	Asymmetric Key	Opaque Object
Create	yes	yes	yes	yes
Import	yes	yes	no	yes
Destroy	Key delete	Delete key by UUID or MUID only	Key delete	Key delete
	custom attribute delete	Delete key of version 0 deletes entire set	custom attribute delete	custom attribute delete

Operation	Symmetric Key	Versioned Symmetric Key	Asymmetric Key	Opaque Object
		Delete custom attribute		
Modify	custom attributes add alias key states key migration to versioned key	custom attributes add alias key states key rotation lifespan interval	custom attributes	custom attributes add alias
Find	By label/name By UUID By MUID By alias	By label/name - last version By UUID By MUID By alias	public key only By label/name	By label/name By UUID By MUID By alias

Key Creation

Key creation allows to create a key whose contents (key material or bytes) is generated by the CM.

Note

- You cannot create a key via the REST API and make it a seed key in one step.
- You must create the key and add it via the CT-VL GUI in separate steps.
- You cannot just pass in **seedkey** as a keyword to the create key REST API. If you do, the key is created, but it is not a seed key.

This example shows how to create an AES 128-bit key named foo123key:

Request

```
curl -k -u vtsuser -X POST 'https://127.0.0.1/vts/km/v1/keys' \
-d '{"size": 128, "name": "foo123key", "kty": "oct"}' \
-H 'content-type: application/json'
```

Response

```
{
  "attributes": {
    "usage": [
      "encrypt",
      "decrypt",
      "sign",
      "verify",
      "destroy",
      "modify",
      "find",
      "export"
    ],
    "size": 16
  },
  "metadata": {
    "key_management": {
      "uuid": "9f3c2775-405b-33e8-91af-904faa0e551f",
      "caching_duration": 44640,
      "state": "active",
      "lifespan_unit": "days",
      "muid": "9f3c2775-405b-33e8-91af-904faa0e551f39b6aee0-6821-39f9-a186-9a9904abff32",
      "caching_enabled": true,
      "name": "foo123key"
    }
  },
  "kid": "tesrn:vts::label:foo123key"
}
```

Key Import

Key import is basically the same as a key create, however the request contains information on the **wrapped** key and the **wrapping** key.

This request imports an AES 128-bit key named foo1234key with key bytes equal to: **"HelloWorldAlways"**.

Request

```
curl -k -u vtsuser -X POST 'https://127.0.0.1/vts/km/v1/keys' \
-d '{"size": 128, "name": "foo123key", "kty": "oct", "wrappedkey": "SGVsbG9Xb3JsZEFsd2F5cw=="}' \
-H 'content-type: application/json'
```

Response

```
{
  "attributes": {
    "usage": [
      "encrypt",
      "decrypt",
      "sign",
      "verify"
    ],
    "size": 16
  },
  "metadata": {
    "key_management": {
      "uuid": "9f3c2775-405b-33e8-91af-904faa0e551f",
      "caching_duration": 44640,
      "state": "active",
      "lifespan_unit": "days",
      "muid": "9f3c2775-405b-33e8-91af-904faa0e551f39b6aee0-6821-39f9-a186-9a9904abff32",
      "caching_enabled": true,
      "name": "foo123key"
    }
  },
  "kid": "tesrn:cts::label:foo1234key"
}
```

Key Delete

This example deletes a key named foo123key.

Note

Upon success, the HTTP status code must be 200.

Request

```
curl -k -u vtsuser -X DELETE 'https://127.0.0.1/vts/km/v1/keys/foo123key'
```

Response

```
200 OK
```

Key Update

Request

```
curl -k -u vtsuser -X PATCH 'https://127.0.0.1/vts/km/v1/keys/fookey' \
-d '{"state": "suspended"}' \
-H 'content-type: application/json'
```

Response

```
{
  "attributes": {
    "usage": [
      "encrypt",
      "decrypt",
      "sign",
      "verify",
      "destroy",
      "find"
    ],
    "size": 16
  },
  "metadata": {
    "key_management": {
      "uuid": "bfd2a7b7-20db-31d7-b22f-01e625a54961",
      "caching_duration": 44640,
      "state": "suspended",
      "versioning_enabled": 1,
      "lifespan_unit": "days",
      "muid": "bfd2a7b7-20db-31d7-b22f-01e625a549618b0ce745-fcb2-3718-97b3-d4a0b415ac5d",
      "caching_enabled": 1,
      "name": "fookey"
    }
  },
  "kid": "tesrn:cts::label:fookey"
}
```

Key Retrieval

Request

```
curl -k -u vtsuser -X GET 'https://127.0.0.1/vts/km/v1/keys/fookey'
```

Response

```
{
  "attributes": {
    "usage": [
      "encrypt",
      "decrypt",
      "sign",
      "verify",
      "destroy",
      "find"
    ],
    "size": 16
  },
  "metadata": {
    "key_management": {
      "uuid": "bfd2a7b7-20db-31d7-b22f-01e625a54961",
      "caching_duration": 44640,
      "state": "suspended",
      "versioning_enabled": 1,
      "lifespan_unit": "days",

      "caching_enabled": 1,
      "name": "fookey"
    }
  },
  "kid": "tesrn:cts::label:fookey"
}
```

Key Export

Request

```
curl -k -u vtsuser -X POST 'https://127.0.0.1/vts/km/v1/keys/export/fookey' \
-d '{"alg": "A256CBCPAD", "params": {"iv": "RERERERERERERERERERERA=="}, "kid": "tesrn:cts::label:foo123key"}' \
-H 'content-type: application/json'
```

Response

```
{
  "exported_key": {
```

```

    "attributes": {
      "usage": [
        "encrypt",
        "decrypt",
        "sign",
        "verify",
        "destroy",
        "find"
      ],
      "size": 16
    },
    "metadata": {

}

```

Wrapping Keys

When importing or exporting a key, it is recommended to use a wrapping key in order not to compromise the key itself.

Note

In the current version of the CT-VL Key Management module, a wrapping key must be an AES 256-bit key, and only the CBC or CBCPAD ciphers may be used.

The ideal method for wrapping a key on both import and export is to use asymmetric keys.

Importing and exporting key requires that the user has a wrapping key, and such key is available on both client and the CT-VL.

Importing with Wrapping Key

When importing with a wrapping key, the following steps need to be taken:

1. Create a 256-bit AES key that is known to the caller and the CT-VL. This is the wrapping key.
2. Encrypt the key bytes with the wrapping key using an AES-CBC or AES-CBCPAD cipher. This is the wrapped key.

3. Call the create endpoint and supply the base64-encoded wrapped key and the wrapping key ID.

Exporting with Wrapping Key

When exporting with a wrapping key, the following steps need to be taken:

1. Create a 256-bit AES key that is known to the caller and the CT-VL. This is the wrapping key.
2. Call the export endpoint, supplying a wrapping key ID. This will return a wrapped key.
3. Decrypt the base64-encoded wrapped key using the wrapping key on the client side.

Importing and Exporting Using Clear Bytes

The API offers the ability to perform import and export functions using raw key bytes, however such method is not recommended.

To import a key using clear bytes, omit the wrapping key ID or give the `clear_key` label. For exporting, give the `clear_key` label as the wrapping key ID. In both cases, the `alg` and the `iv` attributes must be omitted.

Versioned Key Management Examples

This section shows how to use versioned keys within the CipherTrust Cryptographic and Key Management set of APIs.

Versioned Key Creation Example

Creation of an AES 256-bit versioned key named `vkey256` with each version of the key with a lifespan of 7 days.

Request

```
POST /vts/km/v1/keys
{"size": 256, "name": "vkey256", "kty": "oct", "versioning_enabled": true, "version": 0, "version_action": "create", "lifespan_interval": 7}
```

Response

```
200 OK
{"attributes": {"usage": ["encrypt", "decrypt", "sign", "verify", "destroy", "modify", "find", "export"], "size": 16}, "metadata": {"key_management": {"uuid": "9f3c2775-405b-33e8-91af-904faa0e551f", "caching_duration": 44640, "state": "active", "lifespan_unit": "days", "muid": "9f3c2775-405b-33e8-91af-904faa0e551f39b6aee0-6821-39f9-a186-9a9904abff32",
```

```
"caching_enabled": True,
"name": "vkey256"}},
"kid": "tesrn:vts::label:vkey256"}
```

Versioned Key Import Example

Creation of an AES 256-bit versioned key named `vkey256` with each version of the key with a lifespan of 7 days.

Request

```
POST /vts/km/v1/keys
{"size": 256, "name": "vkey256", "kty": "oct", "versioning_enabled":
true, "version": 0, "lifespan_interval": 7, "wrappedkey":
"SGVsbG9Xb3JsZEFsd2F5cw=="}
```

Response

```
200 OK
{"attributes": {"usage": ["encrypt", "decrypt", "sign", "verify",
"destroy", "modify", "find", "export"],
"size": 16},
"metadata": {"key_management": {"uuid": "9f3c2775-405b-33e8-91af-
904faa0e551f",
"caching_duration": 44640,
"state": "active",
"lifespan_unit": "days",
"moid": "9f3c2775-405b-33e8-91af-904faa0e551f39b6aee0-6821-39f9-
a186-9a9904abff32",
"caching_enabled": True,
"name": "vkey256"}},
"kid": "tesrn:cts::label:vkey256"}
```

Standard Key to Version Key Migration Example

Creation of an AES 256-bit versioned key named `vkey256` with each version of the key with a lifespan of 7 days.

Request

```
PATCH /vts/km/v1/keys/existingkey {"version_action": "migrate"}
```

Response

```
200 OK
{
"attributes": {
"size": 32
},
}
```

```

"metadata": {
  "key_management": {
    "uuid": "7f460ca4-04e2-37d9-8d57-b2c36fbed55e",
    "caching_duration": 44640,
    "state": "active",
    "versioning_enabled": true,
    "muid": "7f460ca4-04e2-37d9-8d57-b2c36fbed55ecd222707-123a-3df5-baef-c9b1f77ac3fb",
    "caching_enabled": 1,
    "name": "existingkey"
  }
},
"kid": "tesrn:cts::uuid:7f460ca4-04e2-37d9-8d57-b2c36fbed55e"
}

```

Version Key Rotation Example

Rotation of an existing versioned key named `vkey256` with each version of the key with a lifespan of 7 days.

Request

```
PATCH /vts/km/v1/keys {"version_action": "rotate"}
```

Response

```

200 OK
{"attributes": {"usage": ["encrypt", "decrypt", "sign", "verify",
"destroy", "modify", "find", "export"],
"size": 16},
"metadata": {"key_management": {"uuid": "d0a031de-5102-3bba-80f4-7019306da03e",
"caching_duration": 44640,
"state": "active",
"lifespan_unit": "days",
"muid": "d0a031de-5102-3bba-80f4-7019306da03ed0a031de-6821-39f9-a186-9a9904abff32",
"caching_enabled": True,
"name": "vkey256"}},
"kid": "tesrn:cts::label:vkey256"}

```

Tokenization Examples

CT-VL CLI Reference

The CipherTrust Vaultless Tokenization (CT-VL) Command Line Interface (CLI) is used to configure the CT-VL network and do other system-level tasks.

Listed below are the CT-VL CLI categories and the commands within each category:

- [Authentication Setup Category](#)
- [Cluster Management Category](#)
- [CipherTrust Manager Setup](#)
- [Network Management Category](#)
- [System Configuration Category](#)
- [CT-VL Configuration Commands](#)

Note

- This article provides a high-level overview of each command category. For complete usage details on each command and its options, run the command with the `--help` option.
- For tips on navigating the CLI, see [CLI Navigation Cheat Sheet](#).
- To access the CLI, see [Access the CLI through a Terminal Emulator like PuTTY](#).

Authentication Setup Category

The `auth` category contains authentication setup commands -- for OAuth2 (`oauth2` command), for setting and reviewing optional OAuth2 settings, and the `ldap` command, whose options configure and review the LDAP Server settings.

As an alternative to specifying the various LDAP settings as options to the `ldap` command (for example, `auth ldap --server ldap://hostname:636`), you can run an interactive wizard that prompts you for each setting. Run this wizard with the `ldap --setup` command.

Cluster Management Category

The `cluster` category is a subset of CT-VL commands for use with cluster management.

Below is the cluster management category commands table:

Command	Description
<code>add</code>	Add a node that can later create or be joined to an existing cluster. This command must be used on a node before that node can join a cluster. NOTE: Do not use with <code>remotejoin</code> .
<code>apiadmin</code>	API admin user setup, for automated cluster set up.
<code>create</code>	Create a CT-VL cluster.
<code>join</code>	Join a node to an existing CT-VL cluster. NOTE: Do not use with <code>remotejoin</code> .
<code>remotejoin</code>	Remotely join nodes to a cluster. Use in automated cluster setups.
<code>remove</code>	Remove a node from a cluster.
<code>show</code>	Show cluster settings.

CipherTrust Manager Setup

Use the `icapi` category of CT-VL commands to register the CipherTrust Vaultless Tokenization Server to a CipherTrust Manager (CM).

Below is the CT-VL setup Commands table:

Command	Description
<code>create</code>	Create a private key, or certificate signing request.
<code>enable</code>	Enable or disable the ICAPI interface to CT-VL servers.
<code>register</code>	Register to a CM host.
<code>set</code>	Set ICAPI properties, such as IP addresses, ports, and user credentials to a CM server.
<code>setup</code>	Perform an interactive setup of ICAPI properties (instead of using <code>set</code>).
<code>show</code>	Show ICAPI and CT-VL status and settings.
<code>test</code>	Test connection to a CM server or access to a specified key on the CM server.
<code>upload</code>	Upload a private key, signed certificate, or local CA certificate.

Network Management Category

Use the `network` category to set, modify, or delete system IP addresses, and to set up CipherTrust Vaultless Tokenization Servers. The `network` category also contains commands for showing and testing network configurations.

Note

Each server is assigned a unique IP address.

Below is the network management category commands table:

Command	Description
<code>arp</code>	Manipulate the system ARP cache.
<code>arping</code>	Send ARP requests to a neighbor host.
<code>checkport</code>	Check port connection status of a host
<code>dns</code>	Show or configure settings for the CT-VL DNS server(s).
<code>ethtool</code>	Query network driver and hardware settings.
<code>ifconfig</code>	Show or configure a network interface.
<code>ip</code>	Show or configure the CT-VL network interface settings.
<code>netstat</code>	Print network connections.

Command	Description
nslookup	Query internet name servers.
ntpservice	NTP service.
ping	Pings an IP address, host name, or FQDN.
route	Set static route.
service	Start/stop/restart network service.
set	Configure network device interface.
setup	Network setup wizard.
show	Show network device configuration.
snmp	Show, set, or change SNMP (v2c or v3) server configuration, which can be used to monitor processes, load average, disk space, and file size.
traceroute	Traces route to IP address or host name.

Example - Request:

```
network> ip address
```

Example - Response:

```
1: lo: <LOOPBACK,UP,LOWER_UP> mtu 65536 qdisc noqueue state UNKNOWN group default
qlen 1000
link/loopback 00:00:00:00:00:00 brd 00:00:00:00:00:00
inet 127.0.0.1/8 scope host lo
valid_lft forever preferred_lft forever
inet6 ::1/128 scope host
valid_lft forever preferred_lft forever

2: eth0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc mq state UP group
default qlen 1000
link/ether 00:0c:29:47:22:72 brd ff:ff:ff:ff:ff:ff
inet 10.3.201.140/16 brd 10.3.255.255 scope global dynamic eth0
valid_lft 216sec preferred_lft 216sec
inet6 fe80::20c:29ff:fe47:2272/64 scope link
valid_lft forever preferred_lft forever

WARNING! Changes made using this command are not persistent. Use the setup command
to change network settings permanently.
```

System Configuration Category

The system configuration category enables you to configure the CT-VL host settings (such as, hostname, console port, or timezone), and view and manage other common system administration tasks for the server (such as, reboot or shut down, or view disk space usage or currently logged-in users).

Below is the system configuration category commands table:

Command	Description
<code>banner</code>	Configure SSH banner.
<code>cpuid</code>	Show detailed CPUid information.
<code>cpuinfo</code>	Show CPU information.
<code>daemon</code>	Show daemon services that are running.
<code>date</code>	Print or Set the system date and time.
<code>df</code>	Report file system disk space usage.
<code>free</code>	Display amount of free and used memory in the system.
<code>host</code>	DNS lookup utility.
<code>hostname</code>	Set/Show hostname.
<code>hosts</code>	Update hosts file.
<code>lastlogin</code>	Show last logged-in users.
<code>meminfo</code>	Show memory information.
<code>reboot</code>	Reboot system.
<code>shutdown</code>	Shut down system.
<code>terminal</code>	Show or terminate terminal (CLI) sessions.
<code>timezone</code>	Set or show timezone.
<code>top</code>	Display Linux processes.
<code>uname</code>	Print system information.
<code>uptime</code>	Show how long the system has been running.
<code>vmstat</code>	Report virtual memory statistics.
<code>who</code>	Show who is logged into the system.

CT-VL Configuration Commands

The `vts` category is used to configure the CT-VL, set time parameters, configure GUI login behavior, and upgrade the CipherTrust Vaultless Tokenization Server software.

Note

The CT-VL configuration commands still retain the `vts` category name to ensure backward-compatibility.

The `vts` category consists of the following commands:

Command	Description
<code>batch_size_limit</code>	Tokenization Batch size limit.
<code>cliadmin</code>	Cliadmin user setup. NOTE: If CT-VL runs on an AWS EC2 and has been set to use an EC2 key pair, password access is disabled, and <code>cliadmin password</code> commands will fail with an error message. For example, a password cannot be disabled or unlocked. To view if the <code>cliadmin</code> is using an AWS SSH key pair, run <code>vt cliadmin keys --list</code> CLI command. If the instance uses an EC2 key pair, an entry in the SSH keys will show <code>[ec2]</code>.
<code>client_certificate</code>	Enables client authentication by requiring clients to pass a client key and CA certificate to CT-VL. NOTE: For best security, enable client certificates with identities (the <code>--enable-with-id</code> option) instead of without identities.
<code>cors</code>	Class-Origin Resource Sharing (CORS).
<code>create_superuser</code>	Create a superuser local account for Web administrative GUI access.
<code>logfile</code>	List, view, or tail log files.
<code>loglevel</code>	Set log level.
<code>randommode</code>	Random Mode utility.
<code>rate_limiting</code>	Limit the amount of tokenization requests.
<code>remotelog</code>	Set remote logging.
<code>restore</code>	Restore system from backup.
<code>server_certificate</code>	Creates the self-signed certificate or certificate signing request and import signed certificate.
<code>service</code>	CT-VL Service utility.
<code>show</code>	Show the security settings.
<code>smtp</code>	Configure, view, or test email notifications and underlying SMTP setup.
<code>ssl_ciphers</code>	Show or set SSL cipher suites. WARNING: Non-FIPS approved SSL ciphers will be deprecated in the future. It is highly recommended you configure CT-VL to use the default SSL cipher suite (with the <code>vt ssl_ciphers --setdefault</code> command), otherwise the server can be open to security vulnerabilities.
<code>ssl_protocol</code>	Specifies what version of the SSL (TLS) is supported by the CT-VL.
<code>upgrade</code>	Upgrade CT-VL.
<code>weblogin</code>	Web login setup.

CT-VL Services

CipherTrust Vaultless Tokenization (CT-VL) is a platform-independent appliance (virtual machine or bare-metal) that offers REST-API services to protect sensitive data.

CT-VL Core Services

CT-VL offers the following service category for handling sensitive data:

- **Tokenization service:** Tokenization is frequently used for sensitive data such as credit card numbers, social security numbers, drivers licenses, or other personally identifiable information (PII). Data masking can be applied to any detokenized data to hide sections of the data from different groups of users.

For example, less-privileged database users might view only the last four digits of a detokenized credit card number, while a more privileged user could view the entire card number.

The CipherTrust Tokenization REST APIs are used to integrate this functionality into a developer's application.

Components in a CT-VL Deployment

CT-VL deployment consists of the following components:

- CipherTrust Vaultless Tokenization Server
- CipherTrust Manager
- LDAP/Active Directory Server (optional)
- Remote Logging Server (optional)
- Load Balancer (optional)
- SNMP Server (optional)

Tokenization

- Replaces sensitive data in databases with tokens. This reduces the number of places in which plain text credit card numbers reside, and thus reduces the scope of complying with the Payment Card Industry Data Security Standard (PCI DSS) and corporate security policies.
- Preserves the format of data in a way that reduces the operational impact associated with encryption and other obfuscation techniques. For example, you can tokenize a credit card field in a database, yet keep the tokenized information in a format that is compatible with associated applications.
- Enables outsourcing application testing and running analytics without giving access to sensitive assets because the format of the data has been preserved. To outsource, you can create a copy of the production database and give that copy to the outsourced development team.

- Creates strong separation of duties between privileged administrators and data owners. In this way, IT administrators, such as hypervisor, cloud, storage, and system administrators can perform their tasks without access to the sensitive data residing on those systems.
- Enables dynamic data masking—the ability to establish varying levels of data redaction for different database users. For example, you can enable customer service personnel to access the last four digits of a customer's credit card number, while an accounts payable representative can access the full credit card number.
- Integrates tokenization users with existing LDAP-based identity directories. Security teams can efficiently set granular tokenization policies for specific users and groups.
- Provides high-performance cryptographic operations to protect sensitive data: encrypt, decrypt, sign, and verify. CT-VL allows batch encryption and decryption of data in bulk to achieve high performance.
- Provides an alternative way of managing keys on the CipherTrust Manager.

CT-VL Key Cache

Keys are cached in CT-VL for efficiency and to minimize network latency.

If a key expires (that is, deactivated, compromised, and so on), there is a trade-off that each installation needs to take into account.

- **Integrity** - if this is more important, performance slows down considerably given that network transmission is orders of magnitude slower than accessing data in memory.
- **Performance** - if this is more important, there will be a small integrity sacrifice.

Determining Key Cache Expiration Time

CT-VL key cache has a default expiration time of 300 seconds. However, the expiration time also depends on whether the key is in use for a session or not.

Note

- If a key id has the `:refresh` attribute appended to it, it will clear both **local** and **cryptod** caches. But calling it on every request would degrade its performance, although importantly integrity is preserved.
- The strategy that can be used to find out remaining expiration time is to look at the `deactivation_date` attribute and figure how much time is available until the next rotation.

Automatic vs Manual Key Rotation Process

Automatic Key Rotation

A way to ensure that the key isn't expired is to do a **GET** on the key, and look at the `deactivation_date` attribute value. When you are close to expiration time, append the `:refresh` attribute until you see a different date in the future.

Manual Key Rotation

The `creation_date` can be used to calculate a deactivation date if you have a manual rotation process, and you know how long the key will last. As it is manual, you may want to do refreshes for a grater period of time until you see a new creation date.

Once out of the rotation risk zone, drop the `:refresh`, and you will get better throughput at these times.

There are no performance numbers for key operations, since the original assumption is that keys and their states do not change that often. CipherTrust Cryptographic operations do perform a key fetch internally if not cached.

Key Types and Input Sizes

User permissions (to encrypt, decrypt, sign, verify, hash, or tokenize/detokenize) must be tied to particular keys. The CipherTrust Key Management APIs provide an array of static key management functions, as well as the ability dynamically to create or import keys to the keystore.

Key Type

Key Type	Description
Symmetric	Oct or octet sequence. Used to: • tokenize • detokenize • encrypt • decrypt Symmetric keys are also used for tokenization, and while the symmetric keys are typical AES keys with 128 or 256 bits of key material, the algorithms are FPE (FF3) and FF1. Note: Versioned keys may not be used for tokenization, only non-versioned keys.

Key Input Sizes

For CBC and ECB modes of encryption, the input size should be a multiple of the block size.

Note

The AES block size is 16 bytes (128 bits). If you do not use an input length that is a multiple of the block size, use CTR or CBC-PAD encryption.

Refer to [Creating Static and Dynamic Keys](#) for keys creation.

Creating Static and Dynamic Keys

Keys can be created with either a static or dynamic work flow:

Static Work Flow

Note

It is recommended to use a static key model with tokenization.

In most cases, it is recommended to implement your application using static keys, that is, keys that will change their key material rarely, and thus are rarely created or destroyed in the keystore.

The implementation tasks for static key creation are:

- Decide which actions will be performed (tokenize/detokenize), and which types of keys will be needed to support those actions.
- **CipherTrust Manager:** Create CT-VL-specific keys in the keystore, giving them meaningful names.
- **CT-VL GUI Administrator:** Enter the appropriate key names into the CT-VL GUI, to be stored in the local CT-VL database, and used for assigning encryption and tokenization permissions.
- **Application Developer:** Use the CipherTrust Key Management, Cryptography, and Tokenization APIs to perform the necessary functions in the application being integrated with CT-VL.

Warning

Do not use the REST API *create* or *import* key functions.

Dynamic Work Flow

In some cases, an organization may decide to automate key creation, rotation, or key import in the keystore, using the appropriate CipherTrust Key Management APIs.

Warning

If a key is deleted, all of the ciphertext the key was instrumental in creating is rendered unreadable.

In this case, the implementation team would need to:

- Decide which actions will be performed (tokenize/detokenize), and which types of keys will be needed to support those actions.
- **Application Developer:** Use the CipherTrust Key Management and CipherTrust Cryptography APIs to perform the necessary functions in the application being integrated into CT-VL, including *create* and/or *import* key functions.
- **CT-VL GUI Administrator:** Designate a user (possibly a non-human user), and grant the user permission to create and/or import keys.

Tokenization Groups, Templates, and Masks

In tokenization, sensitive data such as credit card numbers or social security numbers, are replaced with an encrypted *token* which retains the format of the original data. When detokenizing, different users can be authorized to view the entire detokenized/unencrypted value, or authorized to see only a part of the value, with the rest hidden by a *data mask*.

CT-VL includes tokenization groups, templates, and data masks as convenience features to make implementing tokenization easier.

Tokenization Groups

A *tokenization group* is a way to compartmentalize CT-VL at a department level or site level. Each tokenization group has a symmetric key associated with it. While the CipherTrust key management and CipherTrust encryption services refer to keys directly, the tokenize/detokenize services refer to a key indirectly – via the tokenization group.

Managing Tokenization Groups

A *tokenization group* is used as a parameter in the Tokenization API calls, tokenize and detokenize. To use tokenization, you must create at least one tokenization group.

Note

- Have at least one symmetric key created when you create a tokenization group.
- Remember that all symmetric keys used for tokenization must be unversioned keys.

Tokenization Template

Tokenization templates are used to supply parameters to the tokenization/detokenization operation which otherwise would have to be supplied individually in the REST API call, thus making the REST API call both easier to use and shorter.

The CT-VL GUI administrator collaborates with the application developer to create tokenization templates with the appropriate settings, and to give the template a name that developers will use in their code.

Managing Tokenization Templates

Tokenization templates allow you to define the specifics of how you want your data tokenized and detokenized. For example, you can specify that your data be Luhn checked before tokenizing, or that the last four digits of a data string be left unencrypted, or that an identifying prefix be attached to all tokens.

To use tokenization, at least one tokenization template must be created.

Template Value	Description
Name	Name of the template. This name will be used in the API POST commands tokenize and detokenize.
Token Group	The tokenization group for which this template can be used. You must create at least one template for each tokenization group.
Format	Formats to be used to tokenize data: • Format-preserving encryption (FPE) with or without a Luhn check. A Luhn check ensures that a submitted number is a valid credit card number. Note: FPE is an alternate name for FF3. • Random or Random with Luhn check. This format is optimized for use with numbers from 9 digits (without a Luhn digit, for instance SSNs) to 19 digits (including a Luhn digit), like credit card numbers or tax ID numbers. If the data includes more free-form text, such as names and addresses, either the FPE or FF1 format is preferable. Note: In a random or random-Luhn format, the template uses a pseudo-random number generator (PRNG) instead of an encryption algorithm. In addition, the very first symmetric key configured in the CT-VL GUI is not a true encryption key, but instead acts as a seed value for the PRNG. • One of the supported date formats. Use this to anonymize dates. Between the month, date, and year portions of the date format, the input data can include one of the following separators: slash (/), comma (,), hyphen(-), or space (). Date formats are used along with the Start Year and End Year fields. When a user enters a date in YYYY format but the token format requires YY, the system uses only the first two digits of the year for tokenization and maps them to the current century. The last two digits of the year are preserved

Template Value	Description
	exactly as entered during both tokenization and detokenization. Note: In a date format, if a two-digit year format is selected (for example, DDMMYY), the CT-VL assumes that the date is in the twenty-first century; that is, it assumes the first two digits of the year are 20.
Character Set	The character set to use with tokenization.
Prefix	(Optional) An optional prefix to be added to all tokens. Example: CC-1234-1234-1234-1234 or SSN:123-23-1234. Note that the format is no longer preserved with this feature.
Keep Left	The number left digits to leave unencrypted. You need at least a total of two digits to tokenize. Cannot be left blank.
Keep Right	The number right digits to leave unencrypted. You need at least a total of two digits to tokenize. Cannot be left blank.
Irreversible	(Optional) Check this box if you never want the token to be detokenized. For example, if you have production data that you want to tokenize for test or development, and you know you'll never want to decrypt it
Allow empty or 1 character inputs	Enables null, empty, and one-character inputs, which are passed through. The token value returned is the original input value. The single-digit input supports both characters and numerals, and is available for all formats except RANDOM.

Minimum Input Characters with Keepleft or Keepright

If you configure using keepleft or keepright, note the following minimum numbers of input characters, according to tokenization format:

- For FPE: 2 characters plus the number of keepleft or keepright characters.
- For RANDOM Numeric: 9 characters plus the number of keepleft or keepright characters.
- For RANDOM Alphaumeric: 5 characters plus the number of keepleft or keepright characters.

Data Masks

When a user or user group is given detokenization privileges, a data mask must be applied that defines how much of the unencrypted data they are allowed to see.

To create a mask that shows the entire data string, the CT-VL GUI Administrator would enter very large values in the Show Left and Show Right fields (999999).

Understanding CT-VL Authentication and Authorization

CT-VL Users

CT-VL makes no official distinctions between “human user accounts,” for real people, and “service user accounts,” representing daemons, scripts, processes, applications, or groups within applications with programmatic access to CT-VL services. Both are referred to as “users.”

From the point of view of the CT-VL system, the CT-VL REST APIs and the application developer who wishes to incorporate CT-VL services into an application, a basic user account consists of:

- **user name/identifier**
- **password or client certificate** (If authentication is done from a client certificate, the password is not used.)

These attributes form the basis of user authentication.

Note

As a best practice in CT-VL, it is recommended to collect individual users into logical user groups and assign permissions at the group level. See [Understanding CT-VL user groups and permissions](#) for more information.

User Profiles

Users can be human or servers.

Human users

Human users include the administrators, staff, and developers who use the CT-VL interface and/or the CT-VL APIs to install, configure, integrate, and maintain its services.

There are also human “end-users,” such as employees in a customer service department who may be assigned to a CT-VL user group authorized to detokenize credit cards, and to view the last four digits of the card, based on the data mask that was applied to their user group.

Service users

However, most CT-VL usage consists of service users, where various servers and applications pass authentication, tokenization, encryption, and key information between themselves to complete a transaction of some kind.

For example:

A company may set up a structure to assign a financial application as **User1** with a certain number of keys to perform certain operations. Within that same application, **User2** might be a process that uses **key2** to tokenize/detokenize credit cards, and **User3** might be used to encrypt/decrypt social security numbers with **key3**.

CT-VL Authentication Overview

CT-VL first seeks to validate whether the user credentials match entries in its local database. If not, and if AD/

LDAP is configured, then it will check against AD/LDAP settings. When authentication is successful, the system will also check for CT-VL role assignment, any key association, and any active permissions.

AD/LDAP and User Authentication

Companies can choose to use Active Directory/LDAP to store both human and service user accounts for CT-VL, to have a centralized way to manage them. If this approach is chosen, then the implementation involves cooperation between:

- The network administrator, to configure the connection between AD/LDAP and CT-VL.
- The AD/LDAP administrator and other organizational decision makers who decide which users should be imported into the CT-VL database, how to group them, what user group names to assign them in AD/LDAP, and what types of permissions should be granted on a group and/or individual basis.
- The CT-VL GUI administrator, who must manually enter the designated user group names into the CT-VL GUI before the user accounts are imported.

Note

It is also possible to create local user accounts directly in CT-VL. This is useful in test or demo installations of CT-VL or might be used for enhanced security as no AD/LDAP administrator would have access to the local user credentials.

Client Certificates and User Authentication

Client certificates can be used for authentication. The certificate itself is a credential and can be safer than a password, as it cannot be easily shared, duplicated, written on a sticky note, or otherwise carelessly exposed.

Companies might enable simple client cert authentication, to verify that a machine has a valid cert to connect with CT-VL. Or they may choose a more sophisticated implementation.

With CT-VL, it is possible to use the common name (CN) inside a client cert and enter it into CT-VL as a user name, thereby taking advantage of the ability to assign granular permissions and/or associate particular keys to a client certificate. This is known as using a client certificate “with identities.”

Note

Thales highly recommends using client certificates with identities. If you use without identities, you must pass in a username/password along with the certificate, which can be a security vulnerability that client certificates are intended to prevent. The option to use certificates without identities is provided to maintain backward compatibility with the earlier basic authentication flow.

To implement client certs with granular permissions, an organization would need to:

- Have established an in-house Certificate Authority (CA).

-
- Have an exportable CA cert.
 - Issue any number of client certs (signed by the CA) that each contain a common name (CN).
 - Go to the CT-VL CLI to:
 - Upload the CA cert to CT-VL.
 - Enable using client certs with ID.
 - Use the CT-VL graphical user interface (GUI) for:
 - Creating users and entering common names as user names (or import from Active Directory for LDAP).
 - Managing user permissions (If importing from LDAP, you can use the CT-VL CLI setting to designate a user group as the “active” user group thereby activating all members of the group.)
 - Associating key(s) with the cert/user.
 - Assigning permissions to the cert/user.

Note

CT-VL requires that all client certificates be in PEM format.

CT-VL Authorization Overview

CT-VL employs a multi-layered security model with separation of duties and granular permissions settings built in to it. It is also flexible, adaptive to individual corporate structures and policies. This structure implies some inherent complexity, but the concepts below form the foundational assumptions.

CT-VL Roles

When a user is created in CT-VL, it can be assigned one or more of the following core CT-VL roles:

- **Superuser:** Can perform both read and write actions in the CT-VL GUI.

Superusers are GUI administrators who manage users, user groups, keys, tokenization groups, tokenization templates, data masks, and character sets. Superusers associate users with key(s) and assign the crypto, key, and tokenization permissions to other users. Superusers are automatically also “Staff.”

- **Staff:** Users with read-only permission to the CT-VL GUI.
- **Active:** Users must be “active” in order to have encryption, key, or tokenization permissions. Active users are those authorized to use the CT-VL REST APIs.

The role-based permissions (Active/Staff/Superuser) are incremental. With no role assigned, the user cannot

access any CT-VL functionality. (This is equivalent to being deleted, but the information is retained in the database for possible reactivation.)

Tip

- When users are created directly in the CT-VL GUI, they are automatically assigned the status “active,” which can be disabled as needed.
- If users are imported from AD/LDAP, the “active” designator is handled differently.
- If Active is unchecked, the user cannot log in to the GUI even if assigned Superuser/Staff status.

Key-Aware Permissions Matrix

The GUI Administrator can assign permissions based on user (or user group), action, and key.

In the following example, User **CTUser1** may encrypt, decrypt, tokenize and detokenize with symmetric key **Sym_key1**.

Update User Permission

User: vtsuser1 Key: Sym_key1

Encryption	Key Management	Tokenization
☒ Encrypt	☐ Destroy	☒ Tokenize
☒ Decrypt	☐ Modify	☒ Detokenize
☐ Sign	☐ Export	Mask
☐ Verify	☐ Find	last 4 ▼

Apply Cancel

Note

- Permissions can be assigned at the user and the user group level, and are additive.
- Different types of keys (symmetric, asymmetric, and opaque objects) have different permissions

available.

- Tokenize and detokenize functionality require a couple of additional steps. See [Tokenization Groups, Templates, and Masks](#) for details.

Other (Non-Key Dependent) Permissions

Users or user groups can be authorized to dynamically create and/or import key names and key material on the keystore, under the "Other Permissions" column of the Permissions main page.

Create key: Creates the key name and key material in the keystore; the key name will be listed in the CT-VL GUI.

Import key: Used to import any key from one keystore to another, or from an external system into the keystore. The imported key name will be listed in the CT-VL GUI.

Note

The *Other Permissions* assignment window also includes check boxes for Tokenize and Detokenize, along with a warning about overriding symmetric key assignments.

This Tokenize/Detokenize feature is used during upgrade from earlier versions of CT-VL, as its grandfathers in the global tokenize/detokenize feature that was used previously.

Understanding CT-VL User Groups and Permissions

▪ CT-VL role-based user groups:

The three core CT-VL roles (Superuser/Staff/Active) are also three required core CT-VL user groups. An organization may choose to assign different group names, but the meanings are retained. CT-VL GUI administrators must create at least three user groups that correspond to the roles Superuser/Staff/Active.

▪ Assigning users to user groups in two different ways:

- If importing from AD/LDAP, users will be sorted into their role groups from the CLI.
- If entering users directly in the GUI, the administrator will assign the role(s) on the user's page and then check the appropriate group(s).

▪ Adding more user groups:

Additional groups can be added to CT-VL for organizational purposes.

▪ Assigning group permissions:

Key-based and non-key-dependent permissions can be assigned at the user group level or the user level, but assigning at the group level is recommended.

- **Permissions are additive:**

Individual and group permissions are additive. For example, suppose Joe is a member of the user group “Finance,” which has permission to tokenize credit card numbers, and Joe is also a team lead granted user-level permission to detokenize. In total, Joe can tokenize and detokenize.

Users, User Groups, and Tokenization Groups

To allow for abbreviated Tokenization REST API calls and to enable division of an organization into sub-organization either by location or department, CT-VL adds a so-called “tokenization group” concept.

So, there could be a user group “Finance” in San Francisco, and another “Finance” user group in Paris, each associated with its own tokenization group.

CT-VL CLI Navigation Summary and Guidelines

Navigation	Command	Example
Starting prompt	main>	
List CLI categories or the commands within categories	?	<pre>main> ? authAuthentication setup clusterCluster Setup icapiSafeNet ProtectApp Setup networkNetwork Setup systemSystem Setup vaeVAE Configuration vtsTokenization Setup quit q up <ctrl-d>Quit or return to previous menu exitExit application</pre>
Open a category and display its commands	?	<pre>main> cluster cluster> ? addRegister a new node to a cluster apiadminAPI admin user setup createCreate New Cluster joinJoin node to a cluster remotejoinRemotely join nodes to a cluster removeRemove node from cluster showShow cluster status quit q up <ctrl-d>Quit or return to previous menu exitExit application</pre>
Get help: See command usage and example output		<pre>network> checkpoint usage: checkpoint [-h] [-- host HOST] [--port</pre>

Navigation	Command	Example
		<pre>PORT[PORT ...]]</pre> Check port connection status of a host Optional arguments: <pre>-h, --helpshow this help message and exit</pre> <pre>--host HOSThostname or IP address of host</pre> <pre>--port PORT [PORT ...] port numbers to scan</pre>
Have CLI complete a category name, command, or argument when typing	Press	Enter enough characters to uniquely identify a category, command, or argument, and then press the key. The CT-VL CLI will complete it for you.
Return to the main level	up	<pre>main> cluster</pre> <pre>cluster> up</pre> <pre>main></pre>
End the CLI session	exit	

Note

You must enter a category to execute any of its commands. For example, the reboot command is in the system category, so you must first enter system, then enter reboot.

Tokenization Setup Workflow in CT-VL GUI

Although the CT-VL GUI does not constrain you to one particular implementation path, one logical sequence is:

- Specify the CM Keys for Tokenization (must be symmetric keys).
- Create Tokenization Groups and associate it with the appropriate key(s).
- Create custom character sets as needed (optional).
- Create a data mask for dekotenization.
- Create tokenization templates and associate the applicable tokenization group and character set.
- Create users and user groups, assigning a data mask from the drop-down menu.
- Grant tokenization privileges to users and user groups by going to their permissions page, selecting the symmetric key associated with the appropriate tokenization group, and checking the Tokenize box.
- Grant detokenization privileges to users and user groups in the same way.

Note

See [Other \(non-key dependent\) permissions](#) for an explanation of the Tokenize/Detokenize check boxes listed under "Other Permissions" in the Permissions matrix. This feature is included primarily for legacy and upgrade purposes.

CT-VL Tokenization REST APIs

The CipherTrust Vaultless Tokenization API consists of:

- **tokenize** - A POST call that tokenizes data. A user submits sensitive data, the CipherTrust Vaultless Tokenization Server returns a token. The token is then stored in the production database.
- **detokenize** - A POST call that detokenizes data. A user submits a token to the CipherTrust Vaultless Tokenization Server and the actual data is returned detokenized. Permission settings for that user dynamically specify the appropriate data mask.
- **log** - Changes the log level. Four different log levels (error, info, debug, and trace) can be selected. Chose 'error' or 'info' for normal operation, or 'debug' when instructed to do so by Thales eSecurity support.

Using the APIs

To enable tokenization, you do not have to change your database schema, because CipherTrust Vaultless Tokenization preserves the format of your data. However, you must change your application code.

When a user makes a request to tokenize or detokenize, the username and password must be provided. This is a part of a REST request. The username/password is validated by either the AD/LDAP server or CT-VL, depending on where the user is defined.

Note

- The data passed to and from the CipherTrust Vaultless Tokenization Server; user name, tokenization group name, tokens, and sensitive data, is case-sensitive, and the application code that passes data to CT-VL must be aware of this.
- Tokenization input can be a normal text format.

The maximum input data size for CT-VL Tokenization REST APIs is given below:

API	Maximum Input Data Size
Tokenization and Detokenization	128 KB
Batch Tokenization and Detokenization	1.25 MB (maximum records: 5000, maximum individual record size: 128 KB)

Create a Token

Description

Use the `tokenize` endpoint to encrypt a data string to a token using format-preserving encryption (FPE or FF1).

Tokenize Endpoint Details

Data	Description
HTTP Request	<code>https://IP_Address/vts/rest/v2.0/tokenize</code>
Method	POST
CT-VL IP Address	The IP address of the CT-VL instance to access with the API call.
Response Format	JSON
Required Authentication	A valid user name and password must be passed as an argument. The values are case sensitive.

Tokenize Parameters

The parameters for tokenize endpoint are described in the table below:

Parameter	Required	Type	Description
tokengroup	Y	string	Defines a group name space in the configuration database. For example, let's say you are a credit card company and you want the CT-VL to support three departments supporting Store1, Store2, and Store3. You want employees in these departments to have access to data for those respective stores. Two actions are required: • The application code must specify a different tokengroup parameter in the POST calls for each group supported (example: Store1, Store2, and Store3). The tokengroup parameter is case sensitive. • The CT-VL GUI administrator must create token groups that match the tokengroup parameter names used in the

Parameter	Required	Type	Description
			application code. If you do not support multiple token groups, then tokengroup will always be the same value. Example value: store1
data	Y	string	The data string to tokenize. The argument considers case and is limited to 128KiBs Example value: 1432445695309134
tokentemplate	Y	string	CT-VL GUI Administrator-defined name for a group of properties that define tokenization operation. Properties include the token group to which the template applies, the tokenization format (date, FPE or FPE with Luhn check, or FF1 or FF1 with Luhn check, or Random (lookup) or Random with Luhn check), number of leftmost or rightmost characters to not tokenize, whether you wish to never detokenize a tokenized entry, the character set used for tokenization, and an optional prefix for tokens. Example value: Credit Card
returnData	N	string	Tokenization requests can return the plaintext string together with the encrypted data in the response. To enable, add the "returnData" parameter and set it to true.

Tokenize Response Parameters

The tokenize endpoint response parameters, their types, and corresponding descriptions are listed in the table below:

Parameter	Type	Description
token	string	Token for the sensitive data.

Parameter	Type	Description
		Example value: 2134234509874567
status	string	•Succeeded (if request succeeded) •Error (if request failed)
reason	string	If status is Error a reason is displayed. Otherwise the reason is omitted.
data	string	If returnData in the request is set to true, contains the plaintext string for the encrypted data.

Create Token CURL Example

Note

If you use the `--tlsv1.2` CURL Command syntax option, you must use CURL version 7.34 or higher.

Example Request

```
curl -k -X POST -u Donald_Duckmiller:Panda45# -d '{"tokengroup" :
"ctsUsers-t" , "data" : "9453677629008564", "tokenTemplate" :
"ctsUsersTemplate" }' https://192.168.118.140/vts/rest/v2.0/tokenize
```

The user name (Donald_Duckmiller) and tokengroup (ctsUsers-t) are case sensitive.

Example Response

```
{"token":"CC-0332335756020172","status":"Succeed"}
```

If FPE-luhn, FF1-luhn, or Random-luhn is selected in the Change Token Template page of the CT-VL GUI, the data must pass a Luhn check or tokenization will fail with the error message:

```
"status":"error","reason":"Luhn check failed for input data."
```

Tokenizing Multiple Data Items

Up to 5,000 data items can be tokenized in a single `curl` command by submitting a JSON array in the REST request. For example, to tokenize four data items you might enter the following in a `postcnn.txt` file:

Example Request

```
cat postcnn.txt
```

```
[{"tokengroup" : "ctsUsers-t" , "data" : "9453677629008564",
"tokentemplate" : "ctsUsersTemplate" }, {"tokengroup" : "ctsUserst"
, "data" : "9453677629008564", "tokentemplate" :
"ctsUsersTemplate" }, {"tokengroup" : "ctsUsers-t" , "data" :
"9453677629008564", "tokentemplate" : "ctsUsersTemplate"
}, {"tokengroup" : "ctsUsers-t" , "data" : "9453677629008564",
"tokentemplate" : "ctsUsersTemplate" }]
```

```
curl -k -X POST -u Donald_Duckmiller:Panda45# --data-binary
@postccn.txt https://192.168.118.140/vts/rest/v2.0/tokenize
```

Warning

Newlines are NOT allowed in the input.

Example Response

```
[{"token": " 9465976792116170", "status": "Succeed"},
{"token": " 9465976792116170", "status": "Succeed"},
{"token": " 9465976792116170", "status": "Succeed"},
{"token": " 9465976792116170", "status": "Succeed"}]
```

The tokenized data is returned in the CURL Command syntax response, in order of submission.

Get Detokenize Resource Data

Get detokenized data from a resource.

Detokenize Endpoint Details

Data	Description
HTTP Request	https://IP_Address/vts/rest/v2.0/detokenize
Method	POST
CT-VL IP Address	The IP address of the CT-VL instance to access with the API call.
Response Format	JSON
Required Authentication	A valid user name and password must be passed as an argument. The values are case sensitive.

Detokenize Request Parameters

Parameter	Required	Type	Description
token	Y	string	The token to detokenize.

Parameter	Required	Type	Description
			token is case sensitive. Example value: 6029541314537206
tokengroup	Y	string	Defines a group name space in the configuration database. For example, let's say you are a credit card company and you want the CT-VL to support three departments supporting Store1, Store2, and Store3. You want employees in these departments to have access to data for those respective stores. Two actions are required: • The application code must specify a different tokengroup parameter in the POST calls for each group supported (example: Store1, Store2, and Store3). The tokengroup parameter is casesensitive. • The CT-VL GUI administrator must create token groups that match the tokengroup parameter names used in the application code. If you do not support multiple token groups, then tokengroup will always be the same value. Example value: store1
tokentemplate	Y	string	CT-VL GUI Administrator-defined name for a group of properties that define tokenization operation. Properties include the token group to which the template applies, the tokenization format (date, FPE or FPE with Luhn check, or FF1 or FF1 with Luhn check, or Random (lookup) or Random with Luhn check), number of leftmost or rightmost characters to not tokenize, whether you wish to never detokenize a tokenized

Parameter	Required	Type	Description
			entry, the character set used for tokenization, and an optional prefix for tokens. Example value: Credit Card

Detokenize Response Parameters

Parameter	Type	Description
data	string	The detokenized sensitive data. May be masked depending on the configuration. data is case sensitive and limited to 128KiB characters.
status	string	Succeeded (if request successful) or Error (if request failed).
reason	string	If status is Error, then a reason will be displayed. Otherwise the reason will be omitted.

Example

Note

If you use the `--tlsv1.2` CURL option, you must use CURL version 7.34 or higher.

Request

```
curl -k -X POST -u tok-user1:Panda45# -d '{"tokengroup" : "ctsUsers-t" , "token" : "CC-0332335756020172", "tokenTemplate" : "ctsUsersTemplate" }' https://192.168.118.140/vts/rest/v2.0/detokenize
```

If the client authentication feature is enabled, the example syntax is as follows:

```
curl -k --key client.key --cert client.crt -X POST -u tok-user1:Panda45# -d '{"tokengroup" : "ctsUsers-t" , "token" : "CC-0332335756020172", "tokenTemplate" : "ctsUsersTemplate" }' https://192.168.118.140/vts/rest/v2.0/detokenize
```

Response

```
{"data":"9453677629008564","status":"Succeed"}
```

Detokenizing Multiple Data Items

Up to 5,000 data items can be detokenized in a single curl command by adding multiple data items. For example, to detokenize four data items, you might enter the following in the `posttoken.txt` file:

Request

```
cat posttoken.txt

[{"tokengroup" : "ctsUsers-t" , "token" : "CC-0332335756020172",
"tokentemplate" : "ctsUsersTemplate" }, {"tokengroup" :
"ctsUsers-t" , "token" : "CC-0332335756020172", "tokentemplate"
: "ctsUsersTemplate" }, {"tokengroup" : "ctsUsers-t" , "token" :
"CC-0332335756020172", "tokentemplate" : "ctsUsersTemplate"
}, {"tokengroup" : "ctsUsers-t" , "token" : "CC-
0332335756020172", "tokentemplate" : "ctsUsersTemplate" }]
curl -k -X POST -u tok-user1:Panda45# --data-binary
@posttoken.txt https://192.168.118.140/vts/rest/v2.0/detokenize
```

Response

```
[{"data": "9453677629008564", "status": "Succeed"}, {"data": "9453677
629008564", "status": "Succeed"}, {"data": "9453677629008564", "statu
s": "Succeed"}, {"data": "9453677629008564", "status": "Succeed"}]
```

The detokenized data is returned in the CURL response in corresponding order of submission.

Note

Newlines are NOT allowed in the input.

If FPE-luhn, FF1-luhn, or Random-luhn is selected in the Change Token Template page of the CT-VL GUI, the data must pass a Luhn check or detokenization will fail with the error message.

Set Log Levels

Set the log level for the REST API.

Log Endpoint Details

Data	Description
HTTP Request	https://IP_Address/vts/rest/v2.0/log
Method	POST
CT-VL IP Address	The IP address of the CT-VL instance to access with the API call.

Data	Description
Response Format	JSON
Required Authentication	None

Log Request Parameter

Parameter	Required	Type	Description
loglevel	Y	Enum	loglevel can take one of the following values: • error - Default value used in normal production environment. • debug - Use only when directed by support. • info - Do not use unless maximum logging is required.

Note

The performance of tokenization and detokenization operations are severely affected by a log level of **debug**, and substantially affected by a log level of **info**. For maximum throughput, use a loglevel of **error**.

Log Response Parameter

Parameter	Type	Description
status	string	Success (if request succeeded) or Error (if request failed).

Example

Note

If you use the `--tlsv1.2` cURL option, you must use CURL version 7.34 or higher.

Request

```
curl -k --tlsv1.2 -X POST https://127.0.0.1/vts/rest/v2.0/log --databinary '{"log level":"debug"}'
```

Response

```
{"status": "success"}
```

CT-VL Admin REST APIs

The CT-VL Administration REST API allows you to manage the administration of the CT-VL. After completing the administrative tasks, you will be able to run the tokenize and detokenize data commands.

To use the Admin REST API you must be using:

- The CT-VL Server version 2.3.0 or newer.
- Any keystore server version compatible with CT-VL 2.3.0.

Base URL

The following is the base URL for Admin REST API operations:

```
https://<server_address>/api/
```

Authentication

JSON Web Token (JWT) is a compact, URL-safe means of representing claims to be transferred between two parties. The claims in a JWT are encoded as a JavaScript Object Notation (JSON) object that is used as the payload of a JSON Web Signature (JWS) structure or as the plaintext of a JSON Web Encryption (JWE) structure, enabling the claims to be digitally signed or MACed and/or encrypted.

By default, JWT authentication expires in 10 minutes. This setting can be changed using the CLI, under the `auth` menu.

Retrieve a Token Request

Request

```
curl -X POST \
-H "Content-Type: application/json" \
-d '{"username": "admin", "password": "Password123!"}' \
https://{server_address}/api/api-token-auth/
```

Response

```
{ "token": "eyJ0eXA [...] KnA74" }
```

Refresh a Token Request

Request

```
curl -X POST \
-H "Content-Type: application/json" \
-d '{"token":"<EXISTING_TOKEN>"}' \
https://{server_address}/api/api-token-refresh/
```

Response

```
{ "token": "eyJ0eXA [...] KnA74" }
```

Responses

This section describes request response codes and response pagination details.

Response Codes

HTTP status codes are grouped into five categories:

- 1xx for informational
- 2xx for success
- 3xx for redirection
- 4xx for client errors
- 5xx for server errors

Pagination

Requests that return multiple items will be paginated to 25 items.

Responses include a **count** field, which specifies the total number of objects available via pagination.

Responses also include a **next** and **previous** field. If **count** is superior to 25, these fields contain a URL path to access the objects located respectively after or before.

Request

```
GET https://{server_address}/api/v1/users/?limit=100&offset=400
```

Response

```
HTTP 200 OK
{
  "count": 1023
  "next": "https://{server_address}/api/users/?limit=100&offset=500",
  "previous": "https://{server_address}/api/users/?limit=100&offset=300",
  "results": [ ... ]
}
```

Operations

The CT-VL Admin REST API supports the following operations:

Searching

To search objects, add the attribute `?search=` at the end of the URL followed by the pattern you want to look for. All the objects containing that pattern in one of their attributes will be included in the Response.

Request

```
GET https://{server_address}/api/users/?search=robert
GET https://{server_address}/api/groups/?search=finance
```

Ordering

To query object in a specific order, add the attribute `?ordering=` at the end of the URL followed by the attribute you want to order by.

Ordering Examples

Order users by username:

```
GET https://{server_address}/api/v1/users/?ordering=username
```

You may also specify reverse orderings by prefixing the field name with '-', like so:

```
GET https://{server_address}/api/v1/users/?ordering=-username
```

Multiple orderings may also be specified:

```
GET https://{server_address}/api/v1/users/?ordering=username,email
```

Object Format

The response format for all requests is a JSON object.

Creating Objects

To create a new object, send a POST request to the class URL containing the contents of the object. For example:

```
curl -X POST \
  -H '{"Authorization': 'Bearer '+<token>}' \
  -H "Content-Type: application/json" \
  -d '{"name": "User1", ...}' \
  https://{server_address}/api/{some_resource}/
```

Retrieving Objects

To retrieve a list of objects, send a GET request to the class URL. For example:

```
curl -X GET \
  -H '{"Authorization': 'Bearer '+<token>}' \
  -H "Content-Type: application/json" \
  https://{server_address}/api/{some_resource}/
```

Updating Objects

To edit an object, send a PUT request to the URL containing the new content with the object's ID. For example:

```
curl -X PUT \
  -H '{"Authorization': 'Bearer '+<token>}' \
  -H "Content-Type: application/json" \
  -d '{"name": "User1", ...}' \
  https://{server_address}/api/{some_resource}/{id}
```

Deleting Objects

To delete an object, send a DELETE request to the class URL with the object's ID. For example:

```
curl -X DELETE \
  -H '{"Authorization': 'Bearer '+<token>}' \
  -H "Content-Type: application/json" \
  https://{server_address}/api/{some_resource}/{id}
```

Backing up CT-VL

Schedule automatic backups of the CT-VL.

```
GET https://<IP_Address>/api/backup/create
```

This request must be preceded by a successful authentication request. Use the secure token provided with the response in the portion of this example..

Set Backup Endpoint Details

Data	Description
HTTP Request	https://IP_Address/api/backup/create
Method	GET
CT-VL IP Address	The IP address of the CT-VL to access with the API call.
Response Format	JSON
Required Authentication	Yes

Example cURL Requests

Authentication

```
curl -X POST\
  -H "Content-Type: application/json" \
  -d '{username:"ctsuser","password:"Password123!"}' \
  https://cts_server_address/api/api-token-auth
```

Backup Request

```
curl -X GET\
  -H '{Authorization}:"Bearer <token>"}'\
  -d '{username:"ctsuser","password:"Password123!"}' \
  https://cts_server_address/api/backup/create -o backup.zip
```

Unauthenticated Healthcheck

Description

Use the `healthcheck` endpoint to get the status of the CT-VL. This endpoint integrates with load balancers to ensure all the daemons are running, and the tokenization server is healthy. An HTTP response code not equal to 200 indicates failure in CT-VL. The HTTP response also provides a display of status of all services, in JSON format.

Healthcheck Endpoint Details

Data	Description
HTTP Request	https://IP_Address/healthcheck
Method	GET
CT-VL IP Address	The IP address of the CT-VL to access with the API call.
Response Format	JSON

The unauthenticated healthcheck response parameters and their respective types are described in the table below:

Unauthenticated Healthcheck Response Parameters

Data	Type	Description
status	string	• 200 (if request succeeded) • 503 (if one of the daemons is not running)
	string	Configured services are listed along with each one's status (for example: {"name": "vaed", "status": "started"})

Healthcheck Example

Example Request

```
curl -k -X GET https://IP_Address/healthcheck
```

Example Response

```
HTTP/1.1 200 OK
Date: Thu, 29 Oct 2020 22:51:16 GMT
Content-Type: application/json
Content-Length: 310
Connection: keep-alive
Server: CT-VL server
Cache-Control: max-age=0, no-cache, no-store, must-revalidate
Pragma: no-cache
X-Frame-Options: SAMEORIGIN
X-Content-Type-Options: nosniff
X-XSS-Protection: 1; mode=block

    "status": "Started"
  },
  {
    "name": "cryptod",
    "status": "Started"
  }
],
"status": "Started"
}

```

CT-VL with Multiple Key Managers

This section describes the CT-VL operation mode (round-robin or failover) with multiple key managers.

Data Security Manager (DSM)

The VAE agent receives a list of the DSMs to contact during registration. This list is arranged in the order that primary DSM is at the top and failovers at the bottom. When the VAE agent detects that the primary DSM is down, it switches the order of both DSMs (primary and the first failover) in memory. After switching, the first failover DSM is at the top and primary at the second position.

This is done so that the VAE agent does not try to contact the primary DSM and timeout every time before going to the failover. The VAE agent will now skip the primary DSM and go to the failover.

Note

The VAE agent will not automatically failback to the first DSM even if it comes up. The services need to be restarted on CT-VL.

CipherTrust Manager (CM)

CT-VL with the CipherTrust Manager uses the round-robin operation mode. You just specify multiple IP addresses of the CipherTrust Manager servers and internal round-robin load balancing is performed.

Troubleshooting

Tokenization API Call Failure Error Messages and Workarounds

Following error messages may occur when an Tokenization API call is made:

Message	Description
--tlsv1.2: is unknown.	Only CURL version 7.34 or later supports the --tlsv1.2 option. If you get this error message, upgrade to CURL version 7.34 or higher.
API call aborted and no JSON vector elements are processed.	These are error messages which pertain to the whole JSON vector. In other words, in these cases no vector elements are processed at all. The whole operation is aborted.
User name and/or password mismatch.	Due to a wrong user name and/or password, access to the CipherTrust Vaultless Tokenization Server is denied.
Unknown JSON keyword encountered. The valid keyword for the log request is loglevel.	For the REST API called log , the only valid keyword on the left of the JSON valuename-value tuple is loglevel .
Could not parse JSON input, perhaps it is too long.	An input size of 1 MByte cannot be exceeded. It could also mean that the JSON input is malformed.
User name and/or password missing.	Either the user name, or the password, or both are missing from the request.
This user does not have permission to tokenize.	While the user exists and the password is correct, this particular user does not have the permission to tokenize. Consider assigning this user the permission to tokenize via the GUI.
User name found, but the user is not marked active.	While the user exists and the password is correct, this particular user is not marked as an active user. Consider marking this user an active user in the GUI.
Invalid operation. Use /vts/rest/v2.0/tokenize , or /vts/rest/v2.0/detokenize .	An invalid URL was specified. Allowed operations are: /vts/rest/v2.0/tokenize , /vts/rest/v2.0/detokenize , or /vts/rest/v2.0/log .
No password specified.	While a user name was specified, the password is missing.
User name not found.	The specified user name exists neither in the local database which is configured via the GUI, nor in the optional LDAP database.
LDAP user found in local database, but LDAP is disabled.	Presumably due to a prior use of LDAP, an LDAP user was cached in the local database, but LDAP has since been disabled, disallowing authentication with this user. Prior to using LDAP users for authentication, at least one of the groups this user belongs to according to the LDAP database must be configured as a user group via the GUI.
API call aborted, one JSON vector element fails, others are processed.	These messages pertain to only one element of the JSON vector. In these cases, one vector element may result in an error, but all other vector elements are still processed.
The length of the token exceeds 128 Kbytes.	The length of a token is limited to 128 KiB. However,

Message	Description
	the token supplied was longer than 128 KiB.
Unknown JSON keyword encountered. Valid keywords for the detokenize request are tokengroup, token, and tokentemplate.	For the detokenize operation, only three specific keywords are allowed on the left side of a JSON tuple: tokengroup , token , and tokentemplate . Please review and correct your JSON string.
The length of the data exceeds 128 Kbytes.	The length of the input data is limited to 128 KiB. However, the input data supplied was longer than 128 KiB.
Unknown JSON keyword encountered. Valid keywords for the tokenize request are tokengroup, data and tokentemplate.	For the tokenize operation, only three specific keywords are allowed on the left side of a JSON tuple: • tokengroup • data • tokentemplate
Please review and correct your JSON string.	A token group was specified in the JSON input, but it doesn't exist in the GUI-administered configuration database. Consider adding this token group via the GUI.
The requested key name was not found on the CipherTrust Key Manager.	A key name was configured via the GUI and now used in an operation, however this key name does not exist on the CipherTrust Key Manager.
The token group specified was not found in the database.	The token group was not found on CT-VL.
tokengroup not specified in JSON request.	The JSON tuple named tokengroup is missing from a JSON vector element. A tokengroup must be specified.
The requested combination of tokentemplate and tokengroup was not found in the tokentemplate table.	Either the tokengroup specified has not been entered via the GUI, or the tokentemplate has not been entered via the GUI, or the token template of the same name has been entered, but for a different tokengroup. Please ensure that the tokentemplate you are trying to use has been entered for the tokengroup you are trying to use.
It is not allowed to specify the FPE-luhn token format with a non-zero keepright value.	After accounting for keepleft and keepright, not enough input characters are left to successfully tokenize the input. When you use the FPE token format, the number of input characters must exceed the sum of the Keep Left value and the Keep Right value by at least two. When you use the FPE-luhn token format, the number of input characters must exceed the sum of the Keep Left value and the Keep Right value by at least three.
There are not enough input characters for the detokenize operation.	At least two input characters are needed in the token in order to try to detokenize it.
Token format FPE-luhn is only compatible with an alphabet consisting of the 10 decimal digits (in ASCII	The FPE-luhn token format cannot be used with an alphabet containing letters and/or special characters. It

Message	Description
encoding).	must be used with an alphabet only containing the 10 digits.
After accounting for the keepleft and keepright requirements, not enough input characters left to tokenize.	When you use the FPE token format, the number of input characters must exceed the sum of the keepleft value and the keepright value by at least two.
Luhn check failed for input data.	The token format FPE-luhn was specified, but the input data sports an incorrect Luhn checksum. Please check your input data, or change the token format from FPE-luhn to FPE.
After accounting for keepleft and keepright, there are not enough input characters present to successfully tokenize.	• When you use the FPE token format, the number of input characters must exceed the sum of the keepleft value and the keepright value by at least two. • When you use the FPE-luhn token format, the number of input characters must exceed the sum of the keepleft value and the keepright value by at least three.
Token does not begin with the prefix specified in the database.	While a certain token prefix is specified in the token template which is being used in the JSON input, the token seen in the JSON input does not sport this particular token prefix.
The specified token only contains the prefix and no payload.	While the token seen in the JSON input sports the correct token prefix, there are no other characters present in the token.
Luhn check failed for input token.	The token format FPE-luhn was specified, but the token specified sports an incorrect Luhn checksum. Please check your input data.
There are not enough input characters present to successfully detokenize.	• When you use the FPE token format, the number of input characters, not counting the token prefix, must exceed the sum of the keepleft value and the keepright value by at least two. • When you use the FPE-luhn token format, the the number of input characters, not counting the token prefix, must exceed the sum of the keepleft value and the keepright value by at least three.
